(*Rallus longirostris yumanensis*) have been observed in the EIR project area. However, suitable habitat for these species including riparian, emergent wetland, woodlands, and dense shrubby areas are not present along either alternative.

Vegetation

Both alternatives are located in disturbed areas with sparse vegetation. The few large trees and shrubs that are important from both a visual aesthetic viewpoint as well as culturally significant species present in the vicinity of the proposed alignment are spaced widely enough apart that significant impacts to vegetation can be avoided.

Wetlands and Waters

Both alternatives would cross the wash located on the northern side of the CHQ (Figure 1). The wash has been delineated as a Riverine Intermittent Stream Bed Cobble-Gravel Temporarily Flooded wetland (CH2M HILL 2014). The wash eventually flows into the Park Moabi Slough, and ultimately into the Colorado River. The wash is therefore tributary to a Traditional Navigable Water and is considered to be a jurisdictional Waters of the United States under Section 404 of the Clean Water Act. The wash would also be regulated as a stream under Section 1600 of the California Fish and Game Code. In this area, the wash originates at three 8.5-foot-diameter corrugated metal pipe culverts installed under the Burlington Northern Santa Fe railroad tracks. An existing dirt access road is located just east of the culvert outfall and west of the clearly defined wash channel. The access road is currently in functioning condition, but would be upgraded to maintain flows while allowing access to the CHQ. East of the existing road, the wash is characterized by a relatively uniform bed with steep side slopes. The substrate consists of coarse sand with scattered pebbles and cobbles and boulders. Vegetation within the channel includes several small blue palo verde saplings along the edges with scattered creosote bush, brittlebush (*Encelia farinosa*), honeysweet (*Tidestromia oblongifolia*), small-seeded spurge (*Chamaesyce polycarpa*), and Spanish needle (*Palafoxia arida*) within and along the channel.

Under alternative 1, the excavation for the sewer and fire water pipelines would occur in the area where the existing road and proposed upgrades as well as additional utilities lines would be located (Figure 1). Installation of the pipelines in this location would, therefore, not result in additional temporary impacts to the wash.

Under alternative 2, the proposed alignment for the sewer and fire water pipelines would be buried under the open channel northwest from the proposed CHQ. Impacts associated with this alternative are dependent on construction methods. If the pipe were to be installed in an approximately 5-foot-wide open cut trench across the approximately 40-foot wide channel, approximately 200 square feet of temporary impacts would occur. To the maximum extent possible impacts to perennial vegetation would be avoided and minimized. Following construction, the trench would be backfilled and the channel bed would be restored to the original grade. Alternatively the pipelines could be installed using trenchless methods (e.g. horizontal directional drilling) under the wash, thereby avoiding any temporary impacts to the channel.

All work activities within the wash will be conducted in conformance with the Avoidance and Minimization Measures specified by the California Department of Fish and Wildlife for the project and best management practices for work in jurisdictional wetlands and waters of the U.S. All work also will comply with other applicable federal and state requirements, including applicable measures in the Mitigation Monitoring and Reporting Program (MMRP) for the Topock Compressor Station Groundwater Remediation Project.

Notes:

1 - This preliminary list of well locations for borehole groundwater sample collection is subject to change based on observations in the field, and could result in more or less boreholes being utilized for sample collection.

2 - Typically, only one borehole at a given well location (the deepest) will be utilized for borehole groundwater sample collection.

Attachment U: RTC #938

New C/RAWP Section 3.2.1.6, Baseline Well Sampling

3.2.1.6 Baseline Well Sampling

In response to 90% RTC #938 DTSC-167, this section details the plans and methods to collect initial baseline samples from all new extraction, injection, and monitoring wells[1] constructed as part of the groundwater remedy. As new wells are constructed and developed they will be added to baseline well sampling events that will be conducted on a regular frequency (i.e., initiated every 4-6 weeks) during construction. As many new wells as possible will be grouped in each event for efficiency with sampling and laboratory analysis. Baseline groundwater samples will be collected a minimum of 72 hours after well development is completed, thereby allowing the well to stabilize following the extended purge during development, before sample collection in accordance with the SOPs presented in the subsections below.

Baseline monitoring will include two samples collected to establish the baseline conditions; a third baseline sample will be collected if it is necessary to confirm the baseline condition should data from one of the first two events appear anomalous. The two baseline samples will be collected approximately one month apart; however, the time between samples might be shortened if determined necessary to ensure that the collection of these samples does not delay startup of the system. In addition to baseline sample collection at new wells, existing wells will be added to these events as determined necessary. For example, select Category 1 wells will be included in these events beyond the collection of initial baseline samples as determined necessary to inform the location and design of other remedy wells.

Groundwater Sample Collection Methods and Procedures. Sampling and field measurements will be performed in accordance with the SOPs presented in Appendix B. Required sample containers, preservation requirements, sample storage, and QC methods and requirements are described in further detail in the PG&E Program QAPP and QAPP Addendum (see Appendix C).

In continued efforts to integrate sustainability practices into remedial implementation (see Section 4 of the 90% BOD Report), trials of alternative sampling and data collection methods were conducted at Topock to further reduce the overall sampling and project footprint and minimize potential impacts to sensitive resources (e.g., reduce trips to well sites, reduce purge water generation and management, reduce time spent at well sites, etc.).

The trial began in third quarter 2012 (September) and continued through first quarter 2013; it involved testing of two alternative sampling approaches at 18 site wells: the no-purge HydraSleeveTM sampling system and the minimal drawdown (low flow purging) sampling technique. Additional information about these two approaches can be found in numerous publications and public websites including but not limited to the following:

- HydraSleeveTM sampling system (www.hydrasleeve.com): A joint study completed by the U.S. Army Corps of Engineers, the Air Force Center for Environmental Excellence and the Air Force Real Property Agency in 2005 (Parsons 2005)
- Minimal drawdown (low flow purging or micro-purge) sampling technique: USEPA guidance on sampling procedures including the Groundwater Issue Paper: Low-Flow (Minimal Drawdown) Ground-Water Sampling Procedures (Puls and Barcelona 1996) and the Groundwater Sampling Guidelines for Superfund and RCRA Project Managers (USEPA 2002)

---

[1] Sampling of existing monitoring wells to document baseline site conditions prior to remedy implementation are discussed in the Basis of Design Report, Section 2 (Baseline Site Conditions and Pre-Design Work).

Trial results were compared to the current standard three-volume purge technique, and evaluated for use in monitoring of the final groundwater remedy. The 2013 Annual Groundwater Monitoring Report (CH2M HILL 2014a; available on the project website at http://dtsc-topock.com/) presented the trial results (see Recommendations section and Appendix H) along with detailed correlations between the two alternative sampling methods and the current three-volume purge method.

Based on the trial results, PG&E recommended to DTSC the use of micro-purge as the default sampling method for the existing groundwater monitoring and compliance monitoring programs. While micro-purge was recommended for groundwater/compliance monitoring, HydraSleeve and other grab sampling methods are also seen as useful tools for process monitoring during remedy implementation. DTSC completed review of PG&E's recommendations on June 26, 2014, and approved the use of micro-purge techniques for wells with screen length of up to 20-foot saturated thickness in alluvial and fluvial sediments (upland and floodplain locations) (DTSC 2014). Implementation of the micro-purge technique at approved wells commenced in the third quarter of 2014. SOPs associated with these alternative techniques have been included in Appendix A.

Additional trials using alternative sampling techniques will be conducted at monitoring wells with 30- to 50-foot screen lengths, and at bedrock open borehole wells located in TCS or the East Ravine. Trial results have been and will continue to be evaluated and new information incorporated into the sampling and monitoring for the final remedy, as appropriate. Additional SOPs may be developed and added to the lists below, or existing SOPs may be modified and amended. The latest version of the SOPs will be available to the sampling crews at the in project files onsite during construction.

The method used for the collection of baseline samples from injection and extraction wells constructed for the groundwater remedy will ultimately be determined based on the results of the ongoing alternative sampling technique trials. During operation, these large diameter wells will be equipped with dedicated pumps and will be plumbed into the groundwater remedy; however, the infrastructure may not be installed during remedy construction when the baseline samples are collected. Given the relatively large volumes of groundwater that would have to be purged and managed if sampled using SOP-A1, alternative techniques (SOP-A18 and/or SOP-A19) are preferred.

Groundwater sampling from wells will be performed in accordance with the following SOPs, as appropriate (included in Appendix B). Additional SOPs may be added as appropriate.

- SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
- SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
- SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
- SOP-A6 – Sample Field Filtration and Preservation for Metals Analyses
- SOP-A7 – Water Level Measurements
- SOP-A8 – Field Water Quality Measurements Using a Flow-through Cell
- SOP-A9 – Calibration of Field Instruments
- SOP-A10 – Decontamination of Water Sampling Equipment
- SOP-A11 – Total Depth Measurements
- SOP-A13 – Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling

- SOP-A16 – Access Routes
- SOP-A17 – Groundwater and Surface Water Mobile Integrated Sample Tracking
- SOP-A18 – Purging and Sampling of Groundwater Wells Minimal Drawdown Method
- SOP-A19 – Sampling of Groundwater Monitoring Wells Hydrasleeve No Purge Method
- SOP-A23 – Sample Handling and Custody

Groundwater Sample Laboratory Analysis and Management. Baseline groundwater samples will be analyzed at a certified laboratory in accordance with the analytes presented on Exhibit 3.2-4. The laboratory analytical suite for baseline groundwater samples collected from injection and extraction wells is consistent with the analytes listed in Exhibit 4.1-1 (Biological and Geochemical Analytical Monitoring Parameters) of the O&M Manual (Volume 1).

mg/L = milligrams per liter

The contracted analytical laboratory will provide the required sample containers for all samples including QC samples. All containers will have been cleaned and certified free of the analytes of concern for this project. No sample containers will be reused. The contracted laboratory will add preservatives, if required, prior to shipping the sample containers to the field or supply the preservative as appropriate. The laboratory markings will indicate the type of preservative in the container. The date and time of sampling and the initials of the sampler will be recorded on the pre-printed label immediately prior to collection. The waterproof labels will be placed carefully on the proper container, and if waterproof labels are unavailable, they will be secured using clear tape to protect the label. When shipping samples using a freight carrier such as Federal Express, the ice used in shipping containers will be double-bagged and laser printed labels and indelible ink pens will be used to complete sample labels to ensure that the samples arrive at the laboratory dry and appropriately marked. If a laboratory courier is used, no bagging of ice is necessary. Vital information regarding the collection of each sample will be recorded in a field logbook, field sampling form, and/or chain-of-custody (CoC) form, as appropriate. The following information for each sample will be recorded in the field logbook, field sampling form, or CoC form, whichever is appropriate:

- Sampling location and description (sketch and measured distances from reference points will be recorded if there is no established identification for the sample location)
- Sample ID
- Sampler's name
- Date and time of sampling
- Sample designation (e.g., composite, grab, etc.)
- Sample matrix
- Type and ID of sampling equipment
- Field measurement data (e.g., pH, temperature, conductivity)
- Field observations that may be relevant to the analysis or sample integrity (e.g., odor, color, and weather conditions)
- Associated QC blanks
- Shipping details (if the laboratory is providing courier service, the courier must sign and date the CoC forms; copies of the signed CoC forms should be transmitted to the office as soon as practical; if FedEx, UPS, or other courier is used, include shipping information for each shipment)
- Destination laboratory

Sample coolers will be transported to the laboratory immediately after sample collection. An overnight courier may be used to transport the samples. Intermediate stops will be avoided, except for emergencies, in which case the situation will be noted in the field notebooks. The laboratory will be notified that samples are being shipped. The laboratory, upon receipt of the samples, will verify and record the adequacy of preservation and will add additional preservative, if necessary.

New REMEDY-SOP-10: Sampling of Concrete/Asphalt Demolition Waste

Standard Operating Procedure
PG&E Topock Groundwater Remedy
Operation and Maintenance Plan

Title: Sampling of Concrete/Asphalt Demolition Waste

Number: Remedy-SOP-10_Rev0

Creation Date: 6/19/2015

1 Background and Scope

Pacific Gas and Electric Company (PG&E) is implementing a groundwater remedy near the intersection of Park Moabi Road and Interstate 40, approximately 12 miles southeast of Needles, California at the PG&E Topock Compressor Station (TCS). Construction and demolition of remedial facilities is expected to generate concrete and asphalt pavement rubble that will be managed for reuse, recycling, or offsite disposal.

Concrete and asphalt rubble will be managed as waste as outlined in Waste Management Plans for the project: see Appendix F of the Construction/Remedial Action Work Plan (Interim Measure No. 3 Decommissioning, Removal and Restoration Work Plan), and Appendix R of the Construction/Remedial Action Work Plan (Waste Management Plan). For concrete and asphalt associated with known hazardous waste or hazardous materials operations (such as the inside of containment structures for process chemicals) or that exhibit visual evidence of contamination, surface samples will be collected prior to demolition to determine if the material is contaminated. If contaminated, the concrete/asphalt demolition waste will be managed by either (1) offsite disposal under the assumption that the surface sample is representative of the entire mass of the slab, or (2) removing the surface contamination by cleaning (e.g., pressure washing with surfactant solution) or scarifying, and managing the cleaning fluids/scarified materials separately from the remaining concrete/asphalt mass as different waste streams. The classification and management requirements for the waste streams are described in the Waste Management Plans and are not repeated herein.

The objective of this Standard Operating Procedure (SOP) is to describe the procedure for sampling of concrete and asphalt surfaces/slabs to be demolished during the remedial action for purposes of determining whether the material is contaminated. Representative samples will be collected from concrete and asphalt surfaces/slabs associated with known hazardous waste or hazardous materials operations as described herein.

Concrete and asphalt slabs that are not associated with known hazardous material operations and that exhibit no visual evidence of contamination (staining, residue, etc.) will not be sampled. Asphalt that exhibits oil stains in areas with no history of polychlorinated biphenyl use will not be sampled.

2 Equipment/Supplies

- Appropriate personal protective equipment (PPE)
- Health and Safety Plan
- Waste Management Plan (see Appendix F or Appendix R of the Construction/Remedial Action Work Plan)
- Map and/or detailed description of concrete and asphalt sampling locations
- Coring drill and coring barrel, rotary impact hammer variable speed drill, or similar

- Hose and water supply for coring drill
- Aluminum foil
- Stainless steel chisel and hammer
- Stainless steel spoon
- Plastic Ziploc bags
- Sample bottles/jars
- Sample labels
- Sample logbook
- Chain-of-custody forms
- Chain-of-custody seals
- Waste container (e.g., 55-gallon drum)

3 Preconditions

- **Sampling and Analysis Plan:** A sampling and analysis plan will be prepared and provided by the Construction Manager or designee.
- **Sampling Approach:** In general, sampling areas shall be determined based on the history of activities performed in the demolished structure or pavement. The approach is based on defining distinct areas of the structure, roadway, or pad or any other feature (e.g., sump), based on historical use. The preferred sampling timing is prior to the demolition of the concrete or asphalt surface.
    - One composite sample will be collected at each distinct area of the structure for demolition (e.g., roadway, concrete pad, process area, tank containment).The composite sample will be collected from locations most likely to have contacted hazardous waste or hazardous materials, such as knowledge of use (inside containment structures for process chemicals), areas of visual staining, or other indication of potential contamination (coloration, or odor) to identify the nature of the contaminants.
    - Prior to sample collection, sample locations will be marked, typically by painting boxes on the designated slab. The samples will be collected within the interior of the painted box but not the painted surface.
    - Samples will be collected by chipping or coring. Typically samples should be no deeper than 1 inch unless staining or discoloration indicates that contamination may extend below that depth. Sampling logs shall record he depth of core samples. Typically, three chips or cores will be collected from each designated area; sufficient sample will be collected for the designated analytical methods.
- **Analytical Parameters:** Analytical parameters shall be selected based on the history of activities performed in the area. The analytical lab shall be consulted to determine sample volumes, preservatives, containers, and any other special requirements.

4 Procedure

1. Take photograph(s) of sample location.
2. Connect power or water supply line to drill, per the drill manufacturer’s instruction manual.
3. Remove debris with a clean brish or cloth prior to drilling. Place the drill over the specified sampling location.
4. For coring:

- Keep a steady downward pressure on the coring barrel.
- Raise the core barrel every few minutes to facilitate the removal of drill cuttings.
- Drill sample so that it extends throughout the entire thickness of the concrete or asphalt.

- Once the cut has been completed, remove the coring barrel from the hole.Typically the concrete/asphalt core will remain in the core barrel. Tap the outside of the core barrel gently with a hammer until the core drops out.

5. For drilling:
   - Lock a 0.5"-1" drill bit into the impact hammer drill. and an impact drill.
   - Drill vertically to the desired depth, capturing chips or powder with a scoop or spoon. The sampler can also drill multiple holes closely together so that the concrete/asphalt between the drilled holes breaks into chips.
6. Place sample, including powder and smaller chips generated during the drilling, in a stainless steel bowl.
7. To collect a COMPOSITE sample:

   NOTE: If analytical laboratory provides alternative composite sample collection procedures, follow the instructions of the laboratory instead of those listed below.

   - Repeat steps 1 through 6 for core/chip sample locations that are to be composited.
   - After all samples to be composited are in a stainless steel bowl, break samples into smaller pieces (the size of pieces shall be instructed by analytical lab).
   - Use a stainless steel spoon to homogenize the sample.
   - Transfer the sample into sample container(s).
   - Attach sample label, custody seal, and immediately place sample into cooler with ice.
8. Transfer any drill cuttings left over from the sampling into a waste container.
   - Ensure waste container is sealed, labeled, and handled appropriately.

NOTES:

1. SAND SHALL BE USED FROM THE BASE OF THE TRENCH TO 6 INCHES ABOVE THE TOP OF PIPES. SOILS FROM THE TRENCH EXCAVATION SHALL BE MOISTURE CONDITIONED AND USED AS BACKFILL. COMPACT TO 95% RELATIVE COMPACTION TO 12 INCHES BELOW GRADE. FOUR INCHES OF AS-CLASS 2 MATERIAL SHALL BE PLACED ON TOP OF THE COMPACTED SOIL FOLLOWED BY 4 INCHES OF AB-CLASS 2. THE ROADBASE SHALL BE TOPPED WITH A 2-INCH BASE COURSE LAYER AND CAPPED WITH A 2-INCH HMA PG 70-10 SURFACE COURSE.
2. PIPE SUPPORTS AND CLEANOUTS NOT SHOWN FOR CLARITY.
3. ALL COVERS SHALL BE TRAFFIC RATED.
4. CASING SPACERS NOT SHOWN FOR CLARITY.
5. PIPE BEDDING SHALL EXTEND HALF WAY UP THE PIPES PER THE SPECIFICATIONS.

GENERAL NOTES:

A SEE LEGEND, NOTES & ABBREVIATIONS C-08-00 FOR COMPLETE GENERAL NOTES.
B ALL PERIMETER FENCE AND GATE SHALL MEET PG&E PROPERTY FENCE AND GATE STANDARD L-50.

KEYED NOTES:

1 INSTALL ASPHALT PAVEMENT. SEE DETAIL 1/C-08-06.
2 INSTALL CONCRETE SIDEWALK. SEE DETAIL 4/C-08-06.
3 INSTALL 8FT HIGH CHAIN LINK FENCE. SEE DRAWING C-00-06 AND C-00-07.
4 INSTALL PG&E STANDARD PERSONNEL GATE AS MANUFACTURED BY SGS.
5 INSTALL 30FT SLIDE GATE. SEE DRAWING C-00-06 AND C-00-07.
6 INSTALL 8' HIGH CHAIN LINK FENCE ON WALL. SEE DETAIL S-08-09 ON STRUCTURAL PLANS.
7 CONSTRUCT RETAINING WALL. (COORDINATES ARE TO BACK FACE OF WALL). SEE PROFILE C-08-10 AND DETAILS S-08-04 AND S-08-09 ON STRUCTURAL PLANS.
8 SEE STRUCTURAL FOR CONNECTION TO BUILDING WALL.
9 ADJUST EX. WELL TO FINISHED GRADE. COORDINATE FINAL CONDITION WITH PG&E.
10 INSTALL THICKEN EDGE. SEE DETAIL 2/C-08-06.
11 INSTALL BOLLARDS. SEE DETAILS 5/C-08-06.
12 PROTECT EX. CREOSOTE BUSH.
13 INSTALL CURB. SEE DETAIL 3/C-08-06.
14 REFER TO STRUCTURAL DRAWING S-08-09 FOR CONCRETE AND COLUMN INTERFACE.
15 CONFIRM WELL LOCATIONS WITH ARCADIS DRAWING C-07-36.
16 FOR NEW ACCESS ROAD 30% LAYOUT, SEE DRAWING C-08-11.
17 AREA RESERVED FOR ELECTRICAL EQUIPMENT. SEE ELECTRICAL DRAWING E-08-01.
18 PROTECT EXISTING FENCE AND GATES.
19 REINSTATE ASPHALT PAVEMENT AND CURB. MATCH EXISTING CONDITIONS.
20 INSTALL HI-LO CARD READER FOR MAIN GATE AND ASSOCIATED EQUIPMENT. SEE PG&E DRAWINGS S1016, 406169, S1036 THRU 38. COORDINATE ELEC. CONDUITS AND EQUIP. WITH ELEC. DRAWINGS.
21 INSTALL REMOVABLE BOLLARD. SEE DETAIL 8/C-08-06.
22 ACCESS TO TRANSWESTERN GAS METERING STATION YARD MUST BE MAINTAINED AT ALL TIMES.
23 TRENCH F VAULT LOCATION BY ARCADIS SEE DWG C-07-52

GENERAL NOTES:

A SEE LEGEND, NOTES & ABBREVIATIONS C-08-00 FOR COMPLETE GENERAL NOTES.
B THE USE OF MECHANICAL RESTRAINTS IS RECOMMENDED BASED ON UNKNOWN SITE SOIL CHARACTERISTICS. THRUST BLOCK INSTALLATION IS BASED ON INSTALLING THRUST BLOCKS AGAINST UNDISTURBED SITE SOILS. CONTRACTOR IS RESPONSIBLE FOR ADEQUATE THRUST RESTRAINTS ON ALL PRESSURE LINES TO BE INSTALLED. THRUST RESTRAINT SYSTEMS SHALL BE SUBMITTED AND APPROVED BY ENGINEER.
C FOR UTILITY CROSSINGS, SEE DETAILS 4,7/C-08-07.

KEYED NOTES:

1. INSTALL 90° BEND. SEE PLAN FOR ASSOCIATED SIZE.
2. INSTALL TEE. SEE PLAN FOR ASSOCIATED SIZE.
3. INSTALL REDUCER. SEE PLAN FOR ASSOCIATED SIZE.
4. INSTALL 22.5° BEND AND 11.25° FOR TOTAL BEND OF 33.75°. SEE PLAN FOR ASSOCIATED SIZE.
5. INSTALL 45° BEND AND 11.25° FOR TOTAL BEND OF 56.25°. SEE PLAN FOR ASSOCIATED SIZE.
6. INSTALL 22.5° BEND. SEE PLAN FOR ASSOCIATED SIZE.
7. INSTALL POST INDICATOR VALVE. SEE DETAIL 2/C-08-07.
8. INSTALL FIRE HYDRANT. SEE DETAIL 12/C-08-07.
9. INSTALL GATE VALVE AND VALVE BOX. SEE DETAIL 3/C-08-07.
10. INSTALL BUILDING UTILITY PIPE CONNECTION. SEE 6/C-08-07. COORDINATE LOCATION WITH PLUMBING DRAWING P-08-01.
11. APPROXIMATE CONNECTION TO TRENCH F PENDING FINAL DESIGN BY ARCADIS, SEE DWG C-07-52 AND DETAIL 10/C-07-117. COORDINATE FIELD ADJUSTMENT AS NEEDED WITH ARCADIS.
12. VAULTS AND ALIGNMENT OF TRENCH F BY ARCADIS, SEE DWG C-07-52
13. CAP SERVICE AT 6" ABOVE FINISHED GRADE.
14. APPROX. PULL BOX LOCATION. COORDINATE LOCATION PER ELECTRICAL DRAWING E-08-01.
15. INSTALL CLEANOUT. SEE DETAIL 9/C-08-08.
16. INSTALL WYE CONNECTION. SEE PLAN FOR ASSOCIATED SIZE.
17. FOR SEPTIC SYSTEM DESIGN SEE DRAWING C-08-20.
18. REROUTE EX. TELECOM SERVICE. PROVIDE 12" MIN. HORIZONTAL AND VERTICAL CLEARANCE. COORDINATE RELOCATION WITH FRONTIER
19. INSTALL HOSE BIB. SEE DETAIL 1/C-08-08.
20. FOR PIPE MATERIAL OF WATER DISTRIBUTION LINES 2" DIAMETER OR LESS, SEE PLUMBING SPEC. SECTION 22 10 01.
21. EXTEND WATER SERVICE TO WELLS. COORDINATE WELL LOCATION WITH ARCADIS DRAWING C-07-36.
22. FOR ELECTRICAL SERVICE ROUTING TO WELL, SEE ELECTRICAL DRAWING E-08-01.
23. INSTALL 45° BEND. SEE PLAN FOR ASSOCIATED SIZE.

a - Values represent target/estimated design parameters for initial operation; system operation may be modified to optimize system performance.
b - Denatured ethanol assumed; instantaneous dosage concentration will not exceed 1-percent by volume.
c - Average flow rate/concentration over time; carbon substrate dosing will be periodic and duration/frequency will vary.
d - Estimated initial concentration.
e - Total maximum River Bank extracted groundwater flow limited to 500 gpm.
f - Total maximum NTH IRZ extracted/injected groundwater flow limited to 400 gpm.
g - Reference: G-03-01, G-04-01, G-04-02.
h - Total maximum carbon-amended injection well flow limited to 750 gpm; may include freshwater (see G-05-01).
i - Total backwash return water volume per week from NTH IRZ injection will network is approximately 18,000 gallons.
j - Maximum delivered volume = 7,000 gallons.

MW-X and MW-Y

Evaluation of Technical Justification

for Proposed Monitoring Wells MW-X and MW-Y

July 15, 2015

by

Robert H. Prucha, PhD, PE (Integrated Hydro Systems, LLC, Golden, CO)

Margaret R. Eggers, PhD, RG, CHG (Eggers Environmental, Oceanside, CA)

Introduction

At the request of the Fort Mojave Indian Tribe (FMIT), this paper addresses the following:

1) Evaluation of the technical basis used for locating proposed monitoring wells, MW-X and MW-Y (see **Figure 1a**) along the Arizona shore of the Colorado River, across from the northern part of the proposed PG&E remediation system,
2) Description of further testing and evaluations that could be done to better determine the need and locations of the proposed monitoring wells, and
3) Description of an alternative basis for performance assessment of the proposed remedy near the river.

The FMIT objects to the planned monitor wells MW-X and MW-Y at the proposed locations along the Arizona bank of the Colorado River. The objection stems from the fact that the wells are proposed for siting in a "named place," eligible for nomination to the National Register of Historic Places. Additionally, the area is part of a broader traditional cultural landscape and is therefore culturally sensitive. The Tribe believes that the construction and operation of monitor wells within this area will result in a significant and irreversible adverse impact on the area. Accordingly, it is imperative that a decision, such as one that adversely impacts a culturally-sensitive area, be rigorously justified from a technical vantage. This paper addresses the validity of the technical justification which is being relied upon for placing monitor wells MW-X and MW-Y at the locations proposed by the Pacific Gas and Electric Company's (PG&E) consultants.

The focus of this review was to evaluate the technical rationale applied to the siting of proposed monitor wells MW-X and MW-Y including the use of the existing groundwater model and other data. In particular, **the potential for hydraulic communication beneath the Colorado River between the CA and AZ was evaluated**. This necessitated a thorough examination of the assumptions applied in deciding on the need for these wells within the performance monitoring network. The Department of Toxic Substances Control (DTSC) has relied heavily on the groundwater model as the basis for the design and operation of the proposed remedial system (CH2M Hill, 2014a). As such, DTSC has also relied exclusively on the model in its current state to conclude that monitoring wells are needed across the river, at the proposed MW–X and MW–Y locations in Arizona. This paper presents results and recommendations based on the following key findings related to review of the technical basis for proposed wells MW-X and MW-Y.

Figure 1a. Existing and Future Wells, and Proposed Remedy Monitoring Wells (MW-X and MW-Y) along River Bank in Arizona.

Key Findings

The following headings list the various factors examined as part of this evaluation and list findings related to each. Further details are presented in subsequent discussions.

Purpose: The stated purpose of proposed wells MW-X and MW-Y is unclear and seemingly for cross purposes. Some references suggest that their purpose is to act as "sentinel wells." Elsewhere it is suggested that they would be used in conjunction with existing monitor well MW-54 to solve a three-point solution for determining the direction of hydraulic gradient.

Data Evaluations: Evaluation of relevant data sets presented various project documents was performed. The following observations were made.

- The May 2008 IM-3 extraction well shutdown showed no response in Arizona wells.
- The September 2008 IM-3 extraction well shutdown test failed to demonstrate hydraulic connection in groundwater between California and Arizona.
- Based on available data, future pathways beneath the river and into Arizona groundwater are likely south of the proposed MW-X and MW-Y locations.
- The use and interpretation of Arizona groundwater information is limited.
-

Modeling: Available modeling reports were reviewed and the following observations were made.

- Groundwater flow paths beneath the River and into Arizona inferred from the model appear to be the sole technical basis for establishing need and locations of monitor wells MW-X and MW-Y. However, the model is unrealistic and unreliable for estimating current or future flow conditions in the vicinity of the River, both beneath the River and within Arizona. When originally constructed, model development and calibration focused on the plume area in California, and on remedial design/operation. Through the design phases (i.e., 30%, 60% and 90%), projections have been expanded into Arizona, where model performance has not been validated.
- The current Conceptual Site Model (CSM) does not adequately describe the spatial- or time-varying 3-dimensional flow paths in the vicinity of the river.
- The modeling of flow in the vicinity of the river, beneath it and within Arizona is unrealistic and highly uncertain. This makes any model predictions coming from this model unreliable for evaluating potential flow paths beneath the River under the proposed remedial system operation, in the vicinity of MW-X and MW-Y. Model limitations include:
    - Unrealistic and unfounded hydraulic property distributions within the model.
    - Model boundary conditions are physically unrealistic, or inconsistent with other studies in the area.

- Numerical representation of hydrogeologic contacts is inappropriate, and riverbed bathymetry improperly specified.
- Calibration of the model is poorly presented, missing in Arizona, and questionable.
- The groundwater model code doesn't simulate density-dependent conditions, which would predict different results than assuming a constant groundwater density.
- The MODFLOW code does not simulate density-dependent flow, which likely influences potential groundwater flow between the aquifer and the River and beneath the River into Arizona.
- Results for model updates following the 60% BOD were not reported in the 90% BOD, nor provided to tribes for further review.
- Simulated results of freshwater extraction in Arizona (at either HNWR-1A or Site B) appear unrealistic, overly simplified and do not fully assess impacts on groundwater levels, groundwater hydraulic gradients or the effects of River fluctuations in the vicinity of proposed MW-X and MW-Y.

Recommendations for Further Testing/Evaluations: The following program of testing and evaluation merits consideration for the purpose of resolving the uncertainties associated with the need for monitor wells MW-X and MW-Y, and their siting.

- Field Testing:
  - Conduct tracer testing in existing Arizona monitoring wells.
  - Collect additional continuous monitoring data from existing Arizona wells.
  - Develop more appropriate groundwater contour maps in time, using density-corrected data.
- Model Update:
  - Revise CSM with new data (i.e., tracer testing and continuous monitoring).
  - Correct and re-calibrate the model to IM-3 data.
  - Re-simulate future scenarios, evaluating the need and proposed locations of MW-X and MW-Y.

Alternative Basis for Assessment of Remedy Performance: As a possible alternative for monitoring remedy performance, in lieu of using monitor wells MW-X and MW-Y, define a hydraulic target boundary along eastern plume boundary, and 'down-gradient' sentinel wells between the plume boundary and western river bank.

Purpose of Proposed Monitor Wells MW-X and MW-Y is Unclear

Before any new monitoring wells in Arizona are constructed, a clear and unambiguous purpose must be established. Currently, the purpose for MW-X and MW-Y appears unclear and raises additional questions.

In reference to the need for the proposed wells, DTSC has noted that:

> "… *the importance of these wells as sentry wells for the remedy which will purposely accelerate groundwater flow towards Arizona. Fundamentals on capture zone analysis and associated sentry wells can be found in* A Systematic Approach for Evaluation of Capture Zones at Pump and Treat Systems *(USEPA, 2008). DTSC could not approve the remedy without sentry wells. The remedy would have to be drastically modified (groundwater flow in the area would have to move in an opposite direction – towards the west) if sentry wells were to be eliminated."*
>
> "*These wells need to be installed early to establish baseline concentrations for water quality constituents (e.g., baseline chromium concentrations) so any naturally occurring trends can be observed before remedy start up. This will assist in determining if the well has been adversely affected by the remedy.* "[1]

Similarly, the Arizona Department of Environmental Quality (ADEQ) has expressed support for monitor wells at the proposed MW-X and MW-Y locations.[2]

If the proposed wells are to verify hydraulic gradient control of remediation system, this will be challenging for the following reasons:

- As noted in Vol. 2 of the O&M 90% BOD document, it would require 4 different lines of evidence, including use of the groundwater flow model, which is unreliable for this purpose in the vicinity of the river and Arizona where MW-X and MW-Y have been planned. Further adding to the challenge, all time-varying hydraulic stresses (such as other pumping wells and river fluctuations) acting on groundwater in this area need to be considered in the evaluation.

- This could be done more effectively by monitoring groundwater in wells in California, or by simply adopting a more appropriate target capture zone boundary west of the river (as described in the next section).

- Even if hexavalent chromium (Cr(VI)) or byproducts were detected in proposed monitor wells MW-X and MW-Y, or even MW-54, what decisions are then to be made? Would this actually pose any problem that could not be easily remedied by increasing riverbank extraction rates as

[1] See DTSC comment No. 6 on the 90% Design BOD.
[2] Letter from Ms. Taber, ADEQ to Mr. Yue, DTSC, and Ms. Innis, DOI, re "Groundwater Remedy Design Documents – Additional Comments," March 26, 2015.

indicated for Scenario 1 on Figure A1-18 in USEPA 2008? RAO #4 does not prohibit temporary plume expansion, it just cannot be permanent.

On the other hand, if the proposed wells are to also monitor concentration trends:

- It should be noted that multiple sampling events of AZ wells (see Figure 1, page 3 in ADHS, 2005) have already shown broad spatial occurrence of Cr(VI) in AZ wells detected up to ~26 micrograms per liter (µg/l). Therefore, a likely low detection of Cr(VI) in MW-X and MW-Y wells on the AZ side would be at best ambiguous as to its source.

- The USEPA 2008 paper describes details associated with capture zones, but does not consider the added complexity of in situ treatment upgradient of riverbank extraction wells at Topock. As such, the riverbank wells and associated monitoring wells in their vicinity should be considered sentinel wells that monitor both hydraulic capture and concentration trends.

- Arcadis (90% BOD O&M Vol. 2 report, Figure 2.2-1) suggests that these wells are to monitor riverbank extraction (see **Figure 1b**), but it is unclear how this would be done, or how the effects of solely riverbank extraction would be isolated from all other hydraulic stresses that already affect the MW-X and MW-Y area.

- Arcadis (90% BOD O&M Vol. 2 report, page 4-10) states that:

  "*In model layers 3 and 4 (the deep portion of the aquifer where the river bank wells are screened and where the majority of the floodplain Cr(VI) plume exists), 6 well pairs in each model layer were selected to define the expected average hydraulic gradient differences for four scenarios: (1) ambient (non-pumping), (2) nominal river bank extraction (150 gpm), (3) decreased river bank extraction (75 gpm), and (4) increased river bank extraction (300 gpm). In all scenarios, the simulated flow conditions had the NTH IRZ turned off as this is the remedy operating condition for 75% of the time (6 months ON/ 18 months OFF). The 'decreased river bank extraction' scenario (75 gpm) represents an approximation of the threshold where complete hydraulic plume control is achieved above this pumping rate and hydraulic plume control is potentially compromised below this rate. Thus, the well pair average hydraulic gradients simulated for this pumping scenario represent thresholds for hydraulic plume control.*"

  "Neither MW-X nor MW-Y are included in the 6 well pairs in Layers 3 and 4 to demonstrate "complete hydraulic plume control."[3]

Ultimately, if the two Arizona monitoring wells are proposed to confirm that gradients are maintained as predicted by the model, the existing model is deficient in a number of areas. These deficiencies then produce highly uncertain and unreliable results near and beneath the River and in Arizona. Principally, the modeled depiction of the hydraulic conditions beneath the Colorado River was not previously a

[3] Note: gpm = gallons per minute.

focus for this project. Therefore, this area of the model should be carefully reviewed and modified to more closely resemble the anticipated actual River conditions.

Groundwater flow from California toward Arizona beneath the Colorado River is possible due to a) decreased water levels in Arizona side extraction of HNWR-1 and/or Site B wells ranging from 450 to 900 gpm, and b) increased water levels in California due to the net addition of between 450 to 900 GPM in the proposed remediation area (see **Figure 2**). This results in a net increase of flow from California to Arizona of between 900 and 1,800 gpm.

It should be noted that the existing conditions at the site, under the IM-3 pumping influence, have been fundamentally relied upon to develop the groundwater flow and fate/transport models, which are then used to predict future groundwater flow paths, hydraulic gradients and concentration trends. However, an adequate demonstration of model calibration performance against years of carefully monitored groundwater flow and fate/transport data in the principle target remediation area in either California (i.e., IM-3 monitoring data) or Arizona has not been performed. Especially considering that the future pumping conditions will be quite different, the model has many apparent deficiencies which should be addressed prior to attempting to determine whether additional monitoring wells MW-X and MW-Y are needed, and where their locations and construction should be.

Figure 3 shows some simulated groundwater pathlines appear to migrate beneath the Colorado River and into the area of proposed monitor wells MW-X and MW-Y, assuming the National Trails Highway (NTH) In-Situ Reduction Zone (IRZ) system is active. It is our understanding that these model results are the primary technical basis for DTSC's position requiring monitor wells MW-X and MW-Y. However, the model should not be used to make these determinations before addressing the numerous deficiencies in the area beneath the River and along the river banks noted later in this evaluation.

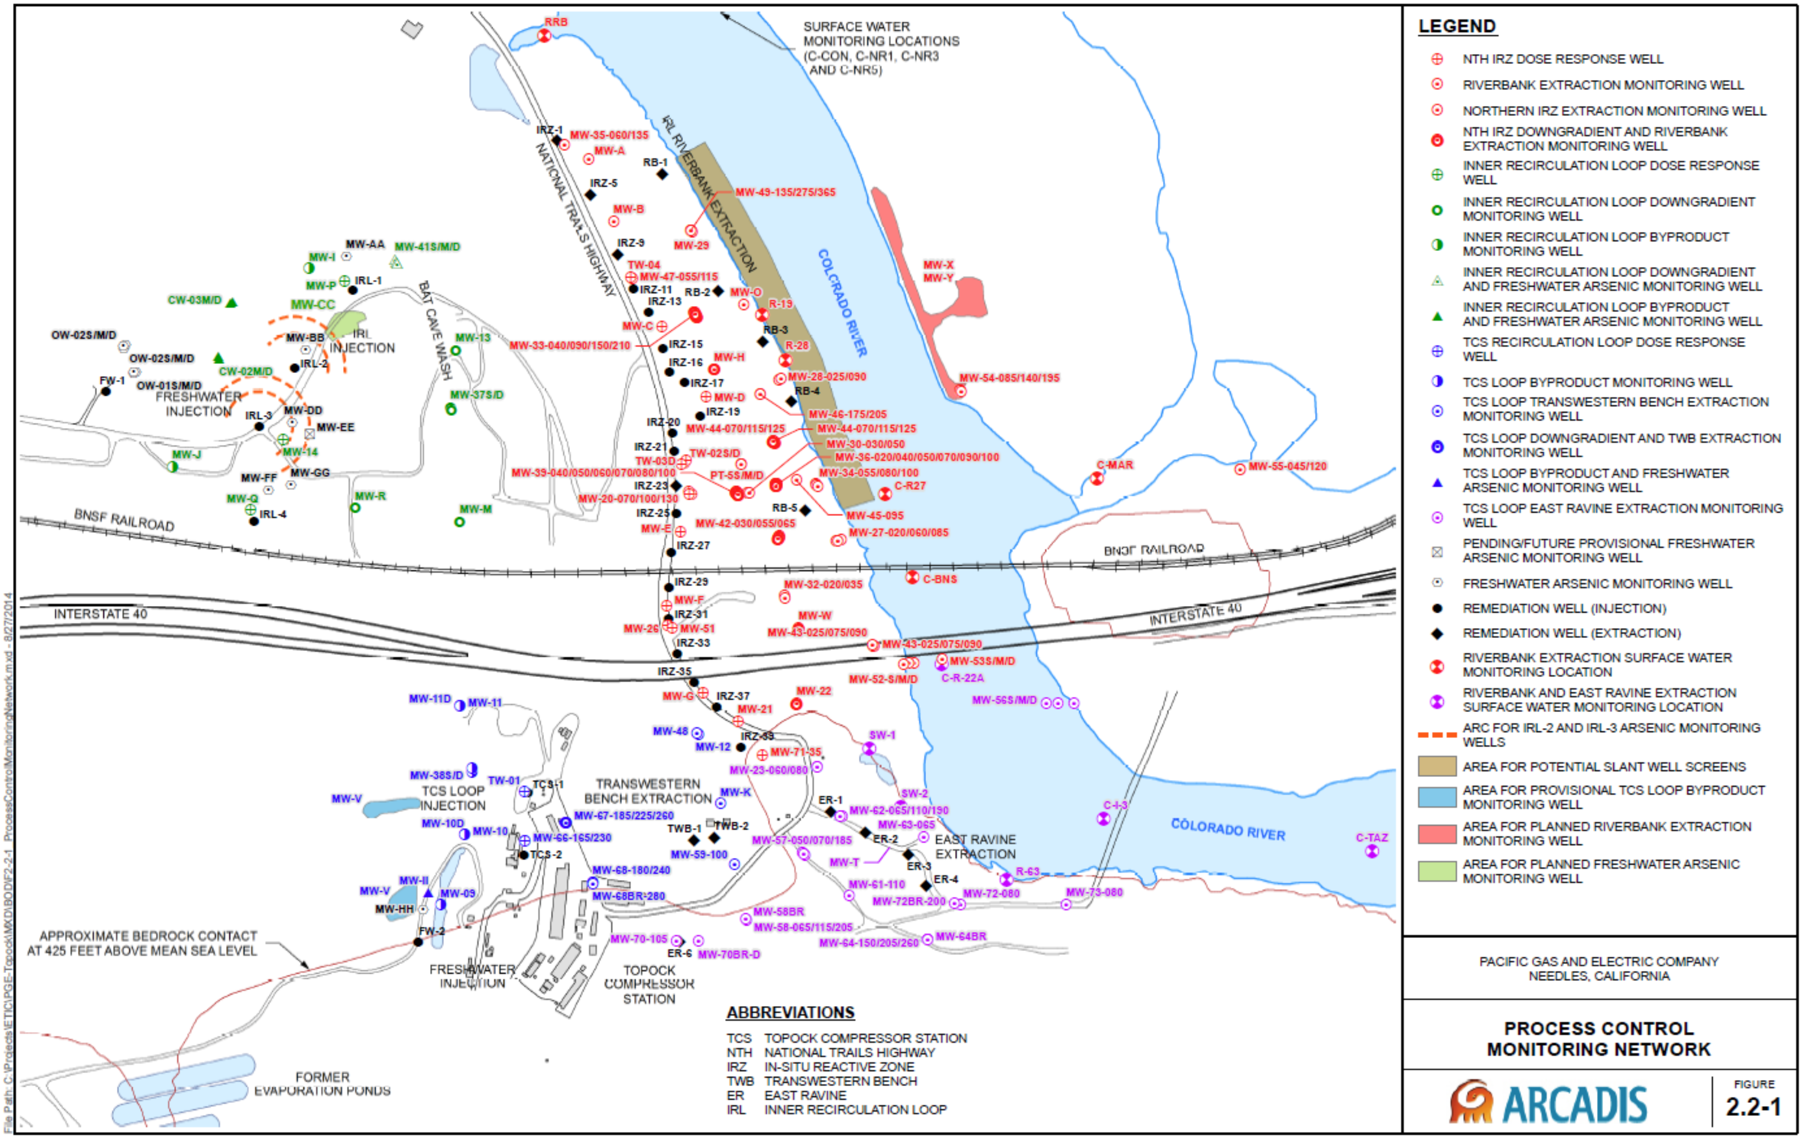

Figure 1b. Monitor wells MW-X and MW-Y are for "Area for Planned Riverbank Extraction Monitoring Well," but it is unclear whether it is for gradient control, detecting concentrations, or both. From 90%BOD OM Volume 2 Report (CH2M Hill, 2014a).

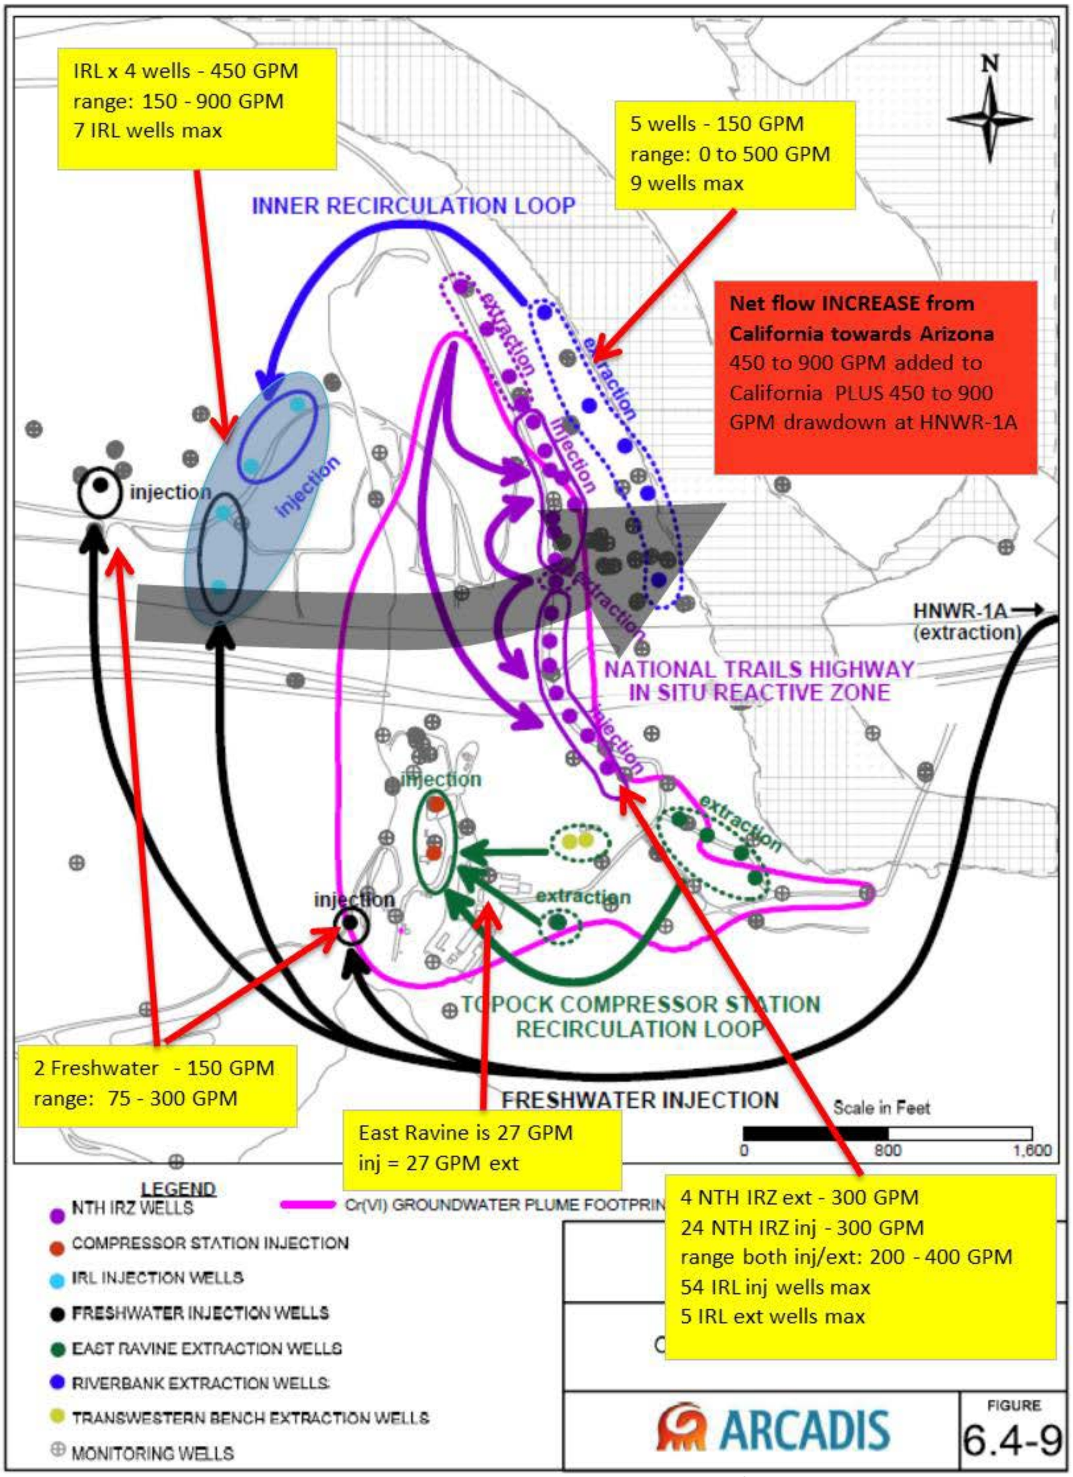

Figure 2. Major proposed remedial components and water routing.[4]

[4] As proposed in the 90% BOD, 450 to 900 gpm will be added in CA concurrent with the extraction of the same amount in AZ, thereby resulting in increased flow from CA towards AZ. By comparison, the current IM-3 extraction of ~130 gpm causes local flow from the direction of the River (possibly from Arizona), but is partially offset by upgradient injection.

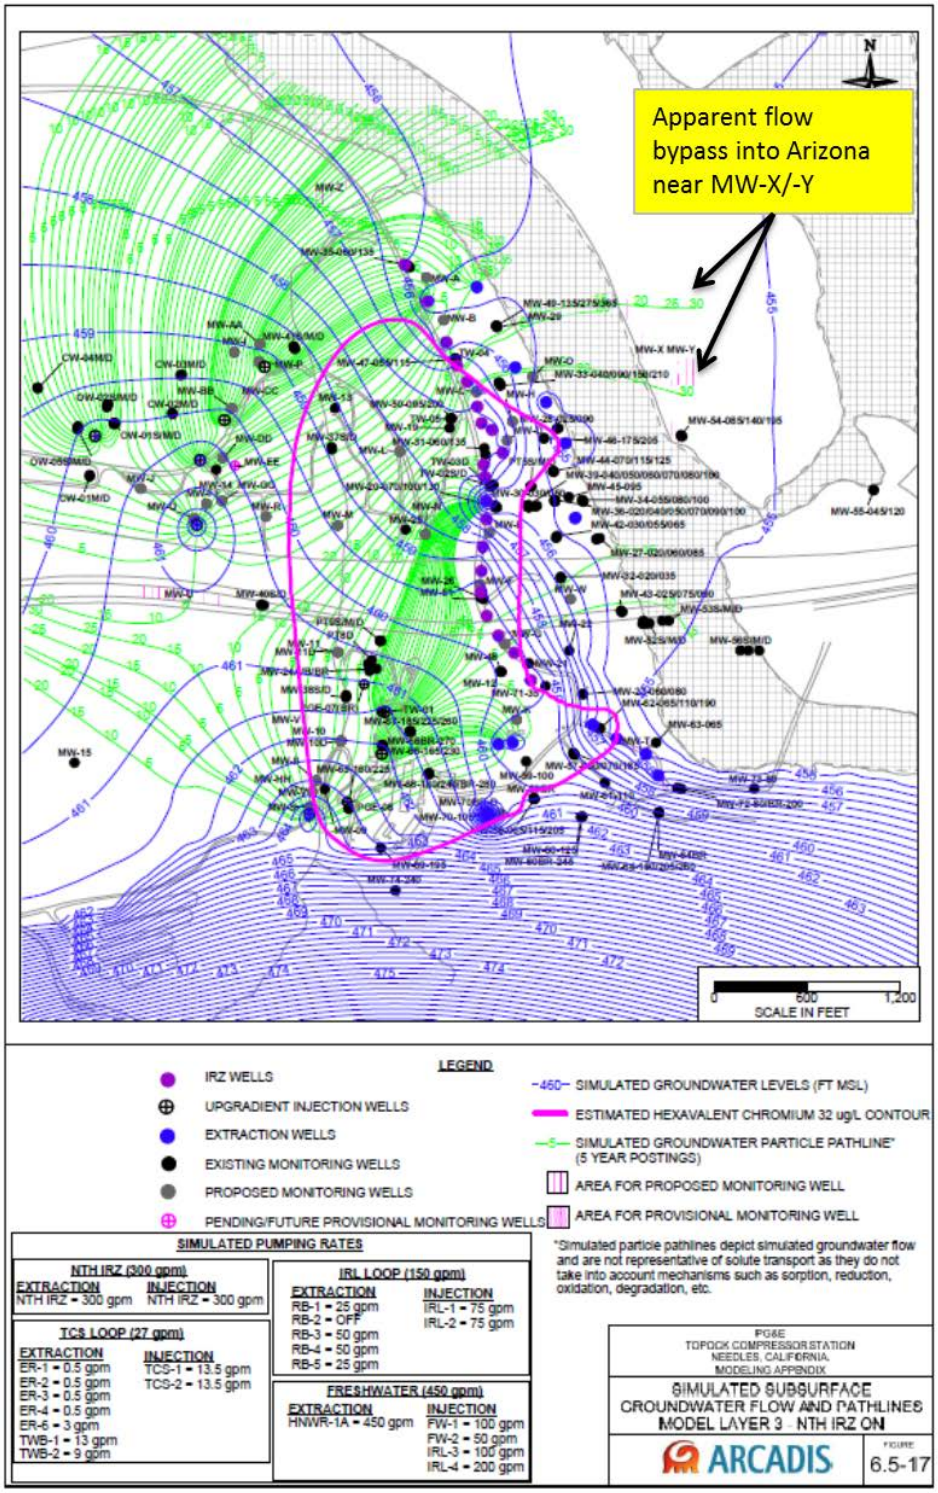

Figure 3. Simulated groundwater particle pathlines for model layer 3 with the NTH IRZ active (CH2M Hill, 2014d).[5]

[5] Some groundwater paths (shown in green) show apparent flow beneath the River and into AZ near proposed monitor wells MW-X and MW-Y. These paths are unreliable, however, due to flaws in the model.

Alternative 'Downgradient' Monitoring Location

A Target Capture Zone (or "Boundary of Hydraulic Containment Area" as shown on **Figure 4** and described at length on pages 6 and 8 of "*A Systematic Approach for Evaluation of Capture Zones at Pump and Treat Systems*" (USEPA, 2008)), could be defined for the Topock site as the eastern boundary of the current Cr(VI) plume, based on meeting the Remedial Action Objectives (RAOs). The 90% BOD report states the following (CH2M Hill, 2014a, page vi):

> *"The Remedial Action Objectives (RAOs) for the selected groundwater remedy at the Topock site are to:*
>
> 1. *Prevent ingestion of groundwater as a potable water source having Cr(VI) in excess of the regional background concentration of 32 micrograms per liter (µg/L[6]).*
> 2. ***Prevent or minimize migration of total chromium (Cr[T]) and Cr(VI) in groundwater to ensure concentrations in surface water do not exceed water quality standards that support the designated beneficial uses of the Colorado River (11 µg/L Cr[VI]).***
> 3. *Reduce the mass of Cr(T) and Cr(VI) in groundwater at the site to achieve compliance with the applicable or relevant and appropriate requirements (ARARs) in groundwater. This RAO will be achieved through the cleanup goal of the regional background concentration of 32 µg/L of Cr(VI).*
> 4. ***Ensure that the geographic location of the target remediation area does not permanently expand following completion of the remedial action."*** [Emphasis added.]

On page 4-8, Section 4.3.1 in the *Sampling and Monitoring Plan* (CH2M Hill, 2014c), the following is stated:

> "*The objective of RAO 2 is to limit Cr(VI) dissolved in groundwater at the site from migrating into the Colorado River. The remedy addresses this requirement through in-situ and groundwater pumping. The groundwater extraction wells are to be installed as part of the NTH IRZ (River Bank Extraction Wells) and the TCS Loop (East Ravine Extraction Wells). The hydraulic control evaluation is to assess the performance of the groundwater extraction well element of the remedy*."

As written, RAO #2 implies that there would be no violation as long as Cr(VI) and Cr(T)[7] concentrations do not cause Colorado River water concentrations to exceed 11 µg/. It can be shown that this would never happen due to the effects of dilution of normal River flow relative to the very small potential groundwater inflow. But, defining the target hydraulic barrier as the eastern plume boundary would provide greater assurance that RAO #2 would never be impacted. This however, would likely require re-evaluation and adjustment to the currently proposed 90% BOD design and operation of the NTH IRZ and Riverbank Extraction wells, such that existing contaminated groundwater does not move east into clean

[6] Note: µg/l = micrograms per liter
[7] Note: Cr(T) = total chromium

areas, between the eastern plume boundary and the river bank. At a minimum, RAO #2 supports making the western River shoreline the vertical target hydraulic barrier.

RAO #4 implies that it is acceptable for the plume to temporarily expand into clean areas, but that such expansion cannot extend beyond the projected remedial timeframe. This provision renders any assessment of the RAO compliance virtually impossible until the end of the remediation. Though the "target remediation area" does not necessarily correlate to the actual plume area, this RAO is interpreted to mean that the Cr(VI)-contaminated area should not expand into currently clean areas. This seems consistent with text on pages 2-3 in the 90% BOD Operation and Maintenance Manual Volume 2 (CH2M Hill, 2014c), that states:

> "*The data collected will be analyzed to ensure that the concentrations of Cr(VI) and remedy by-products, specifically manganese and arsenic, do not permanently increase outside of the baseline Cr(VI) plume*".

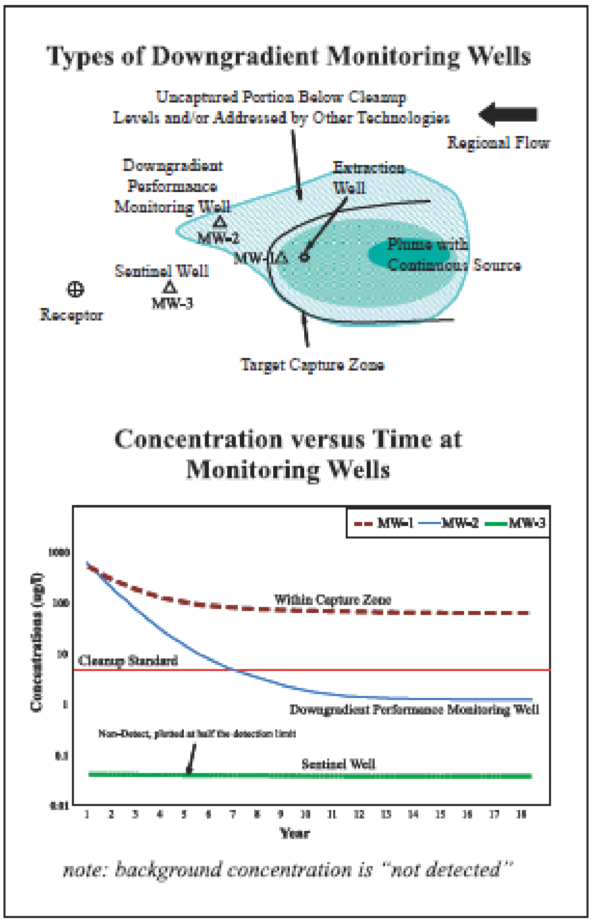

Figure 15. Types of downgradient monitoring wells.

Allowing a system design and operation to cause even the potential movement of the plume into Arizona, with no plan on remediating Arizona groundwater, seems inappropriate.

Because current Cr(VI) contamination is limited to the red outline (**Figure 5**), if a Target Capture Zone boundary is defined along the eastern edge of the plume area, any monitoring wells between the plume edge and the River could then be considered Sentinel Wells (as per Figure 15 in USEPA, 2008, shown to the left), while monitoring wells within the plume area would be considered Performance Monitoring Wells. This would ensure that currently clean areas east of the "baseline" plume extent would not become impacted (RAO #4) and the Receptor (i.e., the River) shown on Figure 15 would not get impacted (i.e., RAO #2), thereby eliminating the need for proposed monitor wells MW-X and MW-Y on the eastern shoreline of the River in Arizona.

Though the USAEPA (2008) Figure 15 (**left**) is a simplified version of the Topock Site, the NTH IRZ extraction wells, represent the 'Extraction Wells' shown, while the Riverbank Extraction wells are a secondary line of extraction intended to intercept treated water and re-inject it back into IRL wells. Extraction wells can be easily added, or rates increased if California monitoring shows expected gradients or concentration thresholds are exceeded.

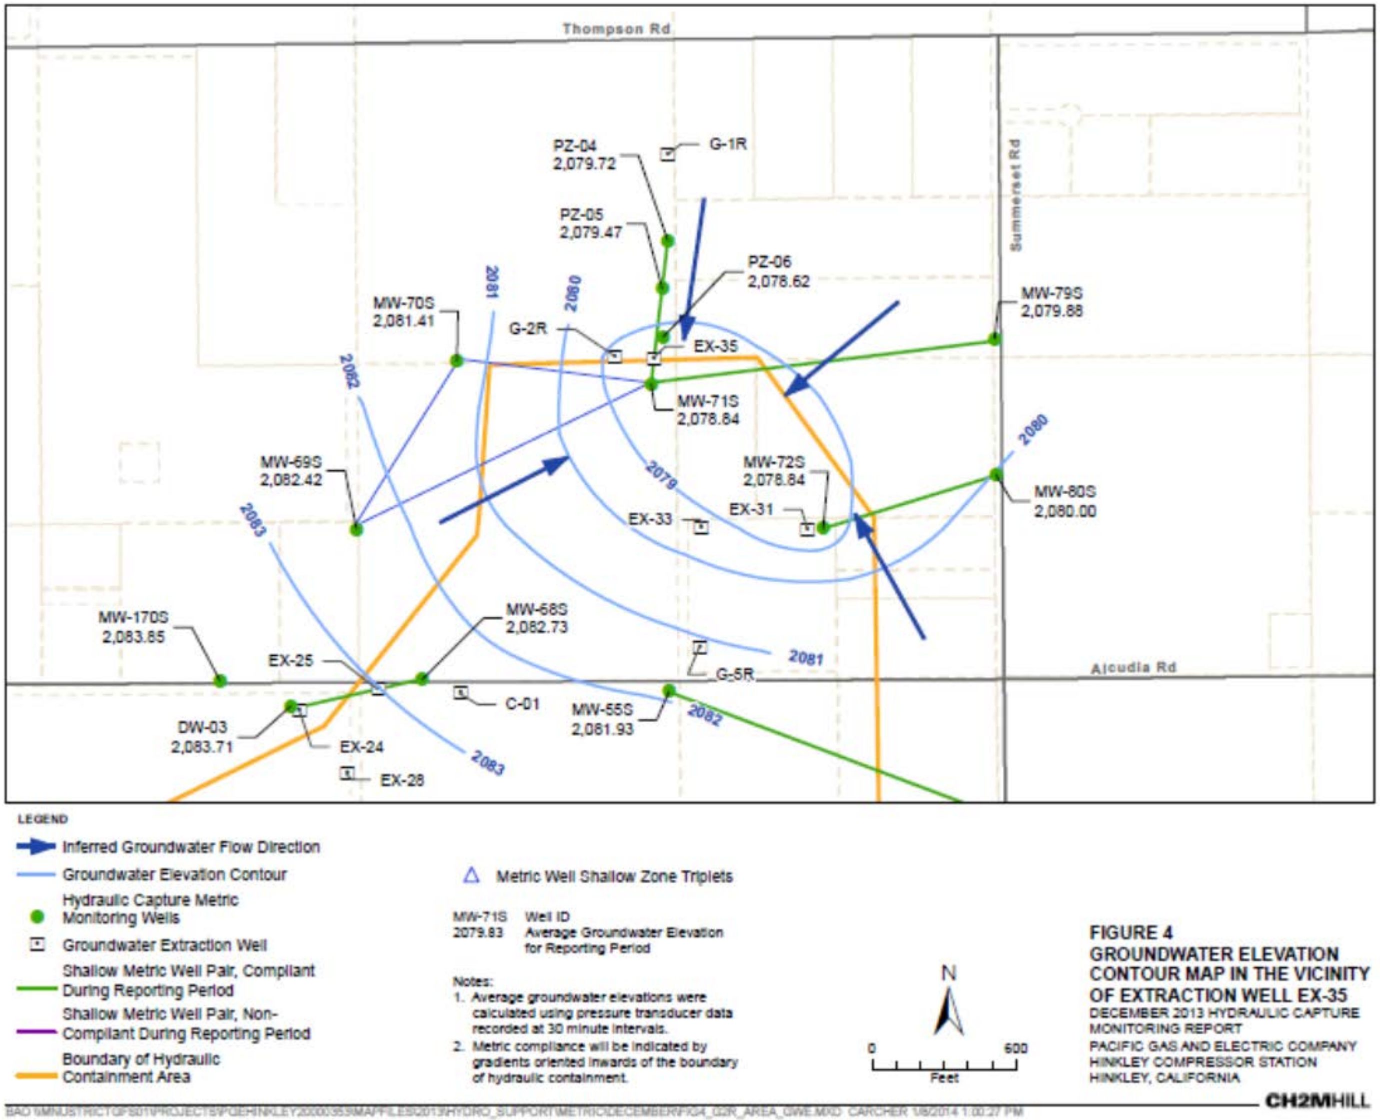

Figure 4. Boundary of Hydraulic Containment Area (orange line) at the Hinkley Site, across which gradients are closely monitored via well pairs/triplets (green lines between wells shown with green dots). (From PG&E, 2014).

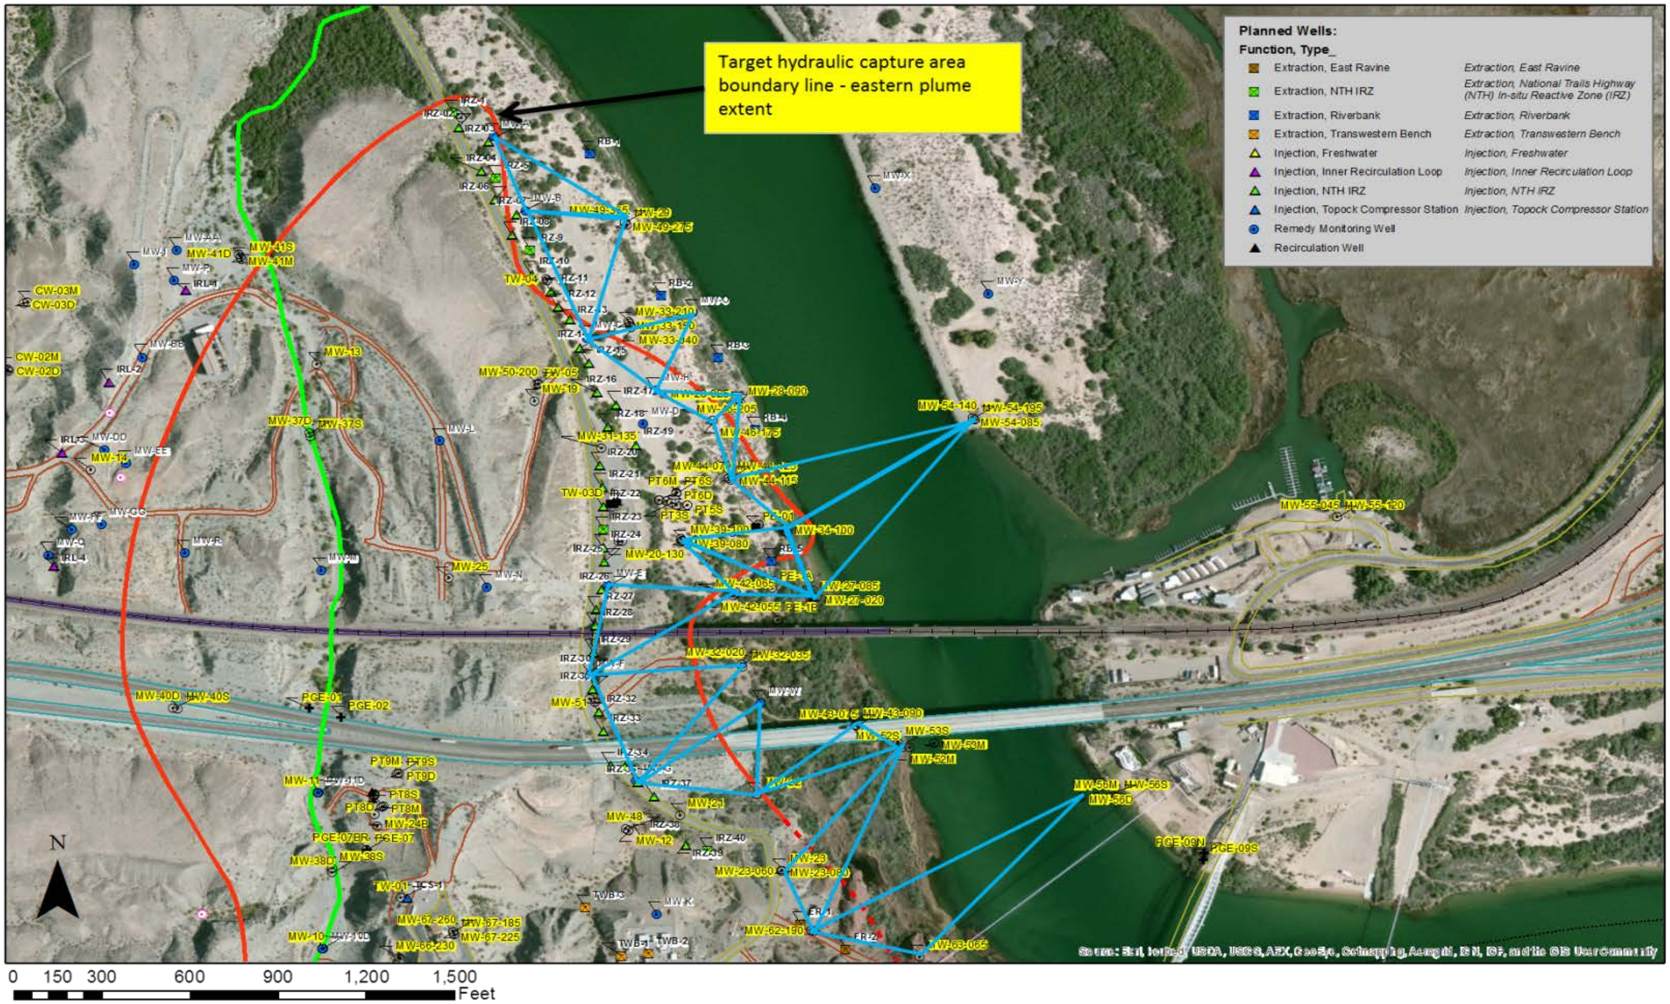

Figure 5. The red line bounds the 32 ug/L Cr(VI) plume (From CH2MHill 2014a).[8]

---

[8] This should be the "Target Capture Zone Boundary", which prevents contamination to the east. Blue lines represent triangles between monitoring wells (i.e., "triplets") that could be used to confirm hydraulic whether gradients are maintained such that contaminants do not move further east than the red line. Precise topographic and water level elevations would be required. Sentinel wells could be placed between the plume's eastern boundary (red line) and River bank.

Possible Pathway into Arizona Groundwater is Likely South of Proposed MW-X and MW-Y

Detectable Cr(T) and Cr(VI) Concentrations in Arizona

Even if a pathway and hydraulic connection exists beneath the river, detectable concentrations of Cr(T) and Cr(VI) at well MW-55-120 suggest it would be situated considerably (~800 feet) south of the proposed locations of MW-X and MW-Y and ~400 feet south and ~1,200 feet east of MW-54 (and ~2,000 feet east of IM-3 extraction well PE-1). If the concentrations of Cr(VI) and Cr(T), detected only in recent quarterly monitoring rounds at MW-55-120 are from the west side of the river, the entire CSM would need to be revised to account for such a pathway (i.e., are there unknown Arizona production wells drawing groundwater eastward). Alternatively, such detections could be from background concentrations in Arizona, similar to those reported by ADHS (2005). In any case, this information suggests monitor wells MW-X and MW-Y are unnecessary because multi-level monitor well MW-54 to the north has consistently shown non-detects for Cr(VI) and Cr(T) in quarterly monitoring reports. **Table 1** (Table 3-1 in CH2MHill, 2015) summarizes current data and suggests that if any "downgradient" Arizona groundwater should be monitored it would be at a location to the south of MW-54, not north where MW-X and MW-Y are proposed.

Table 1. Cr(VI) and Cr(T) concentrations detected at MW-55-120, MW-56S and MW-56M (from Table 3-1 in CH2M Hill, 2015

Several additional points can be made about the plume migration:

- **Figure 6** suggests the plume migrated towards the east, virtually at (or beneath) the Colorado River, near well monitor well MW-34. This migration from the southernmost plume extent strongly indicates a preferential pathway from the western high concentration area (darker plume color) towards the southeast, or towards the area bounded by MW-54 to the north and MW-56 towards the south, and directly towards MW-55 to the east. This direction appears consistent with increased permeability assigned to model layers 2 and 3 and beneath the river, and former areas within the active Colorado River (see **Figure 7** showing 1942 image and former River bank). **Figure 8** shows the maximum annual head difference calculated from continuous measurements.
- The majority of the existing plume (either by area or by mass) in California (**Figure 6**) lies well south of proposed monitor well MW-X and MW-Y locations. Therefore, Cr(VI) concentrations are much more likely to be detected at proposed wells MW-54, MW-55 or MW-56 than MW-X and MW-Y, well to the north, given the southerly average annual flow of groundwater through Lake Mohave Basin flow, which is discharged to the Colorado River as it funnels through the narrow Topock Gorge.
- The highest concentrations (**Figure 6**) within the current plume also occur well south of the proposed monitor well MW-X and MW-Y locations and would most likely be detected at the MW-54, MW-55 and MW-56 wells. So, these wells appear more than adequate to both detect changes in concentration with time and to monitor hydraulic gradients in the area.
- The Colorado River in this area likely acts as a sink, or net discharge location for groundwater, and because groundwater flow is directed from north to south, any “breakthrough” into Arizona groundwater would likely be south of the proposed locations of monitor wells MW-X and MW-Y. This is consistent with-widely accepted regional groundwater flow concepts (e.g., Tóth, 1963, Freeze, 1967).

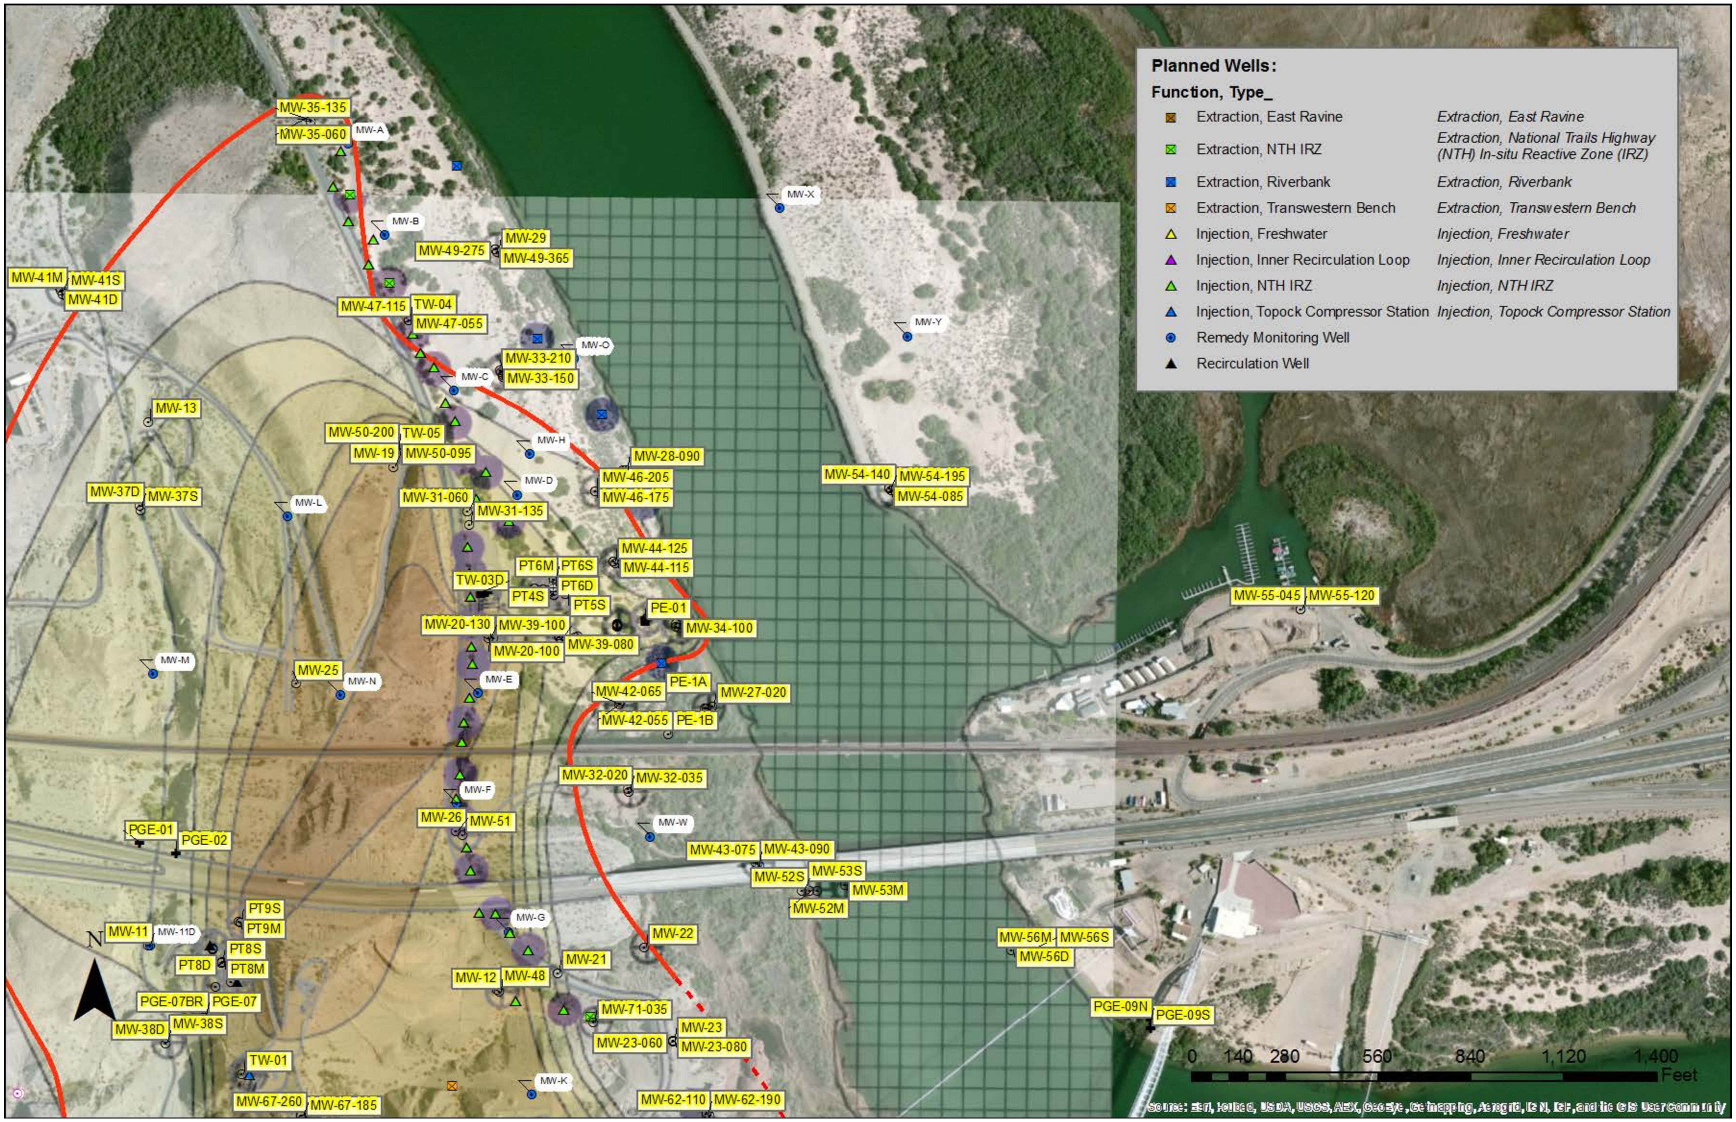

Figure 6. Model Layer 4 concentration contours (from Figure 6.2-4 in CH2M Hill, 2014d). The majority of the plume is well south of proposed MW-X and MW-Y wells.

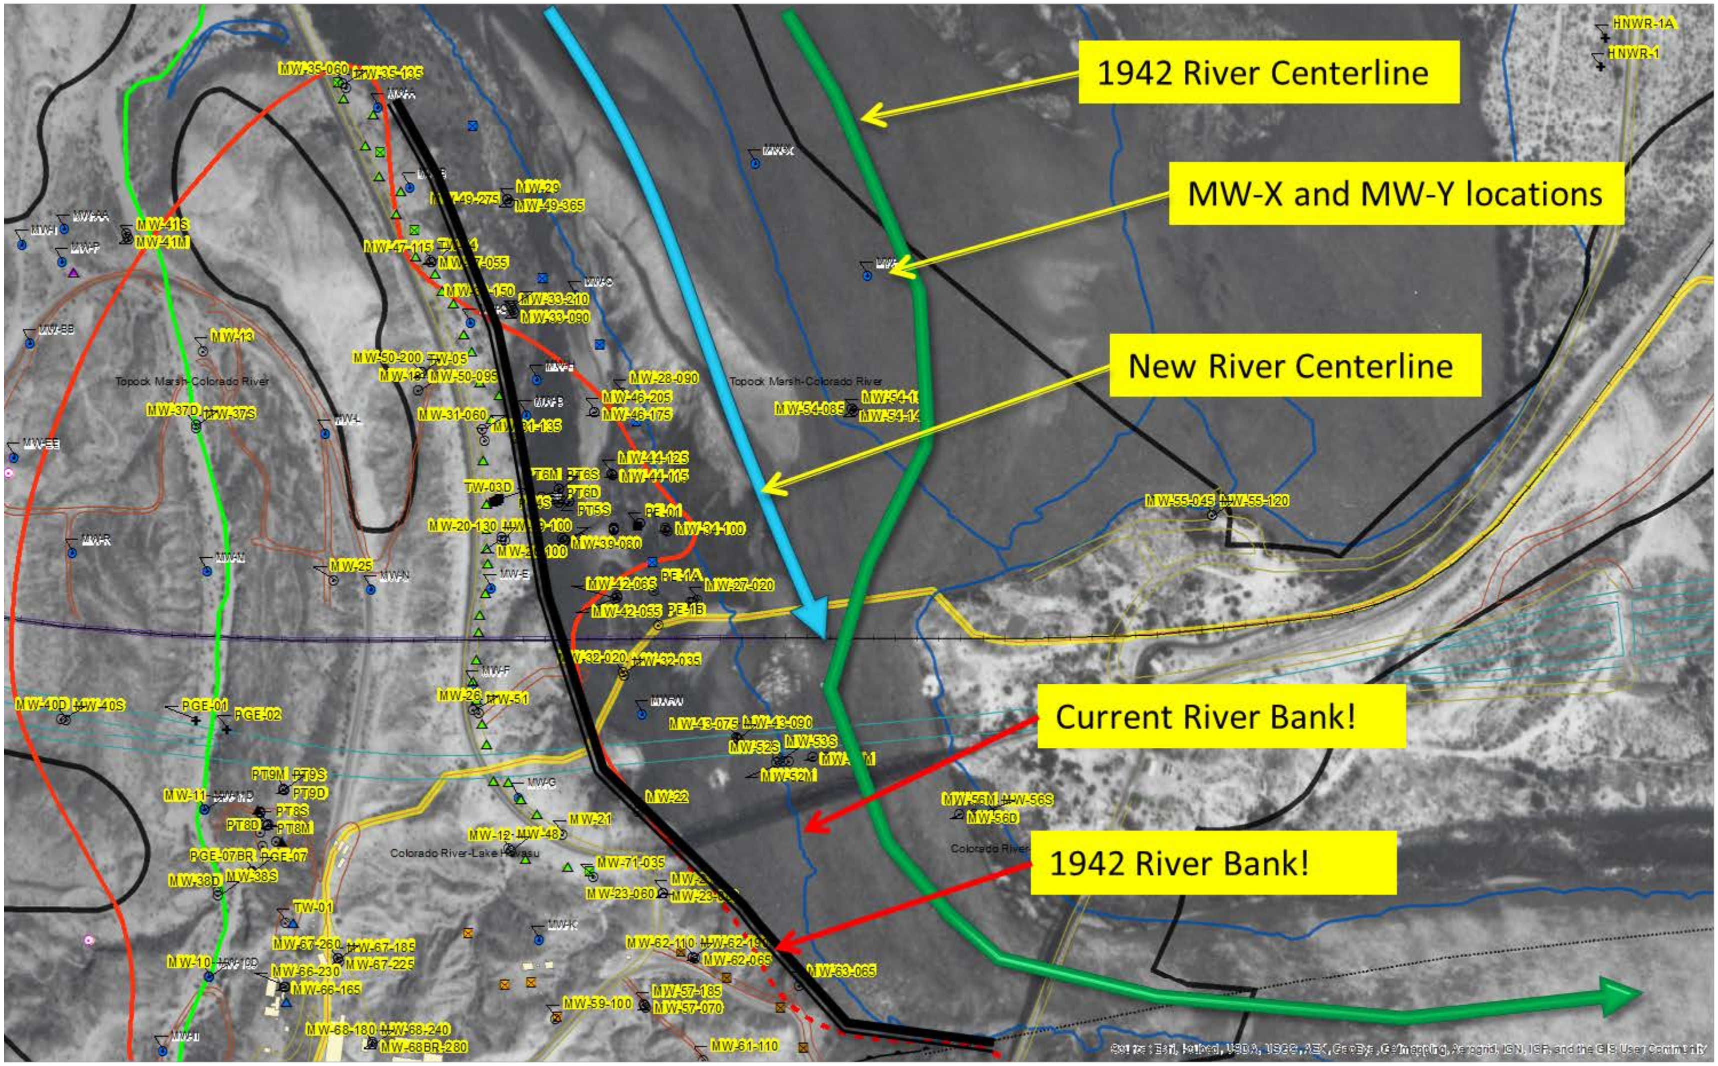

Figure 7. 1942 aerial image with current delineation of monitoring wells and Colorado River/Topock Marsh outline. Note that the River Centerline is actually much further to the east, or right through the proposed locations of monitor wells MW-X and MW-Y.

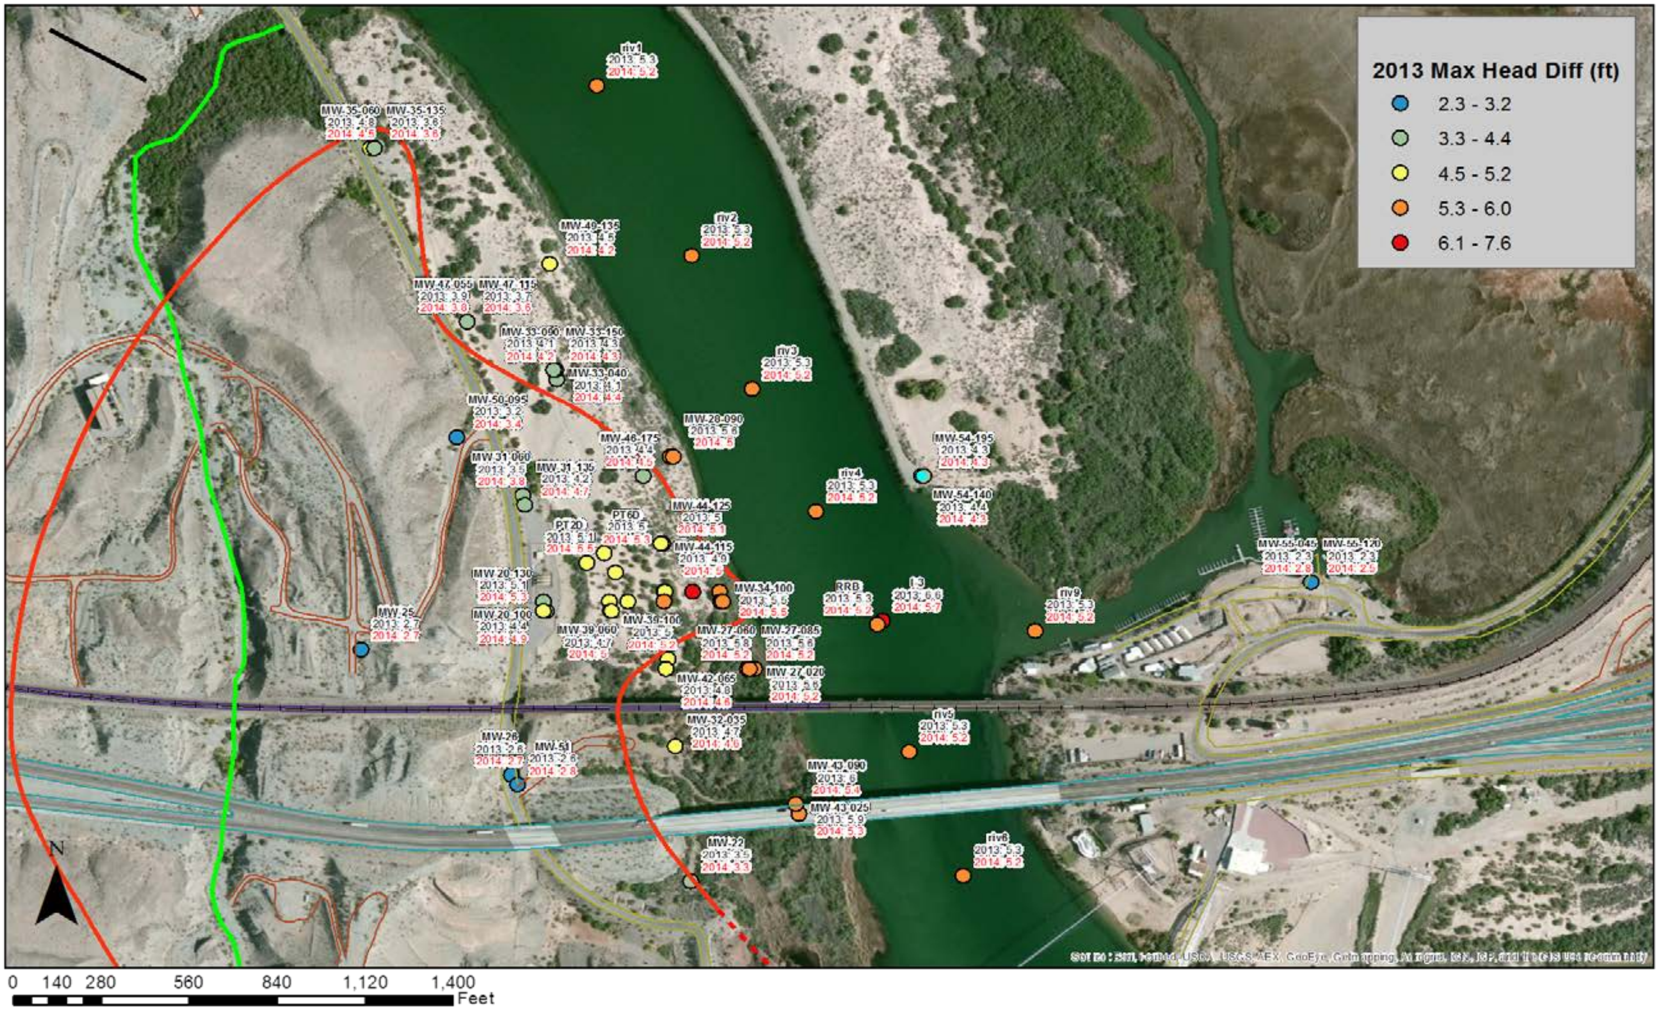

Figure 8. Maximum annual head difference calculated from continuous measurements.[9]

[9] Shows higher fluctuation in IM-3 extraction area better correlated to River stage than other wells with similar distance to riverbank. This implies the River is in greater hydraulic communication with the aquifer in this area, which appears to be an area where the plume has migrated eastward, well south of the proposed locations of monitor wells MW-X and MW-Y and in the pre-dredged area as depicted on Figure 7.

Use and Interpretation of Arizona Groundwater Information Limited

From review of the quarterly IM-3 performance monitoring reports, the following observations have been made:

1) Data from Arizona monitoring wells MW-54, MW-55 and MW-56 are critical to assessing any potential hydraulic connection in groundwater between the two sides of the river.

   i. **Groundwater-Level Data:**

      a. Continuous graphs of hourly corrected heads could not be found for any of these monitoring wells in the IM-3 quarterly monitoring reports, though many others are included relative to river level monitoring well I-3, and annual average values are provided for MW-54 and MW-55. It would be useful to see how their sub-daily groundwater levels respond to Colorado River/Topock Marsh surface water fluctuations.
      b. Though maximum, minimum and average head values are reported for wells MW-54 and MW-55, no values are ever reported for any of the screened intervals in Arizona slant well MW-56, or slant wells in California (i.e., MW-52 and MW-53). These are important locations, especially beneath the river, and should be monitored continuously with transducers, which can be referenced to groundwater elevations by making careful measurements with properly weighted electrical tape measures.
      c. Continuously-recorded water level data could not be found for any other wells in Arizona within the regional model domain, though CH2M Hill (2014c) indicate efforts are being made by PG&E to obtain access to private wells in Arizona. Access to such water level information is important, but would have limited value if only collected once and from pumping wells. Information should also be collected on well pumping details and background Cr(VI) concentrations to support other data in evaluating the hydrogeologic conditions in Arizona and to improve description of the CSM in this area.

   ii. **Aquifer hydraulic properties** – No long term aquifer pumping tests have been conducted at these Arizona wells, probably because extraction could draw Cr(VI) into Arizona. However, conducting a long-term tracer test (see Recommendations section below) could provide valuable information to support parameterization in the model in these areas and to determine the nature of hydraulic connectivity between Arizona and California groundwater.

2) It is unclear what regional wells are currently pumping and potentially influencing groundwater levels near existing monitoring wells MW-54, MW-55 and MW-56. No information was found in any of the 90% BOD documents, or any other reports reviewed. **Figure 20** below shows numerous regional wells obtained from the Arizona Department of Water Resources (ADWR), which

collectively could easily influence groundwater levels at MW-54, MW-55 and MW-56 (and proposed monitor wells MW-X and MW-Y).

Evaluation of Characterizations/Interpretations

To date, characterizations of hydraulic conditions beneath the river and east of it haven't been performed probably due to lack of data, but also because the coupled hydrologic flow system in this area (i.e., 3-dimensional groundwater flow system coupled with the surface water flow system) is complicated. Characterizations (i.e., interpretations of groundwater flow directions) are often aided by iteratively developing and evaluating multiple 3-dimensional CSMs with transient 3-dimensional groundwater modeling, and eliminating alternatives as new data is collected (see Section 5.3 and 5.4 in Neumann and Wierenga, 2003). Such conceptual deficiencies contribute to notable misinterpretations, evident from efforts to contour groundwater levels as discussed below and also typically contribute most to high uncertainty in model prediction (i.e., conceptual uncertainty).

Groundwater Level Contours: A careful review of available reports presenting interpretations of groundwater-level data and contouring resulted in the following observations.

- Meaningful contours cannot be developed from quarterly, averaged heads based on continuously-recorded levels in the presence of such strong river fluctuations. At a minimum, contours calculated over months should not span peaks in river stage, as the actual flow reversals get averaged out. Instead, averages of continuous data should only be done over very short durations (around the peak, or at the low stage) or on just over the rising or falling limbs (longer durations) so that more meaningful flow directions are assessed.

- Some reports include MW-55 and MW-56, but most reports include only MW-54. This results in an incomplete record and requires explanation, which limits development of a more robust CSM in this area of the flow system.

- The configuration of the contours by aquifer layer for different quarterly reports varies significantly. This is most likely due to manual, subjective interpretations by different individuals over time. Why, for example, would not the mid-aquifer depth contours look more like upper layer contours, especially where data are lacking in the middle layer?
- Interpreted 3-dimensional flow paths should be presented to support the CSM. None have been described.

- Though much of the focus has been on horizontal flow gradients, a complete sense of vertical gradients should be assessed during different River stages to get a better sense of how water moves between the different aquifer zones, especially beneath and in the vicinity of the river. This would greatly aid characterization of the groundwater flow directions in 3-dimensions and conceptualization of flow in the vicinity of the River, especially near proposed monitor wells

MW-X and MW-Y. These characterizations are essential to developing a robust numerical flow model whose performance can be verified against this information.

- Simulated contours shown on **Figure 9** appear flawed in Arizona, which we attribute to many factors summarized in a modeling section below. This is compounded by misconceptions with regard to aquifer-River interactions and the overall CSM. Re-contouring as shown using long-term average Arizona values from continuous hourly measurements shows a more realistic conceptualization and better conforms to accepted regional groundwater flow theory.

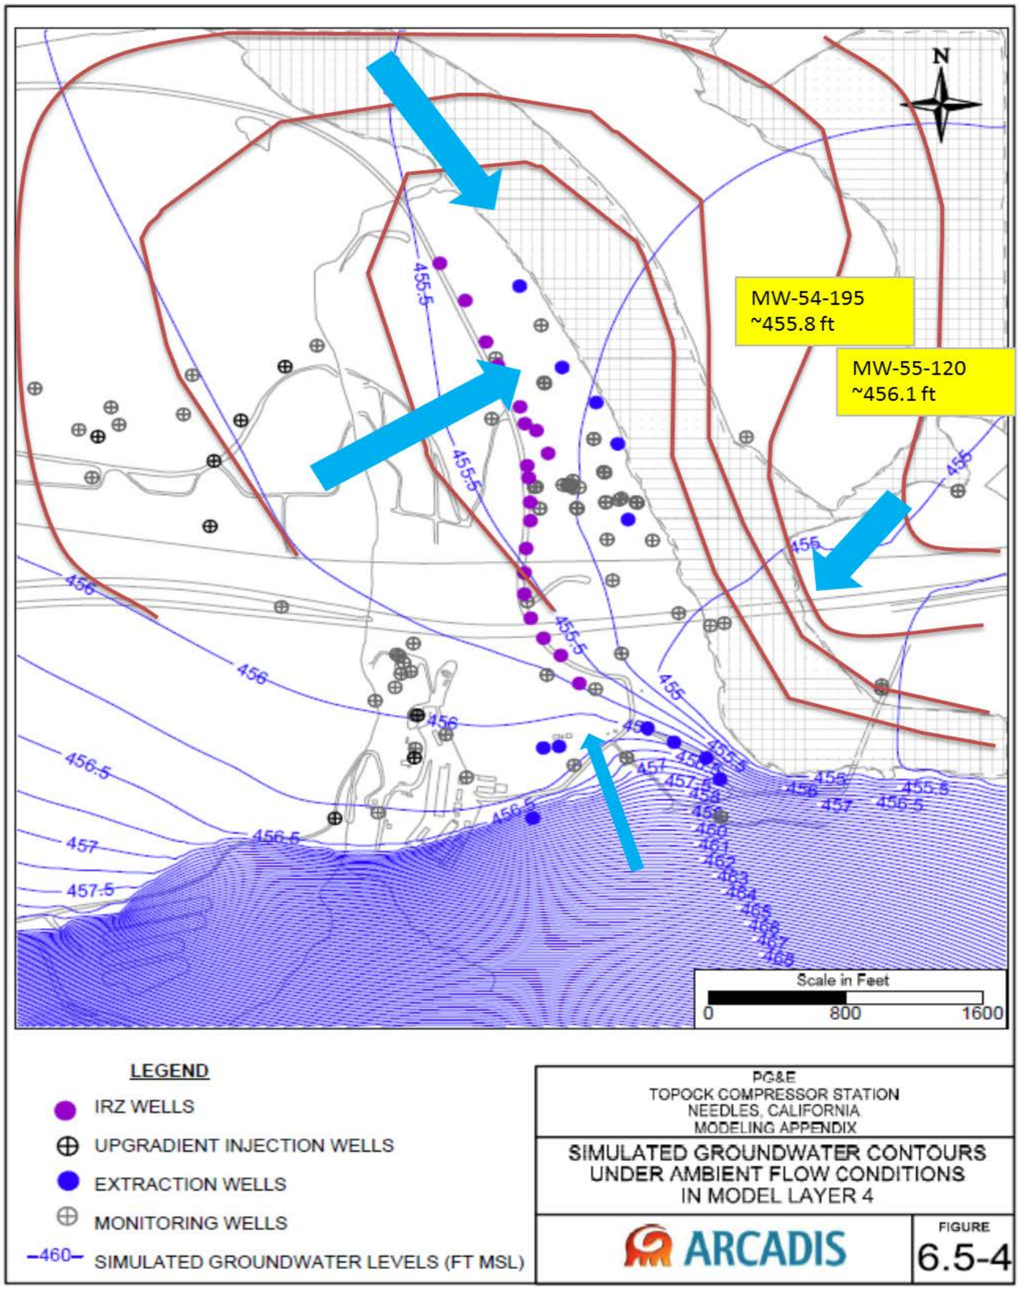

Figure 9. Presumed Average Annual Simulated Head contours for ambient flow conditions (no IM-3 pumping) for the lower aquifer zone.[10]

[10] These contours are lower than average annual heads in lower-screened zones at wells MW-54-195 and MW-55-120, estimated under the potential influence of the IM-3 extraction during 2012 and 2013. Red solid lines denote a reinterpretation of these contours and flow direction (shown as blue arrows) to better incorporate these average annual levels into the simulated groundwater flow. Simulated contours and flow directions do not incorporate the significant model uncertainty. Note that the resulting contour pattern generally reflects a typical conceptualization of regional groundwater flow in a large basin discharging to a river.

The Conceptual Site Model Does Not Adequately Address Areas Beyond West Riverbank

The detailed conceptualization of groundwater flow between the east and west sides of the Colorado River has not previously been a focus of the model. Flows in the vicinity of the River, beneath it and within Arizona are poorly conceptualized. Accordingly, the modeled depiction of the hydraulic conditions beneath the River should be carefully reviewed and modified to more closely resemble actual annual river conditions. In particular, a clear conceptual flow model of the system that fully addresses the dynamic daily and seasonal natural behavior of the aquifer-river flow system should be incorporated into the model as these affect groundwater contouring, which in turn affects conceptualization of flow directions near the River. Developing a 3-dimensional CSM, based on sound characterization of flow and transport, is critical to constructing a reliable and realistic 3-dimensional numerical flow model of the system. Improving this area of the model to produce a more realistic numerical depiction of the area beneath and adjacent to the river is vital for making informed decisions concerning the need for and value of additional monitoring wells, such as MW-X or MW-Y. This is also important because many model results have been presented in the 90% BOD report showing particle paths, concentration distributions, etc. in Arizona, but the associated uncertainties are significant and not explicit in the reporting.

Review of 90% BOD groundwater modeling report (CH2M Hill, 2014d) or related modeling reports revealed no discussion on the characterization or 3-dimensional conceptualization of river-aquifer interaction. These could have encompassed the assumptions and implications to the CSM for parameters like the spatial distribution of hydraulic properties, such as riverbed conductance or horizontal/vertical hydraulic variations beneath the River and their variations in Arizona.

> "*In an area made complex by intersecting alluvial fan and fluvial deposits (both with highly variable hydraulic properties), constantly changing river elevations, and salinity and temperature variability in three dimensions, the model is a simplified version of actual conditions but is considered a valuable tool to apply to evaluation of target pumping rates and remedial alternatives in the immediate site area. Groundwater level changes in response to river fluctuations and to well pumping have been matched to a reasonable degree in areas where data are available.* ***Average groundwater elevations are also reasonably well-matched, given the less reliable data quality****. Simulations of historical Bat Cave Wash discharge have shown general agreement with the current groundwater plume, both in spatial position and in time of travel. As additional information is collected in and around the site, the model will be improved with the new data. Improvements either planned or anticipated for the near future are:* ***(1) calibration to measured heads on the Arizona side of the river;*** *(2) longer-term monitoring of planned injection at IW-2/IW-3; (3) test data from the new PE-1 well near MW-36 in the floodplain; and (4) continuing data collected each month from TW-2D pumping and river fluctuations, including future TW-2D temporary shutdowns.*" [Emphasis added.] [11]

[11] See page 4-1 in CH2MHill, 2005

The reports reviewed also did not discuss subsequent calibration performance and statistics related to Arizona wells. This would be essential information to assess the validity of model predictions such simulated particle tracks for the proposed remediation system design and its operation, contained in the 90% BOD groundwater modeling report (Appendix B). Especially since those predictions are apparently used as the basis for justify the need and locations of planned monitor wells MW-X and MW-Y.

Model Setup is Unrealistic, Uncertain and Unreliable

Only modeling can incorporate all of the complex hydraulic property distributions, combination of complex external stresses (i.e., river fluctuations, pumping, recharge, ET, etc.) and spatial variations in aquifer units (i.e., alluvial/fluvial isopachs and depth to bedrock) in simulating current and future flow conditions that would be influenced by proposed remedial operations. As such, only this tool can provide an adequate basis for determining the need for additional monitoring wells, and if needed, their number(s), locations and screened depth intervals. However a model intended for this purpose would need to be correctly developed and calibrated with estimates of uncertainty to be sufficiently reliable for justifying the need or locations of proposed monitor wells MW-X and MW-Y. This review of the model focused on the MW-X and MW-Y area, and specific model areas which influence current or future simulated flow conditions in this area (i.e., beneath the River and within Arizona).

No single document describes in detail, the development of both the regional microFEM and localized MODFLOW groundwater flow models, all associated setup assumptions, standard calibration details such as Mean Error, Root Mean Square Error, etc.), or even how flow conditions are transferred between these two models (i.e., see 90%BOD DOI comments #429 and #431) . Calibration targets (i.e., average annual heads, monthly heads at selected wells, or localized well shutdown responses) should be provided and shown to be relevant and adequate for the intended uses of the model (i.e., how well does the model reproduce observed remedy performance metrics like hydraulic gradients, flow directions and concentration values or trends as described in the decision/operational framework diagrams shown in Figures 2.2-2 through 2.2-9 in CH2MHill, 2014c). Results of PEST parameter estimation simulations, or specified constraints and their basis could not be found in any available documents, so there is no way to assess parameterization beneath river and east of it, or to assess constraints imposed. Lack of this information makes it difficult to assess overall model performance, for example, the model's ability to reproduce accurate and realistic remedy performance metrics (i.e., observed hydraulic gradients, groundwater flow directions, or concentration trends or values) especially beneath the river and in Arizona proximate to the proposed MW-X and MW-Y locations.

The 90% BOD report (CH2M Hill, 2014a) summarizes modeling Appendix B (CH2M Hill, 2014c), but this mostly discusses the calibrated model, and provides only a brief overview of generalized assumptions on model input. It is neither comprehensive, nor detailed enough to fully assess model calibration performance of either the MODFLOW sub-model, or MicroFEM regional-model. Detailed assumptions, calibration statistics and inputs (i.e., head residuals for all wells, different screened depths, etc.) are not presented. The following is a review of earlier modeling reports issued for the project.

Arcadis (2013) provided 60% BOD modeling file inputs for a specific scenario to Dr. Prucha of the Technical Review Committee (TRC). Dr. Prucha ran this and evaluated both input and output using ESI's Groundwater Vistas program (http://www.groundwatermodels.com/). Some of the input was compared against other spatial data in ArcGIS.

This review indicated a number of reasons, listed below, why the 90% BOD simulated results of future remedial system operation should not be considered reliable enough to justify the need for and locations of proposed Arizona monitoring wells MW-X and MW-Y. The model should be updated and revised using both existing data and new data that could be collected right now (as outlined in the recommendations section below) so that significant conceptual and model input uncertainty can be reduced before attempting to justify two additional monitor wells (MW-X and MW-Y), and before guessing where these should be optimally located and screened for monitoring.

General modeling observations include:

- Two different IM-3 shutdown tests in 2008 failed to demonstrate clear hydraulic response in Arizona monitoring wells MW-54, MW-55 and MW-56. To date, no hydraulic connection, or the nature of such a connection between California and Arizona groundwater has not be clearly demonstrated.
- Water level corrections should incorporate salinity/temperature variations with depth.
- Calibration results are poorly presented. The model inputs should be calibrated against the best available data (IM-3 response to years of extraction and injection).
- Specific input details, assumptions and results of post-60% BOD modeling updates were not provided for tribal review, which limited any evaluation of simulated flows within Arizona, and in proposed monitoring locations MW-X and MW-Y.
- Effects of the extraction of Arizona groundwater (Site B, HNWR-1 or HNWR-1A) e on groundwater conditions at MW-X and MW-Y appears unrealistic and uncertain.
- Various model inputs are unrealistic or unjustified near the river and in Arizona:
    - Model layers do not correlate with hydrostratigraphic unit (HSU) contacts.
    - Evapotranspiration representation should be more realistic.
    - River-aquifer exchange should reflect natural conditions.
    - Recharge input parameters should be more realistic.
    - Distribution and magnitudes of hydraulic conductivity beneath river and in Arizona show considerable variations over many orders of magnitude in areas where no data exists – likely due to poorly constrained automatic parameter estimation.
- Simulated mass balance and head contours appear unrealistic.
- Bedrock depths in the model in Arizona appear inconsistent with other reported depths (Richard et al, 2007).

- Density-dependent flow conditions are not simulated, which affects predicted flow conditions near MW-X and MW-Y.
- Groundwater pumping effects at either the regional model, or sub-model boundaries may not be adequately accounted for in the model, which can affect flow conditions near MW-X and MW-Y.
- Calibration results, especially in Arizona wells, are questionable for intended purposes.

Hydraulic Property Distributions Unrealistic/Poorly Justified

Subsurface hydrogeological model inputs on the Arizona side appear to be based on very limited data for aquifer hydraulic conductivity, storage parameter distributions, and HSU thicknesses. The implications were never assessed on future predicted flows beneath the River, or in Arizona with all of the complicating time-varying stresses such as fluctuations in the River and Topock Marsh area, and existing/future groundwater extraction in Arizona.

Figure 10 below (CH2M Hill, 2014c) shows a very complex distribution of hydraulic conductivity for one model layer (3), which strongly controls lateral groundwater flows beneath the River and vertical flows beneath the River and water exchange between the River and the aquifer. While distributions may actually vary orders of magnitude, the abrupt changes and lack of any data beneath the River indicate that this is unrealistic and non-unique. Though the authors indicate it was derived for each layer through use of a parameter estimation code, unless highly constrained, these tools do nothing more than generate non-unique or "guessed" distributions. Use of the PEST program is not unreasonable, but it is incumbent upon the modeler to clearly convey the implications of the non-uniqueness and implications on the model predictions. The modelers made no attempt to evaluate the validity or range of implications of these assumed significant variations in hydraulic conductivity on model predictions, particularly related to simulated flow paths (particle tracks), which appear to break through the riverbank extraction well network. This is analysis is used as the primary justification for siting of proposed monitor wells MW-X and MW-Y. Any simulations or modeling performed within this area of loosely assumed parameters should be clearly presented with strong qualifiers that these results are at best a gross estimation of how the natural system might actually respond. Accordingly, the current model should **not** be used to determine locations, numbers, or depths of monitoring wells including proposed monitor wells MW-X and MW-Y. The number, locations, screened depths of any monitoring wells in addition to MW-54, MW-55 and MW-56 should not be proposed based on results from this model until it is corrected and better calibrated using all available existing data (IM-3 system), and potentially new data are applied as suggested below.

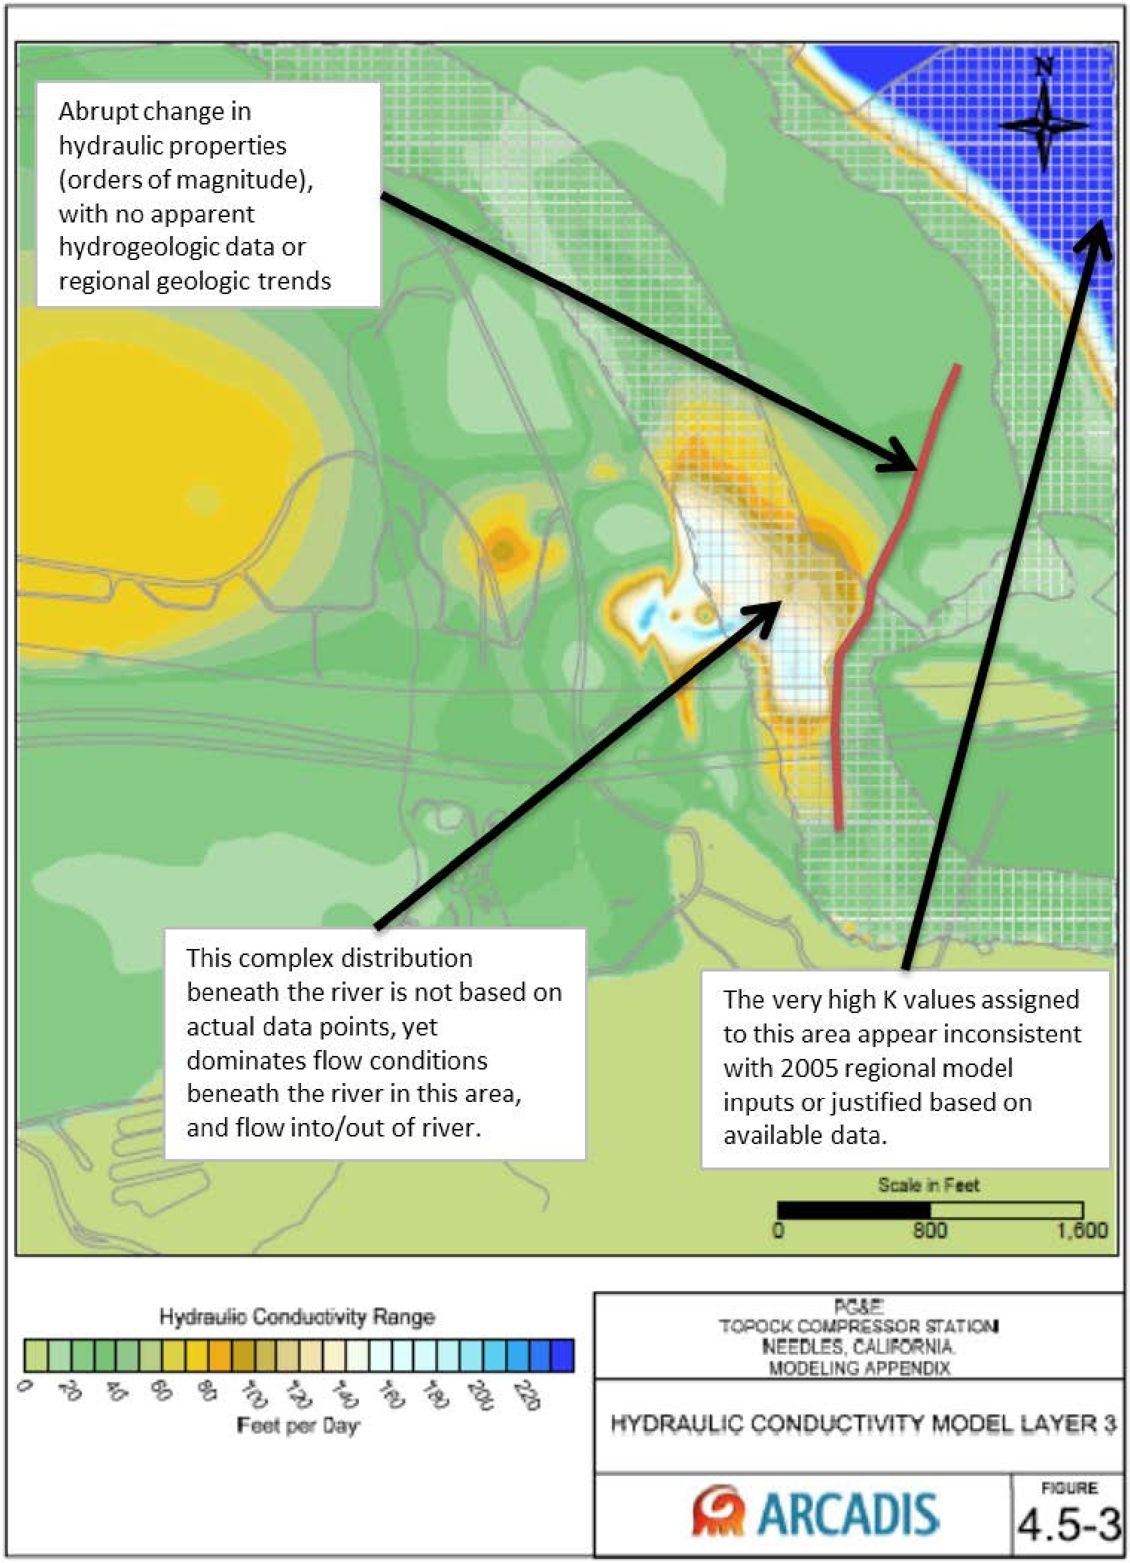

Figure 10. Hydraulic conductivity values used in Model Layer 3, and several unrealistic aspects of the distribution/magnitudes.

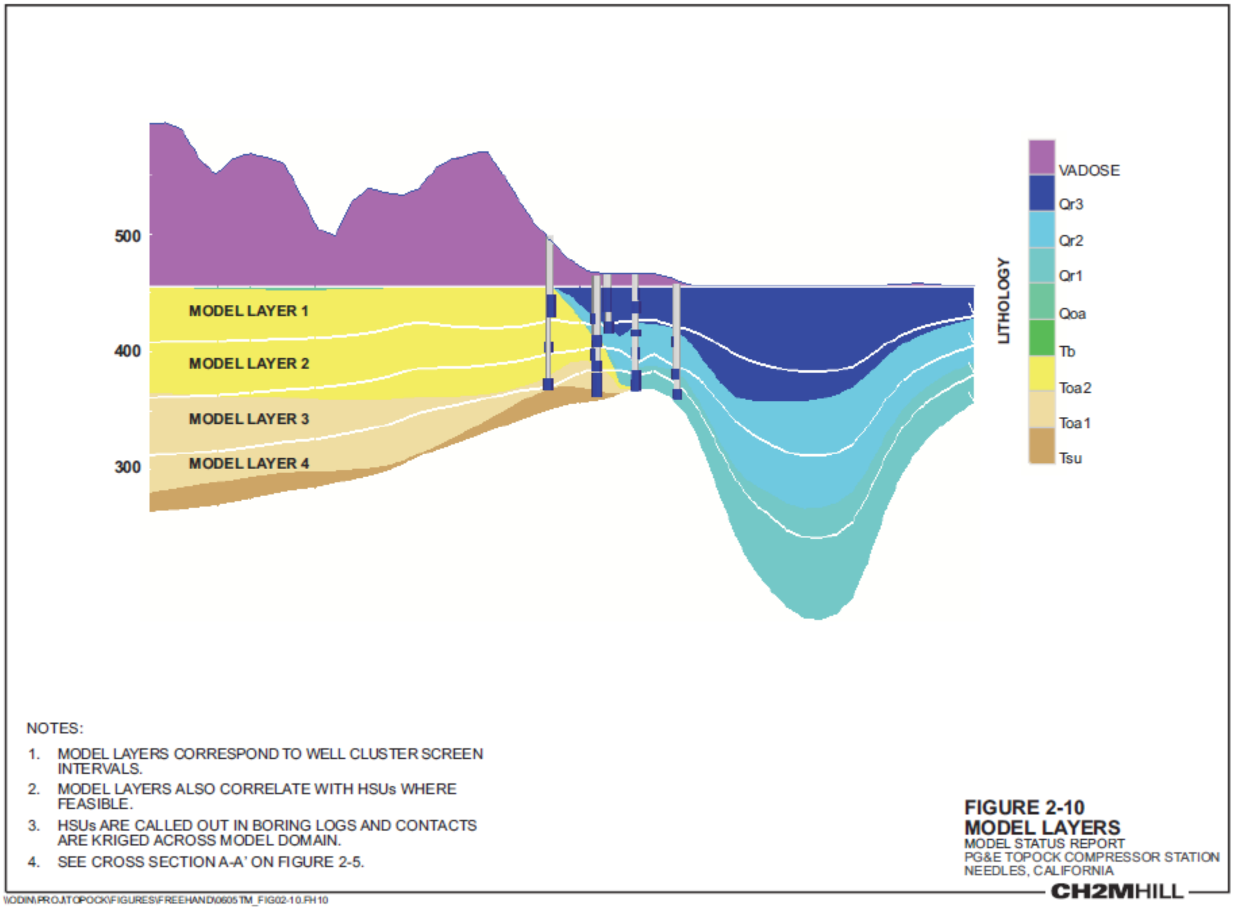
Model Layers

Figure 11. Model layers do not follow hydrostratigraphic unit (HSU) contacts (see Figure 2-10 below, CH2MHill, July 2005), especially beneath the river. See 90% BOD TRC comment #60.



The conclusion drawn from this figure is that this model structure reduces the ability of the model to correctly simulate flow beneath the river, or the interactions between groundwater and river water. More importantly, lumping important hydrogeologic properties based on well screen intervals instead of hydraulic properties strongly affects fate/transport simulations. This also renders the results of flow and fate/transport modeling beneath the river and into Arizona unreliable. The analysis should follow HSUs, even adding more layers, especially for fate/transport, to better simulate 3-dimensional flows and contaminant transport.

The top layer is modeled as unconfined, using surface topography everywhere, except over the river, where it uses the average river surface water, including the Topock Marsh. This incorrectly simulates porous media flow in the area between mean surface water and the river bathymetric surface, despite controlling flows in and out of the river with the river package. Actual river bathymetry should be used for the top model layer surface to correctly simulate heads and flow paths within the system in this critical area.

Boundary Conditions Poorly Prescribed

Groundwater Recharge Unrealistic

Groundwater recharge is specified as zero everywhere in the model, except for a few cells along the south in the Chemehuevi Mountains (mountain front recharge). Specification of recharge cells appears inconsistent with literature on where and how focused recharge occurs in mountain front/stream-bed areas in semi-arid/arid environments (see Simmers, 1998). In the Bat Cave Wash drainage, highly focused, efficient recharge in the mouth of the highly permeable (gravelly), widening streambed is very evident, but no recharge is specified here, where it would be most expected. The Bat Cave Wash has a very extensive watershed (more than 5 miles long, and greater than 4 square miles). Instead it was specified in impermeable exposed rock ridge areas, where recharge would likely be near zero. It should be applied in drainages where focused runoff meets permeable alluvium, especially in Bat Cave Wash adjacent to the Compressor Station.

No-Flow Lateral Flux Boundary Conditions Specified from Regional to Sub-Model

Review of 60%BOD Modflow model input, and 90%BOD PG&E response to comments (#429 and #430, or DOI-49 and DOI-50 and #425 – FMIT) suggests the Sub-Model boundaries are specified as No-Flow. This implies that lateral inflows or outflows from the regional model are not transferred from the Regional model to the Sub-Model, which will influence flow conditions in the MW-X and MW-Y area.

Specification of River in Model Unrealistic

The following observations were made with regard to the conceptualization of the River within the model.

- River cells appear missing in critical areas (see **Figure 12**, below). This is an important oversight which will affect simulated groundwater levels, flow paths and magnitudes in the northern portion of the local MODFLOW model. This will directly affect simulated flow paths from freshwater injection, flow beneath the River and simulation results for groundwater in Arizona. Without correctly simulating these boundary conditions, the model will not produce realistic predictions, and should not be used as a basis for justification for the AZ monitor wells MW-X and MW-Y.

- Specification of river cells does not accurately reflect current or future bathymetry or surface water levels in the Topock Marsh. Constant river stage (455.1 ft, msl) and river bottom (452.1 ft, msl) elevations were specified over the entire Topock Marsh (see **Figure 13** below). But aerial images clearly show only a smaller surface flow channel is present in the area, as the U.S. Fish and Wildlife Service (USFW) closely controls discharge via the South Dike control structure

(USFWS, 2006). A sonar-derived bathymetric map was derived for the Topock Marsh, north of the southern outlet control (http://proceedings.esri.com/library/userconf/proc99/proceed/papers/pap396/p396.htm). Based on the constant elevation prescribed in the local MODFLOW model in the Topock Marsh area near the Golden Shores Marina (south of the controlled marsh area), the microFEM regional model likely also prescribes a simplistic, constant bathymetric surface north of the control structure. It is important to specify the correct bathymetry as it controls the spatially variable simulated influx of surface waters in the marsh to underlying groundwater as a function of depth of water in the Marsh. This is not likely critical to simulating flows in the immediate area of the proposed remedy on the California side. However, this will be important in simulating 3-dimensional groundwater flows on the Arizona side, especially considering planned long-term extraction at wells HNWR-1A and/or Site B. These impacts, along with other Arizona extraction could influence water levels and interpretations of flow direction at the proposed locations of monitor wells MW-X and MW-Y.

- The river stage was set to a uniform value for all of Topock Marsh, which is clearly dry much of the year now due to the controlled discharge at the southern end of the South Dike (USFWS, 2006). Recent 2014 aerial images (ArcGIS World Imagery) show the discharge control structure and lack of standing water. This area in the model should be simulated using the MODFLOW ET module so that a constant river stage does not dominate groundwater levels in the area. Realistic stage levels in this area should be specified.

- Steady stages in the river and marsh do not allow adequate calibration of the model parameters and do not correctly simulate the actual water conditions within the system, or potential pathways. Appropriate fluctuating daily and seasonal river levels and Topock Marsh levels should be imposed in the proper areas of the model for transient simulations to correctly simulate groundwater levels and flows (3-D paths and magnitudes). Water levels within the Topock Marsh are controlled by the outlet structure and are fairly-well known based on available graphs (USFWS, 2006).

- Riverbed conductance (vertical hydraulic conductivity divided by assumed streambed thickness and multiplied by flow area) controls the rate of flow between the River and underlying aquifer. Conductance values were obtained from the 60% BOD Report (CH2M Hill, 2014d) MODFLOW input files provided by Arcadis (July 2013, Jonathan Roller at Arcadis). A plot of the riverbed conductance values (**Figure 14**) shows an interesting distribution, which was never reported. The distribution is complex, with the highest values adjacent to the East Ravine discharge area, lower values along the eastern side of the river, and the lowest values in Topock Marsh and just east of the IM-3 extraction wells at PE-1/TW-03D (central river). This may explain how simulated drawdown somehow propagates from these extraction wells toward MW-54-195. The riverbed conductance distributions here are based on estimates derived through PEST simulations rather than using actual measurements. This distribution is critical to controlling what flows between the River and Topock Marsh surface waters and underlying groundwater. It also plays a critical role in determining how influential the river itself is in acting as a hydraulic barrier to flow between Arizona and California.

- A sensitivity evaluation of riverbed conductance does not appear to have been performed. Here, a "sensitivity evaluation" means varying assumed spatially distributed values over a range that is physically-realistic. Without conducting a sensitivity analysis, the modeled conductance distribution is a significant assumption directly influencing important predictions in the model (i.e., RAO #2 flows into the River), which underpin the entire conceptualization of how the river water flows through the aquifer, 3-dimensional flow paths near and beneath the River/Topock Marsh, etc. At a minimum, the basis and conceptual rationale for the conductance distribution should be presented in detail before relying on it to assess hydraulic connection beneath the river (i.e., for IM-3 testing) and for future predictions of performance with the full remedial system in operation. The conductance distribution and the magnitudes have a direct bearing on whether proposed monitor wells MW-X and MW-Y are needed, and, if so, where they should be placed.

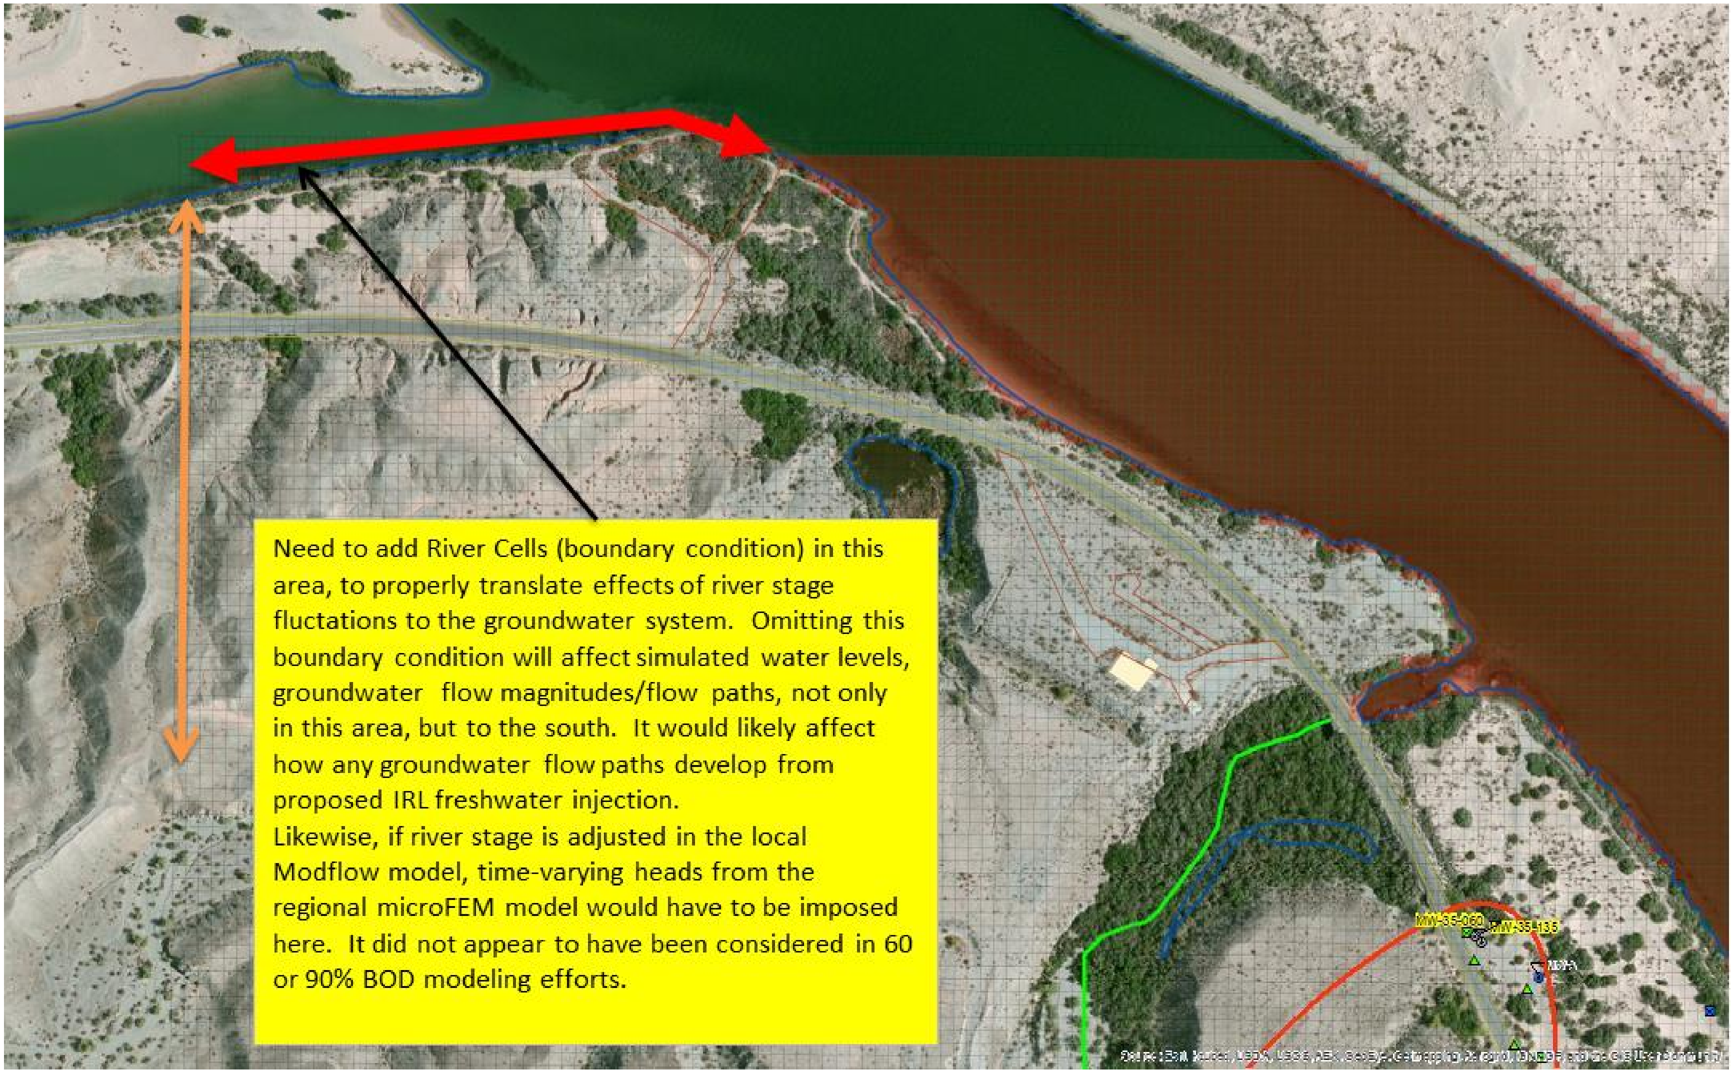


Figure 12. 60% BOD MODFLOW model "River Cells" (in red), which align with the river boundary, except along the northern edge (red arrow) where Beale Slough joins the River at Park Moabi. This slough should have had river cells in order for the model to correctly simulate river-aquifer flows and fluctuations (model cells shown in site ArcGIS document developed for the site).

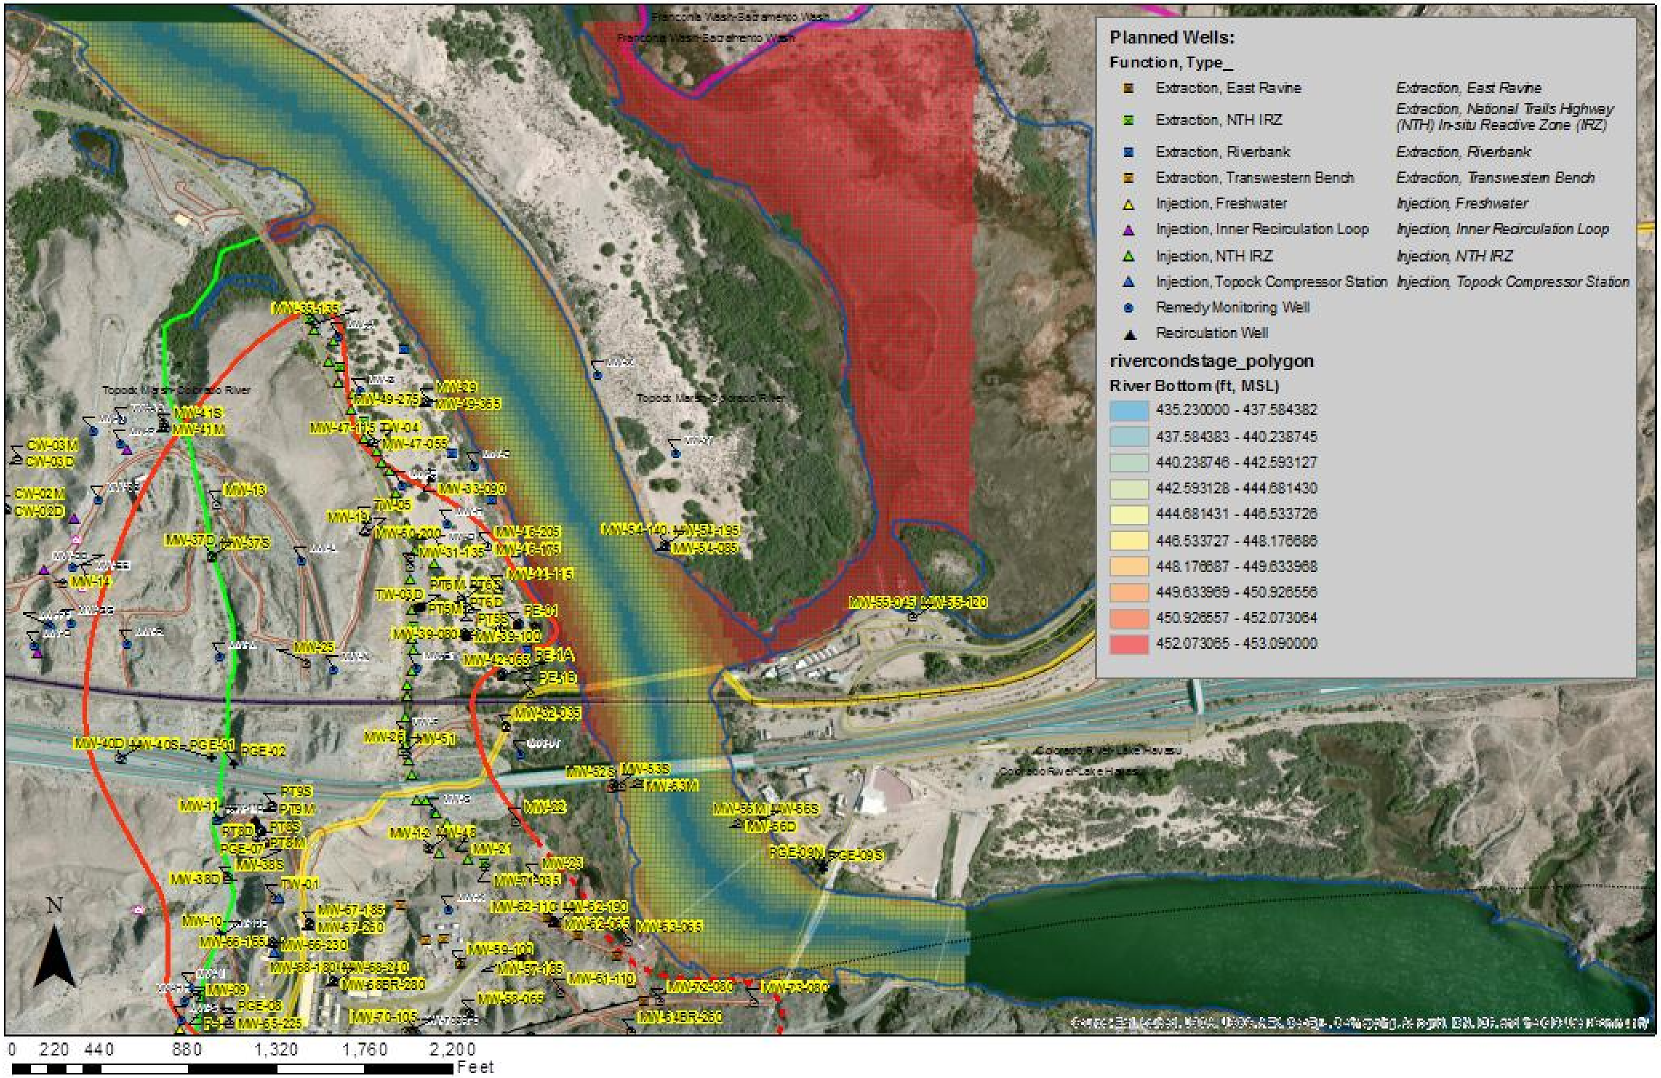

Figure 13. River bathymetry (bottom depth) is deepest in center, but it is unclear if bathymetry used in the model reflects all the actual measurements done in this segment of the river (data from Jonathan Roller, Arcadis July 2013 – 60% BOD MODFLOW Input Files).

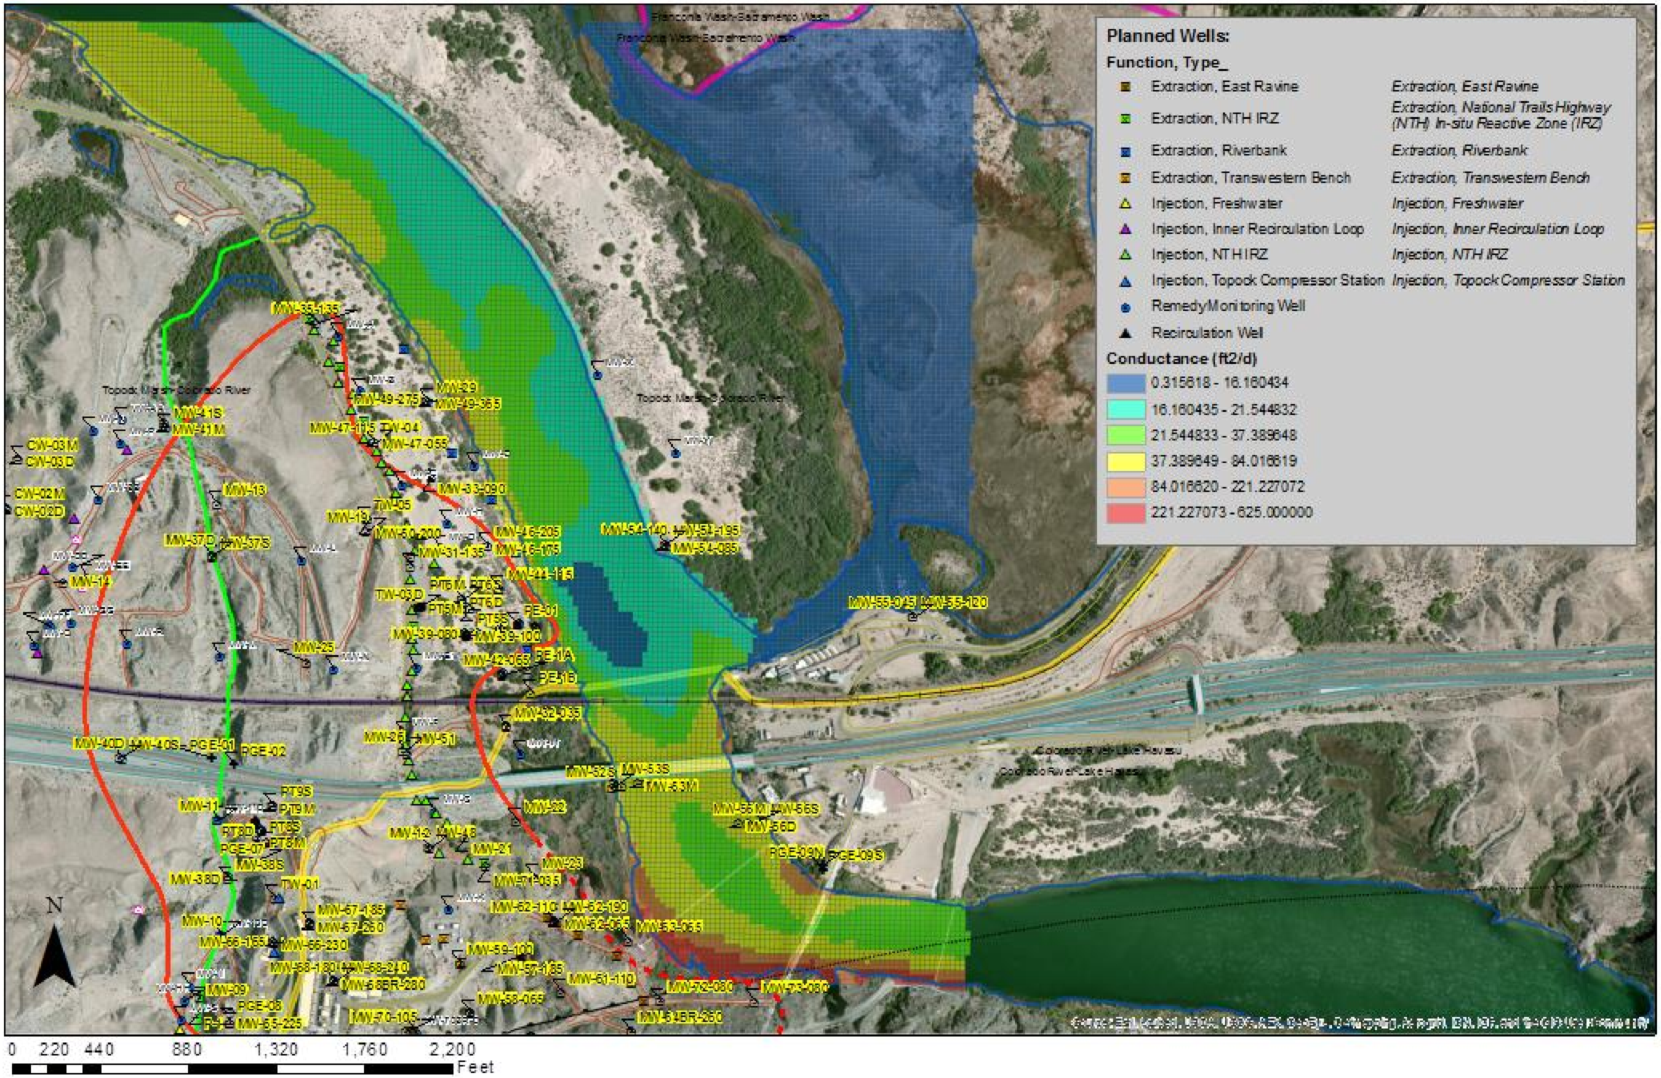

Figure 14. Specified river conductance values (ft^2/d). Note the higher conductance values on western bank, very high values along the western bank of East Ravine, low values just east of IM-3 Extraction wells (PE-1 and TW-03D), and low values in Topock Marsh.

Actual Evapotranspiration (AET) from Groundwater Unrealistic

The MODFLOW model specifies three evapotranspiration (ET) zones – phreatophytes, the River and everything else, though only two are indicated in the 90% BOD report. It is appropriate that ET in the river be zero. But the phreatophyte zone does not capture all variability in phreatophyte vegetation coverage with ET Cells **(Figure 16),** and does not capture differences in arid zone vegetation, which have different rooting and transpiration depths. Most of the lower Topock Marsh (near Golden Shores Marina) is assigned zero ET, because it is simulated as a river. Instead it should be simulated using realistic ET values. This will impact flow conditions along the AZ river bank and has implications for propagating effects from pumping at from HNWR-1 and/or Site B.

The July 2005 update report on modeling (CH2M Hill, 2005) states the following:

> "*Evapotranspiration (ET) losses occur in the floodplain areas and Topock Bay/Topock Marsh. An average maximum ET rate of 0.42 in/yr was assigned to all model nodes except those in the river. This rate was not designed to correspond to published plant ET rates, but as a value averaged over nodal areas which consist of both bare soil along with plant growth*."[12]

However, the 60% BOD report (CH2MHill, 2013) showed two different zones were used to define Actual Evapotranspiration (AET) rates; one for phreatophytes (4.2 in/yr) and the other for non-phreatophytes (0.42 in/yr). The specified AET rate of 4.2 in/yr (0.35 ft/year) for phreatophyte zones seems excessively low as noted in TRC 60% BOD comment (#365). Hill (1993) indicates that AET rates in a comparable region (Yuma) should be more like 3.5 to 7 ft/yr. The phreatophyte zone with a higher specified rate shows dense coverage, but seems to omit important areas of the model which occur in phreatophyte areas within the Topock Marsh. In the graph below (**Figure 15**), AET rates are plotted for different riparian vegetation from Hill's (1993) report, and the graphs clearly show that the AET should be several orders of magnitude higher than what has been used for the Topock MODFLOW model. The model predicted AET loss of 140 ac-ft/year to phreatophytes is likely vastly underestimated, by at least an order of magnitude for this area.

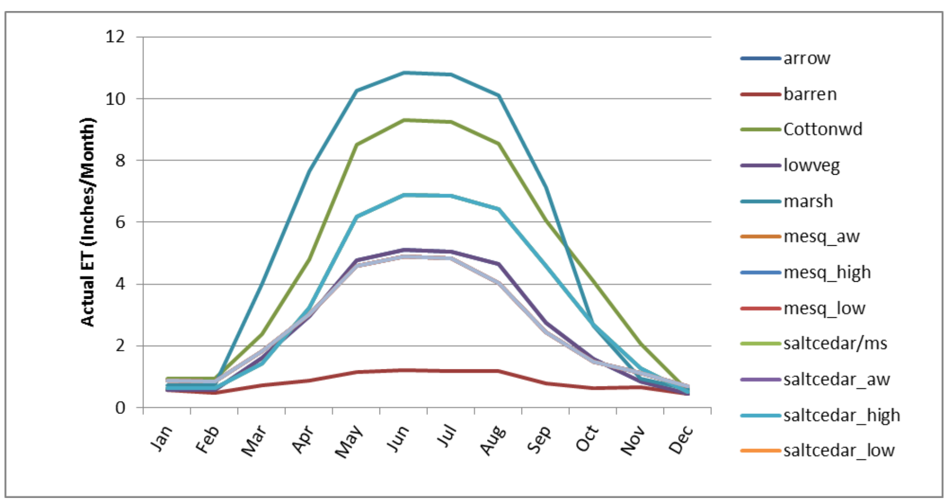

Figure 15. Phreatophyte water use by type.

[12] Note: in/yr = inches per year; ft/yr = feet per year; ac-ft/yr = acre-feet per year (approximately 326,000 gallons)

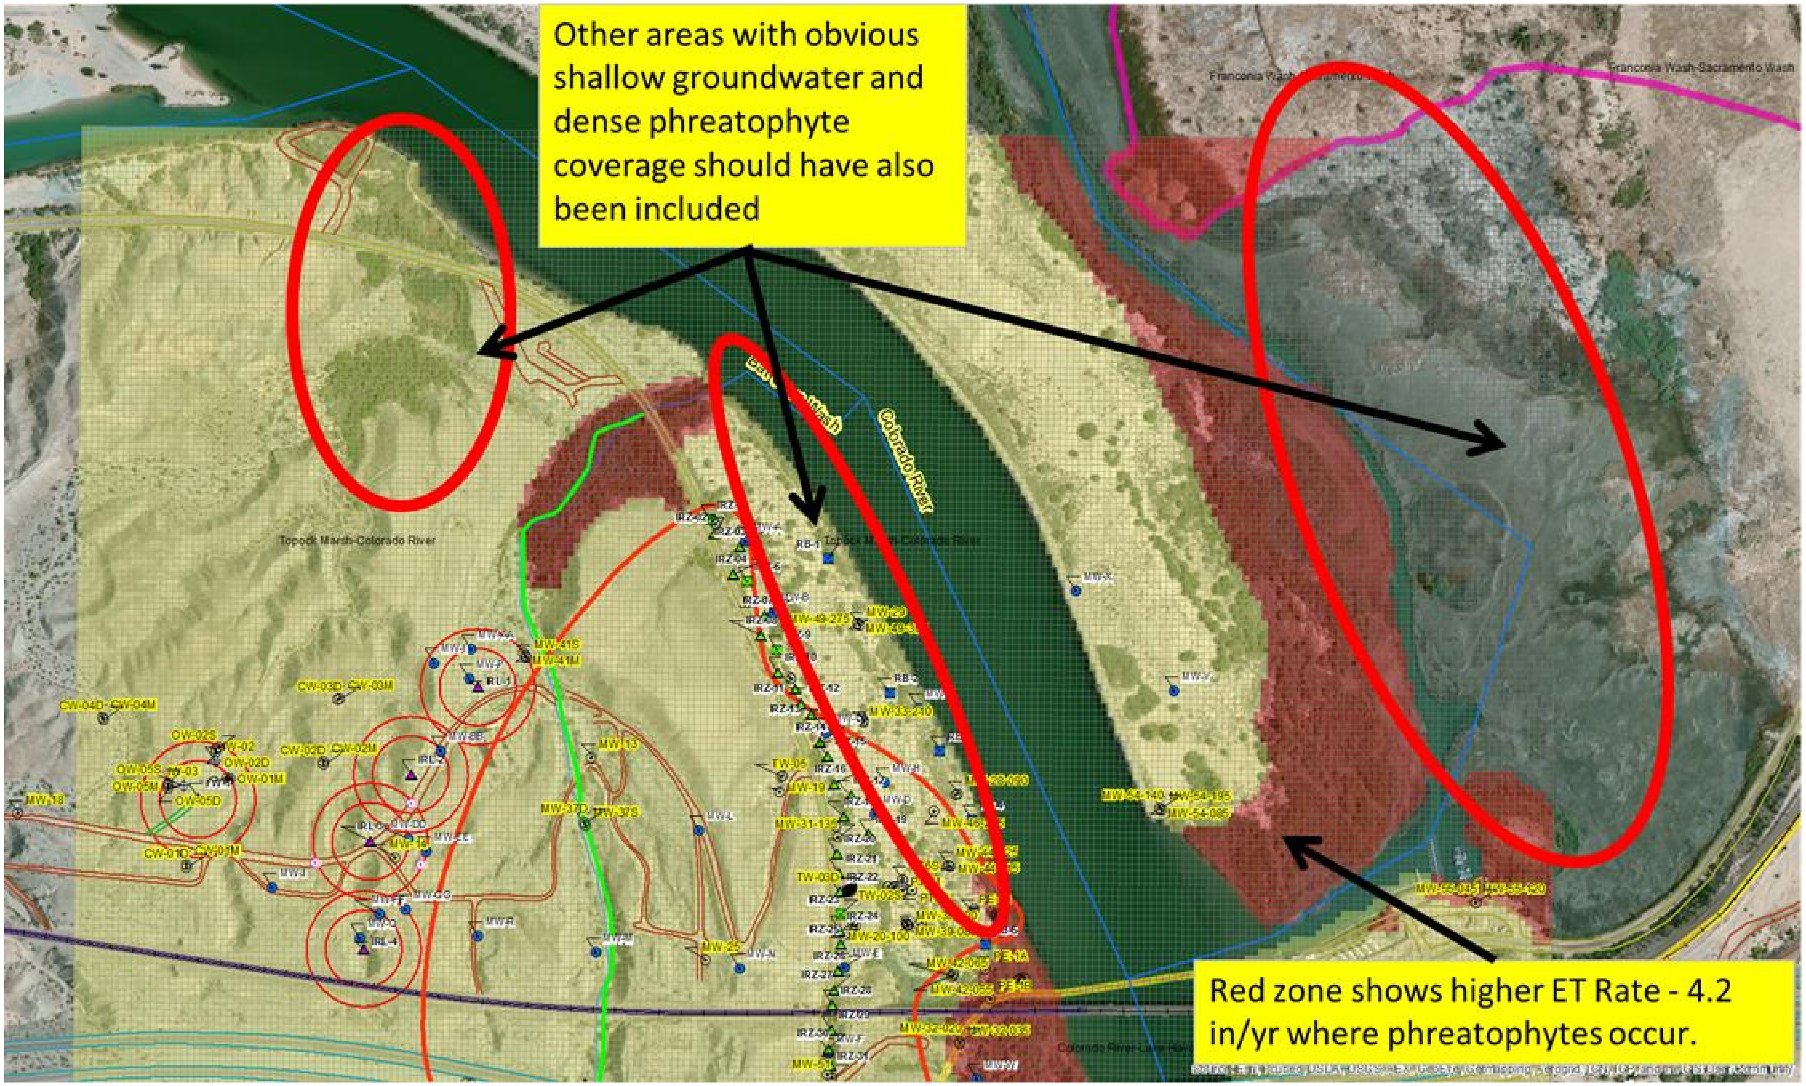

Figure 16. Project MODFLOW model ET zones, where red has a higher rate (4.2 in /yr) for phreatophytes, and 0.42 in /yr everywhere else except rivers. Figure developed in ArcGIS, using data from Jonathan Roller, Arcadis July 2013 – 60% BOD MODFLOW input files.

The Evapotranspiration "Extinction Depth" specified in the model (10 ft), which effectively represents the maximum depth that phreatophyte roots would withdraw water, appears too low and instead should be at least 20 to 30 feet (see Hill, 1993). Other sources suggest this could be as deep as 50 feet (see Table 1 on page D54, Anderson and Freethy (1995), depths from 0 - 50 feet, and ET maximum rates from 3 to 10 ft/yr at 100% density). The density of phreatophytes from aerial imagery appears to be very high. No technical basis for the 10-ft extinction depth is offered. Setting the extinction depth too low reduces the distributed groundwater discharge to phreatophytes, and also affects the 3-dimensional flow paths in the shallow aquifer. Thus, instead of all groundwater moving towards the river, it would be redirected locally towards phreatophyte areas, which were not well-defined to begin with (see discussion above).

Simulated Water Balance Components are Questionable

Other regional studies suggest the water balance results summarized in the 2005 modeling report (Figure 2-14 in the CH2M Hill, 2005) suggest the evapotranspiration from the regional model (**see Figure 17**) is likely much too low (owing to deficiencies noted above). Table 21 (below) in Owens-Joyce and Raymond 1996 (USGS paper) reports AET by phreatophyte density, by month in Mohave Valley.

Table 21. Water-use rates for vegetation types and densities along the lower Colorado River, 1984, calculated by the Lower Colorado River Accounting System

River reach and vegetation type	Monthly water-use rate, in feet												
	Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec	Total
Hoover Dam to Davis Dam—Willow Beach, Arizona[1]													
Phreatophytes													
Medium	0 00	0 22	0 41	0 48	0 72	0 75	0 81	0 73	0 62	0 33	0 21	0 00	5 28
Sparse	00	18	32	38	57	60	65	58	50	26	17	00	4 21
Mohave Valley—Bullhead City, Arizona[1]													
Alfalfa	00	31	56	66	97	1 00	72	70	82	44	14	00	6 32
Cotton	00	00	00	05	19	44	70	92	68	28	00	00	3 26
Wheat	14	27	75	86	30	00	00	00	00	00	00	00	2 32
Phreatophytes													
Dense	00	28	52	61	90	92	1 01	92	77	41	25	00	6 59
Medium	00	24	43	51	75	77	84	76	63	34	21	00	5 48
Sparse	00	19	34	41	60	62	67	61	51	27	17	00	4 39

In fact, Guay, et al., (2006) state*: "In summary, Mohave Valley is a losing river reach where Colorado River water is later lost to ET and open water evaporation."* This implies that ET is so significant that there is a net recharge from Colorado River leakage into the aquifer, whose levels are being strongly controlled by the phreatophytes and direct evaporation from open waters in the area. This is actually opposite from what is stated in the CSM and simulated in both the regional and local models, where the river is acts a net annual sink or discharge feature in the system.

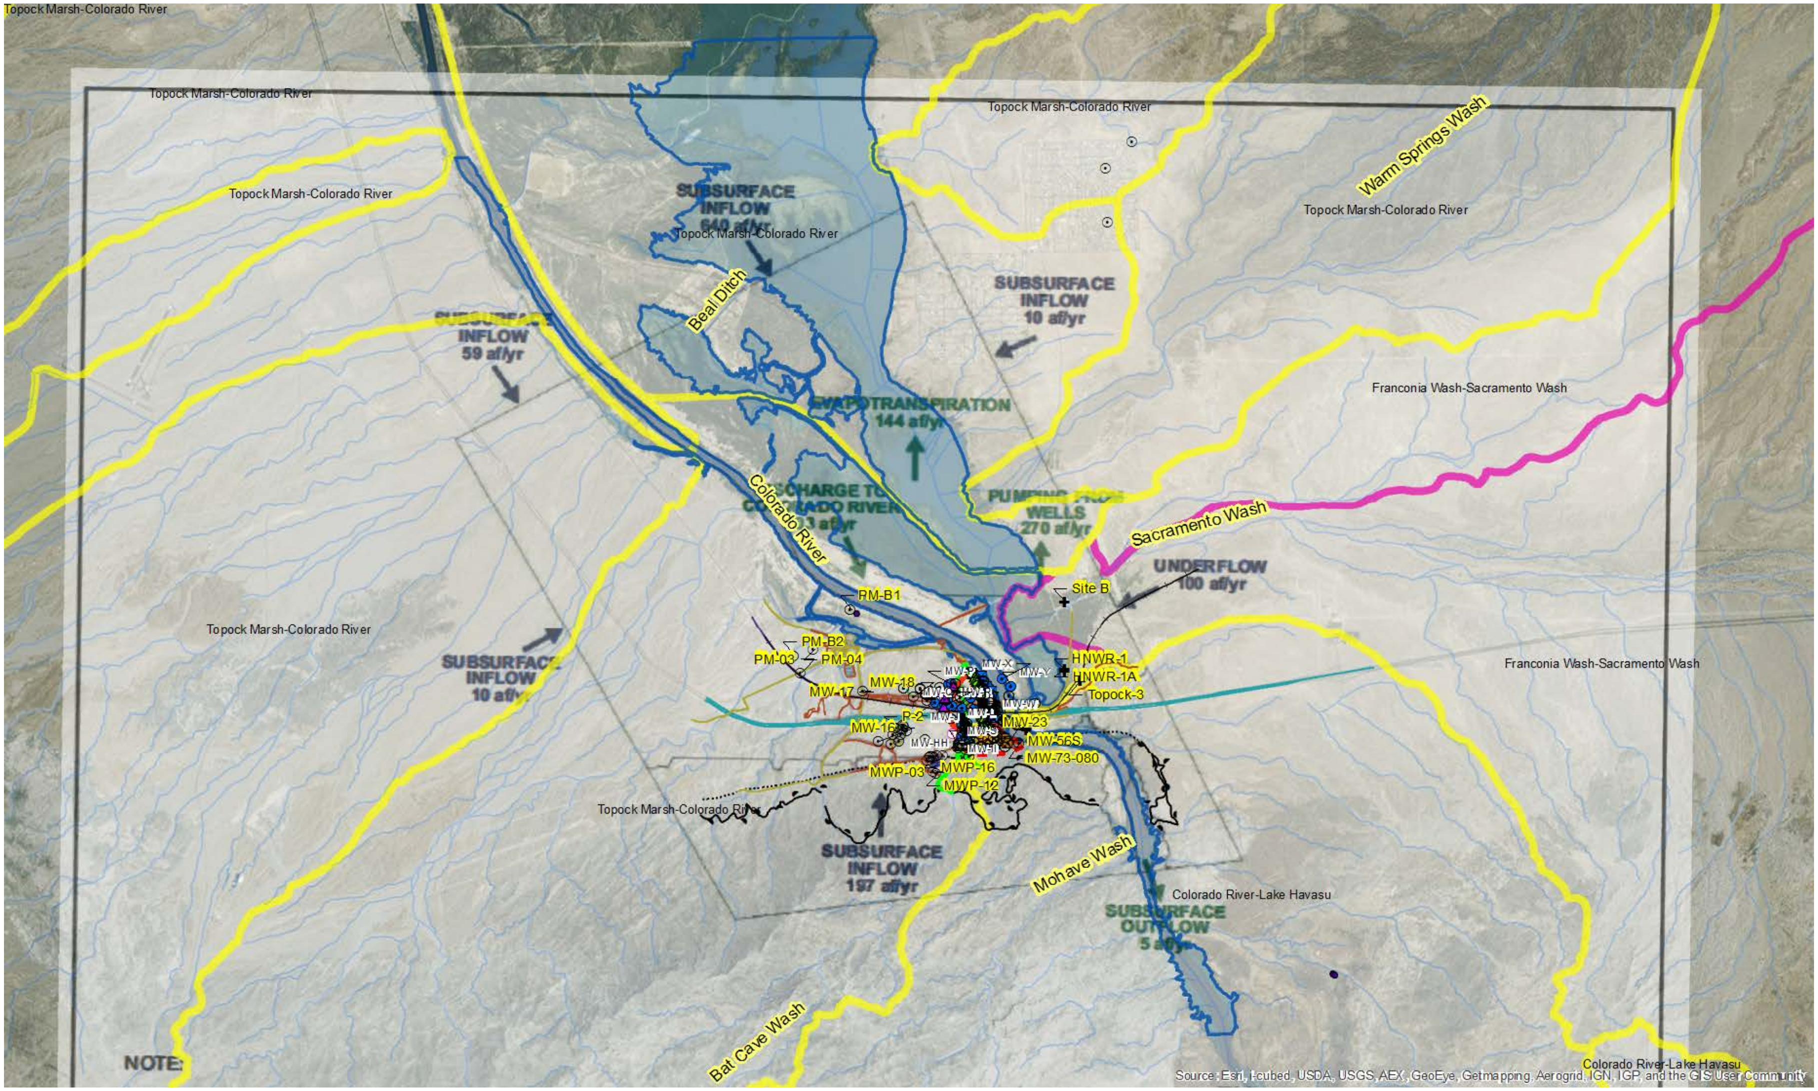

Figure 17. Shows Evapotranspiration of 144 ac-ft/yr from groundwater(Figure 2-14 in the CH2M Hill, 2005). This is likely much too low over this spatial extent. Subsurface “underflow” of 100 af/yr from Sacramento Wash is much less than the 2,400 ac-ft predicted by a recent USGS report (Tillman et al, 2013).

A water budget from a detailed USGS study (Table 10 below from Tillman et al, 2013) of the Sacramento Wash, Hualapai and Arizona Lake Mohave Basin indicates the groundwater discharge through unconsolidated deposits within Sacramento Wash is much higher (at least 1 order of magnitude) than the 100 ac-ft/yr simulated with the regional microFEM model as summarized on Figure 2-14 (i.e., 2,440 ac-ft/yr to 5,600 ac-ft/yr from Sacramento Valley in Table 10). The significantly underestimated maximum ET rate and ET extinction depths noted above likely vastly under predict the actual ET in this area, which would have reduced the 2,440 ac-ft/yr inflows, though recent fires in the lower Sacramento Wash by the USFWS would reduce the AET. In any case, higher subsurface inflows and ET losses should be simulated where they occur as they dictate flow conditions and pathways in the proposed MW-X and MW-Y monitoring locations.

Table 10. Simulated predevelopment groundwater budget for runoff-recharge scenario.

[Values are in acre-feet per year; –, no data]

Water-budget component	Detrital Valley	Hualapai Valley	Sacramento Valley
Inflow from natural recharge	1,870	3,680	6,720
Inflow from adjacent valleys	0	50	1,310
Inflow at Truxton Wash (Hualapai Valley only)	–	800	–
Net outflow to Colorado River	1,780	4,500	2,440
Outflow to adjacent valleys	95	40	[1]5,600

[1]Outflow from Sacramento Valley to Lake Mohave Basin discharges to Topock Marsh and the Colorado River near Topock.

Bedrock Depths Appear Inconsistent

The basis for the modeled bedrock depth in Arizona could not be determined in available reports. The surface appears to be somewhat inconsistent with other reported surfaces (Richard et al, 2007). This would influence simulated groundwater flow gradients/directions in Arizona, especially responding to well production and river fluctuations. The source of information and assumptions used in developing the bedrock surface in the model(s) should be provided to the Tribes for review.

Density-Dependent Flow is Not Simulated with MODFLOW Code

The MODFLOW code does not simulate density-dependent flow, which introduces additional errors in predicting 3-dimensional flows within the model domain, where higher density waters are present. DOI comment #9 on the 90% BOD Appendix B points out that high density dissolved solids concentrations can result in errors predicting flows and can produce uncertainty in capture zone analysis. Simulating the correct flow dynamics of relatively high density variations beneath the river, with strong driving river stage fluctuations, requires a more appropriate modeling tool, especially if the model is going to be used as the primary technical basis for locating and specifying parameters for additional monitor wells such as MW-X and MW-Y. Many codes have the capability of simulating the density-dependent flow conditions (see https://www.twdb.texas.gov/innovativewater/bracs/doc/bracs_gw_model_rpt.pdf for a list of codes).

Groundwater Pumping Effects at Model Boundary

It is unclear whether time-varying effects of all regional groundwater pumping effects both within the regional MicroFEM model and outside are actually incorporated into the model, particularly in the Arizona side. **Figure 18** below shows the local MODFLOW boundary (black box) and the eastern boundary of the MicroFEM regional model with an orange line. Review of earlier modeling reports (CH2M Hill, 2005) indicate that pumping from some of these wells was incorporated into this model (i.e., the Golden Shores community wells to the north) by using a single representative well. Though this appears reasonable, it is unclear whether effects of the groundwater pumping at wells outside of the MicroFEM boundary, but still close enough to affect flow conditions at or within the MicroFEM model boundary were incorporated into the internal modeled flow conditions. In addition, as DOI points out in 90% BOD comments 14, 15, 16 and 41, the proper translation of groundwater pumping effects and other dynamic boundary conditions as a dynamic flux boundary condition from regional MicroFEM model to the local MODFLOW model should be confirmed.

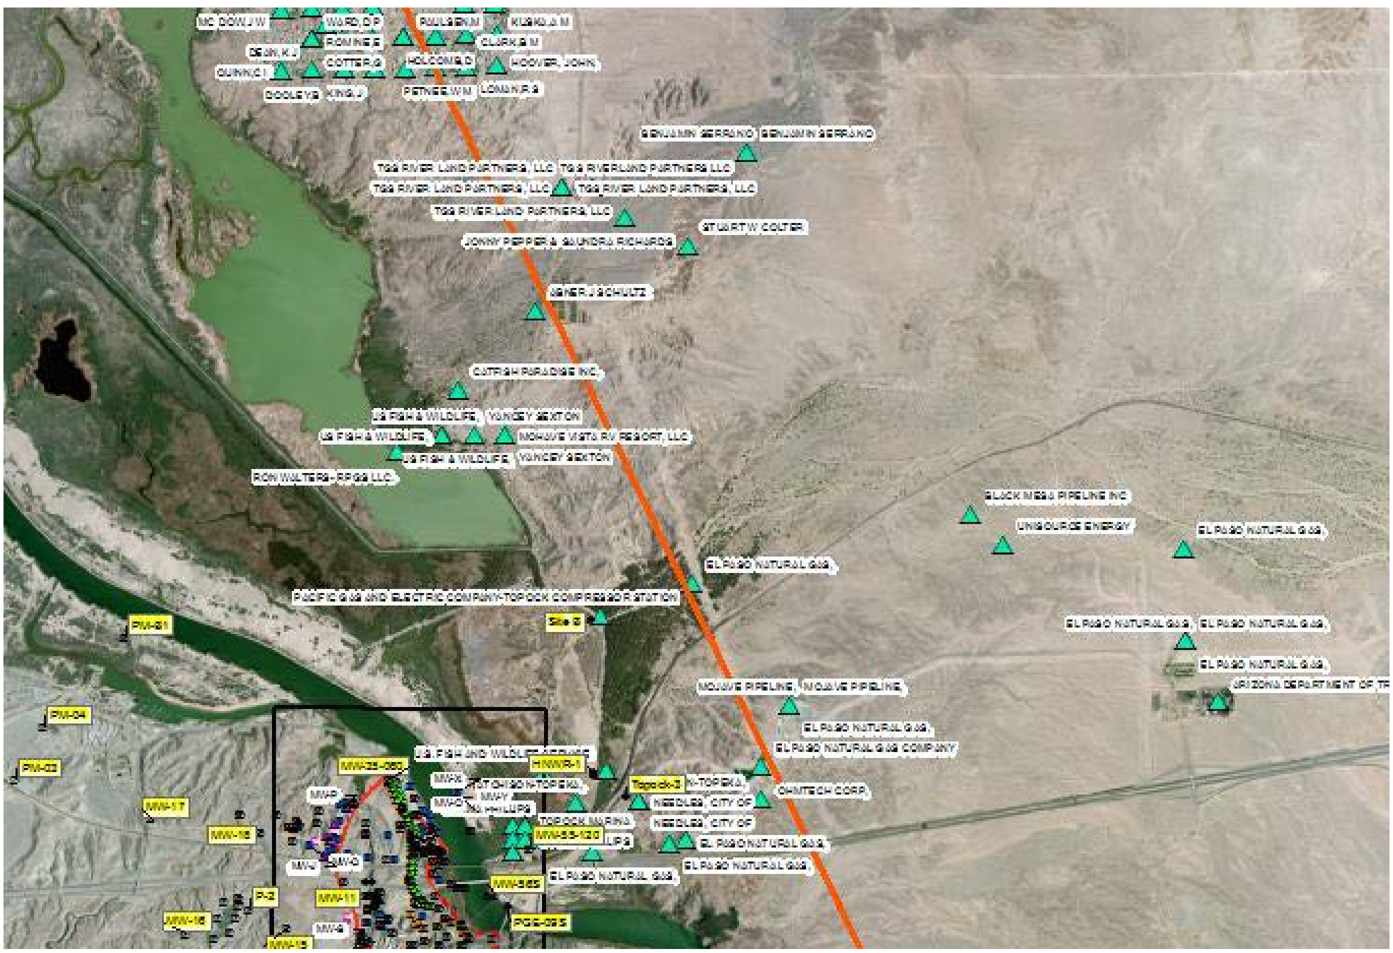

Figure 18. Regional wells from Arizona Department of Water Resources registered well database. Most can be assumed to be pumping, though this information was not reviewed any further than plotting locations here. Figure developed using ArcGIS project file with imported ADWR data.

September 2008 IM-3 Extraction Well Shutdown Test Fails to Demonstrate Hydraulic Connection in Groundwater Between California and Arizona.

CH2M Hill (2009, Appendix E, page E-1) states:

> "*The California Environmental Protection Agency, Department of Toxic Substances Control requested that demonstration of model accuracy be performed by using the model to forecast the hydraulic data collected after the calibration period (between 2005 and 2008). Specifically, the Technical Work Group agreed that the validation should consist of comparing simulated data to: (1) the monthly average groundwater levels in monitoring wells in response to changing monthly average river levels, and (2) the response of Arizona wells in the MW-54 cluster to the May 2008 Interim Measure No. 3 (IM No. 3) pumping shutdown event. However, **due to anomalous river** levels during the deconvolution fitting period of the May 2008 IM No. 3 shutdown, detection of well response in the MW-54 cluster (located across the river in Arizona) was incomplete. As a result, a second IM No. 3 shutdown event was simulated with the model in September 2008, and improved results were obtained. The September 2008 evaluation was conducted in response to a United States Department of the Interior (DOI) comment on Appendix C of the Draft CMS/FS Report*" [Emphasis added.]

CH2M Hill (2009, Appendix E, page E-3) states:

> "*Figures E-2c through E-2g show the deconvolution analyses for the MW-54 and MW-55 wells in Arizona. In general, the detection limit for observable water-level fluctuation was estimated to be 0.1 foot; however, the detection limit for water level change in the MW-55 well cluster was estimated to be 0.05 foot due to a less noisy baseline in this well. Measurable water-level recovery of 0.1 foot was observed in the deep well at MW-54 (MW-54-195). Water-level recovery in the other Arizona wells was below the estimated detection limits.*"

It seems arbitrary to select 0.1 ft as a detection limit, and then decide that a variation of only 0.05 ft at MW-55 implies a hydraulically connection across the river. The potential error in the adopted deconvolution method could be substantial, especially given the combination of complicating factors which include barometric effects, solid earth tides, river fluctuation, and density/temperature variations. A review of the actual deconvolutions and comparison of simulated vs. observed drawdown for MW-54-195 (see **Figure 19**, below) does not convincingly demonstrate any hydraulic connection (as the May 2008 test showed), or that the model is able to capture the response. It is unclear why the variation in river stage over the test was not included in the modeling as this drives much of the transient fluctuation in all wells evaluated. The river fluctuation could have been left out of the deconvolution analysis to directly compare results. Also, it seems like the relatively high water density variations in formations beneath the River would also need to be considered in the modeling, as drawdown changes would likely dampen out beneath the River due to upconing (buoyancy effects).

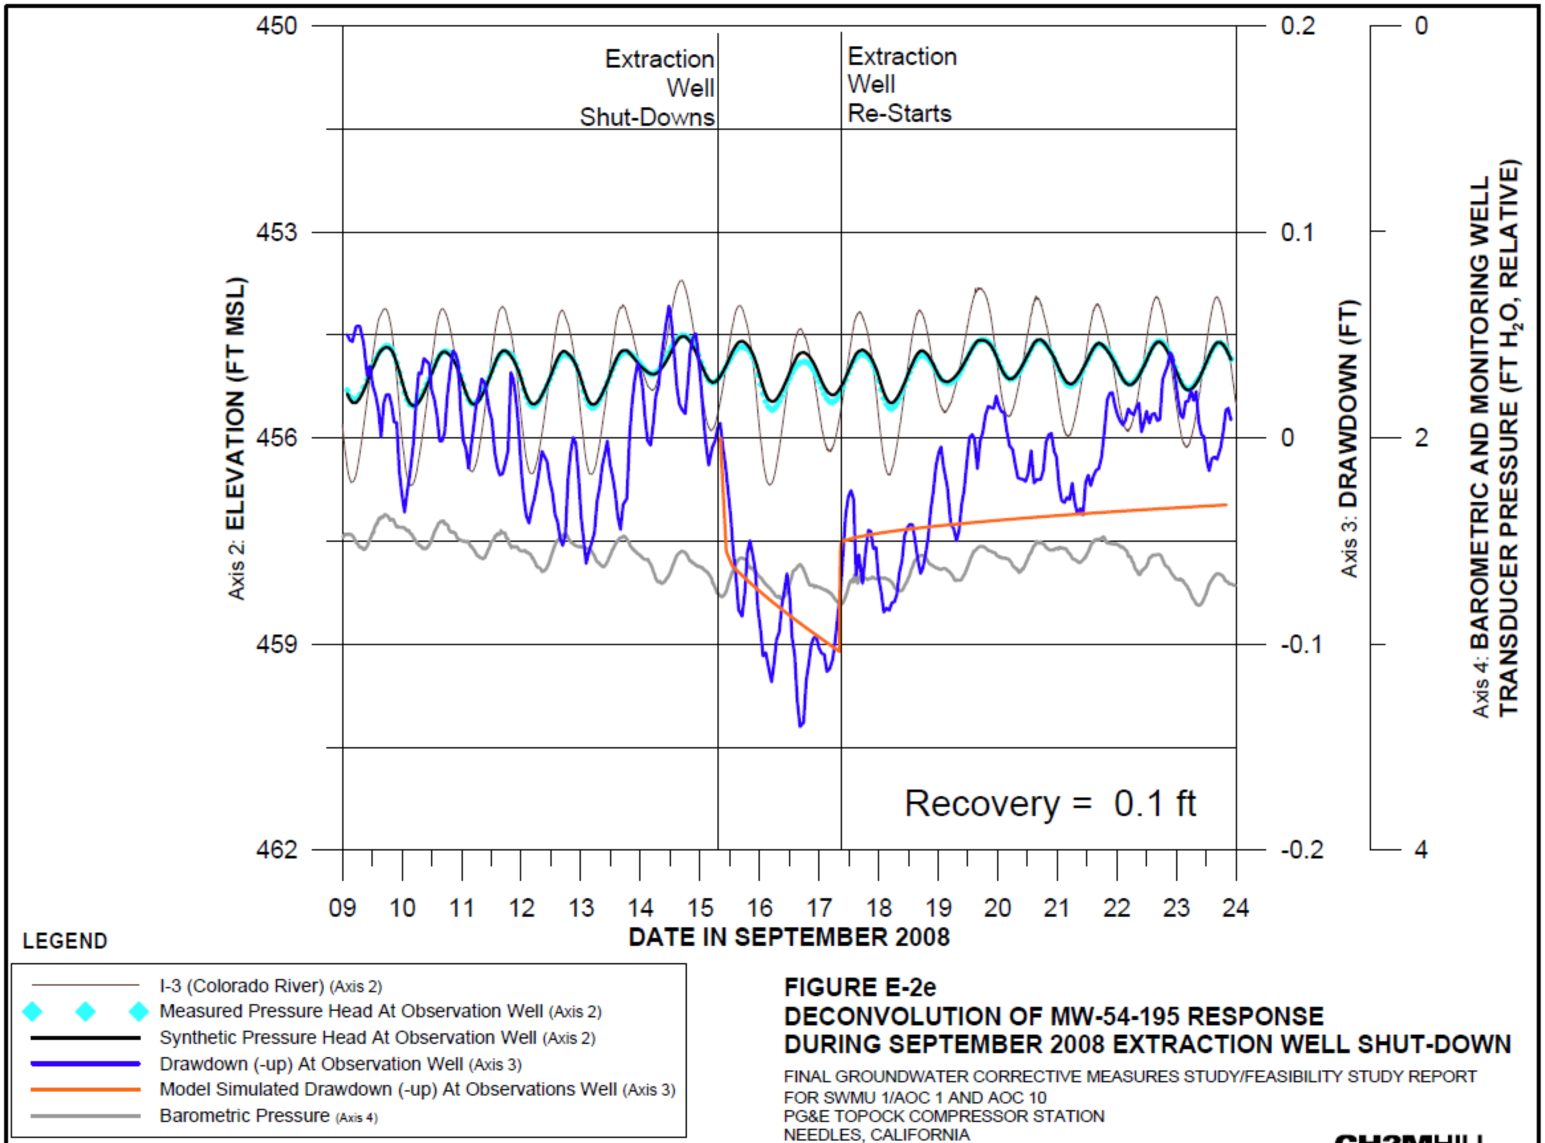

Figure 19. Reproduction of Figure E-2e from CH2M Hill (2009).

The application of the USGS Halford method (Halford, 2006) used here did not indicate that the effects of solid earth tides were incorporated in the plotted data. Earth tides can easily vary up to 0.1 ft, which is similar to the variations recorded at MW-54 and MW-55. In addition, the use of two different plotting axes does not show the errors introduced in matching synthetic and measured well response (before the shutdown), which also appear to be easily within the 0.1 ft perturbation. Figure 21, below, shows that the magnitude of "drawdown" shown by the blue line (calculated by subtracting synthetic pressure from measured pressure) during the pre-shutdown period (i.e., September 9 through 15) is as great (~0.1) as during the shutdown (September 15-17), or even after it, probably because the synthetic pressure did not capture all influences, or incorporate all measurement errors (i.e., like solid earth tides, diffuse areal recharge fluctuations; in addition to barometric and river fluctuations, were not incorporated). In other words, the water level variations in MW-54 and MW-55 recorded during the shutdown period are indistinguishable from the variability observed before and after the shutdown period, which suggests these wells did not respond to the shut-down.

Simulated transient well responses to river fluctuations ((Appendix E in CH2MHill, 2009, see Figures E-1a through E-1p) appear to reproduce observed monthly responses in the selected California wells over a 2 to 3 year period. However, no such comparison was made to Arizona wells MW-54 and MW-55 (or MW-56) at different levels. It is unclear why this is the case, but this fact precludes any evaluation of model performance (i.e., calibrated) in this local area within Arizona. Why install monitoring wells MW-X and MW-Y if the existing monitoring wells MW-54 to MW-56 have not been used to calibrate the model?

More convincing evidence must be presented to all stakeholders before concluding that Arizona groundwater will be affected by California activities. Before concluding a hydraulic connection could exist under the operational conditions of the proposed remediation system operation and requiring additional undesired monitoring wells, a more rigorous testing program is needed. Options include imposing a much greater stress on the system (i.e., an aquifer pumping test) to propagate drawdown from the California side than that induced by the shutdown at PE-1 and TW-03D for just two days. A longer pump test would register a much clearer and unambiguous response in existing Arizona wells MW-54, MW-55 and MW-56. Also, a tracer test could be used to evaluate if an actual connection is present. Ultimately, the model, despite its clear deficiencies, should have been used in conjunction with fully transient river and Topock Marsh fluctuations, to evaluate the potential impacts of the shutdown on Arizona wells rather than attempting a deconvolution. The model has the benefit of including other important factors that influence drawdown propagation (i.e., associated rise due to shutdown of PE-1 and TW-03D) such as the variation in assumed hydraulic conductivity, riverbed conductance and variation in bedrock surface and layer thicknesses.

May 2008 IM-3 Extraction Well Shutdown shows no response in Arizona

From the CH2M Hill (2008; see **Figure 20**) 54-well construction/testing study, it is learned that:

> "*Hydraulic response attributable to the shutdown of groundwater extraction in wells PE-01 and TW-03D was observed in wells up to 1,600 feet away from the nearest extraction well. The*

hydraulic response attributable to the shutdown of injection well IW-3 was observed in wells up to approximately 1,300 feet away. ***Hydraulic response if present, is too low to quantify on the Arizona side of the river. For the MW-54 and MW-55 monitoring well clusters, the lack of quantifiable response is likely due to multiple complex and poorly understood overlapping processes, the largest of which is the Colorado River stage fluctuations. "*** [Emphasis added.]

Calibration Results are Questionable

Four target datasets were used (CH2MHill, 2005) for calibration of the groundwater flow model:

a. Recovery in transducer-equipped monitoring wells following shutdown of TW-2D in November 2004
b. Average monthly groundwater elevations in transducer-equipped monitoring wells (available data between 2003 and March 2005)
c. Recovery in Observation Wells during injection well testing at IW-2 and IW-3 in January 2005
d. Estimated velocity and flow orientation of chromium plume development between initial discharge in 1951 to detection at MW-20 in 1999.

Results of the model calibration in the vicinity of the River and in Arizona are questionable for several reasons:

1. Neither the flow, nor the fate/transport model were calibrated to years of carefully monitored water level and concentration data (i.e., Quarterly IM-3 Monitoring reports) associated with operation of the IM-3, following the 2005 calibration period. The accuracy and reliability of model predictions are critical for demonstrating the model performance not only in the vicinity of IM-3, but also near MW-X and MW-Y.

2. Standard calibration statistics (Anderson and Woessner, 1994) were never presented (i.e., Root-Mean-Square Error, or RMSE, values by layer, or spatial distributions to show bias) for the calibration to average monthly groundwater elevations (b above), or in any of the modeling-related documents reviewed for the Topock groundwater remediation project. Though the model seems to reproduce qualitatively reasonable monthly fluctuations at many wells, some don't compare well and ultimately, there is no way to determine whether calibration is actually adequate for the intended purposes, and how calibration errors may influence key model predictions (i.e., flow rates, well spacings, etc.). Comparison of simulated and observed well water levels reveals that many of the wells show deviations approaching or exceeding 1.0 ft (**Figure 21**). This error greatly exceeds the 0.1 ft simulated difference observed in the September 2008 shut-down test response at MW-54-195. The May 2008 shutdown test response actually showed no response, but was disregarded due to unexplained 'anomalous' river readings (CH2MHill, 2009). Finally, though response is reported for wells in 3 different depth zones, assessment of model performance in terms of vertical gradients,

or even flow directions (i.e., flow up or down) is never presented. It is unclear whether the model predicts the correct vertical flow direction, especially near the river and in Arizona.

3. Neither the groundwater flow model, nor fate/transport model were calibrated against key remedial performance metrics such as hydraulic gradients/flow directions and concentration trends. Yet these model predictions will be used to make critical decisions on whether the system is performing as expected, and if not how to modify design or operations (see Tables 2.1-4, 2.1-5 and Figures 2.2-2 through 2.2-9 in the 90%BOD O&M Volume 2 report – see CH2MHill, 2014c).

4. The model was apparently calibrated to historical plume movement (i.e., target d above), but even a qualitative calibration performance assessment was never presented in the CH2MHill, 2005 report. This should have been provided to gain perspective on the model's performance near the river, and beneath it in Arizona near MW-X and MW-Y.

5. Calibration to response to shutdown of extraction well TW-2D, and injection wells IW-2 and IW-3 only provides a very localized sense of performance assessment near these particular wells. In addition, the implication of the calibration to these events or relevance to eventual remedial system performance metrics is never discussed. This would be especially important when considering the need or locations for proposed monitoring wells MW-X and MW-Y. Results at some wells showed notable deviations from actual observed conditions.

6. Simulated groundwater levels shown on **Figure 21** stop abruptly at the river, and therefore offer no insight into the model performance (or accuracy) in Arizona, especially in at wells MW-54, MW-55 and MW-56 installed in 2008. Though the model was calibrated in 2005, no attempts appear to have been made to update this to well response in these three Arizona monitoring wells. At a minimum, this should be done to improve the reliability of the model before attempting to predict future remedy bypass into Arizona, requiring wells at locations MW-X and MW-Y.

No Results Provided for Model Update after 60% BOD

Page xii of the 90% BOD Report (CH2M Hill, 2014a) states:

> "*Additional modeling efforts completed since the 60% design include an update of the regional groundwater flow model ("the regional flow model") and groundwater flow submodel to reflect hydrogeology encountered at Site B in the vicinity of HNWR-1*".

Details describing all assumptions, calibration, and long-term response with all possible stresses do not appear to have been presented anywhere. So it is impossible to assess the performance of the model in Arizona.

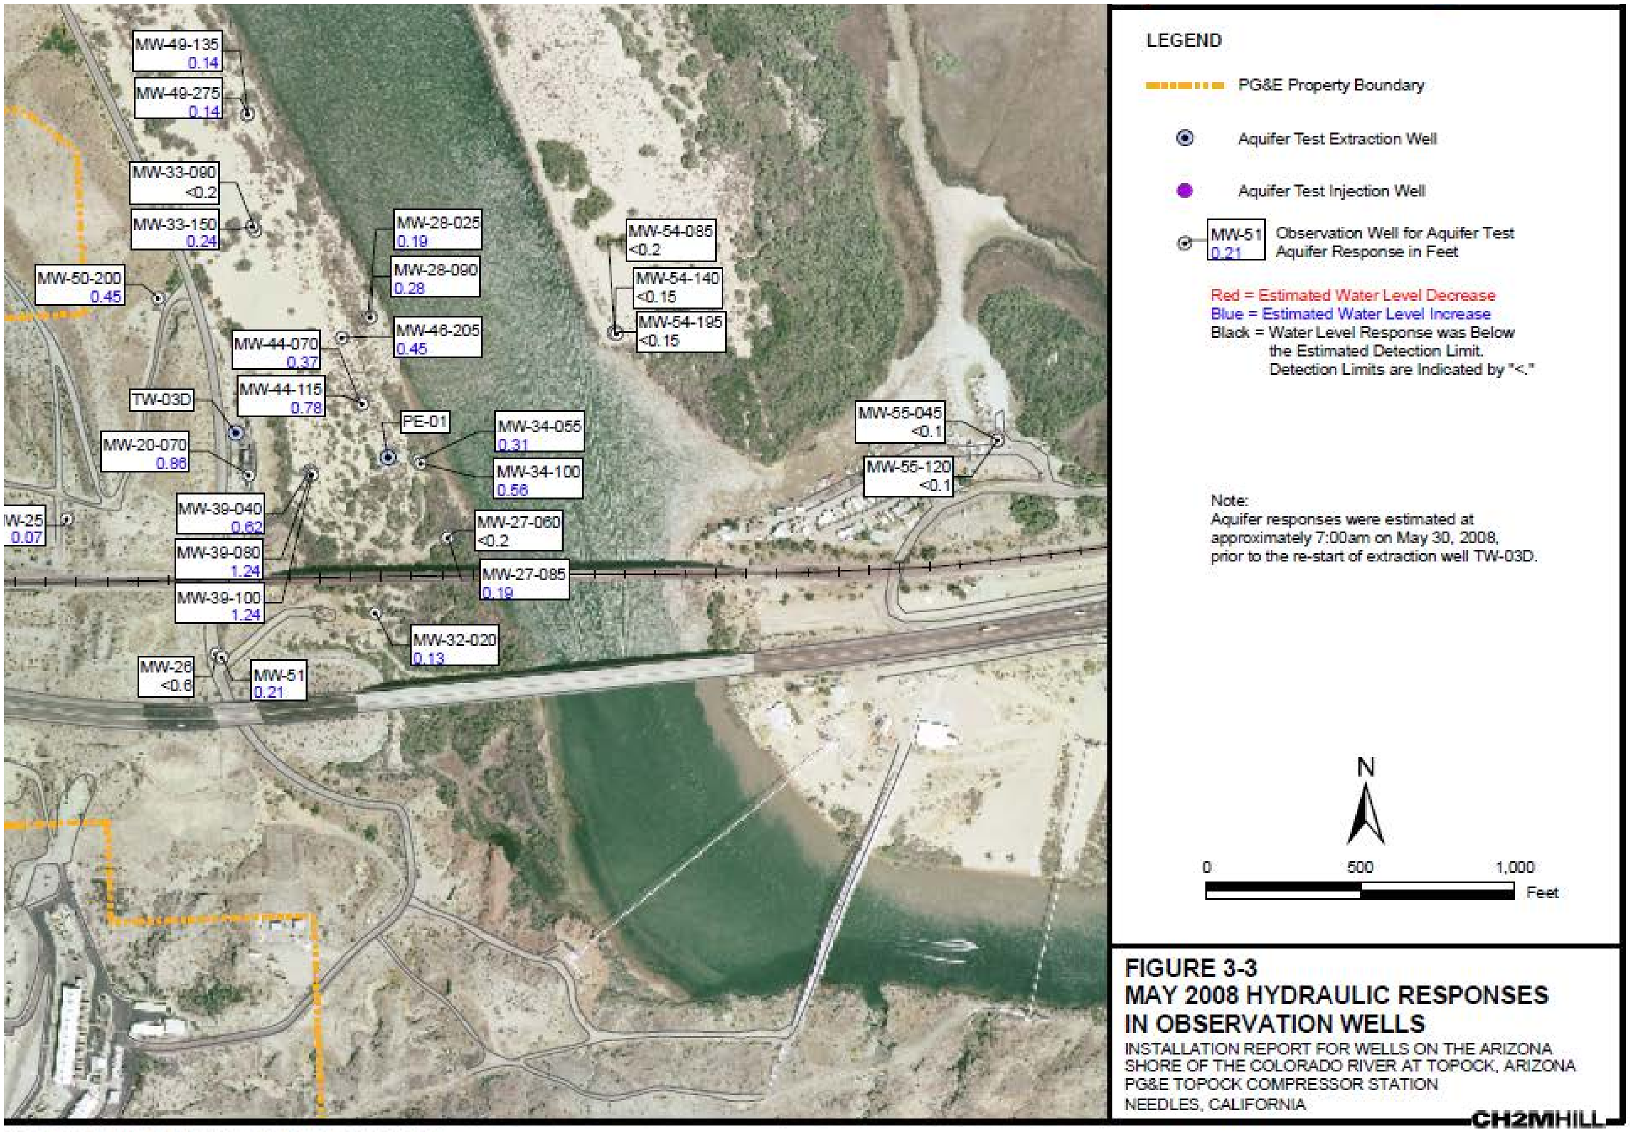

Figure 20. Documentation (CH2MHill, 2008) that MW-54 and MW-55 displayed no hydraulic response to the shutdown of IM-3 extraction wells PE-1 and TW-03D in 2008.

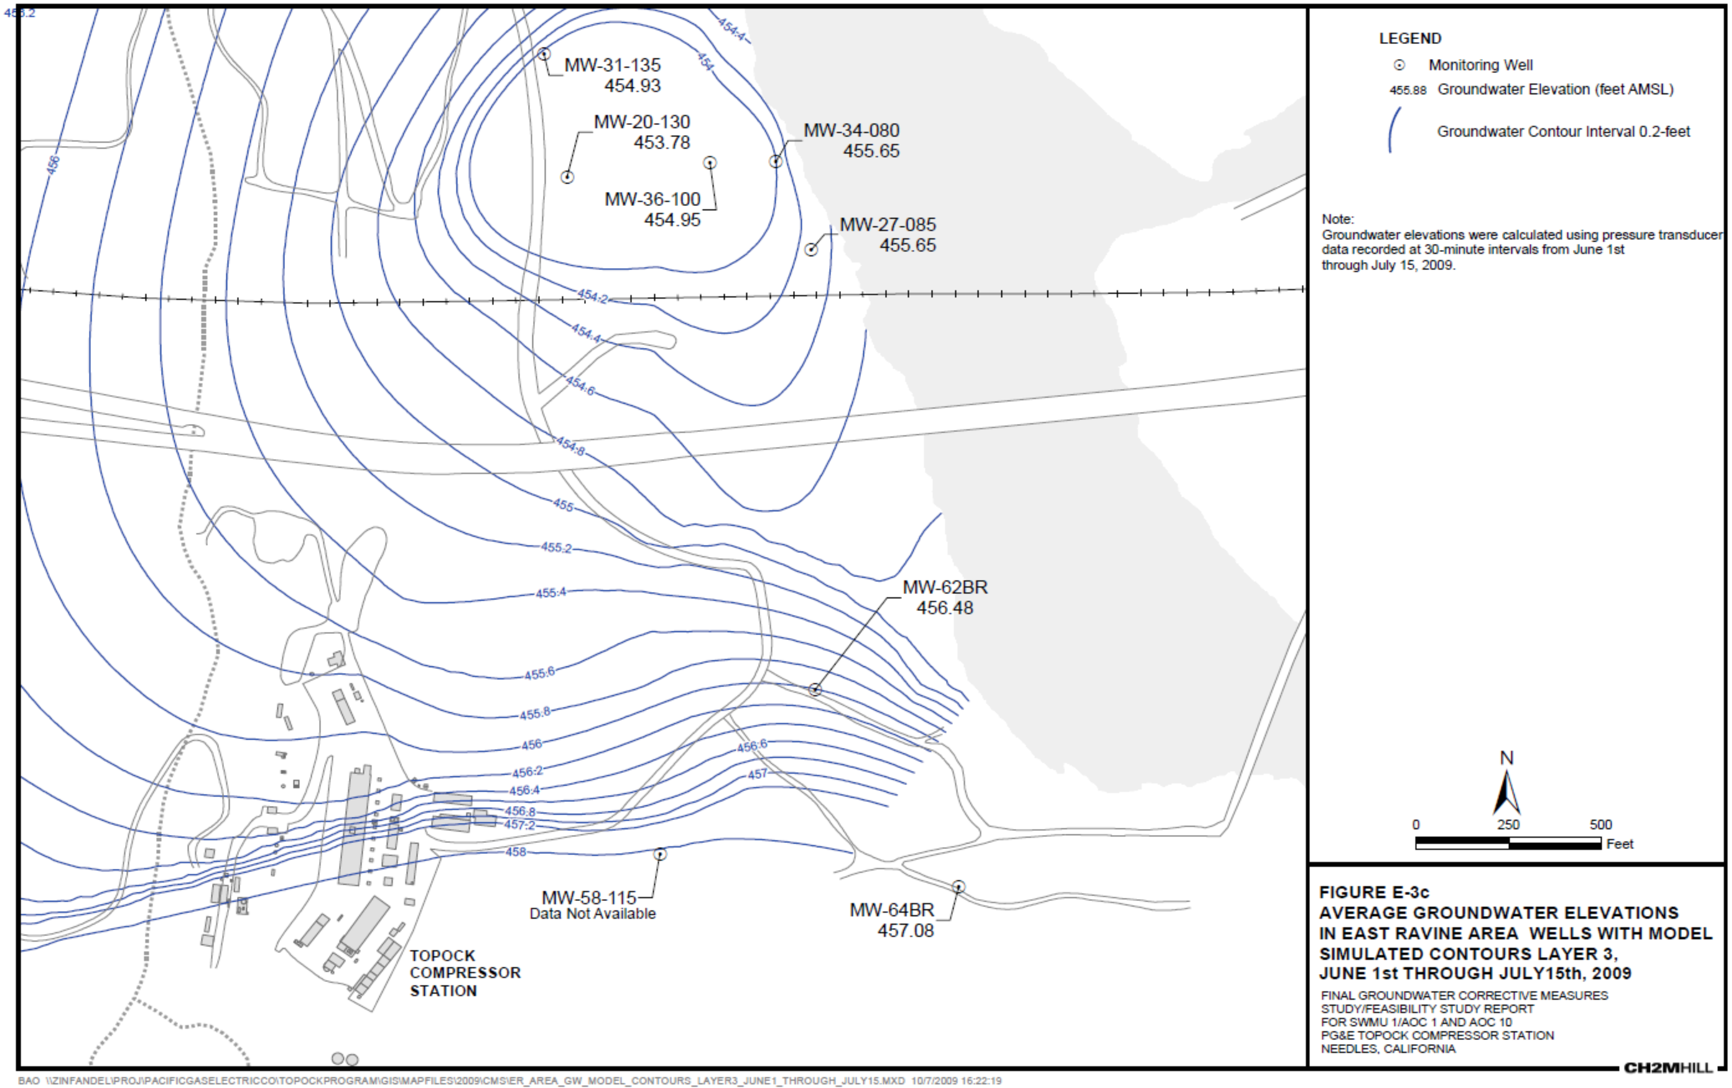

Figure 21. Simulated contours compared to observed, time-averaged (pressure transducer) groundwater levels for model layer 3 (CH2MHill, 2009).

Simulated Results of Site B Extraction Questionable/Uncertain

Exhibit 3.3-3 on page 3-39 (CH2MHill, 2014a), reproduced below as **Figure 22**, shows a concentric ring around HNWR-1/HNWR-1A, representing a simulated 5-year cone of influence (based on AZ guideline fixed-radius equation referenced in CH2MHill, 2014a). If the regional microFEM model was updated with hydrogeologic data from Site B, a perfect concentric cone of influence would not develop like this. Instead, a non-circular drawdown cone would develop as a function of variable aquifer thickness, overlapping drawdowns from other wells in the area, complex, dynamic seasonal interaction with surface waters (Topock Marsh, Colorado River), and complex ET and heterogeneous distribution of hydraulic properties within the aquifer. In any case, details of the subsurface such as the bedrock surface configuration beneath Site B and how it changes up into Sacramento Wash, and changes in hydraulic properties by depth, etc. should be addressed at this point at least on a conceptual level. This would allow a better understanding of how dewatering from Site B and HNWR-1A might influence and complicate flow paths beneath the River during full remedial system operation.

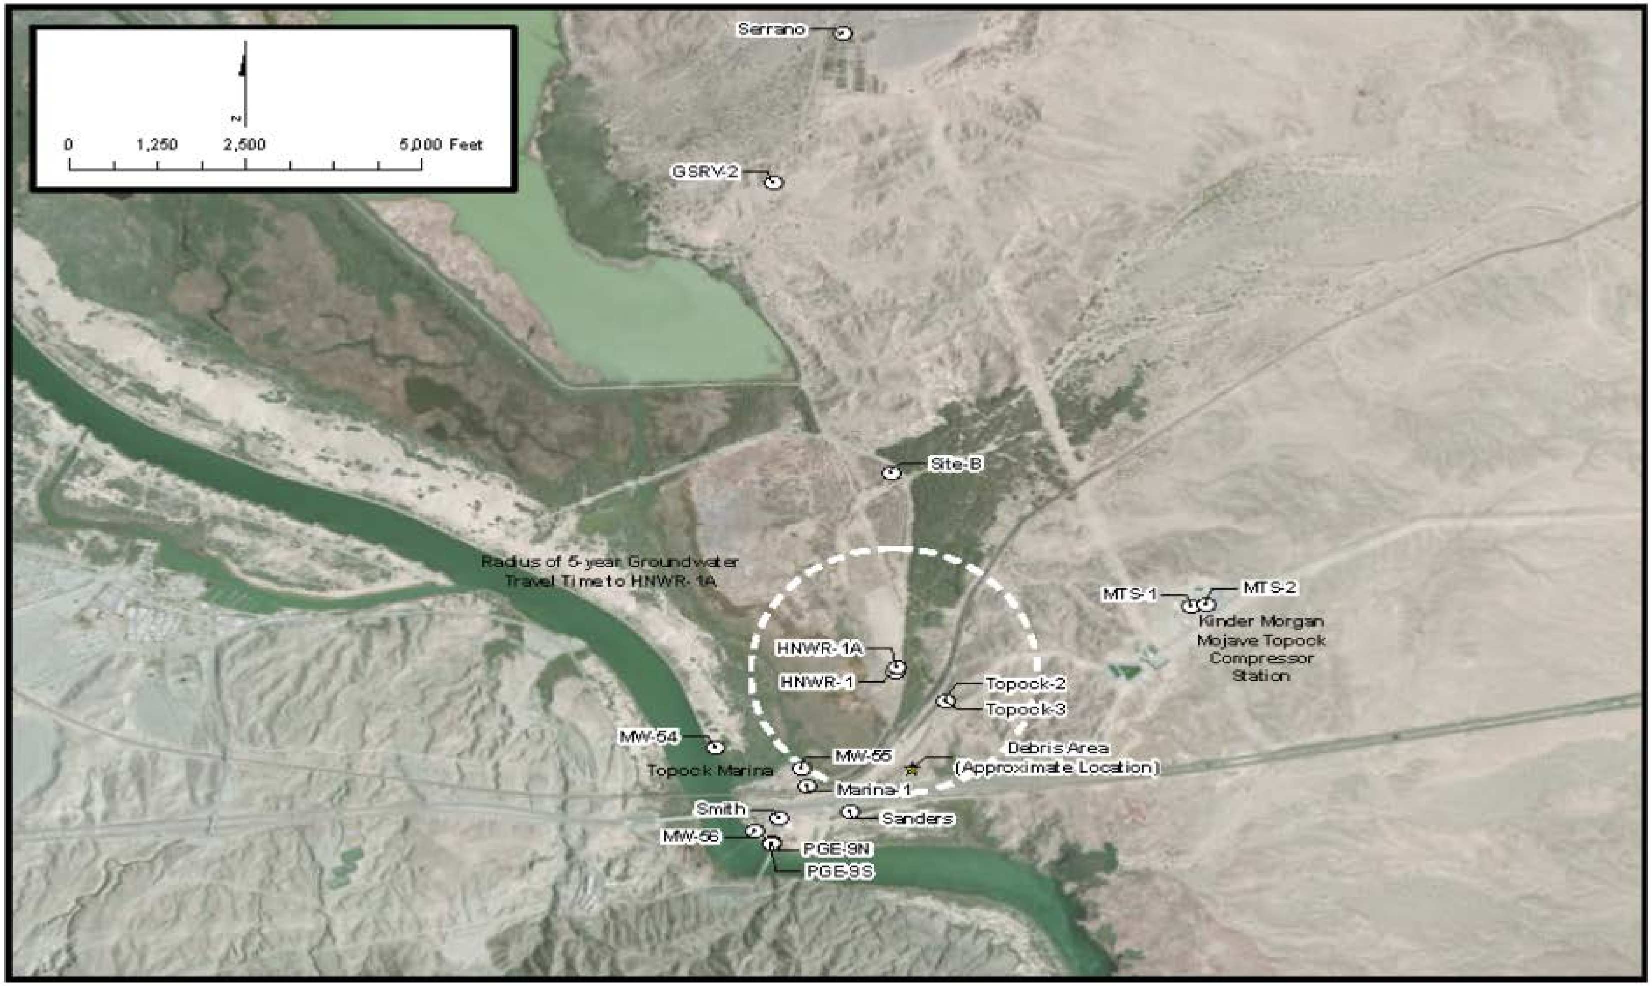

EXHIBIT 3.3-3
RADIUS OF FIVE-YEAR GROUNDWATER TRAVEL TIME TO HNWR-1A WELL
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Figure 22. Calculated radius of influence of freshwater supply well HNWR-1A at 5-years based on Arizona fixed-radius equation (page 3-37, CH2M Hill, 2014a). This should be calculated for life of remedial system (i.e., 30 years or more) and using an updated regional MicroFEM model.

Figure 6.5-17 in 90% BOD App B Groundwater Modeling report (CH2MHill, 2014a), reproduced earlier in this paper as **Figure 3** above, indicates some potential for flow breakthrough to the proposed MW-X and MW-Y location(s) during IRZ operation. However, two considerations are worth noting:

a. Monitoring wells between River Bank Extraction Wells (MW-29, MW-49, MW-33, etc.) would show concentration exceedances and violate hydraulic gradients for capture long before any impact would be seen at proposed MW-X or MW-Y. These wells are intended to monitor for bypass of the IRZ treatment area before concentrations were to enter the river or worse, move into Arizona. Monitoring wells located between extraction wells are roughly in the center of each river bank extraction well, where the potential for migration past the capture zone barrier created by the river bank extraction wells would be greatest. So these well locations would be the best locations to monitor for a breakthrough. River bank extraction wells are the least likely breakthrough points as they act as groundwater sinks.

b. In addition, simulated gradients, heads and particle paths are highly uncertain in this area and especially beneath the river. Until the multiyear IM-3 system is simulated and compared against flow and transport response data, model predictions beyond the western river bank should not be relied upon.

From review of the 90% BOD report (CH2M Hill, 2014a) the following were noted:

- For the 90%BOD review, no documentation was provided to the Tribes on the updates to the regional flow model (microFEM presumably performed by CH2M Hill which incorporated additional data from Site B drilling).
- No documentation was provided to the Tribes describing what specific changes were made to the 60% BOD sub-model (MODFLOW and MT3D) in going from 60% to 90%, nor were updated model input files provided for review as was done for the 60% BOD review.
- These updates and all inputs and assumptions are important to Tribes for assessing the performance and reliability of the constructed models and their predictions.
- It does not appear that water extraction from HNWR-1A or the Site B well extraction plus time-varying stage in the Colorado River and Topock Marsh area were ever simulated to better assess probable changes in flow paths.

Recommendations

Several actions could be undertaken immediately to improve understanding of groundwater flow beneath the River and on the Arizona side without incurring considerable cost or schedule delays. The ongoing unrelated project delay due to Subsequent Environmental Impact Report (SEIR) development, combined with the time needed for construction of the system, and system startup/testing should offer sufficient time for PG&E to address some of the limitations noted above. This should provide much needed justification to all parties, especially the Tribes, that any new monitoring wells in addition to MW-54, MW-55 and MW-56 are in fact needed, and that proposed numbers, locations, depths and sampling frequencies have a sound basis.

Field Testing/Monitoring

1. **Tracer Test.** Conduct a tracer test immediately to determine the nature of any hydraulic connection between existing Arizona monitoring wells and California IM-3 extraction and/or monitoring wells:
    a. Introduce different tracers into the deep zones of wells MW-54, MW-55 and MW-56. Based on the current understanding, this is the only likely pathway beneath the Colorado River.
    b. Monitor individual tracer breakthroughs at various depth zones in monitoring wells between PE-1 and TW-3D and Arizona wells (i.e., at MW-34 near PE-1, or at MW-54, if injecting at MW-55).
    c. Utilize the current MODFLOW model with transient river fluctuations, or ideally an updated model, to help predict breakthrough times for each tracer. Even if the time it takes for a tracer to migrate from any of these wells to the west side takes more than a year (i.e., 1 to 2 years based on current gradients and assumption that a flow path exists and does not stop at a potential hydraulic river barrier at depth), even extending into startup of the proposed remedial system (i.e., NTH IRZ injection/extraction wells, Riverbank wells, etc.), the information gained by any tracer test (i.e., just showing hydraulic connection) would be highly valuable in revising the CSM, and model flow and fate/transport parameters. These updated parameters could then be used to assess the number, locations, and depths of any additional monitoring wells beyond MW-54, MW-55 and MW-56.

2. **Monitoring Data.** Monitor head, temperature and conductivity continuously (i.e., hourly) using dataloggers/transducers at all AZ wells (at least MW-54, MW-55, and MW-56).

3. **Revised Contour Maps.** Prepare groundwater contour maps across the entire area bounded by continuous monitoring wells in both Arizona and California for specific times (at a certain hour in a day) using the continuously monitored (hourly) data, incorporating River and Topock Marsh surface water fluctuations in appropriate layers (similar to DOI comments #104 and #105).

Model Revision and Re-Evaluation of Monitoring Need/Locations

1. **Conceptual Model Update.** Develop and clearly describe a conceptual flow/fate/transport model that describes 3-dimensional (horizontal and vertical) flow conditions, based on available data and characterizations, in the vicinity of the River , beneath the River, and into Topock Gorge, and within Arizona to all areas that have stresses (i.e., pumping) that may affect groundwater flows within the eastern banks of the River, or which might be influenced by the remedial system, including the freshwater sources.

2. **Use Current Industry-Standard Modeling Tools.** If PG&E is committed to continuing to using MODFLOW/MT3D, at least consider using more up to date standard MODFLOW packages which would simulate ET, Recharge and River-Aquifer exchange processes more realistically:
   a. ET boundary condition – Instead of using the original MODFLOW EVT package which treats ET loss as a linear function of hydraulic head (not very physically realistic), consider using MODFLOW Riparian ET package (available for MODFLOW-2005) http://pubs.usgs.gov/tm/tm6a39/pdf/tm6a39.pdf, or even the ETS package (http://pubs.er.usgs.gov/publication/ofr00466).
   b. Recharge boundary condition – See the following publication on the Basin Characterization Method (BCM) currently used by the USGS in a number of southwestern basins. (http://pubs.usgs.gov/pp/pp1703/b/pp1703b.pdf) or (http://pubs.usgs.gov/sir/2007/5099/).
   c. River boundary condition – Consider using alternative, newer and more robust stream-aquifer packages to simulate the interaction between the Colorado River and the underlying aquifer(s):
      i. STR package (older than the subsequent two SFR packages, but more robust than RIV package used in the Topock MODFLOW modeling (http://water.usgs.gov/nrp/gwsoftware/modflow2000/MFDOC/index.html?riv.htm)
      ii. SFR1 package - http://pubs.er.usgs.gov/publication/ofr20041042
      iii. SFR2 package - http://pubs.usgs.gov/tm/2006/tm6A13/
   d. Consider simulating flow conditions using a density-dependent flow code (i.e., FEFLOW, SEAWAT (MODFLOW/MT3DMS-based) , SUTRA/Sutrasuite, or even MODFLOW-SURFACT) so that the effects of density and temperature variations could be considered in the modeling as they affect current and future remediation-affected flow paths.

3. **Revise Model Layers.** Revise model layers to coincide with hydrostratigraphic units (and screened zones where possible), and consider adding more layers (i.e., subdividing single units) so that surface water interaction with groundwater, and flows and fate/transport can be simulated more realistically. Not doing so can produce misleading fate/transport estimates (i.e., concentration trends, pathways, etc.).

4. **Recalibrate the Model.** Re-calibrate the existing flow and fate/transport models to the many years of readily available IM-3 quarterly monitoring response data, including fully transient river and Topock Marsh stage fluctuations. Use information from tracer testing in existing Arizona wells (MW-54, MW-55 and MW-56) as described in recommendation #1, continuously monitored and correctly salinity-adjusted Arizona well water levels, and revised conceptualization to assess more realistic/consistent 3-D flow paths beneath the river and into it.

   Reassess and revise all model parameters during calibration, especially parameterization of hydraulic conductivity, storage and riverbed conductance beneath and east of river. These distributions are far too complex due to poorly constrained parameter estimation in this area using PEST. Also reassess and revise ET parameters, recharge and river cells, as detailed above.

   i. Show 3-dimensional particle flow paths, if any are found to exist beneath the river, and in California.
   ii. Utilize PEST where possible, but better constrain the distributions such that critical parameter distributions such as hydraulic conductivity or riverbed conductance don't abruptly change in physically unrealistic/unjustified ways beneath critical parts of the river (i.e., between MW-34 and MW-54 and MW-55.)
   iii. Provide calibration statistics in a more standard and transparent way so all stakeholders can gain confidence in future predictions in key areas of interest, especially in the MW-X and MW-Y proposed area.

5. **Validate the Model.** As an alternative to re-calibrating the model to IM-3 data above, consultants could demonstrate acceptable performance of the model by validating it to IM-3 data as per modeling guidelines outlined on page 12 of this California DTSC document (https://www.dtsc.ca.gov/PublicationsForms/upload/GW_Modeling_for_Hydrogeo_Characterization.pdf).

6. **Conduct Simulations to Predict Future Flow Conditions.** Estimate all future flow paths and fate/transport for the current proposed remedial system with **transient conditions** instead of the steady state approach used in 90% BOD. This should include site conditions such as IRZ on and off, variable stage for the Colorado River and HNWR Topock Marsh, and influence of HNWR-1 (+/- Site B) well extraction, with/without the west side river bank extraction wells operating. Using a transient model that includes the time it takes for the California-side groundwater levels to adjust to IRZ wells being turned off or on with overlapping seasonal and daily fluctuations of the river will greatly aid future tribal (and all stakeholder) visualization and interpretation of the potential for predicted groundwater flow paths in the vicinity of the river, beneath it and into Arizona. This should also greatly aid in evaluating whether monitoring wells MW-X and MW-Y are needed, and whether their locations are appropriate.

7. **Optimize Operations.**
   a. Consider using a standard optimization approach (Optix w/Feflow, or HGL's PBMO software that works with MODFLOW/MT3D (http://www.hgl.com/expertise/modeling-and-

optimization/software-tools/pbmo-toolkit/)) to optimize proposed remedial system decision variables (pumping rates, TOC injections, cycles, pumping depths, injection/extraction well locations, etc.) given various implicit/explicit optimization constraints (i.e., minimizing remedial time, minimizing spatial extent of plume, minimizing by-products) with a new constraint that limits impacts of Arizona water by California remediation operations (i.e., extraction at River Bank wells). Additional constraints could also be considered – going forward w/O&M – which include minimizing pumping rates, TOC injection rates, cycling periods etc.

b. Consider Federal Remediation Technologies Roundtable Remediation Optimization approaches: http://www.frtr.gov/optimization/default.htm or USGS GWM-2000 approaches: http://water.usgs.gov/nrp/gwsoftware/mf2k-gwm/MF2K-GWM.html; see also: http://pubs.usgs.gov/fs/2005/3095/ .

c. Using the revised model, determine whether any additional monitoring wells are actually needed AND if actually needed, then optimize their number/placement – for all proposed remedial system designs/operations and any changes in the proposed system (including HNWR-1A, Site B, River Stage, or any other nearby pumping stresses). The model is the only tool available that can account for all known complexities/conceptual flow conditions, as long as all variables are addressed within the model. Assess 3-D, time-varying (seasonal) pathways between the west and east sides of the Colorado River, if any exist, given annual variations in pumping (west and east sides) AND seasonal variations in river and HNWR Topock Marsh stages.

Define an Alternative Basis for Performance Assessment of the Proposed Remedy

1. **Define a more appropriate target hydraulic containment boundary.** The 90% BOD report (CH2MHill, 2014a) does not mention “hydraulic boundary” or “hydraulic containment” area similar to what is done at the Hinkley Site. To meet RAO objectives (i.e., RAOs #2 and #4 (CH2M Hill, 2014a)), the target hydraulic containment boundary should be either:
    i. The eastern boundary of the Cr(VI) plume, which varies with depth. This boundary is ideal as it prevents migration of the plume into clean areas to the east. This may require additional refinement of the proposed NTH IRZ injection/extraction and Riverbank well extraction strategy, but it can likely be done.
    ii. The western bank of the River, or center line of the river as this technically represents the primary hydraulic boundary between west and east groundwater flows (and it represents the state boundary).

2. Define well pairs/triplets on the western side of the river to monitor gradients and concentration trends such that Cr(VI) does not move east of the current western plume boundary at any depth, or does not move to the edge of the western river bank, except in the vicinity of MW-34, where the plume has migrated furthest to the east at depth. In this area, wells MW-54, MW-55 and MW-56 more than adequately provide eastern monitoring points for assessment of eastward migration.

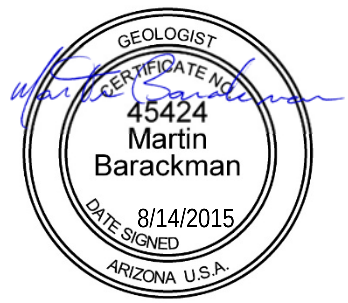
TECHNICAL MEMORANDUM

PG&E Response to MW-X and MW-Y Whitepaper

PREPARED FOR:	Pacific Gas and Electric
COPY TO:	Jon Roller/ARCADIS Fred Stanin/ARCADIS
PREPARED BY:	Martin Barackman/CH2M Mike Cavaliere/CH2M
DATE:	August 14, 2015
PREPARED FOR:	Pacific Gas and Electric



Expires 12/31/2015

As an action item from the July 23, 2015 Technical Work Group Meeting, this memorandum was prepared to present PG&E's review of a whitepaper, titled *Evaluation of Technical Justification for Proposed Monitoring Wells MW-X and MW-Y*, prepared by Robert Prucha and Margaret Eggers, dated July 15, 2015. The whitepaper addresses several technical aspects of the Topock conceptual site model and associated groundwater models as they relate to the location and purpose of the proposed monitoring wells MW-X and MW-Y in Arizona. PG&E's review is organized in the same general order as the whitepaper:

- Principal Premise – Purpose of MW-X and MW-Y
- Alternative Downgradient Monitoring Locations
- Use and Interpretation of Available Groundwater Level Data
- Groundwater Model Setup and Calibration
- Whitepaper Recommendations

Principal Premise -- Purpose of MW-X and MW-Y

The white paper states:

> "*The focus of this review was to evaluate the technical rationale applied to the siting of proposed monitor wells MW-X and MW-Y including the use of the existing groundwater model and other data. In particular, the potential for hydraulic communication beneath the Colorado River between the CA and AZ was evaluated. This necessitated a thorough examination of the assumptions applied in deciding on the need for these wells within the performance monitoring network. The Department of Toxic Substances Control (DTSC) has relied heavily on the groundwater model as the basis for the design and operation of the proposed remedial system (CH2M Hill, 2014a). As such, DTSC has also relied exclusively on the model in its current state to conclude that monitoring wells are needed across the river, at the proposed MW–X and MW–Y locations in Arizona.*"
>
> "*Currently, the purpose for MW-X and MW-Y appears unclear and raises additional questions.*"

As to the purpose for MW-X and MW-Y, the following is stated in DTSC's July 2014 presentation (titled "Proposed New Monitoring Wells for 90% Design" dated June 18, 2014) to the TWG:

> "*7. Arizona Sentinel Wells: At least two wells to monitor hydraulic capture and confirm that plume does not expand over the life of the remedy.*"

The importance of capture zone monitoring is supported by the agencies' direction letter on the remaining 60% design issues dated April 4, 2014:

> "*It is imperative that appropriate and acceptable plume control for both contaminants and byproducts be evaluated and established for the remedy. Furthermore, capture zone monitoring must provide definitive criteria and sufficient data that would allow DTSC to meet the plume control determination as specified in Exhibit A5a of the DTSC 2012 settlement with FMIT and to enable DTSC to reach findings required under Exhibit A1 and A2 for decommissioning of IM-3.*"

In addition, DTSC noted in its response to 90% comment #17 that these wells (i.e., MW-X and MW-Y) need to be installed early to establish baseline concentrations for water quality constituents (e.g., baseline chromium concentrations) so any naturally occurring trends can be observed before remedy start up. This will assist in determining if the well has been affected by the remedy.

Therefore, PG&E understands the need for MW-X and MW-Y to be as follows:

- Provide monitoring of chromium and byproducts downgradient from the treatment zone (i.e. sentinel wells).
- Provide groundwater levels for evaluating hydraulic influence of river bank wells and better defining capture zone.
- Provide baseline characterization of the aquifer in an area that is currently poorly characterized but important to the remedy and the model.

More importantly, PG&E also understands that the need for downgradient/sentinel wells such as MW-X and MW-Y is not driven by model results, and would not be negated by a model.

The following sections provide PG&E's response to the whitepaper, with the topics in the same general order as they were originally presented.

Alternative Downgradient Monitoring Locations

The whitepaper proposes that the river bank extraction wells could be moved inland so that hydraulic capture could be achieved around the margin of the chromium plume and downgradient monitoring could be implemented on the California floodplain. Moving the pumping wells closer to the IRZ increases the velocity through the sections of the IRZ closest to each river bank extraction well. With uneven flow velocity across the IRZ, there is a risk of chromium breakthrough in the higher velocity sections. To prevent breakthrough more carbon would have to be added, which could result in excess carbon and excess byproduct generation in the lower velocity sections of the IRZ. More organic carbon and in-situ byproducts would reach the extraction wells, leading to increased well maintenance on both extraction and injection wells. The separation between the IRZ and the river bank extraction wells in the current design is the minimum needed to avoid negative impacts of the wells on the IRZ and vice-versa. Moving the extraction wells inland of the plume boundary would require relocating the IRZ a similar distance further inland, into the upland area. A significant portion of the plume containing relatively high concentrations of chromium would then be located downgradient from the IRZ, presumably to be captured by the relocated river bank extraction wells. A treatment plant could be needed to remove chromium from the water pumped by the extraction wells prior to its re-injection in the IRL wells. Thus, establishing hydraulic capture in the floodplain with the river bank extraction wells relocated inland would result in a major re-design of the remedy, additional impacts in the uplands, and potentially expanded treatment system infrastructure and footprint. This could be considered a different remedial approach than approved by the DOI (Groundwater ROD, Dec. 2010) and DTSC (Resolution Approving the Final Remedy Project, Jan. 2011), could potentially take the project back to the CMS/FS stage.

Use and Interpretation of Available Groundwater Level Data

General Groundwater Flow Patterns near Topock

Based on the discussion and figures provided, it appears there may be a misconception in the whitepaper about groundwater flow patterns near the site. In order to be sure that there is common understanding, PG&E would like to provide some clarification of the conceptual model of groundwater flow at the southern end of the Mohave Valley. Figure 9 in the whitepaper is a groundwater contour plot showing groundwater flow from Arizona converging at the river channel and exiting southward through the narrow "notch" where the river flows between two bedrock outcrops. Only a small fraction (<10%) of the groundwater leaving the Mohave Valley flows through the notch where the river exits the valley. The majority (>90%) flows through a much deeper and wider paleo-channel beneath the Topock Marina. The existence of this paleo-channel and its inclusion in the model was directed by the USGS (Peter Martin, Program Chief of the Desert and Eastern Sierra Nevada of the California District) and is supported by geomorphology work done by Dr. Keith Howard of the USGS, which included carbon dating of sediments from boreholes on the Topock floodplain that showed the age of the fluvial material beneath the current river channel to be less than 12,000 years.

Although there are currently local gradients defined by MW-54 and MW-55 that show westerly flow, these westerly gradients are likely in large part a response to IM-3 pumping. The overall groundwater flow pattern under non-pumping conditions likely has an easterly component, from the Topock floodplain toward Arizona where most of the groundwater flows out of the valley. During the final remedy, the pumping of freshwater from Arizona will strengthen the natural easterly component of the gradient, resulting in increased potential for easterly migration of groundwater from California if the capture zone of the river bank extraction wells is incomplete. This easterly component would be most prevalent in the northern portion of the floodplain, where MW X and Y are proposed.

The groundwater contours in Figure 9 of the whitepaper are not consistent with the overall conceptual model of the site and are not representative of what would be expected during the operation of the final remedy. PG&E is concerned that much of the discussion about location of MW's X/Y and the hydraulic connection between Arizona and California in the whitepaper may be affected by what appears to be a basic misunderstanding of the groundwater flow patterns in the southern portion of the Mohave Valley.

Use of Water Level Data from Arizona Wells in Model

In response to questions raised in the whitepaper, PG&E can confirm that continuous water level data has been collected from the vertical well clusters in Arizona, MW-54 and MW-55 since 2008. These wells were not installed until late 2007, so the data from them were not available in during original calibration of the groundwater flow model in 2005. Although they were not incorporated in the original model calibration, the depth to bedrock in the model was subsequently revised to account for the observed bedrock contacts in the MW-54 and MW-55 boreholes and the depth to bedrock estimations from the USGS seismic survey conducted in the river channel at about the same time. The revised model projections were compared with measured water levels in the MW-54 and MW-55 wells and the match was determined to be reasonable. Therefore, no model recalibration was considered necessary based on data from these wells. As noted in the whitepaper, no long-term pumping tests have been conducted in the vicinity of MW-54 and MW-55 and the influence from IM-3 pumping at these locations is too slight to provide reliable measurements above the river fluctuations. Continuous water level data are available from these wells starting in 2008 and the average water levels from them are presented in the PMP reports.

As noted in the whitepaper, continuous water level data are not collected from the slant wells, MW-55 and MW-56. Slant wells were originally proposed as individual wells, each in a separate borehole. This would have required 6 boreholes at each slant well location. In order to minimize the number of boreholes, PG&E developed a design that allowed three monitoring intervals in each slant well borehole. Conventional well construction techniques could not be used due to the instability of the boreholes and the extreme angle at which they drilled. Consequently, the screened intervals in these wells consist of small diameter porous tubes (similar to Barcad® samplers) connected to small diameter (3/8") flexible tubing. The upper portion of the wells is 1" PVC pipe, which can accommodate a small transducer but is too narrow allow insertion of a sounder in the well while the transducer is installed. Manual water level readings using a sounder are needed to calibrate a transducer in order to obtain a precise water level elevation. Even if sounders could be inserted, precise measurements of the angle of the pipes would be needed to establish the vertical depth to water. In addition, precise knowledge of the vertical depth of the monitoring interval would be needed to calculate a salinity correction and allow the water level to be referenced to mean sea level datum. The angle of the boreholes and depth of the monitoring intervals is not known with sufficient precision to allow these wells to be usable as water level monitoring points. The inability to get accurate water level data from these wells was anticipated and discussed at the time they were installed. It was understood that this was a trade-off the project stakeholders were willing to make in exchange for obtaining sufficient water quality data while minimizing the number of boreholes.

Water Level Averaging to Evaluate Gradients

The whitepaper contends that averaging of water levels from the transducers is not an appropriate way to measure average gradients. We believe this is incorrect. This issue was debated at length among all the stakeholders in late 2004 and early 2005 when the gradient metrics for IM-3 were being established. Particle tracking was conducted to show that groundwater movement in the floodplain could be predicted equally well with monthly average gradients or daily or hourly gradients. This method of monthly averaging of water levels has proven to be reliable over a decade of monitoring at this site. Water levels all across the site fluctuate in response to changes in river elevation, so a snapshot of water levels at one time of day may show flow toward the river while at a different time of day it would be away from the river. A groundwater divide is seen in snapshot water level plots that moves back and forth through the day. Without averaging, there is no way to make meaningful conclusions about overall groundwater flow patterns at a site where water levels are fluctuating several feet per day.

Model Setup and Calibration

The whitepaper raises numerous issues about the setup and calibration of the models. The information in this section is intended to provide clarification and address some of these issues. The groundwater flow model was developed over more than a decade, with ongoing improvement at each stage. Many of the ideas raised in the whitepaper have been discussed before and some may be implemented in future updates of the model. Other issues are based on misconceptions that we will attempt to clear up.

Model Boundary Conditions

There appears to be a misunderstanding in the whitepaper about the linkage between the flow and transport models. The whitepaper seems to indicate that the edges of the transport model are no-flow boundaries. As described in Appendix B of all the basis of design reports (30%, 60% and 90%), all the boundaries around the edge of the transport model are prescribed flux boundaries. The boundary fluxes are exported from the flow model. The transfer of boundary flux from a larger model to smaller, more detailed model provides a linkage between the models so that the water balance from the larger regional model is preserved in the smaller transport model. The whitepaper suggests the transport model is deficient because the river cells are not specified along the section of the northern boundary coincident with the river. The river flux in and out of the cells along the northern boundary is incorporated in the boundary fluxes imported from the larger flow model. Specifying river cells at the boundary in addition to the specified flux already assigned there would introduce errors in the model. The river cells are assigned in the interior of the transport model, but not at the boundaries.

The stage in the river and marsh are set to annual average conditions and the flow model is run in steady state. This is considered appropriate for the purposes of evaluating a remedy that is designed to perform for decades. The short term daily and monthly river level fluctuations are not critical to understanding overall remedy performance.

Bathymetry in the river was established based on the USGS seismic survey data in the vicinity of the site and estimated elsewhere. Considering that the model is run in steady state and the water table is generally coupled to the river and the marsh, it is unlikely to be sensitive to the bathymetry. If the model was run in transient mode to simulate a low river level where a portion of the marsh were dry, then more accurate bathymetry would be needed.

Riverbed conductance has not been measured and could not be directly measured without wells installed into the river bottom. Conductance would have a much larger influence on the steady state model results than bathymetry. The conductance in the marsh was set to a lower value than the river in recognition of the muddy bottom typical in marsh environments compared to the sand bottom in the river channel.

Evapotranspiration (ET) is another parameter that is difficult to measure and therefore typically assigned based on literature values. The ET rate in the model is based on the fact that the vegetation is sparse, so that in any one model cell there are areas of bare ground and areas covered by plants. The ET rate in the model was developed through calibration to the areas of the site were groundwater level data were available, primarily in the California floodplain. As suggested in the whitepaper, literature suggests a higher ET rate could be appropriate, but when a higher rate was applied, the simulated water levels in the southern floodplain, where vegetation is most prevalent, were excessively low. Because neither river conductance nor ET are tightly constrained, it’s likely that a calibration could be achieved with a higher river conductance (to provide more water) and a higher ET rate (to extract more water). Because most of the phreatophytes are near the river, the net result of an increased ET rate on the groundwater flow across the site would likely be small. Because the river represents an essentially unlimited source of water to the model, the water removed by a higher ET rate would be provide by the river cells nearby. There would more water exchanged between the river and the vegetation but the effects of additional ET in areas away from the river would be muted.

Water Balance

The whitepaper questions the discrepancy in the water balance between a regional USGS model and the local scale Topock model. This discrepancy was noted at the time the Topock model was being calibrated. At that time the USGS model was unpublished, but the USGS was heavily involved in the

Topock project and provided a “preview” of the USGS model. PG&E attempted to apply the large volume of Sacramento Wash underflow that is suggested by the USGS model to the Topock model, but it resulted in water levels far above land surface all throughout the eastern side of the model. The inconsistency between the two models was noted but the reason for it was never resolved. At the time, USGS scientist Peter Martin agreed that the Sacramento Wash underflow in the Topock model was more reasonable than the value in the USGS model. He believed it was possible that there was another outlet from the Sacramento valley where groundwater could move south without flowing down the Sacramento Wash valley.

Model Layering and Depth to Bedrock

The model layers do not correspond to hyrostratigraphic units everywhere in the model. Shortly before the CMS was prepared, there was a considerable discussion about revising the layering in the model to make it more consistent with the geology and initial efforts were undertaken to accomplish this. It was recognized at the time that this change was largely cosmetic and would likely not make a meaningful difference in the model projections. Because it would have added significant time to the schedule, it was not completed and the layering in the model remains as it was in 2005.

The whitepaper questions the assignment of depth to bedrock in Arizona. Further information about the depth to bedrock in the Arizona portion of the model is provided in a tech memo titled “Additional Details on Aquifer Test Interpretation and Groundwater Flow Model Updates for the Arizona Portion of the Topock Remediation Project Area, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California”, distributed by e-mail from Christina Hong to the CWG members on August 12, 2015.

Density Dependent Flow

The issue of density dependent flow has been previously discussed in the Appendix B of the 90% BOD report, which states:

> *“With respect to TDS and density variations, while it is acknowledged that effects of density-driven flow may be possible, they are not expected to be significant. Given the aquifer heterogeneity and vertical anisotropy, and the relatively high expected flow velocities within the system in the vicinity to the freshwater injection wells, advection-driven flows are expected to allow adequate horizontal flows to develop and be maintained at all depths between freshwater injection wells and River Bank extraction wells. If however, effects of density are observed during remedy implementation (i.e. slower, or ‘short-circuiting’ of flushing within the deeper, more saline portions of the aquifer in areas some distance away from the injection wells with respect to monitored average hydraulic gradients), steps can be taken to mitigate these impacts.”*

Incorporating density dependent flow into the model would make it a very cumbersome tool for use in remedial design.

Aquifer Response to IM-3 Shut Down

The whitepaper seems to suggest that because the effects of shutting off the IM-3 were not clearly observed in wells in Arizona, there may be some kind of hydraulic barrier or at least poor hydraulic communication between California and Arizona. PG&E sees no geologic basis for this interpretation. A much more likely explanation is that the signal generated by the modest amount of IM-3 pumping is simply not strong enough to propagate to the wells in Arizona and be seen above the noise of the river fluctuations. It should be noted that even in the floodplain near the pumping wells, the amount of water level change observed from the IM-3 shutdown test was generally less than 6 inches. PG&E believes that there was a likely a small response observed in the Arizona wells, but it was just too small to be quantified against the noise of the daily river fluctuations. The lack of response from the IM-3 shutdown test does not suggest the lack of hydraulic communication.

Whitepaper Recommendations

PG&E responses to the recommendations in the whitepaper are presented in this section.

Tracer Test

The whitepaper recommends a tracer test to evaluate groundwater flow between existing Arizona monitoring wells at the MW-54 location and IM-3 extraction wells in California under the Colorado River. PG&E conducted a modeling analysis to gauge the duration and the scale of such a tracer test under current pumping conditions. Current pumping of IM-3 consists of PE-1 at 30 gpm and TW-3D at 100 gpm, and was simulated to continue for 5 years into the future. First, the groundwater flow model was utilized to conduct a pathline analysis where particles were initialized around the existing MW-54 monitoring wells to represent tracer injected into the middle and deep screened intervals of the well (Model Layers 3 and 4, respectively). The particles were then tracked for a 5 year period which represent the average groundwater flow movement, and while particles traveled farther in Model Layer 3 than Model Layer 4, after 5 years particles still did not reach extraction well PE-1 in California. After 5 years, the full remedial design, including groundwater extraction along the river bank, was simulated and the particles shifted their migration path towards RB-4.

The potential impact of pumping from a future Topock Marina groundwater supply well (not associated with the Topock Remediation Project) was also evaluated with the pathline analysis. The pumping rate at this hypothetical well was assigned as 16 gpm, based on the anticipated future water demand reported by the Topock 66 Resort. The hypothetical well was located at the same location as the current Topock Marina well (which pumps brackish water) and screened in model layers 3 and 4. It's meant to simulate a potential future well that could be drilled somewhere on the marina property and produce water of sufficient quality for use at the marina. The pathline analysis indicates that tracer particles also have the potential to eventually arrive at such a hypothetical future Topock Marina supply well.

To further evaluate the tracer test, a solute transport model simulation was conducted to account for mechanisms such as dispersion and advection. The solute transport model was run using the same IM-3 hydraulic stresses as the groundwater flow model for a 5 year period. A theoretical conservative tracer was simulated without sorption or degradation originating at the MW-54 location in model layers 3 and 4. This transport analysis indicates that in order for an average concentration of 10 ppb (typical detection limit for bromide) tracer to arrive at PE-1 after 5 years, approximately 58,000 gallons of 2,000 ppm tracer would need to be introduced at MW-54. This would only be indicative of the arrival of the leading edge of the tracer mass. Significantly more than 5 years would be needed to observe the arrival of the center of the tracer mass and observe the tailing off of the concentrations, which is necessary in order do any quantitative analysis of a tracer test.

Based on the model simulations, it is apparent that a relatively significant volume of tracer and a long period of time would be needed to conduct a tracer test beneath the river. While a tracer test conducted under IM-3 gradients may show hydraulic connection, it is not representative of final remedy pumping conditions and will neither confirm nor refute the basis for the need for monitoring wells MW-

X and Y. Injecting a large volume of tracer that could linger in the aquifer for decades also increases the risk of tracer emerging in the river or arriving at future pumping wells.

Water Level Monitoring and "Snapshot" Contour Maps

As discussed earlier in this technical memorandum, continuous water level data are available from MW-54 and MW-55 wells, however it is not possible to get water levels from the slant wells with sufficient accuracy to support contouring with other wells at the site. The whitepaper recommends "snapshot" water level contour plots using water levels from a specific hour of the day. It is not clear what insight could be gained from this. Each hour of the day would show a different set of water level contours as the river signal propagated through the aquifer. While it is possible to gain insights and even develop estimates of hydraulic parameters by observation of aquifer response to changing river levels, these insights cannot be gained through snapshot contour plots, but rather by comparison of water level hydrographs to the river hydrograph. This hydrograph approach was used during model calibration to estimate hydraulic properties in the floodplain. Without a better understanding of how the interpretations would be used, PG&E does not see value in producing hourly water level contour plots.

Model Revisions

The whitepaper has many recommendations for revisions to the model, including use of different model packages and codes, revisions to the model structure, recalibration, validation, and optimization of the model. As noted above, the model has developed over a decade and will continue to be updated throughout the implementation and operation of the final remedy. The current model was initially built (as a flow model) to support comparison of remedial alternatives in the FS, then later augmented to provide solute transport capability in support of the design of the final remedy. It is anticipated that as new data become available and the project objectives change, the model will continue be improved and the recommendations in the whitepaper, along with others, will be considered at each step. Some of the recommendations, such as incorporating density dependent flow, could render the model unwieldy and therefore less useful as a tool for remedy design and operation. Others could add value and therefore be warranted. Each revision will be evaluated according to the model objectives at that particular time. Based on that evaluation, changes that could make the model less usable for its intended purpose and provide no greater accuracy should not be implemented.

Summary

The whitepaper appears to reflect some misunderstanding of groundwater flow patterns, model boundary conditions, and constraints on operation of the IRZ near pumping wells. It is hoped that this memo has provided some clarification of these issues. The whitepaper offers a number of recommendations for improvements to the Topock groundwater models which should be evaluated during future model revisions and updates. However, the need for and location of MW-X and MW-Y were not based exclusively on the model. Until the final remedy is installed and operating, it won't be possible to validate the model projections of capture zone extent and flow patterns associated with the river bank wells or the pumping in Arizona. Therefore, the need for MW-X and MW-Y cannot be negated by any improvements that could be done to the model at the present time. Analysis shows that the proposed tracer test could likely not be completed before IM-3 is scheduled to be shut down, might result in tracer eventually emerging in the river or in future supply wells, and would likely not yield data pertinent to the operation of the final remedy.

Response to PG&E August 14, 2015 Response to July 15, 2015 MW-X and MW-Y Whitepaper

Friday, August 21, 2015

Robert H. Prucha, PhD, PE (TRC)

Margaret R. Eggers, PhD, PG, CHG (TRC)

1) Evaluating tracer movement, timing and breakthrough with the current model is flawed, due to incorrect setup of several model inputs, highly uncertain parameterization and lack of any sensitivity/uncertainty analysis beneath river and in Arizona to qualify results.
    a. Flow and fate/transport model parameters have still not been calibrated to the available well data in Arizona or the near decade of IM-3 data in California. The latest PGE documents confirm this. Standard calibration statistics have still not been provided to stakeholders in any available online reports. Based on limited plots showing observed and simulated groundwater levels, model errors exceed 1 foot in key areas, like MW-34-80 (see page 50 of MW-X/MW-Y white paper). As a result, the model or the tracer test results cannot be relied upon. This is magnified by the strong sensitivity of tracer flow paths and times to gradient.
    b. The whole point to the proposed tracer test was evaluate model performance in a critical area of the model. It was not to use the current flawed model to demonstrate that a tracer test is not feasible. The tracer test was proposed in an effort to fill a glaring data gap, including:
        i. evaluate the potential for and nature of any hydraulic connection, particularly given the complex and poorly known hydraulic conductivity and riverbed conductance beneath river and in Arizona.
        ii. utilize the tracer results to revise the existing model. Using the existing model (un-calibrated in Arizona, and in need of several corrections) to calculate breakthrough times and flow paths under existing IM-3 extraction or proposed remediation, with average riverbank extraction rates (knowing these could be increased to reduce bypass) is flawed.
        iii. use the updated, improved model to re-evaluate the need for and valid locations for MW-X/MW-Y.
    c. Based on available data, reasonable estimated of hydraulic conductivity, and a simple Darcy velocity calculation, tracer breakthrough times were estimated at between 41 and 471 days, (See Table 1).
    d. There is no guarantee that:
        i. tracer movement could be greatly enhanced by continuously injecting water and increasing the gradient from MW-54 to MW-34. The challenge would be finding a source of water to inject into the well (river?). We originally assumed gradients resulting only from the existing IM-3 continuous extraction.
        ii. These high values seem very possible given the conceptual basis suggested in the August 11, 2015 CH2MHill Technical Memo clarifying details on aquifer test interpretations in Arizona. The memo suggests highly conductive gravels from Sacramento Wash moved into the Colorado floodplain and were deposited as shown on Figure 3. The problem is that the actual area of the high conductivity zone is arbitrarily assumed, as the model is not calibrated in Arizona. More likely the area of high conductivity extends into the actual Colorado River, coincidently, right across from where the Topock Marsh drains into the Colorado River. This is also roughly where the CrVI plume from California

appears to have migrated furthest to the east at the edge of the river AND where the high permeability zone in Layer 3 extends beneath the river, but then abruptly transitions into lower permeability material with no justification (Figure 2).

2) It is strange that the conclusion is now that IM-3 shutdown test resulted in no clear response in Arizona. It appears that the lack of connection is now used to justify not conducting a tracer test.

3) The conceptual model of 90% of Mohave Lake Basin flow through a hypothesized paleochannel (see Figure 4), based on unpublished discussions with USGS and no data, is surprising. No previous mention of this feature and it's important implications seems contradictory to previous conclusions in available documents. Figure 5 shows inferred bedrock surface elevation contours which suggest groundwater flows would still be directed beneath the Topock Gorge, as it is more deeply incised in this area. It is unclear why important details, for example, groundwater contours, mass balance, and calibration have still never been provided for the AZ side of the river provided earlier. As Prucha and Eggers (July 15, 2015) point out in their whitepaper, key specified or calculated water flows into/out of the model seem much too low, such as the estimated 3 gpm beneath the entire Colorado River at the southern end of the regional model (see Figure 6).

   It is equally unclear why an evaluation of the effects of alternative conceptual models in AZ (i.e., different paleochannel configurations) on proposed remedial design and system operation have not been conducted. Such predictions increase the level of transparency to all stakeholders on critical issues, such as the likelihood, extent and nature of any CrVI or byproducts that may be pushed into Arizona waters. Results of this analysis would be very relevant to all stakeholders now rather than after the system has been built. During the TWG meeting on August 19, 2015, PGE Consultant Martin Barackman indicated that calibration in the California proposed remediation area showed no difference when the hypothesized paleochannel was either included or left out. We strongly recommend that PGE Consultants review ASTM Standard D-5611 94 (Standard Guide for Conducting a Sensitivity Analysis for a Ground-Water Flow Model Application) on how to conduct such a predictive sensitivity analysis and to assess implications of having similar calibration results for different model setups, but differing predictions (i.e., a paleochannel vs. no paleochannel).

4) Only a select number of model deficiencies were discussed. The key deficiencies weren't addressed, and obvious corrections should be made to the model before utilizing it to assess any flow and/or fate/transport conditions beneath or across the river. At a minimum, if any results are shown, the model should be calibrated in this area and an uncertainty analysis performed on all predictions.

5) What are the realistic ramifications of tracer detections in the Marina well? The Marina well is only hypothetical – but would this really be something that would occur, given the increasing CrVI levels at MW-55 and MW-56 and the possibility and significant uncertainty for breakthrough from California to Arizona?

6) The point to MW-X/MW-Y is still unclear. For example:

   a. What does the existing model predict for the range of CrVI concentrations in that area? We expect any by-pass concentrations would be low and likely well within observed range of background CrVI. Therefore, how could these wells actually be considered "sentinel' wells?
   b. Data from wells MW-54, MW-55 and MW-56 were never used to calibrate the model, even after 10 years of data collection. In addition, the recent August 14, 2015 Technical Memorandum from Martin Barackman and Mike Cavaliere entitled "PG&E Response to MW-X and MW-Y Whitepaper" concludes that no discernible drawdown is observed in wells MW-54, MW-55 or MW-56 despite continuous 130 gpm extraction at IM-3 pumping wells. The total proposed Riverbank well extraction is only 150 gpm, but distributed over 5 wells. Any impact on drawdown at proposed monitoring wells MW-X and MW-Y will likely be even less than the negligible, if any, response at MW-54. The MW-54 data were initially thought to indicate some affect from IM-3 pumping, but later any impact was deemed to be so negligible as to be indistinguishable from variations in the fluctuating river level. In fact, it is likely that any affect from the IRL injection wells would be difficult to discern given the overlapping effects of river stage fluctuations, ET, well extraction at Riverbank wells, HNWR-1A, Site B and other production wells. So again, we strongly believe any water level data at MW-X or MW-Y would provide little value as either a sentinel monitoring well to monitor riverbank extraction performance, or to improve the conceptual site model or the numerical model.
7) What are details of the plan if CrVI is detected in AZ and attributed to California source?
   a. Once detected at MW-X and MW-Y, additional wells would be needed to characterize the extent of any new plume propagation and configuration within Arizona. The number and location(s) of additional wells is unknown.
   b. What would be the remediation plan in Arizona? The current proposed California remediation River-Bank extraction system would likely be unable to capture the Arizona contamination without compromising the performance objectives within California. If River-bank extraction rates are increased in an attempt to capture Arizona by-pass contaminants, this would increase the potential negative effects in the remediation system, such as striping, or increased by-pass.
   c. Not remediating all Arizona contamination (CrVI, Mn, As, etc.) violates RAOs. Would this additional remediation involve pump and treat in Arizona? Certainly some amount of additional infrastructure, roads, buildings, contractor activities etc., would be needed in Arizona.
   d. Worst case scenarios should be considered in any decision to install new monitoring wells in Arizona. At a minimum, the current entire proposed remediation design really needs to be re-thought here. Certainly, the possibility of expansion of the plume into Arizona was not considered during the early process of remedy selection.
8) A key recommendation at this point, which is echoed in comments by DOI consultant David Back, is to simply wait to determine the need, number and locations of any additional Arizona groundwater monitoring wells (i.e., MW-X and MW-Y), until new data is collected during system construction and startup testing. After the model is updated and re-calibrated, various

scenarios can be run and explored to evaluate possible locations in Arizona. We fundamentally believe that fixing all of the model issues now, and re-calibrating to available Arizona groundwater and the nearly 10-years of IM-3 data, is crucial to maintaining the model as a predictive tool. Proposed remediation design and operating scenarios can then be simulated which incorporate a fluctuating river and different conceptual models of the poorly characterized subsurface system in Arizona. Scenarios might be run with or without a permeable paleochannel, or extending the high permeability (500-900 ft/d) material from Sacramento Wash into the Colorado River and connecting it with the MW-34 well area material. Such applications of an improved model would provide the necessary confidence to all parties that the model predictions, as well as the remedy as designed, will function as planned. Once the remedy is installed, it will be too late to avoid unnecessary components, and additional wells and infrastructure may be needed to address unforeseen shortcomings in the system.

9) How much tracer volume is really required to see tracer compound detections at CA wells? The >50,000 gallons estimated by PG&E consultants seems highly excessive.

The high volume estimate included an assumption of 35% porosity – initialized both mobile and immobile. Initializing this with a more realistic effective porosity of 12% would greatly reduce tracer volume required. The estimate was made by modeling one addition of tracer into a single 25’ x 25’ model cell instead of using an actual well borehole volume. This seems to have only been done for the purpose of doing the estimation within the model itself. Evaluating this same situation but using the well borehole volume for a 4-inch to 12-inch well seems more appropriate, and more realistically, and greatly reduces, the estimated tracer volume required. We believe much lower injected volumes would be needed to produce detectable concentrations at wells near MW-34 in California (IM-3 Area).

Table 1. Estimated Tracer Breakthrough Times

Note 1. See Figure 1 for distance between MW-34 and MW-54.
Note 2. See Figure 2 for the values and distribution of conductivities in model layer 3 between MW-34 and MW-54.
Note 3. See CH2MHill, August 11, 2015. Technical Memorandum from Martin Barackman to PG&E. "Additional Details on Aquifer Test Interpretation and Groundwater Flow Model Updates for the Arizona Portion of the Topock Remediation Project Area, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California"

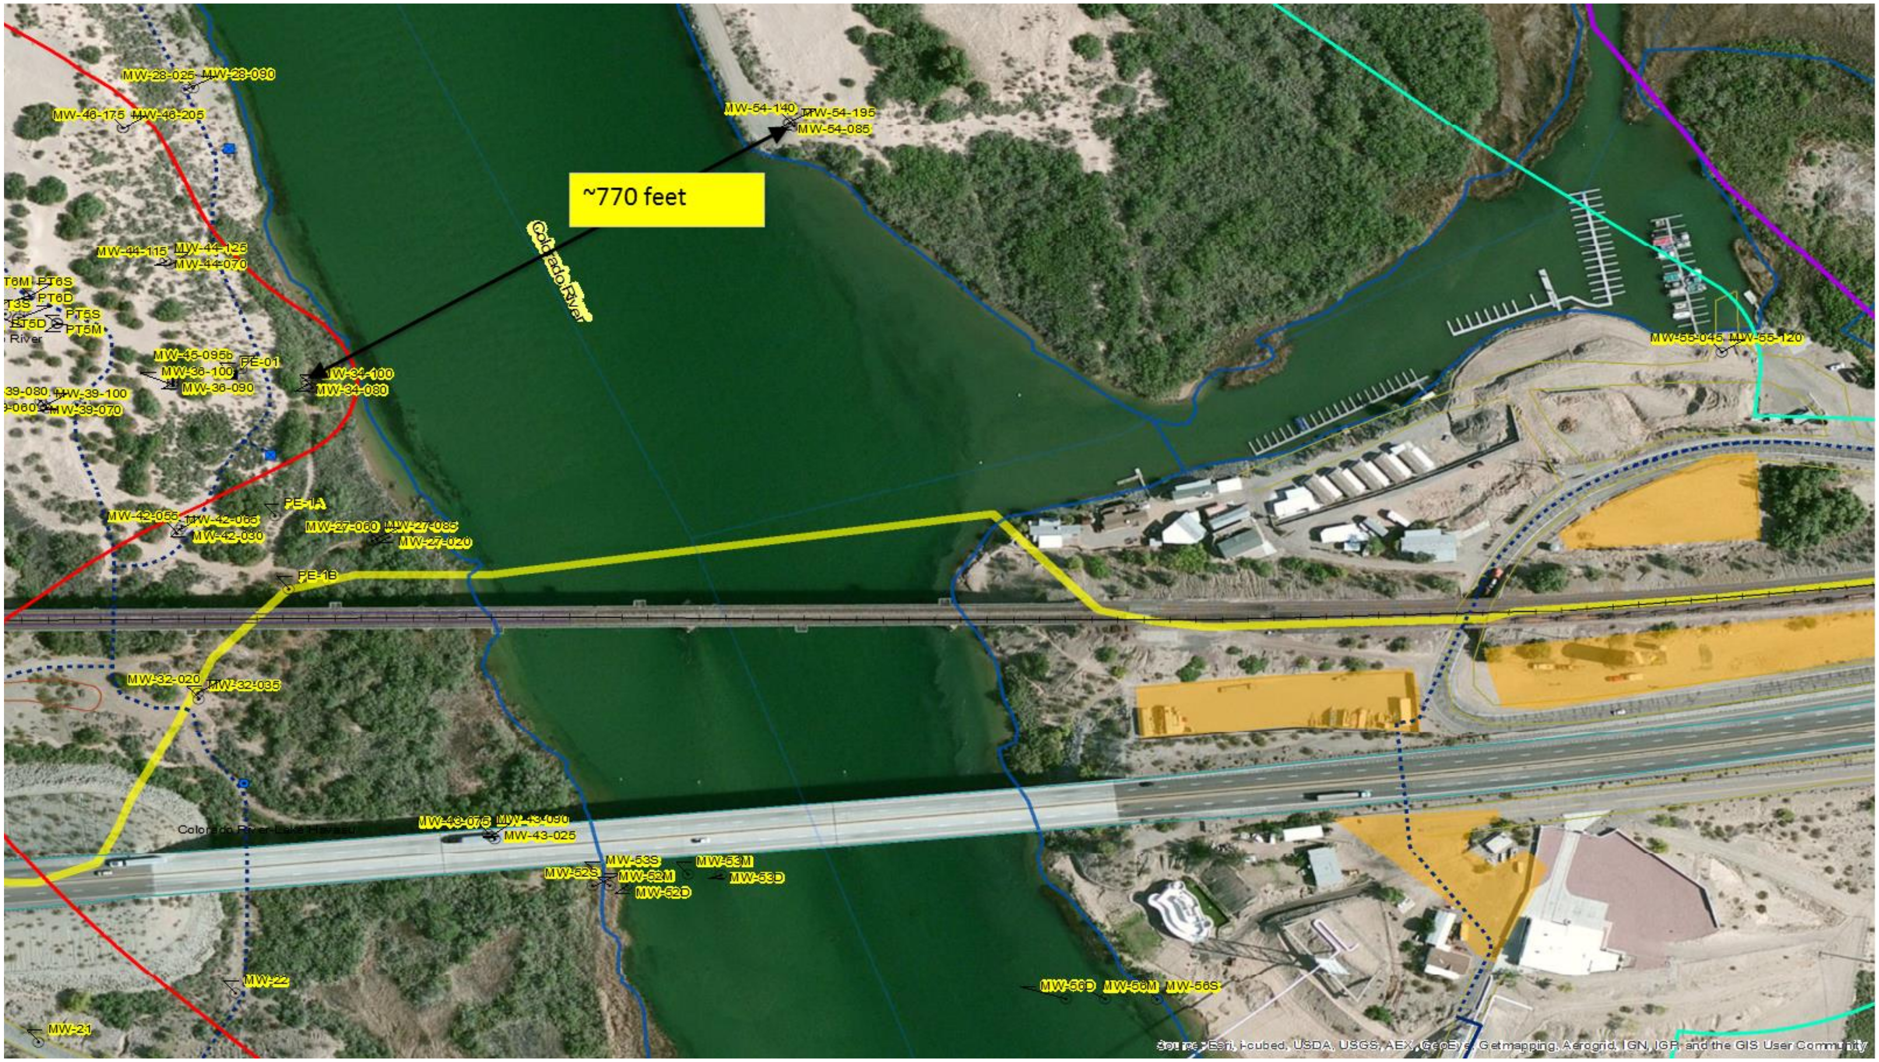

Figure 1. Shows distance between wells MW-34 (California) and MW-54 (Arizona).

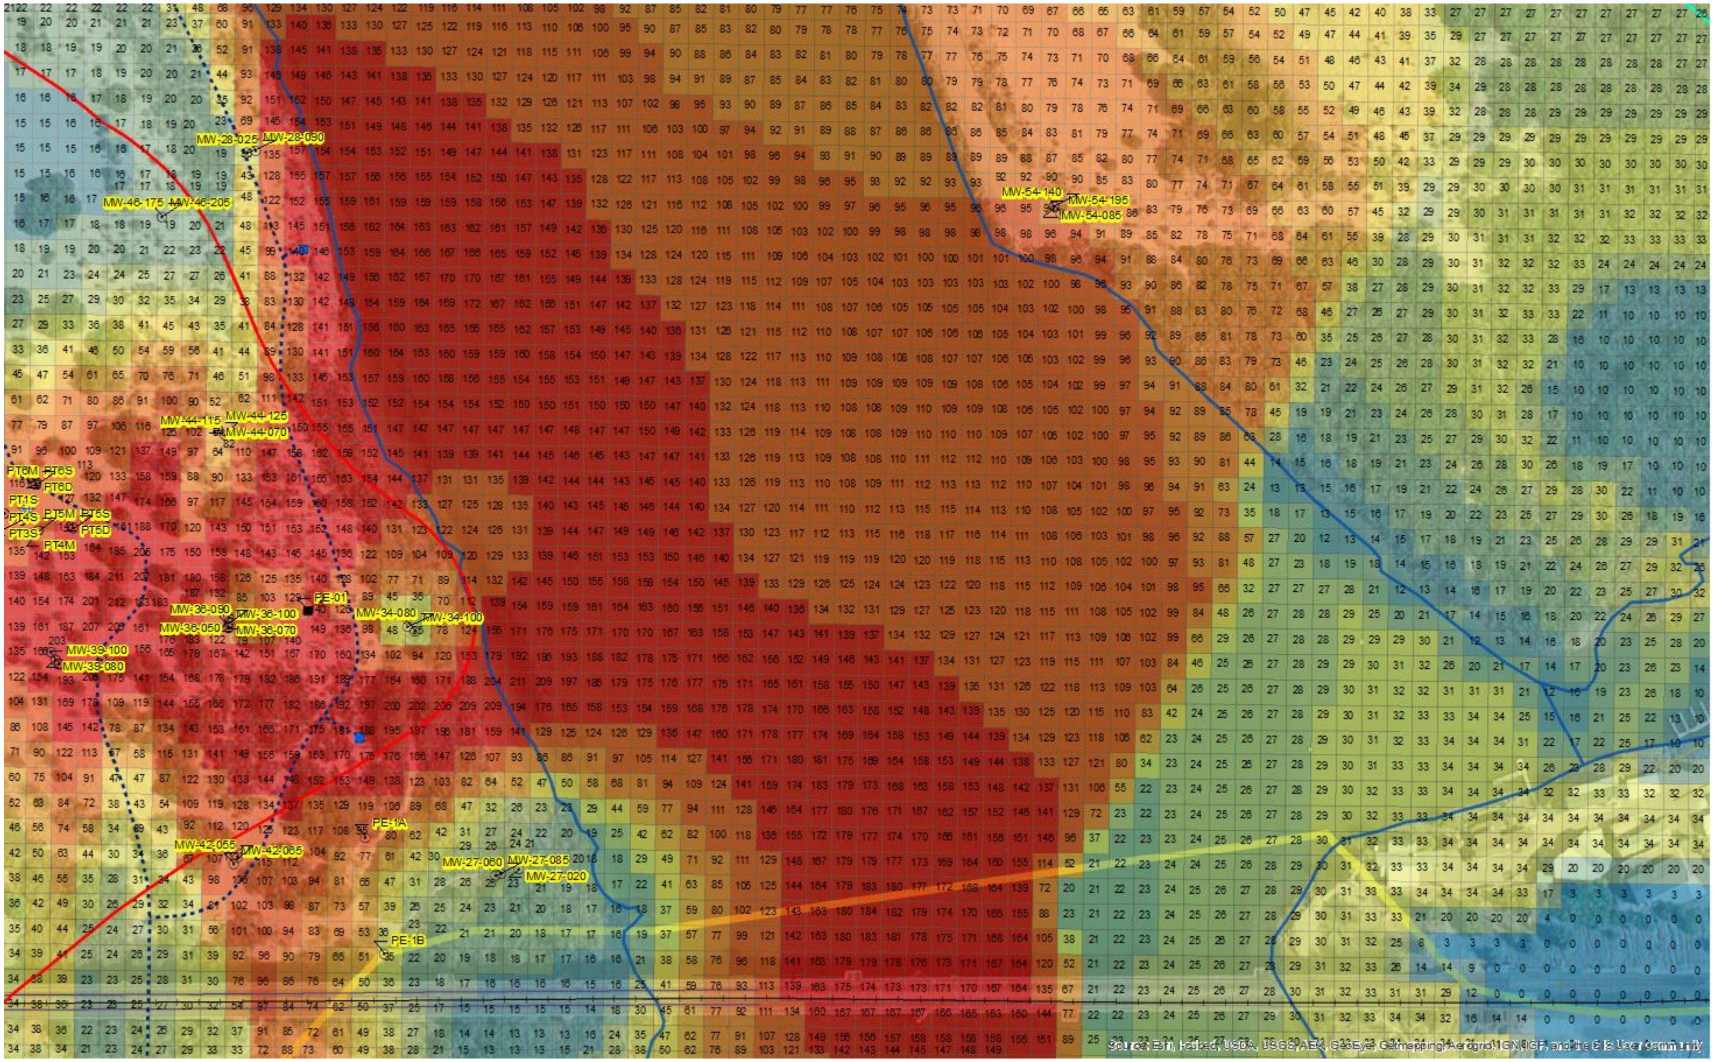

Figure 2. Shows 60%BOD Modflow Model Layer 3 Hydraulic Conductivity Values Between MW-34 and MW-54 (ft/d).

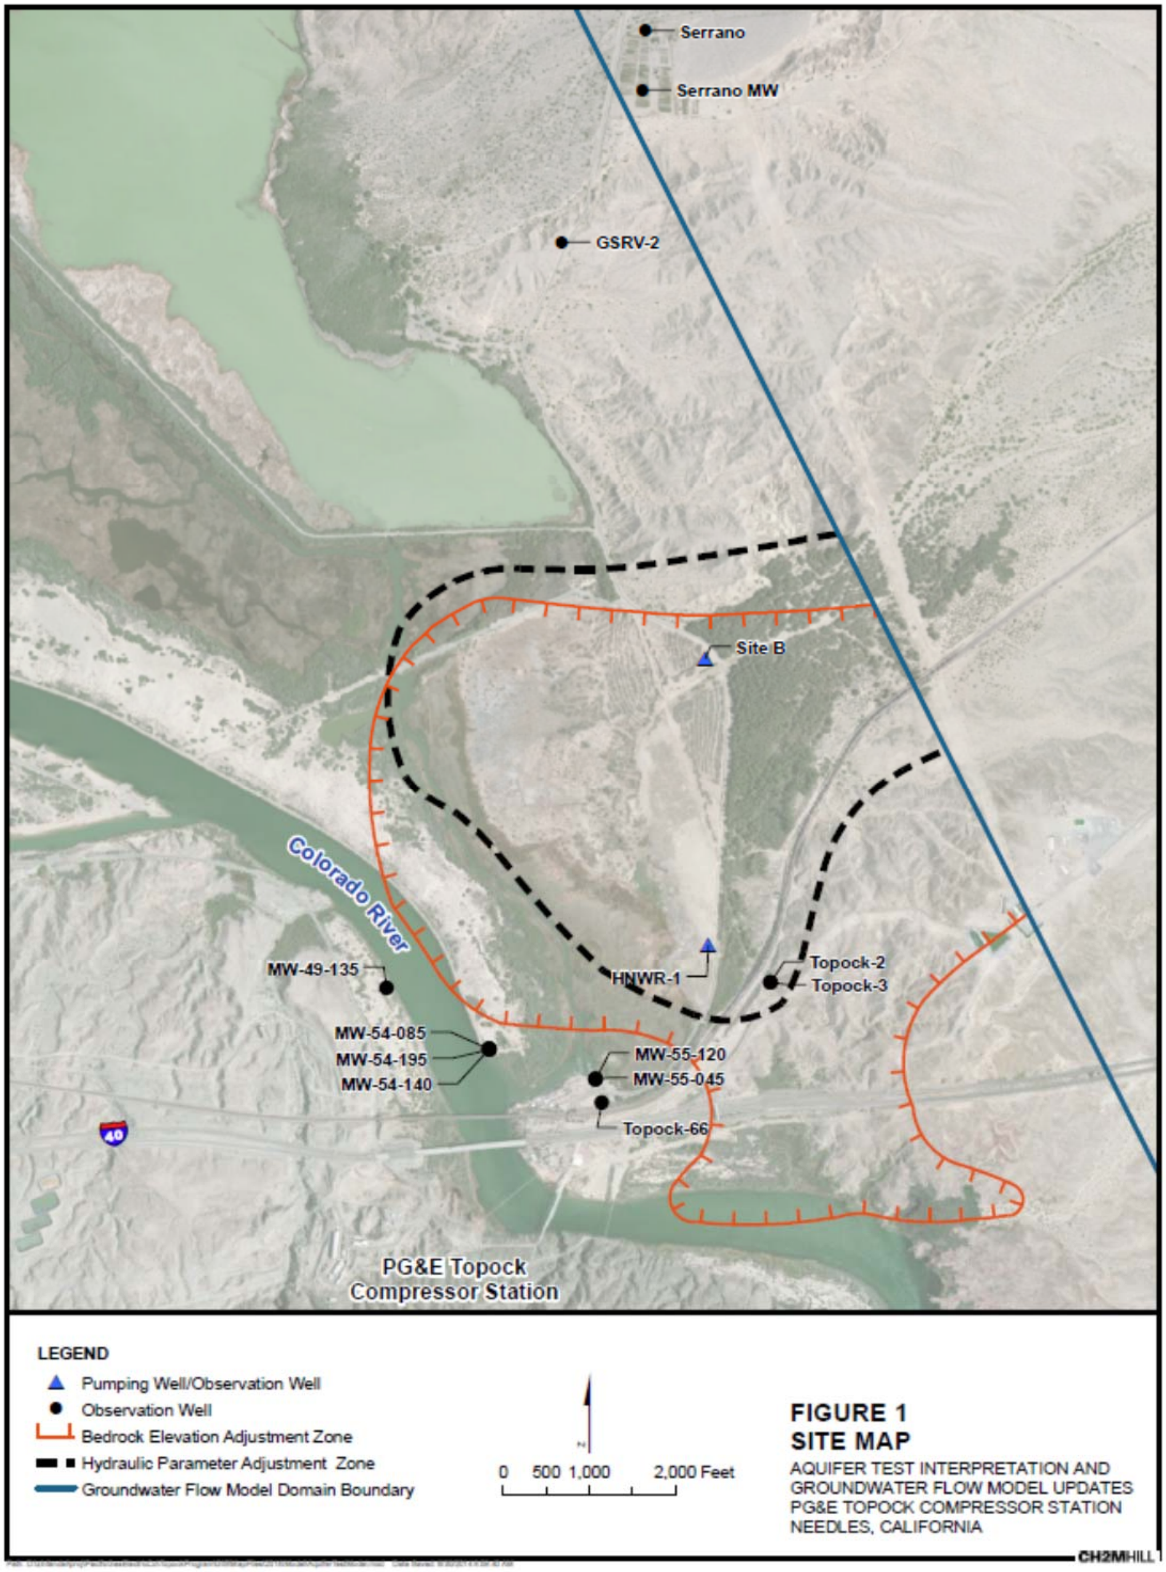

Figure 3. Hydraulic Parameter Adjustment Zone – where high hydraulic conductivity assigned, but arbitrary given no calibration east of River.

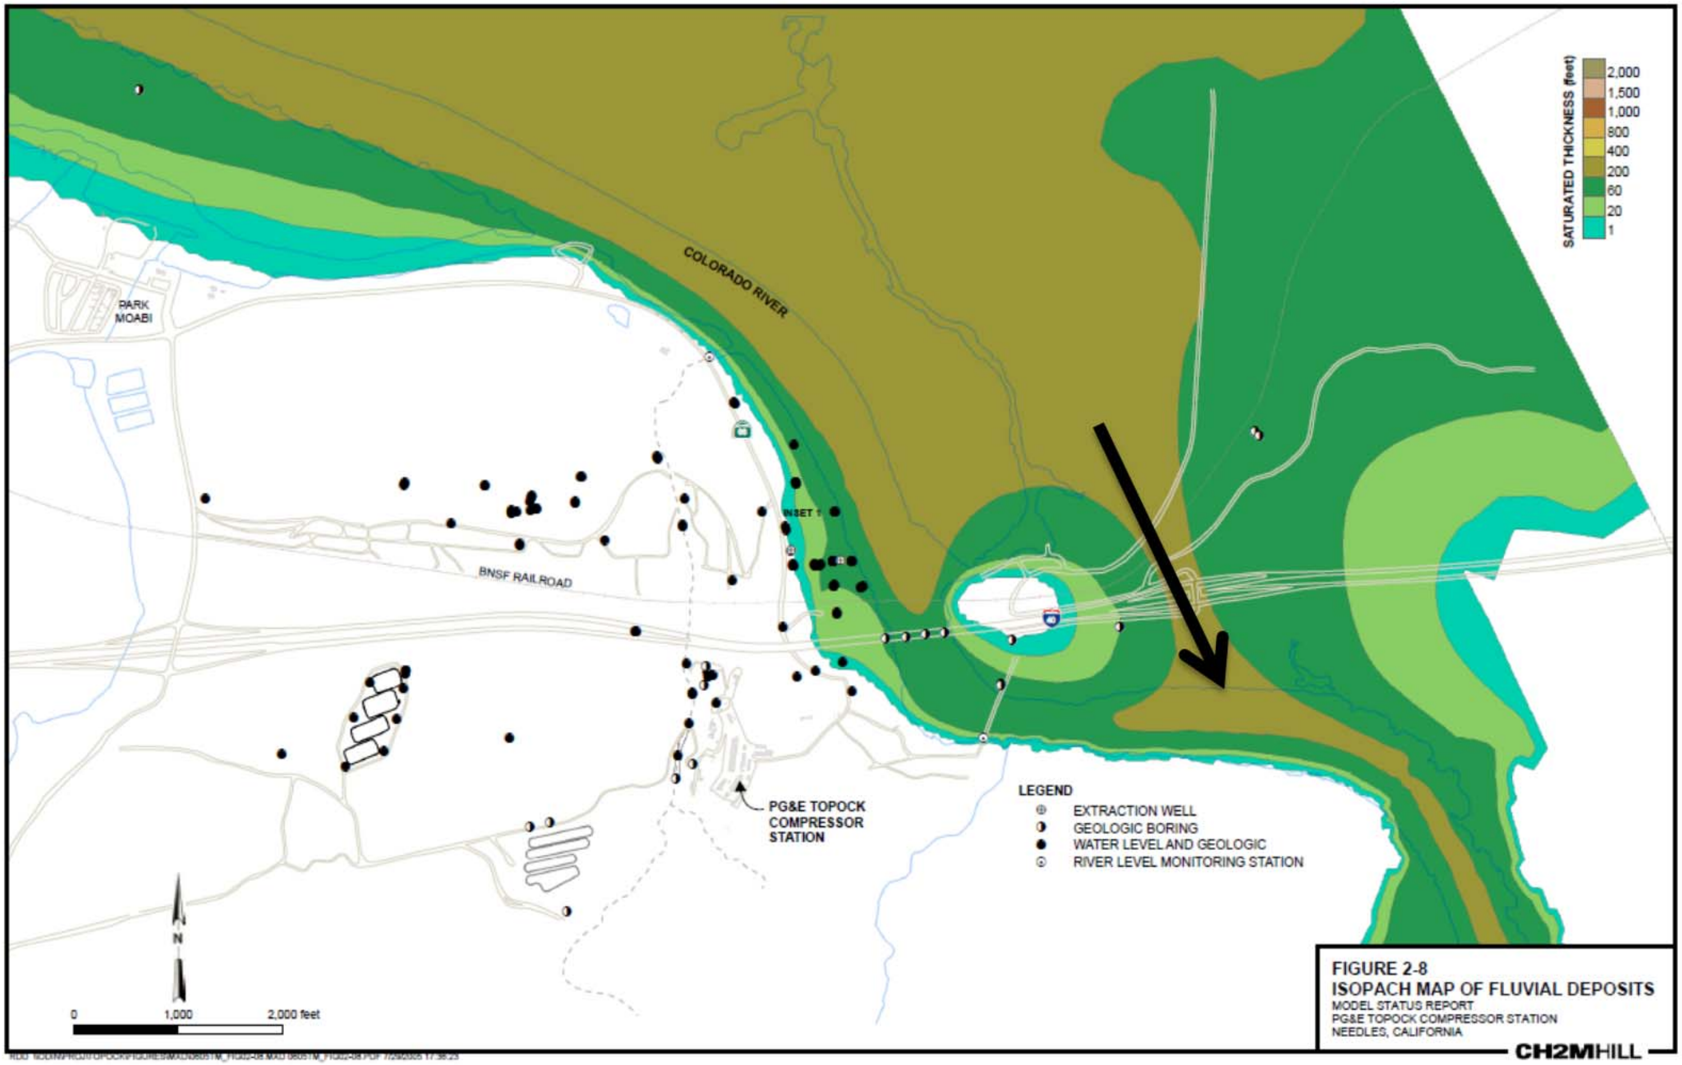

Figure 4. Shows assumed Fluvial Deposit (black arrow), through which CH2MHill argues 90% of groundwater from entire Mohave GW system discharges to the south and into material beneath Colorado River. However – there are no data to support this, no CrVI has been detected in AZ from California which seem more likely given increased potential flow from PGE site to this fluvial outlet. GW contours don't seem to support this concept (i.e., MW-54, -55 and -56 are oriented towards Colorado River (natural gradient if discharge is via Colorado River in lower aquifer)).

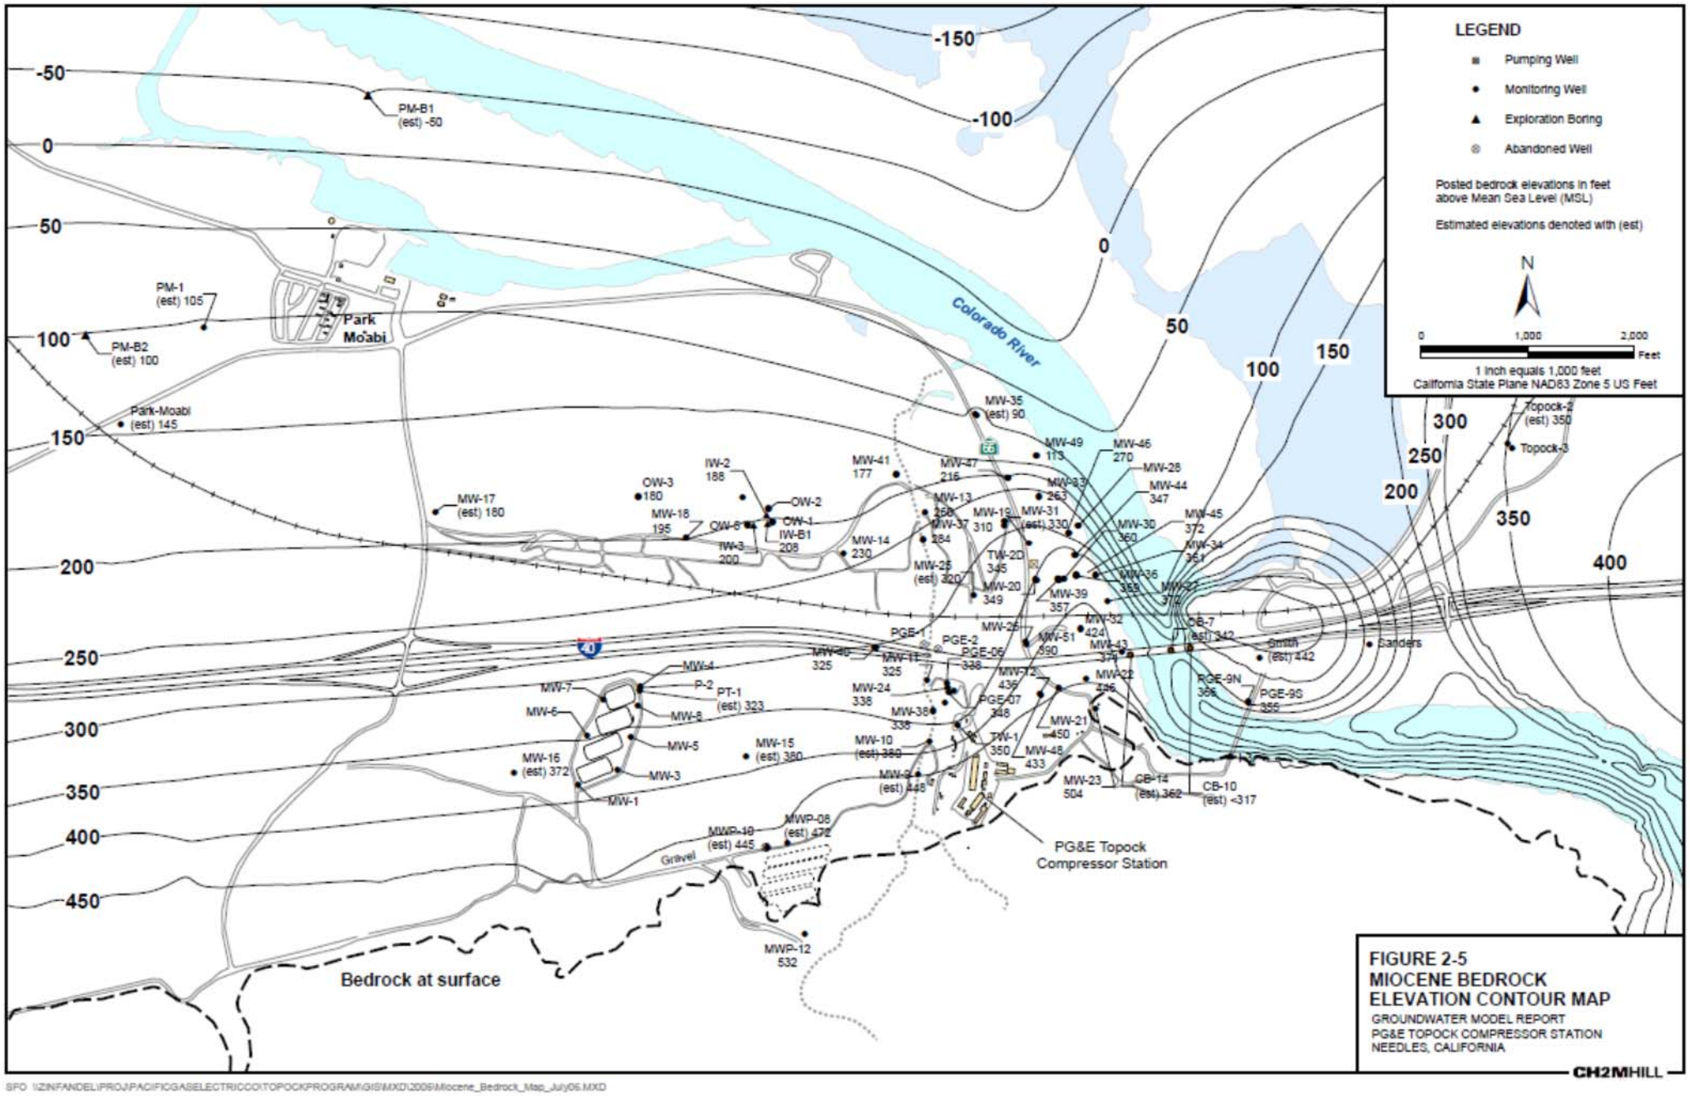

Figure 5. The estimated bedrock surface, revised with USGS seismic data suggests the primary discharge area is through the Topock Gorge, versus through the paleochannel, hypothesized immediately south of the Topock Marsh, east of Topock Marina, which connects up with the Colorado River to the south.

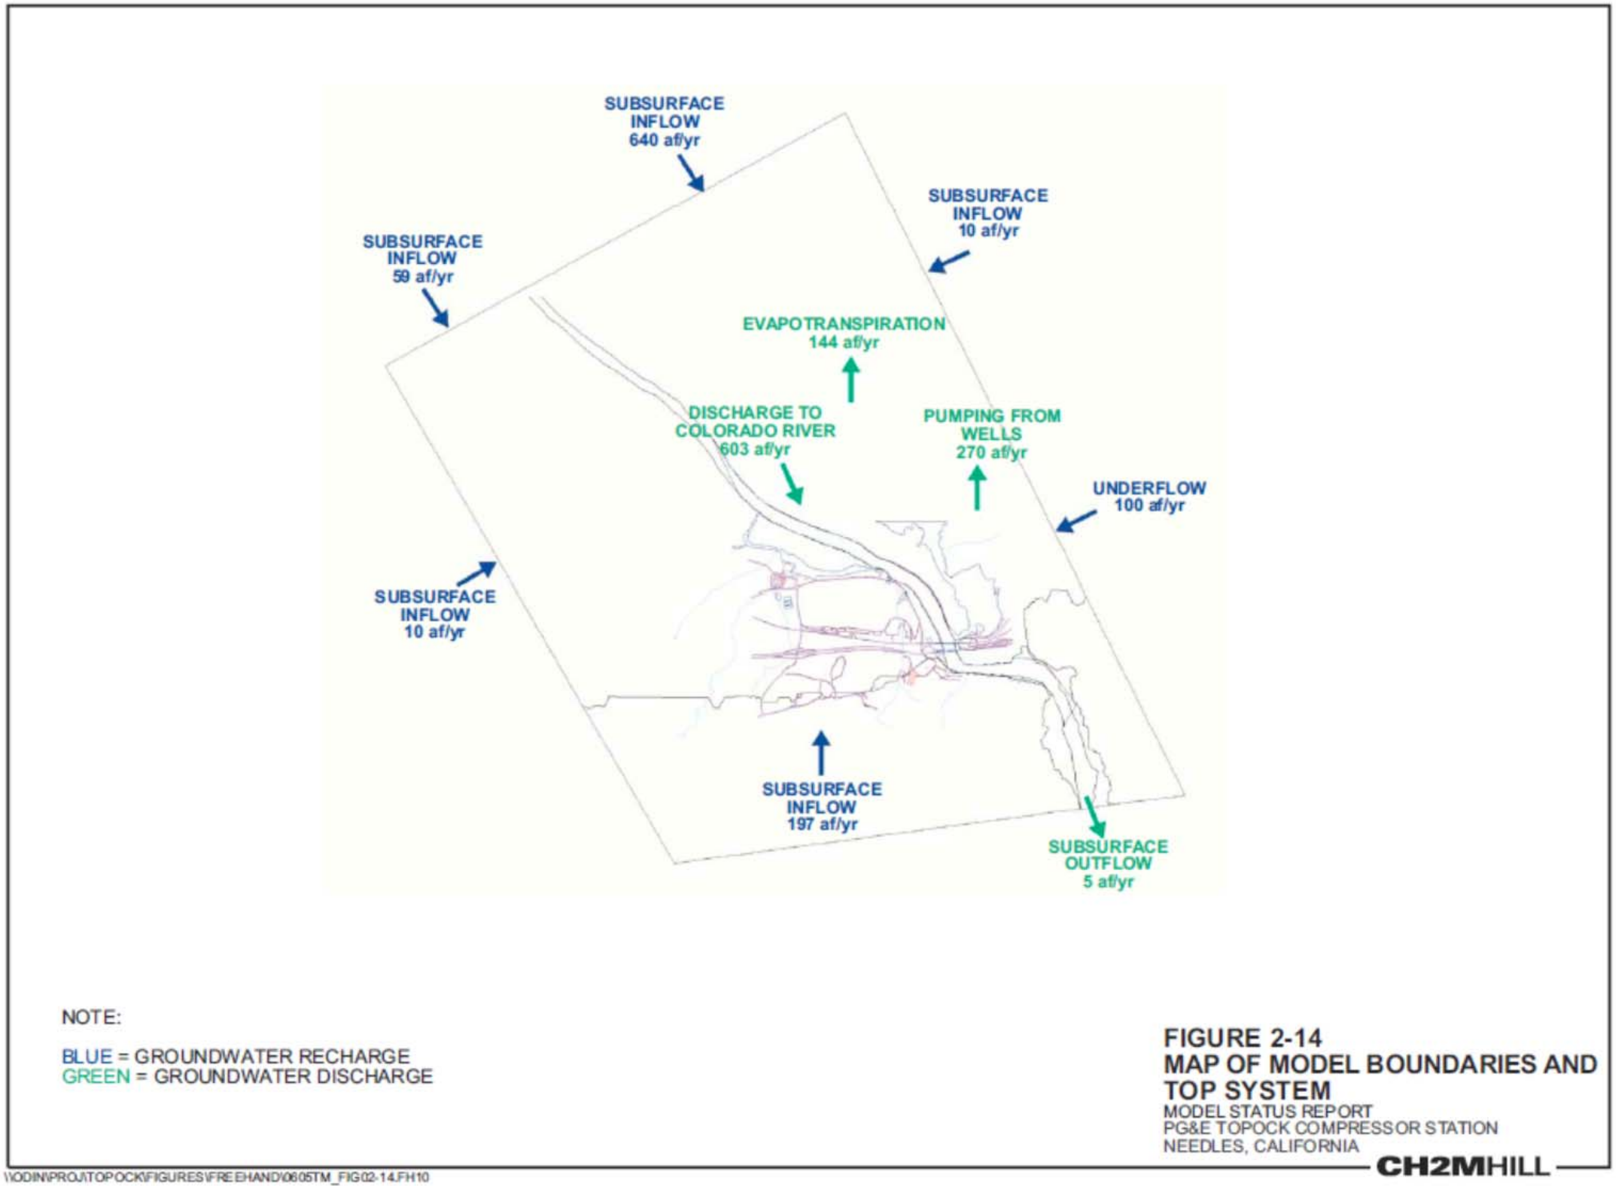

Figure 6. Shows Calibrated model external water balance specifications. Subsurface outflow is only 5 ac-ft/yr beneath Colorado River. This equates to only 3 GPM, or a low flow garden shower. Conceptually this appears unrealistically lower than might be expected below the mighty Colorado River, nearly 3 football fields wide.

Pamela_Innis@ios.doi.gov

Dear Mr. Yue and Ms. Innis:

Topock Groundwater Remediation Project
Response to Comments on the 90 Percent Design Documents

The Metropolitan Water District of Southern California (Metropolitan) appreciates the opportunity to submit comments for your agencies' consideration in providing direction to Pacific Gas and Electric (PG&E) on the final design for the groundwater remediation project at the PG&E Topock Gas Compressor Station site. On June 26, 2015, we received the Response to Comments (RTC) on the 90 Percent Design Documents and have participated in subsequent Technical Work Group (TWG) meetings, held in July and August 2015, focused on resolving outstanding project concerns. Metropolitan's 90 percent design comments have been adequately addressed in the RTC. We are providing additional comments below, based on recent TWG discussions regarding the proposed MW-X and MW-Y monitoring wells and construction sequencing.

Comment 1

Metropolitan affirms the critical need for monitoring wells, MW-X and MW-Y. The groundwater remedy involves accelerating groundwater flow eastward, towards an In-situ Reactive Zone (IRZ) located west of the Colorado River in California. Monitoring wells, MW-X and MW-Y, are proposed to be located downgradient from the remediation zone and east of the Colorado River in Arizona. We agree with the Department of Toxic Substances Control's (DTSC's) determination (per RTC table comments #10 and #17) that the wells are needed to establish baseline concentrations for water quality and to monitor for chromium-6 and byproducts generated from treatment downgradient of the remediation zone. Overall, the MW-X and MW-Y wells would serve as sentinel wells to confirm hydraulic gradient and capture in the remediation zone and to ensure protection of the Colorado River.

Comment 2
At the August 27, 2015 TWG meeting, PG&E presented a proposed construction sequence schedule that would involve shut-down of the Interim Measure 3 (IM-3) treatment and start-up of the IRZ operations, almost two years prior to completion of the groundwater remediation system and the start-up of the riverbank extraction wells. Metropolitan understands the importance of shutting down IM-3 sooner to be able to evaluate the IRZ start-up without influence from IM-3 extraction and to collect additional information needed to refine the groundwater remedy construction. However, we are concerned with the potential for IRZ to not perform as modeled. If groundwater movement and transport of chromium-6 and remedy byproducts are not as predicted and instead they move significantly towards the Colorado River prior to PG&E completing construction of all groundwater remedy components, the riverbank wells will be needed as a contingency to protect the Colorado River. Metropolitan requests that PG&E consider the installation of the riverbank wells a priority in the construction sequence and that these wells be available for pumping when IM-3 is shut-down and IRZ begins operation.

We thank DTSC and the U.S. Department of the Interior (DOI) for considering our comments in providing direction to PG&E on the final design. Also, we value DTSC and DOI's extensive collaboration with stakeholders to adequately address outstanding project concerns, while ensuring that the final remedy moves forward in a timely manner. If you have any questions, please contact me at (213) 217-5646 or bkoch@mwdh2o.com.

Very truly yours,

Bart Koch

Appendix I
Responses to Comments on the Basis of Design Report/Intermediate (60%) Design Submittal

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
General Comments										
1	DOI-1	General		A final decision is necessary regarding above ground versus below ground piping in the uplands area and for the fresh water pipeline. In order to adequately evaluate the differences between the options, DOI, in consultation with interested Tribes, is submitting a matrix of evaluation factors to use in comparing the current design and three above ground pipeline options. Proposed evaluation criteria are also included. Please complete the pipeline matrix evaluation for use during comment resolution and final consideration of the pipeline layout. When completing the evaluation of alternatives, for each criterion consider all aspects of the project in the evaluation, including handling and storage of residual soils. Please see Attachment A – Above ground/below ground pipeline evaluation matrix.	See information included in DOI's pipeline evaluation matrix and associated visualizations (included in **Attachment A**, at the end of this table).			The FMIT, the Hualapai Tribe, and the Cocopah Indian Tribe each provided the tribe's assessment and comments on the alternative pipeline routings. The CRIT also provided feedback via email on this subject. The Tribes' letters and email are included in **Attachment A**, at the end of this table.	Information presented in DOI's pipeline evaluation matrix and associated visualizations were discussed with the agencies, Tribes, and stakeholders at the November 19-20, 2013 TWG meeting. Tribes' response was presented at the December 17-18, 2013 TWG meeting and subsequently provided in a draft technical memorandum from TRC (Charlie Schlinger) to PG&E, DTSC and DOI/BLM dated Dec 17, 2013 (also included in **Attachment A**, at the end of this table). A site walk was held on Dec 27, 2013 to further discuss the piping options. Representatives from DOI, FMIT, Hualapai Tribe, Chemehuevi Tribe, TRC, and PG&E participated in the site walk. A presentation was made by TRC (Charlie Schlinger) at the January 23, 2014 TWG meeting (presentation materials are included in **Attachment A**, at the end of this table). Additional analysis was performed by PG&E on Segments 1 and 2 of Pipeline A, and presented at the February 11, 2014 TWG meeting. Presentation materials are also included in **Attachment A**, at the end of this table.	The 90% design complies with the Agencies' directive on aboveground/belowground pipeline infrastructure in the April 4, 2014 letter titled *"Directives on Outstanding Issues of the Response to Basis of Design Report/ Intermediate (60%) Design Comments for PG&E Topock Compressor Station Remediation Site"*.
2	DOI-2	General		In correspondence dated October 23, 2008 from DOI to PG&E (Attachment B) regarding the National Wildlife Refuge System Administration Act and the corresponding Appropriate Use Analysis and Compatibility Determination, FWS identified key elements that need to be evaluated during the remedial alternative analysis. These elements must also be addressed during the design. While much of the necessary information is contained within the 60% design document, it is difficult to locate. In order to memorialize that these	See attached table titled *Supplemental Information for ARAR #7_AUA_CD* (included in **Attachment B**, at the end of this table).		Comment resolved pending review of the 90% design.		Comment resolved.	Updated information is included in Table 6.2-1A of the 90% BOD, titled "*Information for the Havasu National Wildlife Refuge's Appropriate Use Analysis and Compatibility Determination (AUA/CD)*".

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				elements have been addressed, please include them in the "Action Section" of the ARAR tables, Item 7, and identify or reference the actions specified in the current design. Additionally, for the remaining elements, please identify proposed actions to be included within the 90% design submittal.						
3	DOI-3	General		When referring reader back to an Appendix, it is recommended that the exact location, (e.g., page number or Section number), be provided to enable readers to easily search for the referenced information.	Comment noted.		Comment resolved.		Comment resolved.	Section numbers have been added to Appendix references throughout the 90% documents.
4	DOI-4	General	Time to remediate plume	With regards to the timeline for remediating the plume, a 30-year period is discussed; however, the number of pore volume flushes is not. The number of pore volumes provides the reader with a more tangible sense of the hydrodynamics of the system. Please provide a discussion regarding the number of pore volume flushes in the text.	The following sentence will be added to the text: "Based on an average groundwater flow velocity of 1 ft/d, a total of approximately 6 pore volumes flushes are projected to occur over the 30 year period of remediation." Because the remedy involves active remediation of the hexavalent chromium through carbon amendment, the performance of the remedy is not solely dependent on groundwater pore flushes, but rather the active geochemical reactions in conjunction with groundwater flushing.		Comment resolved pending review of 90% design.		Comment resolved.	90% BOD Apdx B Section 6.4.
5	DOI-5	General		Some in-text citations have commas and others do not. A single format should be chosen, and then review and modify the document for consistency.	Comment noted. The current convention is in-text citation without commas in the 60% BOD and this will continue into the 90% BOD. Citations will be reviewed and any with stray commas will be corrected. Editing/modification of a previously published report (published prior to the BOD but included as an appendix), for the sole purpose of updating its citation convention is not warranted.		Comment resolved.		Comment resolved.	Corrections have been made as indicated in the response.
6	FMIT-1 Hualapai-1 Chemehuevi-1 Cocopah-1 CRIT-1	General		A conceptual narrative for the anticipated steps in the decommissioning of this proposed remedy should be included to assist in both evaluating the design elements and how they would impact removal of the remedy infrastructure, and in evaluating the total, cumulative impacts of this project.	A narrative for the approach of the steps to decommissioning of the proposed remedy will be provided in the 90% design.			Comment resolved pending review of the 90% design. Tribes request that, if possible, this information be provided prior to submittal of the 90% design.	Comment resolved.	A narrative was developed in response to this comment. See **Attachments T** at the end of this table.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
7	FMIT-2 Hualapai-2 Chemehuevi-2 Cocopah-2 CRIT-2	General		The Response to Comment process (for the 60% Basis of Design report) and the following development of the 90% Basis of Design report needs to include face-to-face consultation with tribes to document/demonstrate that tribal issues/criteria are being addressed.	Comment noted. As discussed at the July 18, 2013 TWG meeting, face-to-face meetings will be held to discuss and resolve comments on the 60% design. PG&E defers to DOI on Tribes' request for consultation.		As noted by PG&E, face-to-face comment resolution meetings have been scheduled for the 60% design. In addition, DOI and BLM have scheduled a face-to-face meeting to discuss the RTCs with the Tribes coinciding with the October 29, 2013 CHPMP meeting. We also anticipate Technical Working Group (TWG) meeting in between comment resolution and the 90% design deliverable.	Okay.	Comment resolved.	Not applicable ***Note to BOD Reviewers - As indicated in RTC #485 FMIT-148, when the "Final Comment Resolution" indicates "Comment resolved" and this column indicates "Not applicable", it means that the comment has been resolved and there is no need for modify the cited text/ tables/ figures in the next iteration of the BOD. For brevity, this note will not be repeated throughout this RTC table.***
8a	FMIT-3	General		It is apparent from a comparison of comments the Tribe issued for the 30% BOD and the 60% BOD document that the alternative designs of certain project components certain that the Tribe expressed preferences because they related to tribal religious and cultural issues were not factored or substantively considered in engineering designs. At a minimum, equal scientific/engineering rigor should be given to these legitimate alternate design constraints. For example, the Tribes expressed strong preferences for above-ground utility routings, however, the utility routings in the 60% BOD are almost exclusively routed below ground. Additionally, at one of the TWG meetings, PG&E provided a screening matrix for alternative routings in the East Ravine area. While this type of decision information is quite helpful in understanding the underlying decision rationale, it does not factor in tribal preferences.	The preference stated by the FMIT and by other tribes for aboveground facilities was substantively considered in formulating the 60% design. PG&E believes that the proposed 60% design represents the most practical design in the Topock site setting, which incorporates the Tribes' preferences to the extent practicable, is most protective of remedy infrastructure, most O&M friendly for the decades-long life of this remedy, and most consistent with the certified EIR. As documented in the 30% RTC table (60% BOD Appendix I), PG&E has incorporated Tribal preferences to eliminate the BCW trenching (an area that is in close proximity to the Topock Maze), to relocate wells in the upland (one of these well relocations requires building a new access road into a wash) (RTC #185 HA-36), as well as to reduce the number of transformers and site all transformers aboveground (RTC #183 HA-34). Regarding the topic of aboveground vs. belowground, this was discussed with Agencies and Tribes during the 3/20/2012 meeting and the 30% design comment resolution meetings. PG&E's rationale for below-ground construction is well documented in 30% RTC #159 HA-21, #182 HA-33.			Comment resolved.	Comment resolved.	The 90% design complies with the Agencies' directive on aboveground/ belowground pipeline infrastructure in the April 4, 2014 letter titled *"Directives on Outstanding Issues of the Response to Basis of Design Report/ Intermediate (60%) Design Comments for PG&E Topock Compressor Station Remediation Site"*.

TABLE I-1

Response to Comments on Basis of Design Report/Intermediate (60%) Design

Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					PG&E has and will continue to collaborate with Tribes and Agencies towards a satisfactory resolution of Tribal concerns. More specific evaluation of aboveground piping alternatives is provided in the response to comment #1 DOI-1.					
8b	Hualapai-3 Chemehuevi-3 Cocopah-3 CRIT-3	General		It is apparent from the 30% to the 60% designs that certain tribal preferences relating to tribal religious and cultural issues were not factored or substantively considered in engineering designs. At a minimum, equal scientific/ engineering rigor should be given to these legitimate alternate design constraints. For example, the Tribes expressed strong preferences for above-ground utility routings, however, the utility routings in the 60% BOD are almost exclusively routed below ground. Additionally, at one of the TWG meetings, PG&E provided a screening matrix for alternative routings in the East Ravine area. While this type of decision information is quite helpful in understanding the underlying decision rationale, it does not factor in tribal preferences.	See response to comment #8a FMIT-3.			Comment resolved.	Comment resolved.	The 90% design complies with the Agencies' directive on aboveground/ belowground pipeline infrastructure in the April 4, 2014 letter titled *"Directives on Outstanding Issues of the Response to Basis of Design Report/ Intermediate (60%) Design Comments for PG&E Topock Compressor Station Remediation Site"*.
9	FMIT-4 Hualapai-4 Chemehuevi-4 Cocopah-4 CRIT-4	General		The Tribes expect that both short-term and long- term disturbances to the ground surface and below ground be avoided and minimized. Subsurface disturbances permanently change the natural order of the land and require disruptive removal of these utilities once the remedy is complete. Invasive subsurface disturbances need to be avoided to the extent practicable. Installation of remedial infrastructure on the ground surface itself needs to be minimized in terms of its footprint. The Tribes have provided input on their preferences for installation methods in comments on the 30% BOD that call for minimization of subsurface disturbances.	PG&E understands the importance of and appreciates the Tribes' position on avoidance and minimization of subsurface disturbance. To this end, PG&E notes that while there is short-term disturbance associated with the construction/removal of belowground utilities, there is less disturbance in the long-term associated with O&M. Aboveground utilities will inherently require more maintenance than belowground utilities, especially in an environment like Topock (e.g., heat, vandalism). It should also be noted that for an above ground configuration, thermal design considerations may require substantial additional footprint to allow for expansion/contraction loops as well as a potentially large support structures (e.g., pipe racks, conduits or cable tray, shade assemblies).				This comment and response are being discussed as part of the evaluation of aboveground piping alternatives (#1 DOI-1, #8a FMIT-3, and #8b Hualapai-3/ Chemehuevi-3/Cocopah-3/CRIT-3).	The 90% design complies with the Agencies' directive on aboveground/ belowground pipeline infrastructure in the April 4, 2014 letter titled *"Directives on Outstanding Issues of the Response to Basis of Design Report/ Intermediate (60%) Design Comments for PG&E Topock Compressor Station Remediation Site"*.

10a	FMIT-5	General		Since the basic operational methods of the proposed remedy and IM-3 are fundamentally incompatible, and therefore, once the proposed remedy begins, IM-3 cannot be used. The start- up strategy for the final remedy needs to be efficient, thereby assuring the earliest possible demonstration that the remedy is “operating properly and successfully” (OPS) so that the IM3 plant can be decommissioned.	It is agreed that the transition between IM-3 and implementation of the proposed remedy is an important step, and this transition phase was considered and simulated with the solute transport model. The key criteria considered during this transition were to: 1) minimize duration of IM operation; 2) control and reduce the mass of chromium in the floodplain as quickly as possible; 3) minimize the migration of the chromium plume in the floodplain during remedy start-up; and 4) maximize control of implementation risks during initial implementation of the NTH IRZ. The simulated transition between IM-3 and the proposed remedy is presented in Section 7.3 of the 60% BOD. In this section, four potential start-up scenarios for the proposed remedy were evaluated with varying durations and remedial component order. The criteria for decommissioning IM-3 as well as the definition of “operating properly and successfully” for the purposes of the overall groundwater remedy are specified in the 2012 Settlement Agreement between DTSC and the FMIT.			Comment resolved.	Comment resolved.	Not applicable
10b	Hualapai-5 Chemehuevi-5 Cocopah-5 CRIT-5	General		The basic operational methods of the proposed remedy and IM-3 are fundamentally incompatible, and therefore, once the proposed remedy begins, IM-3 cannot be used. The start-up strategy for the final remedy needs to be efficient, thereby assuring the earliest possible demonstration that the remedy is “operating properly and successfully” (OPS) so that the IM3 facility can be decommissioned. 				comments and to allow sufficient time to exercise their rights to government-to-government consultations with the agencies in regard to project impacts. An ongoing dialogue with the Tribes during the interim period between the 60% and 90% documents would be helpful as PG&E's consultants deal with the issues raised in these comments to the 60% design. Also, the Tribes request consultation with the agencies regarding the potential impacts of the proposed final design against the design presented in the FEIR so that there is sufficient time to discuss those impacts and the sufficiency of mitigation.						
12	FMIT-7 Hualapai-7 Chemehuevi-7 Cocopah-7 CRIT-7	General		The current "project boundary" limits as depicted in various project maps have been shown to be incomplete and/or inconsistent with sensitive areas that should be avoided. This conflict needs to be resolved such that all sensitive areas are excluded from any project activity prior to completion of the 90% design document.	The project boundaries as shown in various project maps are not incomplete. With respect to avoiding sensitive areas, the design is consistent with the EIR's requirement in Mitigation Measure CUL-1a-10 to avoid "any direct physical impact on the Topock Maze, as it is manifested archaeologically." The design complies with that requirement by avoiding placement of any infrastructure in the Topock Maze as it is manifested archeologically. Additionally, in compliance with Mitigation Measure CUL-1a-10, PG&E is designing the remedy to prevent all indirect (e.g. noise, aesthetics) impacts on the Topock Maze to the maximum extent feasible as determined by DTSC.	DTSC would like to clarify that the map of the project area in the certified EIR is not meant to depict or define archaeologically sensitive areas. In compliance with the CEQA Guidelines (California Code of Regulations, Title 14, Division 6, Chapter 3), Section 15124(a), the programmatic EIR described the location and boundaries of the proposed project for evaluation and review of the potential environmental impacts associated with the proposed project. Please note that as a result of our review, DTSC adopted mitigation measures, including CUL-1a-10, to ensure project activities would avoid direct physical impact on the Topock Maze as it is manifested archaeologically.				Not applicable
13a	FMIT-8	General		Chemicals that are foreign to the natural environment are a concern to the Tribes. Additionally, some chemicals may be more offensive for use in a sacred area than others. It is necessary to fully disclose the types, volumes, and frequencies of chemical usage associated with the project. The Tribe requests consultation prior to any changes in chemical additives.	PG&E shares the Tribes' concern about chemicals and their usage in the remedy, including the sustainability perspective. At the 60% design stage, the types, volumes, and frequencies of potential chemicals anticipated for use in remedy operations are included in Section 3 and Appendix D of the 60% BOD report, as well as Volume 1 of the O&M Manual. Specifically, the O&M Manual			FMIT clarified that its reference to consultation in its original comment was to notification and discussion.	Comment resolved.	Exhibit 4.2-5 of O&M Plan (Volume 1 of the O&M Manual). Exhibit L2.2-1 of the main text of the O&M Manual.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
15	MWD-1	General	Communication	A communication action plan should be developed to ensure ongoing coordination with agencies and stakeholders throughout the life of the project. Plan should identify key agency stakeholder contacts (to be updated as needed) and identify proposed notifications (i.e., monitoring, project updates, river threat notifications). In addition, the CWG communication structure, which has worked effectively, could continue to meet on a less frequent basis, such as annually. A new section should be included in the BOO report to discuss proposed communication with project stakeholders.	In compliance with requirements in the CD and the CACA, the Draft O&M Manual, Section L2.2 (page L2-1) and Exhibit L2.2-3 (pages L2-5 through L2-7) present a preliminary framework for communication, and is intended to be used by PG&E to inform, seek inputs, seek approval from agencies, resolve issues, and/or comply with requirements. Specifically, Exhibit L2.2-3 lists the types of communications, the triggering events (e.g., progress update, compliance reporting, discovery, releases, etc.), the regulations/ plans/ agreements that require such communications, the parties initiating and receiving the communications, and general communication procedures and protocols. PG&E welcomes inputs from agencies, Tribes, and stakeholders on this preliminary framework, and is open to repeating this or similar information in another section of the design report. Note that as required by the CD and CACA, this or similar info will also be included in the forthcoming Remedial Action Work Plan. PG&E defers to DTSC on the CWG communication structure and meeting frequency.	DTSC intends to continue the CWG meetings on a frequency that best serves the project stakeholders and the Tribal nations. DTSC conducts a routine meeting survey at the last scheduled CWG meeting of the calendar year to seek input and feedback on meeting frequencies, and locations. Furthermore, DTSC also welcomes feedback of meetings throughout the year and will strive to ensure that the meetings are purposeful and relevant to the project.			Comment resolved.	Exhibit L2.2-1 of the main text of the O&M Manual. Table 2.3-1 of the Construction/Remedial Action Work Plan.
Specific Comments – Executive Summary										
16	FMIT-10	Executive Summary		The Executive Summary states that a pretreatment system to polish Arizona groundwater to California standards is part of the BOD. This item was not included in the project description for the groundwater remedy as outlined in the FEIR. What will be the process for comparing the final design against the FEIR project description? How will the Tribe be included in those discussions?	PG&E defers to DTSC on FEIR content and process related the FEIR.	The January 2011 Certified EIR was prepared as a programmatic EIR with as much information known to us at the time. As the project design evolves, all concerned parties should take note of changes from the conceptual design of the remedy. DTSC will conduct a final CEQA analysis to compare the potential impacts from the existing design with the concepts evaluated in the Certified EIR. DTSC will release all findings in accordance with CEQA guidelines. DTSC, however, encourages the Tribes to present any concerns during the design evaluation				Not applicable

21	DTSC-2	Executive Summary, Page v, Third Paragraph.	…PG&E has made the conservative assumption for freshwater pre-injection treatment goals, specifically that the arsenic treatment goal will be to reduce concentrations below the federal/state Maximum Contaminant Level (MCL) of 10 micrograms per liter (µg/L) and that the fluoride treatment goal will be concentrations below the state MCL of 2 milligrams per liter (mg/L).	DTSC and PG&E have independently concluded that although fluoride concentration from Arizona source well might be above MCL, that the receiving water body in California is similar in concentration and treatment of fluoride is presently optional and at PG&E's discretion. Therefore, designing a goal to attain 2 mg/L for fluoride is futile as higher concentrations already exist in the area where fresh water will be injected. Please revise. It is recommended that the text (here and throughout the entire document) be revised to indicate that fluoride treatment is not likely, based on existing data, due to elevated background values already above the MCL where water will be injected. Suggest supporting the issue by calculating a fluoride background number for the injection area. Show all fluoride data and calculations so that the background number and method can be verified. An arsenic background specific for the injection area should also be calculated. Clarify that arsenic treatment will be fully developed, regardless, in the 90% and final designs. If arsenic treatment is not required by the State Board now, it should be ready as a contingency should arsenic levels rise over the course of the remedy.	In response to this comment, PG&E will calculate a fluoride background concentration for the injection area, and will submit to DTSC when it is available. As for an arsenic background concentration, PG&E does not feel that this is necessary because the State Board letter allows for, under specified conditions, the injection of freshwater with naturally occurring arsenic at levels above the levels in the receiving groundwater basin. As directed by DTSC, PG&E will include a freshwater pre-injection treatment for arsenic only in the 90% and final designs as a contingency. The cited text will be revised to reflect this response throughout the 90% BOD.	Comment resolved pending review of the 90%. Include the fluoride and background in the 90%. 25	FMIT-13 Hualapai-11 Chemehuevi-11 Cocopah-11 CRIT-11	Executive Summary p. vii	*Ensure that the geographic location of the target remediation area does not permanently expand following completion of the remedial action.*	Shouldn't this say that the geographic "area" should not permanently expand, rather than "location"?	The reference text is accurate and consistent with the wording of RAO #4 in the CMS/FS (CH2M HILL 2009), the ROD (DOI 2011), and the Statement of Basis (DTSC 2011). The intention of this RAO is to ensure that the plume boundary (32 ug/L) does not permanently expand after completion of the remedial action.			Comment resolved.	Comment resolved.	Not applicable
26	DTSC-4	Executive Summary, page viii	central maintenance/ storage facility that will house site operation and field staff, remote control and monitoring equipment, an on-site laboratory, a document repository center, a training/conference room, equipment storage, etc.	To minimize the groundwater remedy footprint at the site, PG&E should only consider infrastructures that are critical to the operation and maintenance of the remedy. PG&E should provide specifications for minimum footprint of all required infrastructure with design basis. Allocation of space for training, conference room, library, and patio uses should not be conjoined with the remedy as required infrastructure.	Conducting meetings with stakeholders/ Tribes/ Agencies, providing trainings to project workers/ contractors, and record keeping are amongst the essential elements of the Topock remediation project and are required to comply with agencies' processes (EIR mitigation measures, ARARs, CD, CACA, etc.). The "library" is intended as a repository of essential project documents at the site for purposes of referencing, training, and record keeping. Allocation of space to ensure that these functions can be accommodated at the Topock site in the long-term is necessary. The current practice of borrowing the sole existing TCS conference room for remediation meetings/trainings is not a long-term solution, as this conference room is often needed for meetings/trainings by PG&E Gas	DTSC agrees that meetings and record keeping are essential functions of the project, however, most of these activities are currently outsourced to off-site venues. Continuation of this practice is encouraged in order to minimize infrastructures at the site. Since PG&E is now possibly proposing a change in the suggested design, DTSC will defer comments on this matter pending submission of modified infrastructure layout and design. DTSC awaits PG&E's evaluation/ proposal.			Comment resolved.	90% BOD Table ES-1 and Section 3.5.3.

32	FMIT-15	ES-3 and Section 2.4.1		Please explain Note 1 stating that PG&E has "a possessory interest" on two parcels (650-161-11 and 650-161-12) owned by the Havasu National Wildlife Refuge. Please provide more detail including the nature of this possessory interest and when this interest was granted, its duration and whether any consideration was paid.	PG&E's easement interest in parcels 650-161-11 and 650-161-12 was granted by the U.S. Bureau of Land Management in 1955, for the operation of a compressor station and associated pipelines. Per San Bernardino County Assessor's Office parcel map 0650-16, the total area for parcel 0650-161-12 is 25.72 acres. No acreage information is provided for parcel 0650-161-11 on the County map. Consideration was paid for the interest. The term of the easement is perpetual.			Comment resolved.	Comment resolved.	Not applicable

36	DTSC-5	Executive Summary	Figure ES-11	According to Appendix L, Operation and Maintenance Plan, IRZ-40 should be depicted as an IRZ extraction well, not an injection well. Please revise.	Figure ES-11 will be revised as requested (IRZ-40 is a provisional extraction well).	Okay.			Comment resolved.	90% BOD Figure ES-11.
37	FMIT-16	Figure ES-11		Figure ES-11: Please explain in narrative form (in one section) what infrastructure has been proposed to be subtracted from and added to the FMIT parcel. It would assist the Tribe's understanding of the design if a section of the 90 % BOD could describe the design in detail relative to that Parcel, the Maze and other especially culturally-sensitive locations.	Comment noted. Text will be added to the Executive Summary in the 90% BOD to describe remedy infrastructure proposed to be subtracted from 60% design and added at 90% design to the FMIT parcel. In addition, a description of the design relative to that Parcel, the Maze and other especially culturally-sensitive locations will also be provided at 90% design. Information will be provided to the FMIT for preview prior to 90% submittal.			Comment resolved.	Comment resolved.	90% BOD Section ES.3 of the 90% BOD describes remedy proposed on the FMIT parce, and changes from 60% to 90%l. Figure ES-12 illustrates the changes graphically. Tables 6.1-1 and 6.2-2 provide further information on steps taken in the design of the groundwater remedy to avoid any direct physical impact on the Topock Maze, as it is manifested archaeologically, prevent indirect impacts on the Topock Maze, to the maximum extent feasible, and avoid, minimize, or mitigate impacts on other historical and archaeological resources to the maximum extent feasible.
38	DTSC-6			Summarize/tabulate short term criteria/goals that will be the basis to assess if the remedy is operating adequately and potential contingency actions for not meeting those short term criteria/goals.	Short term goals and timeframes have implicitly been established in the Transition Plans evaluated in Section 7.3 and the Sampling and Monitoring Plan (Appendix L, Volume 2). These short term goals and a reference to the adaptive operations activities specified in the Sampling and Monitoring Plan will be summarized in the Introduction of the 90% BOD. The short-term goals summary is being developed in coordination with the agencies.	DTSC has been requesting the development of measurable short term remediation goals since the Corrective Measure Study. Although the goals stated in the response are appropriate, they lack specificity for measurement and decision making. PG&E will need to develop explicit, discrete, measurable goals/metrics in the 90%. These may be in addition to less quantifiable goals. DTSC will work with PG&E on the short term goal summary for the 90% BOD.	DOI will work with PG&E on the short term goal summary for the 90% BOD.		This topic will be carried forward. Resolution of this comment will be included in the 90% design.	PG&E is working on the short-term goals in coordination with DTSC and DOI.
39	DTSC-7			East Ravine pipeline. DTSC prefers that pipelines not be run through an active AOC that The might require characterization or remediation in the future provided that alternative access ways exist. Therefore, DTSC requests that an alternative pipeline path leading to extraction well ER-6 be selected.	PG&E is evaluating alternative pipe routing for ER-6 extraction piping, power and control conduits (see **Attachment C**, at the end of this table). It should be noted that, while any work around ER-6 will cause disturbance to the AOC, an effort will be made to minimize the amount of soil disturbed.	DTSC understands that PG&E is contemplating different approaches for the East Ravine pipeline alignment and looks forward to its presentation to agencies and stakeholders as part of the 90% design process.			PG&E and DTSC have discussed this comment and the alternative pipe routings shown in **Attachment C**, at the end of this table on December 19, 2013. As directed by DTSC, PG&E presented the alternative pipe routings to the agencies, Tribes, and stakeholders at the TWG meeting held on February 11, 2014. The ER-6 pipeline route was addressed in the letter	90% BOD Figure ES-4 and Appendix D, Drawing C-07-59.

51	DOI-18	Section 2.1.1, Page 2-1	"The Topock site is situated in a basin-and-range geologic environment in the Mohave Valley."	The Chemehuevi detachment fault should be shown in Figure 2.1-1. The text should include some discussion of the significance of the fault to the hydrogeology of the Topock site.	The surface expression of the Chemehuevi detachment fault will be shown on Figure 2.1-1. The following text will be added to Section 2.1.1, as a footnote at the end of page 2-1: "[1]The following discussion focuses on the influence of the Chemehuevi detachment fault on groundwater flow in the vicinity of the compressor station. The 2006 Bedrock Tech Memo (*Information Review of Groundwater Conditions in Bedrock Formations at PG&E's Topock Compressor Station, Needles, California. March 15, 2006*) provides additional information on the detachment fault and the influence of faults on groundwater flow in nearby basins. The footwall of the Chemehuevi detachment fault is the exposed metadiorite bedrock on the slopes south of the compressor station. In most locations near the compressor station, alluvium lies in contact with the metadiorite, so the tectonic features associated with faulting are less apparent, although distinct tectonic features are observable in some outcrops nearby and in rocks in the mountains south of the compressor station. In some locations in East Ravine and the compressor station, Miocene conglomerate overlies the metadiorite and evidence of faulting has been observed in rock cores across this contact.. Evidence of faulting within the metadiorite has not been identified in site core. The contact between the conglomerate and the metadiorite has only been encountered at depth during the installation of three wells; MW-57, MW-67, and MW-68. At MW-67 only	Comment resolved. Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					7 feet of conglomerate were encountered, which may have been a boulder laying on the metadiorite rather than an intact part of the conglomerate formation. In MW-57, the conglomerate near the contact was dry when drilled but once saturated began to collapse into the hole. The conglomerate at the contact had been altered and exhibited mylonitic texture and very weak cementation. In the three wells where the contact between the conglomerate and the metadiorite was encountered. The conglomerate at the contact was completely dry. The lack of cementation in the conglomerate would tend to heal fractures that formed at the contact. Thus, the most obvious feature of the detachment fault, the contact between the conglomerate and the metadiorite does not represent a conduit for groundwater flow. Hydraulic testing from two wells that are screened across this contact also shows that it does not produce water. In MW-57, depth specific flow measurements were conducted that did not identify any flow at the contact. Depth specific flow data were not collected from MW-68BR-280, but this well is open across the contact and produces very little water. It will pump dry at a rate of 0.5 gpm. The contact was encountered in the very bottom of MW-67 but the no depth specific flow testing was done and the well is not screened across the contact. It should be noted that the fault is a zone of fracturing, not just a single break in the rock. Slickensides (evidence of rock movement along a fracture) have been observed on fracture surfaces within the metadiorite. Given the regional nature and advanced age of the detachment fault, it is likely that all the bedrock wells at the site are technically within the fault zone, so the fault itself is not an important feature in the groundwater flow at the site. The fault does not affect the chromium plume in the alluvial aquifer, all of which lies above the

58	DTSC-12	2.2 Chromium Plume Dimensions, First Quarter 2012, P.2-3		Minor Edits: Table 2.2-1 footnotes are not numbered properly and do not correlate with the Notes section under the table. Table 2.2-2 should indicate why the maximum concentration for mercury is "0".	The footnotes in Table 2.2-1 will be corrected, and the numbered notes will be numbered accordingly to include information for the following table items: 1. Results Summary for RFI/RI Wells. 2. Background Comparison 3. Chemical-Specific ARARs 4. Number of Wells with Average Exceeding UTL. The maximum concentration for mercury is 0.4 µg/L. This table will be updated in the 90% BOD.	Comment resolved pending review of the 90% BOD.			Comment resolved.	90% BOD Tables 2.2-1 and 2.2-1.
59	DTSC-13	2.2 Chromium Plume Dimensions, First Quarter 2012, P.2-4	The volume of the plume within the East Ravine bedrock formation is believed to represent less than 2 percent of the total plume.	Calculations supporting the 2 percent value should be included in the document. If this calculation is located elsewhere in the design document, please reference.	This estimate derives from the groundwater transport model. The model is initialized with the February 2012 chromium plume. The porosity values in the model are as follows: a) alluvial aquifer porosity is 12% mobile and 23% immobile; b) bedrock aquifer porosity is 2% mobile and 0.1% immobile. Assuming these porosity values with equal concentrations in mobile and immobile phases, the volume of the chromium plume in bedrock is less than 1% of the total. The figure of <2% was used to account for the uncertainty in the bedrock porosity value. The above explanation will be added to the 90% BOD.	Comment resolved pending review of the 90% BOD.			Comment resolved.	90% BOD Section 2.2.
60	DTSC-14	2.3.1 Constituents of Potential Concern (COPCs), P.2-4	It should be noted that the COPCs (selenium, molybdenum, and nitrate) are not expected to impact remedy performance	The statement is a little confusing. The remedy design must account for monitoring of these parameters. Action levels or goals should be developed to ensure elevated concentrations do not adversely affect the environment or the remedy (e.g., reduce nitrate to below MCL; contain elevated COPCs within the	For consistency with response to comment #61 DTSC-15, the first sentence of the cited text will be revised to: "It should be noted that the COPCs (selenium, molybdenum, and nitrate) are not expected to ~~impact remedy performance and, therefore, do not~~	DTSC conceptually agrees that the COPCs should not have significant effects of the performance of the in-situ remedy. However, PG&E should develop, as part of O&M, action levels and procedures for dealing with the COPCs in the unlikely event			Comment resolved.	90% BOD Section 2.3.1. 			and, therefore, do not impact the remedy design. Further, the 2009 Groundwater Risk Assessment (ARCADIS 2009) concluded that selenium, molybdenum, and nitrate do not represent a significant health risk to future hypothetical users of the groundwater.	boundary of the chromium plume). PG&E has indicated that the remedy should only help to reduce the concentrations of these particular constituents. Modification of the sentence is required. The 2009 risk assessment is not up to date with current data, especially new data collected at the TCS and East Ravine. For instance, new nitrate data collected were higher than that utilized in the 2009 risk assessment. Therefore, modifying risk assessment conclusions is requested.	~~impact the remedy design~~ have any significant effect on the performance of the in-situ reduction. However, the COPCs will be monitored throughout the remedy. Remedy pumping and injection will be operated so that the extent of elevated concentrations of COPCs at the completion of the remedy does not extend beyond the current extent of the chromium plume. The COPCs can be removed from groundwater within the IRZs. During operation, the areas of elevated COPCs are not expected to expand beyond the current boundaries of chromium plume or the floodplain down gradient from the IRZ. COPC concentration trends in wells on either side of the IRZ will be monitored to evaluate the degree to which COPCs are being attenuated by the IRZ." Threshold concentrations and a decision tree for assessment of elevated COPCs will be included in the 90% design. As agreed in the Human Health and Ecological Risk Assessment Work Plan Addendum 2 memorandum (RAWP Addendum 2 – Scope; ARCADIS 2013), an outline of the approach to evaluate the new groundwater data collected since the 2009 Groundwater Risk Assessment (GWRA; ARCADIS 2010) will be presented in the upcoming RAWP Addendum 2, and the results of the evaluation presented either as a technical memorandum or an addendum to the GWRA. Note, however, that the new groundwater data collected in the TCS and East Ravine have been evaluated and the results of the evaluations presented in the "Addendum to the Summary and Findings Associated with the East Ravine Groundwater Investigation" dated November 15, 2012 (CH2MHILL 2012). As stated in the November 2012 document, the new data do not suggest any previously unknown hotspots or contaminant source areas.	that the COPCs are more prominent than expected. Comment resolved pending review of the 90% design.

62a	FMIT-19	Section 2.3.1p. 2-4	*It should be noted that the COPCs (selenium, molybdenum, and nitrate) are not expected to impact remedy performance and, therefore, do not impact the remedy design.*	Elevated concentrations of nitrate in groundwater were caused by repeated evaporation of naturally occurring nitrate (see PG&E Technical and Ecological Services, Bat Cave Wash, 1995; and RFI-RI, Volume 2, 2008). Elevated selenium concentrations in water from wells in the study area appear to correlate with nitrate concentrations (See Exhibit VI); therefore, it might be that selenium concentrations are a reaction product of the high nitrate concentrations (possibly the solid-phase selenium in aquifer sediments is being oxidized by nitrate). Carbon amendments to the aquifer will treat and remove both nitrate and selenium; however, as the nitrate plume is hydraulically pushed into the IRZ line, nitrate will inhibit the reduction of chromate? Can the model be used to forecast arrival of the nitrate plume and reactions at the IRZ line?	The agency approved Final RFI/RI Volume 2 Report discusses several potential sources of nitrate in site groundwater besides the evaporative concentration in original blowdown water. Section 5.3.1.6 on page 5-19 of the RFI/RI Volume 2 states: "The nitrate in these wells may be associated with mountain front recharge, as the wells lay at the base of an alluvial fan within or near incised drainage channels running northward. Numerous studies have documented nitrate generation through lightning discharges in thunderstorms.. Recent research has shown that a significant reservoir of nitrate can accumulate in the soil beneath areas of desert pavement in the Mohave Desert (Graham, 2008 [*Large near-surface nitrate pools in soils capped by desert pavement in the Mojave Desert*. California Geology. Volume 36, No. 3. R.C. Graham, et al.])… Another potential source of nitrate is historical blasting associated with railroad, freeway, compressor station, and pipeline construction, and with the quarry behind the Old Evaporation Ponds. Other potential nitrate sources include animal grazing, which historically took place on portions of			Comment resolved.	Comment resolved.	O&M Manual Volume 2 Section 4.2.1. 					the site, and evaporative concentration of natural nitrate in blowdown water at the facility." It is possible that nitrate (and other oxyanions) may compete with the reduction of chromate by organic carbon. However, compared to the mass of chromate in the plume, the mass of nitrate is relatively small. Therefore, PG&E will closely monitor the concentrations and movement of nitrate and other nitrogen compounds (nitrite and ammonium), and operate the remediation system as efficiently as possible, and to anticipate and prepare for the effects of competing oxyanions on the efficacy of carbon amendments. Monitoring of nitrate has been included in Table 2.1-2 of the Draft O&M Manual, Volume 2 (Sampling and Monitoring Plan). This table will be revised in the 90% BOD to include monitoring of other nitrogen compounds.

			footprint, since historical samples collected outside the RFI/RI from the Old Evaporation Ponds wells ranged between 500 and 10,000 mg/L.		must represent a mixture including TDS associated with waste discharge from the compressor station."					
67	DTSC-20	2.3.3.1 Total Dissolved Solids, P.2-9 && 2.3.3.2 Sulfate, P.2-9	TDS is not expected to impact remedy performance nor impact the remedy design. In particular, Cr(VI) reduction was observed in the presence of elevated TDS concentrations, as presented at the January 19, 2012 TWG meeting. Additional discussions are included in Appendix B (Groundwater Modeling) of this BOD Report. Similar to TDS and the COPCs (selenium, molybdenum, and nitrate), sulfate is not expected to impact remedy performance nor impact the design.	Please delete the cited paragraph/sentence as they are redundant with language on page 2-8, section 2.3.3. See DTSC comments on 2.3.1 Constituents of Potential Concern (COPCs), P.2-4 and 2.3.1.1 Selenium, P.2-4 above. What are the TDS limits for injection? Waste discharge limits issued from the Regional Water Quality Control Board for IM-3 were specified and PG&E complied with them. It seems there should be some general minerals limit for waters injected into the aquifer that are not eventually captured by the proposed remedy. Start with IM3 WDR limits and discuss rationale for any excursions from those limits. Need to establish discharge limits for large suite of parameters: Title 22 metals, general minerals, etc.,	The cited sentences will be removed in the 90% BOD. It is unclear as to how the second part of this comment is related to these sections of the BOD, which are intended to describe the baseline conditions for TDS and sulfate. Nonetheless, as discussed in the response to comment #145 DTSC-50, PG&E believes that TDS limits for injection is not required for the remedy. It is important to note that the purpose for injection with respect to the remedy is different from the purpose of discharge with respect to IM3. The selected remedy relies on the ability to inject water in order to mix water throughout the treatment zone, therefore, setting discharge limits is inconsistent with the selected remedy. The purpose of IM3 discharge is a sustainable way to retain water in the groundwater basin and to minimize the amount of trucking needed for off-site disposal. Setting discharge limits for IM3 is appropriate to ensure the quality of water being returning to the basin.	Ok DTSC agrees that discharge limits should not be described in the referenced section of the design report. However, DTSC disagrees with PG&E that discharge limits are not warranted for the remedy because the purpose of remedy is different from IM3. Although the reasons for water injection might be different, the goal of both actions is to ensure the quality of the water returning to the basin and to ensure that the beneficial use designation of the basin plan is maintained outside of the plume area. DTSC disagrees that setting discharge limits are inconsistent with the selected remedy. Also see response to comment #145.			Discussion between DTSC, DOI, RWQCB, and PG&E is ongoing to resolve this comment. This topic will be carried forward. Resolution of this comment will be included in the 90% design. 81	DOI-32	Figure 2.4-3	Notes	The in-text citation for CH2M HILL 2009 is not listed in the Reference section.	The 2009 East Ravine Investigation Report is Appendix A to the CMS/FS (CH2M HILL 2009d), which is listed in the Reference section. The letter “d” will be added after 2009 on Figure 2.4-3.		Comment resolved.		Comment resolved.	90% BOD Figure 2.4-3. The letter “e” instead of “d” was added after 2009 to reflect updated reference section in the 90% BOD.
82	DOI-33	Figure 2.4-4		The font in the legend and figure are very small and difficult to read. At the minimum, it would be helpful to show a larger label and arrow identifying the locations of AOCs 11 and 12 since they are called out in the text (first paragraph of Section 2.4.3).	Figure 2.4-4 will be revised to show larger labels and arrows.		Comment resolved.		Comment resolved.	90% BOD Figure 2.4-4.
83	DOI-34	Figure 2.4-11		Indigenous plants of traditional cultural significance within the EIR project area in compliance with mitigation measure CUL-1a-5: Arrowweed is not included on the map but should be as it has been identified as a plant of cultural significance.	Culturally significant plants shown in Figure 2.4-11 included only those species that were included in Appendix PLA of the Final EIR. The list in Appendix PLA is based on a list of Colorado River Indian Ethnobotany. Arrow weed is not included on that list. Arrow weed however will be protected during construction as a mature plant under AES-1a. Populations of arrow weed were mapped in the Mature Plants Survey Report included in Appendix A7 of the 60% BOD (see Figure 3, page 509 of the PDF).		Add a footnote to Figure 2.4-11 noting that the Tribes have stated that Arrow weed is an ethnobotanical sensitive plant (June 2011).		The following note will be added to Figure 2.4-9 in the 90% BOD: “Tribes have stated that Arrow weed is an ethnobotanical sensitive plant (June 2011). Arrow weed however is not on the Appendix PLA of the FEIR. Arrow weed will be protected during construction as a mature plant under AES-1a.”	90% BOD Sections 2.4.6 and 2.4.7, and Figrue 2.4-11.
84a	FMIT-22	Figure 2.4-11 Indigenous Plants Of Traditional Cultural Significance Within The EIR Project Area In Compliance With Mitigation Measure Cul-1a-5	Note on map reads: *“Note that in compliance with EIR mitigation measure CUL-1a-9 as well as PA and CHPMP mitigation measures, the pipeline along the dirt road west of National Trails Highway is located in an existing, previously disturbed, access road. In addition, the location of the road and the pipeline was field verified and does not*	The statement that “the location of the road and the pipeline does not create any direct effect on the Topock Maze,“ which is made based on alleged compliance with EIR mitigation measure CUL-1a-10, PA and CHPMP should be removed from the text. It is overstated and misleading. Compliance with these measures does not ensure that the cultural and spiritual integrity of the site is unaffected. It should be emphasized that the Tribe was not sufficiently made part of the groundwater EIR process. Tribes have the singular capacity to evaluate whether there are impacts on the Maze. Additionally, some of the recent archaeological surveys performed by the Tribes in cooperation with PG&E and DTSC contractors indicate there may indeed be direct effects on the Maze. Would it be possible to place all of the infrastructure on the east side of National Trails Highway to	PG&E understands and the EIR acknowledges that the mitigation measures do not ensure the spiritual integrity of the site is unaffected. The note does not state that compliance with mitigation measures would ensure that the cultural and spiritual integrity of the site is unaffected. As disclosed in the EIR, even with implementation of CUL-1a-9 and CUL-1a-10, the impact on the Topock Cultural Area as a historic resource would be significant and unavoidable. (Final EIR at p. 4.4-61.) As the note on Figure 2.4-11 states, however, compliance with the requirements of the PA, CHPMP mitigation measures, and EIR mitigation measures CUL-1a-9 and CUL-1a-10 will prevent direct impacts on the Topock Maze as archeologically manifested. Through discussions with the Tribe, PG&E understands that the Tribe’s comment that the “Tribe was not sufficiently made part of the EIR				PG&E’s response was discussed with the FMIT, and revised in response to that discussion. In addition, PG&E evaluated moving all NTH IRZ wells to the east side of National Trails Highway and the results of the evaluation was presented at the February 11, 2014 TWG meeting (map is included in **Attachment D**, at the end of this table). PG&E understand that this comment is resolved.	Several figures in the 90% BOD show all NTH IRZ wells on the east side of National Trails Highway (e.g., Figures ES-4A, ES-10, etc.)

			create any direct physical impact or effect on the Topock Maze, as it is manifested archaeologically, in compliance with EIR mitigation measure CUL-1a-10 and PA and CHPMP mitigation measures."	better avoid cultural resources that may be eroding from the mesas?	process" does not refer to the overall EIR process, but is specific to the initial archeological surveys of the Maze. In addition, PG&E understands that the comment is not intended to be a claim against the EIR process. PG&E notes for the record that DTSC provided all stakeholders with the opportunity to comment on the Draft and Final EIR pursuant to CEQA, and made a special effort to consult with the Tribe. The Tribe availed itself of those opportunities, submitting numerous comments. (See, e.g., Final EIR, Vol. 1, at pp. 4-2-112, 4-170-78.) The Final EIR responds to the Tribe's comments and numerous changes to the EIR were made based on the Tribe's input. (*Id.* at pp. 4-113-69, 4-179-84.) See response to comment #12 FMIT-7. PG&E is committed to complying with the state and federal mitigation measures to ensure that the Project will not have a direct impact on the Maze as it is archeologically manifested. PG&E understands that the Tribes have conducted a Tribal Cultural Values Assessment, which is currently under review by the agencies and PG&E. The issue of the Maze boundaries and the Project's compliance with applicable state and federal mitigation measures will thus be a subject of further discussion between PG&E, the Tribes, and the agencies. In response to the question about the possibility of placing the infrastructure on the east side (instead of the west side of NTH), and based on the comment clarification discussion with the Tribes on 9/5/13 and subsequent discussions at the December 2013 TWG meeting, PG&E reviewed the locations of all provisional IRZ wells below the mesas and determined that these provisional wells could be moved to the east side of NTH. Specifically, the proposed new locations for four provisional wells (IRZ-12, IRZ-14, IRZ-22, and IRZ-24) were included on a map that was made available to stakeholders,

					Tribes, and the agency representatives who participated in the October 28, 2013 site walk (map is included in **Attachment D**, at the end of this table).					
84b	Hualapai-16 Chemehuevi-16 Cocopah-16 CRIT-16	Figure 2.4-11 Indigenous Plants Of Traditional Cultural Significance Within The EIR Project Area In Compliance With Mitigation Measure Cul-1a-5	Note on map reads: *"Note that in compliance with EIR mitigation measure CUL-1a-9 as well as PA and CHPMP mitigation measures, the pipeline along the dirt road west of National Trails Highway is located in an existing, previously disturbed, access road. In addition, the location of the road and the pipeline was field verified and does not create any direct physical impact or effect on the Topock Maze, as it is manifested archaeologically, in compliance with EIR mitigation measure CUL-1a-10 and PA and CHPMP mitigation measures."*	The statement that "the location of the road and the pipeline does not create any direct effect on the Topock Maze", which is made based on alleged compliance with EIR mitigation measure CUL-1a-10, PA and CHPMP, should be removed from the text. This statement is overstated and misleading. Compliance with these measures does not ensure that the cultural and spiritual integrity of the site is unaffected. It should be emphasized that the Tribes were not sufficiently made part of the groundwater EIR process. The Tribes have the singular capacity to evaluate whether there are impacts on the Maze. Additionally, some of the recent archaeological surveys performed by the Tribes in cooperation with PG&E and DTSC contractors indicate information to the contrary. Would it be possible to place all of the infrastructure on the east side of National Trails Highway?	PG&E understands and the EIR acknowledges that the mitigation measures do not ensure the spiritual integrity of the site is unaffected. The note does not state that compliance with mitigation measures would ensure that the cultural and spiritual integrity of the site is unaffected. As disclosed in the EIR, even with implementation of CUL-1a-9 and CUL-1a-10, the impact on the Topock Cultural Area as a historic resource would be significant and unavoidable. (Final EIR at p. 4.4-61.) As the note on Figure 2.4-11 states, however, compliance with the requirements of the PA, CHPMP mitigation measures, and EIR mitigation measures CUL-1a-9 and CUL-1a-10 will prevent direct impacts on the Topock Maze as archeologically manifested. With respect to the claim about tribal participation in the EIR process, PG&E notes for the record that DTSC provided all stakeholders, including Tribes, with the opportunity to comment on the Draft and Final EIR pursuant to CEQA, and made a special effort to consult with interested Tribes. This effort to communicate with interested Tribes is summarized in the Final EIR at Volume 1, page 4-201, and Volume 2, pages 4.4-14, 4.4-26 to 4.4-37. Interested tribes availed themselves of the opportunities to comment, for example by submitting numerous comments on the Draft EIR. (See Final EIR, Vol. 1, at pp. 4-185, 4-191–96, 4-200, 4-202, 4-204–9, 4-218–19.) The Final EIR responds to the comments from interested Tribes and numerous changes to the EIR were made based on input from the interested Tribes. (Id. at pp. 4-186–90, 4-197–99, 4-201, 4-203, 4-210–17, 4-220–21.) With respect to impacts on the Maze, PG&E is committed to complying with the state and federal				PG&E evaluated moving all NTH IRZ wells to the east side of National Trails Highway and the results of the evaluation was presented at the February 11, 2014 TWG meeting (map is included in **Attachment D**, at the end of this table). PG&E understand that this comment is resolved.	Several figures in the 90% BOD show all NTH IRZ wells on the east side of National Trails Highway (e.g., Figures ES-4A, ES-10, etc.)

87	MWD-6	3.1, Appendix B, Section 4	Constant flux boundary for wells.	The text does not describe how groundwater extraction/injection is assigned to respective wells in the model. The flux can be explicitly assigned to each well node (i.e. layer) or can be assigned passively using MODFLOW's Multi Node Well Package. The latter approach would be preferred based on the planned screens crossing multiple aquifer/model layers that would produce/receive flow dependent on the layer's hydraulic conductivity. Explicitly assigning the flux for extraction/injection well layers could erroneously estimate the amount of plume or reactant capture and/or movement.	The multi node well package was utilized to automatically distribute the extraction/injection rates across multiple layers at a single well based upon the simulated transmissivity. In the instances where discrete screen intervals were anticipated, layer-specific rates were assigned directly.				Comment resolved.	Not applicable
88	DTSC-24	Section 3.2.1.1, Well Maintenance and Rehabilitation Reagents		Please provide the MSDS for NuWell 120 and NuWell 310 as part of the project H&SP.	Material safety data sheets for NuWell 120 and NuWell 310 will be provided as part of the project H&SP.	Okay.			Comment resolved.	O&M Manual Volume 5.
89	DOI-37	Section 3.2.1, Pages 3-4 and 3-5	"● Up to 24 injection wells (i.e., NTH IRZ Injection Wells) situated … ." "● One provisional extraction well (IRZ-40) and up to 30 … ."	The 16 locations and 19 locations of the more numerous injection wells referenced in these bullets are not evident from the map. Suggest deleting the term "locations".	Note that the map (Figure 3.0-1) depicts the 16 NTH IRZ Injection Well locations and 19 provisional NTH IRZ Injection Well locations and not individual wells. In some cases, multiple wells will be installed at a single location, hence the distinction between "wells" and "locations". The legend of Figure 3.0-1 will be updated as follows: 1) green triangular marker will represent "Injection Well <u>Location</u> (NTH IRZ)" instead of "Injection Well (NTH IRZ)"; and 2) gray triangular marker will represent "Future Provisional Injection Well <u>Location</u>" instead of "Future Provisional Injection Well". No changes to the text are proposed.		Comment resolved.		Comment resolved.	90% BOD Figure 3.1-1.
90	DTSC-25	3.2.1.1/3-7	In-well components include pneumatic packers	Please consider using self-sealing threaded packers for ease of use and longevity in lieu of the pneumatic packers.	PG&E proposes to use fixed head packers that may be pneumatically or hydraulically inflated to isolate zones within a well. These packers are capable of higher inflation pressures, which are required due to the anticipated pressure differentials during operation of the remediation wells. Further, the seal can be monitored to confirm packer functionality. K-packers are typically only used for low-pressure differential applications. K-packer	Comment resolved. See response to comment #232 DTSC-103.			Comment resolved.	Not applicable

				changed throughout.	borehole logs." This sentence will be modified in all places throughout the report.					
94	DOI-40	Section 3.2.1.1, Exhibit 3.2-1 And Section 3.2.1.1, Page 3-9	Exhibit 3.2-1 Carbon substrate dosing and flow rate 3.2.1.1 Organic Carbon Dosing and Delivery Strategy	PG&E learned from its work at the Hinkley Compressor Station site that arsenic had a two fold increase and manganese had a 249 to 2186 fold increase in concentrations with the introduction of ethanol into the aquifer system. Similar results were observed during the Topock site pilot tests. PG&E plans on making field adjustments to chemical infusion/amendment concentrations to find the right dose to minimize the generation of byproducts. What is the basis for the 100 mg/L nominal concentration for carbon substrate dosing and the nominal flow? To what extent is the dosing value based on experiences at Hinkley?	The 100 mg/L nominal concentration for carbon dosing is based on the results of pilot testing and solute transport modeling. Specifically, pilot test results indicated that Cr(VI) reduction could be achieved with TOC dosing of between 10 and 50 mg/L carbon (Appendix B, Section 3.4-1). The injection concentration of 100 mg/L carbon is based on the results of solute transport modeling, which indicate that the injection of 100 mg/L carbon achieves the distribution of 10-15 mg/L of TOC in the zones between injection wells that is necessary to achieve a complete IRZ (see Appendix B, Section 6.4.1). The following text describing the use of pilot test results and solute transport model predictions to inform TOC injection concentrations will be added to Section 3.2.1.1 in the 90% Design Submittal: "Based on ISPT results summarized in Section 3 of Appendix B, a sustained TOC concentration between 10 and 50 mg/L is sufficient to establish chromium reducing conditions. The injection concentration of 100 mg/L carbon is based on the results of solute transport modeling, which indicate that the injection of 100 mg/L carbon achieves the distribution of 10 to 15 mg/L of TOC in the zones between injection wells that is necessary to achieve a complete IRZ (see Appendix B, Section 6.4.1)" The dosing value was based on pilot test data and solute transport modeling specific to the Topock site, rather than the Hinkley site. However, the concentrations proposed for Topock are consistent with the range of concentrations applied at Hinkley, i.e., 5 to 400 mg/L TOC.		Comment resolved pending review of 90% design.		Comment resolved.	90% BOD Section 3.2.1.

95	DOI-41	Section 3.2.1.1, Page 3-9, Portable Tanks		It should be noted that portable tanks may be used with provisional wells in the future for treatment of recalcitrant zones.	The following text will be added to Section 3.2.1.1 – Portable Tanks: "<u>In addition, portable tanks may be used with provisional wells in the future for treatment of recalcitrant zones.</u>" See also response to comment #96a FMIT-25 for information regarding the anticipated footprint for portable tank use.		Comment resolved.		Comment resolved.	90% BOD Section 3.2.1.
96a	FMIT-25		Section 3.2.1.1 p. 3-9	A topic at the 6/18/2013 TWG meeting in Henderson included a discussion of individual well footprints. The added footprint of portable tanks at the wellhead was not discussed. Furthermore the visual and cultural impacts associated with presence of portable tanks have not been evaluated within the groundwater EIR. In addition the Tribe has not been asked which wellheads would be an acceptable location for a portable tank. The impacts associated with use of portable tanks should be evaluated with input from the Tribes, and the added footprint at the wellhead should be clearly documented and presented to the Tribes for input.	The intention of the section of the text in question was to describe the flexibility of the design that allows for the injection of carbon substrate directly to a well through connections in the well vault in the NTH IRZ. The 90% Design Submittal will be clarified to also include this flexibility for the TCS and IRL injection wells. Portable tanks are not anticipated to be "installed" at wellheads for semi-permanent use. Rather, it may be necessary at times during the remedy to complete those injections by pulling a portable tank to the well on a trailer or in a smaller vehicle carried by an operator during work hours. The anticipated footprint of these operations will be similar to that for sampling or maintenance. See Draft O&M Manual, Volume 2, Appendix A, SOP-A13 for spill prevention, containment, and control measures for well development, sampling, and purging.	The potential use of portable tanks was fully disclosed as part of Chapter 3, "Project Description" in the Groundwater Final EIR. As a program-level analysis, the visual and cultural impacts associated with all potential types of infrastructure were described in the Final EIR to the extent practicable given the level of design detail available at the time. The impact analysis presented in the Final EIR was provided for the "proposed project" which includes the construction of wells, pipelines, access roads, and other project facilities including tanks (which could include portable tanks based on the Project Description provided in the Final EIR). See supporting text from the Final EIR in Project Description - pp 3-14 Reductant Storage and Associated Facilities, pp. 3-22 Construction of Wells, pp 3-27 Operation and Maintenance of Proposed Project; Aesthetics – pp 4.1-25, pp 4.1-28 Table 4.1-2. 		Maintenance and Rehabilitation Reagents, 3rd paragraph	removed … .”	suggest the following language: “ … and any residual Cr(III) not removed will re-precipitate …”.	shown in ~~strikethrough~~ typeface): "The dissolved Cr(III) will ~~either~~ be removed from the well during rehabilitation, ~~or will~~ and any residual Cr(III) not removed will re-precipitate as pH is buffered following rehabilitation."					
98	DOI-43	Section 3.2.1.2, Page 3-11, In-Situ Pilot Tests, 3rd paragraph		The “short-circuiting” is not well explained, nor is there a discussion of how this “short-circuiting” will be adequately addressed by the design. Please provide clarification.	The following text will be inserted in this section to explain "short circuiting": "The Upland ISPT was designed with two recirculation wells. Each well was screened in two depth intervals (shallow and deep). Pilot test injections were performed by injecting into one of the two screened intervals at each well and extracting from the other interval—i.e., each dual-screened well was used for both injection and extraction. By injecting and extracting at different depths, the goal was to create a depth-dependent forced gradient laterally between the two wells. However, the result was that a substantial portion of the injected solution was re-extracted by the same well (from the opposing depth interval)—i.e., it "short-circuited" vertically, limiting lateral (horizontal) distribution of carbon away from the wells. This point is discussed in detail in Section 3 of Appendix B." A figure will also be included. This short-circuiting is addressed in the design by not using dual-recirculation wells. Each IRZ well will be used exclusively for either injection or extraction of groundwater at any given time, eliminating the possibility of vertical short-circuiting.	Suggest adding a figure to illustrate short-circuiting if not already included.	Comment resolved.		Comment resolved.	90% BOD Section 3.2.1.
99	DTSC-26	3.2.2 Inner Recirculation Loop. P.3-12 Also see Exhibit 3.2-2	…and (3) provide secondary protection for the Colorado River by controlling the migration of potential byproducts generated by the NTH IRZ in	This suggests that the shallow portion of the aquifer and river may not be protected by byproduct migration. Contingency measures may be necessary. Ensure shallow well monitoring is enhanced in this area (including evaluation of particle flow paths in the area).	An extensive monitoring program has been designed to evaluate byproduct migration downgradient of the NTH IRZ and in the vicinity of River Bank Extraction Wells in both the shallow and deep portions of the aquifer. This monitoring program (specifically, the IRZ downgradient monitoring and riverbank extraction/northern NTH extraction monitoring elements of the performance monitoring program,	What would be PG&E’s contingencies if the actual concentrations of by-products are higher than solute transport model predictions? What are the action levels and triggered response? If the model is correct, then all is fine, but if model is incorrect, PG&E must have response in place. There is concern that a contingency does not exist to			Comment resolved. Per DTSC request, particle track figures for Layers 1-4 were submitted to DTSC on March 11, 2014 (see **Attachment R** at the end of this table). Particle tracking figures will continue to be included in the 90% Design document.	90% BOD Section 3.2.2. 90% BOD Apdx B Section 6.5. O&M Manual Volume 3.

			the deeper portion of the aquifer.		described in detail in Appendix L, Volume 2, Section 4.2) includes a combination of existing wells and proposed wells (wells H and O) which will provide adequate coverage for byproduct monitoring in the shallow zone. Cross sections along the NTH IRZ and the shoreline will be produced to show monitoring well screens and chromium plume delineations (included in **Attachment Q**, at the end of this table); these cross sections will help to illustrate monitoring well coverage in the shallow zone. Placement of the shallow monitoring wells was guided by the solute transport modeling results. Consideration of byproduct migration was an important element of monitoring well location, analyte selection, and sampling frequency. Simulated solute transport results indicate byproduct concentrations (Mn and As) generated from the NTH IRZ are within the range of the naturally occurring shallow Mn and As concentrations in the floodplain. Solute transport modeling is a superior tool for assessing remedy performance and designing the monitoring program; and PG&E recommends continued use of the solute transport model, rather than particle tracking, for monitoring well network design. Simulated flow fields will be provided to illustrate the simulated groundwater flow directions (included in **Attachment E**, at the end of this table). The flow fields will be generated with the same hydraulic parameters as the simulated hydraulic capture zones presented in Appendix B Section 6.5 and Figures 6.5-9 to 6.5-12. Contingency measures will be evaluated and presented in the 90% design.	capture/ mitigate potential eastbound byproducts or chromium in the floodplain south of RB-5 towards bedrock (e.g., MW-23). DTSC awaits proposed cross sections to aid in assessing monitoring programs. Comment resolved pending review of the 90% design.				
100	DTSC-27	3.2.2.1 Description. River Bank Extraction Wells, P.3-12		No provisional river bank extractions well locations are identified. As the river is a significant receptor important to all stake holders, it is requested that at least six provisional well locations be included as a contingency measure should additional extraction be needed to	Although no provisional River Bank Extraction Wells are identified, significant capacity and system flexibility have been built into the design of the river bank extraction system should additional extraction be needed. Modeling indicates that hydraulic capture of the deeper	A site walk was conducted on October 28, 2013. PG&E, tribes, stakeholders, and agencies attended. PG&E illustrated four potential provisional river bank extraction locations that were located in the field			Comment resolved.	90% BOD Section 3.2.2. 90% BOD Apdx B Section 6.4.2. 				control contaminants, byproducts, or enhance hydraulic control.	portion of the alluvial aquifer is achieved at a total average extraction flow rate of 150 gpm with operation of four of the River Bank Extraction Wells (see Table 3.2-2 of the BOD/60% Design Submittal). However, flexibility has been provided (1) with an additional well [RB-2], and (2) to increase the total flow rate to as much as 500 gpm should additional extraction capacity be needed. Additionally, all of the River Bank Extraction Wells have been designed with two screened intervals: a lower screened interval to target the deeper portions of the unconsolidated alluvial sediments and an upper screened interval to allow for shallow groundwater capture, if necessary. The shallow screens will be isolated from the well pump unless the need to pump in the shallow unit proves necessary. In addition to the operational flexibility measures summarized above, up to four future provisional River Bank Extraction Wells will be added (see map included in **Attachment D**, at the end of this table). The four proposed future provisional River Bank Extraction Well locations are located roughly midway between the five current River Bank Extraction Well locations (RB-1 to RB-5). Future provisional wells could potentially be installed at these locations to supplement extraction wells RB-1 through RB-5 if needed to provide the intended Cr(VI) migration control. Additional future provisional extraction well locations north of RB-1 or south of RB-5 were also considered. However, it is unlikely that installing a well further south of RB-5 would provide significant benefit because the saturated thickness decreases as the bedrock contact is approached in this direction. Additionally, the reducing rind extends down into model Layers 3 and 4 south of RB-5. Installing a well north of RB-1 would also provide minimal benefit because the diffuse Cr(VI) upgradient of the NTH IRZ will be contained by the northern NTH IRZ Extraction Wells. Potential	approximately half way between proposed RB wells. Locations were described as general areas that could be shifted as needed based on data gathered during implementation of the remedy. Attendees should be well informed regarding this matter and PG&E should proceed with its proposed modifications cited in the response to the left. Comment resolved pending review of the 90% design.

					locations for the additional provisional River Bank Extraction Wells will be selected during a later stage of the 60% BOD response-to-comment process considering both technical criteria and knowledge of sensitive areas. The precise locations of the provisional wells, including areas south of RB-5 and the need for additional extraction wells will be evaluated and considered as operational data is collected and system performance evaluated.					
101	DOI-44	Section 3.2.2.1, Page 3-13	"A packer will be installed in the well to separate the upper and lower screened intervals."	Will a dual packer system be used to isolate the zones?	A single fixed-head packer will be used to isolate the two well screens. This installation is detailed on Drawing M-05-01 in Appendix D.		Comment resolved.		Comment resolved.	90% BOD Appendix D Drawing M-05-01.
102	DOI-45	Section 3.2.2.1, Page 3-13	"The purpose of the upper screen is to allow . . . ."	The text states that the upper screen will be installed on the River Bank Extraction Wells to allow for <u>additional</u> groundwater capture if monitoring data indicate this is needed. This indicates groundwater is not pumped from the upper screen unless it is necessary. Please provide additional details on what the monitoring data would show that would trigger <u>additional</u> groundwater capture, and clarify that groundwater is indeed not continuously pumped from the upper screen. If the upper screens were to be pumped, what impact would they have on the capture zone?	The Sampling and Monitoring Plan provides extensive detail on what monitoring observations would trigger the need for shallow riverbank extraction, as addressed by NTH IRZ DQO-3 (Section 2.2.1, Appendix L, Volume 2). Specifically, shallow riverbank extraction would be implemented only if other measures to control byproduct generation and migration (e.g., adjustment of reagent type, dosing concentrations, injection rates, etc.) were ineffective (see Figures 2.2-2 and 2.2-5, Appendix L, Volume 2). A reference to the Sampling and Monitoring Plan (Appendix L, Volume 2) will be added to this paragraph in the 90% Design Submittal. Figures 6.5-10 and 6.5-11 of Appendix B show the estimated hydraulic capture in the shallow zone when the River Bank Extraction Wells are operated without shallow intervals on. As shallow screens are opened and riverbank extraction rates are increased, the capture zone in the shallow depths would expand, while maintaining the capture zone at deeper depths. 104	DOI-46	Section 3.2.2.1, Page 3-14, Inner Recirculation Loop Injection Wells, 1st paragraph		Supplement the discussion on the disposition of river bank extracted groundwater if freshwater is injected in to all four IRL wells.	The text will be modified as follows (added text shown in <u>underline</u> typeface and deleted text shown in ~~strikethrough~~ typeface): "However, the final ~~layout~~ <u>design</u> of the Inner Recirculation Loop <u>Injection Wells</u> will be flexible enough to accommodate either injection water source (i.e., extracted water from the River Bank Extraction Wells or fresh water from the freshwater supply system) <u>at each well</u> to minimize potential byproduct impacts. <u>All groundwater extracted from the River Bank Extraction Wells will be re-injected into one or more of the Inner Recirculation Loop Injection Wells. Total flow to the Inner Recirculation Loop Injection Wells will be supplemented with flow from the freshwater supply system, as needed.</u>"		Comment resolved.		Comment resolved.	90% BOD Section 3.2.2.
105	DOI-47	Section 3.2.3.1, Page 3-18, East Ravine Extraction Wells, 1st paragraph	" . . . this design has since been revised to five extraction wells operating at a total nominal flow rate of 5 gpm . . . "	This estimated long term flow rate (5 gpm) is half the previous estimate (10 gpm) based on the results of the short term pump tests identified in Section 2.1.2. Further, it is anticipated at this lower rate that the pumps may run "dry" and thus need to be operated on a cyclical basis. Should the combined flow rates over a long period of time result in more than one well being cycled on-off, what impact could this have on the estimated time to clean-up the site? Is it possible should more than one pump need to be cycled on-off that the capture zone may be disrupted and fragmented? If so, how would this be addressed?	East Ravine wells ER-1 to ER-4 are proposed to be operated at rates of 0.5 gpm each due to the low anticipated yield in the fractured bedrock. ER-6 located at Site H is proposed at 3 gpm due to the identification of a higher attainable yield at the MW-70BR-225 well. Given the variable nature of the fractured bedrock and the interconnectivity of these fractures, the actual yield of these wells will be evaluated during remedy operation and adjusted accordingly to obtain a maximum sustainable rate. Additional provisional east ravine wells will be considered in the event of poor performance of the proposed east ravine extraction wells (See response to comment #109 DTSC-30). It is not anticipated that cycling the east ravine bedrock extraction wells would have a		Comment resolved.		Comment resolved.	90% BOD Section 3.2.3.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					significant impact on the capture zone because as the area in the vicinity of bedrock wells dewater, minimal hydraulic capture will occur. As the bedrock rebounds during an off-cycle, the groundwater will collect in the well(s). Once the well is turned back on the water will be captured due to the slow groundwater velocities in this area.					
106	DOI-48	Section 3.2.3.1, Page 3-18, East Ravine Extraction Wells, 4th paragraph	"The East Ravine Extraction Wells will be constructed using up to 12-inch nominal diameter well casing with one or two screened intervals . . . "	This text is inconsistent with the text found in Section 3.2.5.1 which calls for borehole design without a well screen with potential diameter of four inches.	The inconsistencies will be corrected in the 90% Design Submittal. It is anticipated that the extraction wells within the bedrock will be installed with one continuous open interval so that groundwater is extracted from all permeable fractures. If the wells penetrate intervals of poor rock quality, the borehole will be "sleeved" with well casing and/or screen to maintain borehole integrity during operation. If rock quality is so poor that fine-grained materials must be managed in the subsurface, then a conventional filter-packed screen might need to be installed.		Comment resolved pending review of the 90% design.		Comment resolved.	90% BOD Section 3.2.3.
107	DOI-49	Section 3.2.3.1, Page 3-18, East Ravine Extraction Wells, 4th paragraph	"Therefore, the screened intervals of the extraction wells as shown on Table 3.2-3 are preliminary, . . . "	A review of Table 3.2-3 identifies screen length but not the interval, nor does it mention multiple screens to target specific bedrock intervals. Is the word "interval" being used in the text to describe model layer? Also, in what model layers (screen intervals) will each of the East Ravine Extraction wells be set? Please provide some discussion on the hydrogeologic conditions that would merit multiple screens versus a single screen or open borehole.	The word "interval" does not specifically relate to model layers and is simply intended to identify the entire saturated thickness at a given location. Based on the specific capacity of existing wells constructed in the East Ravine area, it is anticipated that the East Ravine extraction wells will be installed to depths that happen to penetrate all model layers such that there is sufficient available drawdown during operation. See response to comment #106 DOI-48 regarding anticipated well construction.		Comment resolved.		Comment resolved.	90% BOD Section 3.2.3.
108	DTSC-29	3.2.3.1/3-18	The groundwater production and radius of influence of the East Ravine Extraction Wells is expected to be small.	Please utilize geophysical logging tools including an acoustic borehole televiewer, heat pulse flow meter, and video log. Conduct evaluation/interpretation of cores (fracture orientation, aperture, density, etc.) and packer testing in the exploratory boreholes to characterize fractures, hydraulic conditions (whether and at what depth fracture flow is occurring), and water quality. In addition, to determine transmissivity with depth, consider drop tests using blank	The design goal for the East Ravine Extraction Wells is to construct wells that will produce adequate flow with sufficient drawdown to maximize hydraulic control. Therefore, the key design criterion will be to have a borehole of sufficient depth to allow for the requisite available drawdown with a pump set in the open borehole. Well design and construction will be an iterative process of drilling and well testing as part of adaptive design. The use of geophysical methods and other kinds	Better understanding flow dynamics in bedrock is desirable and the design document needs to have provisions to utilize advanced techniques to assess fracture flow systems. 				borehole liners such as FLUTe.	of testing is not necessary to accomplish the design goals. A variety of tools, as listed, will be available to evaluate high production zones if determined necessary.					
109	DTSC-30	3.2.3.1 Description. East Ravine Extraction Wells, Page 3-18, and Exhibit 3.2-3	Initial estimates, presented in the 2009 CMS/FS, held that approximately 15 wells, pumping a combined total of up to 10 gpm, would be required to provide hydraulic capture of the area of Cr(VI) in the East Ravine bedrock. However, this design has since been revised to five extraction wells operating at a total nominal flow rate of 5 gpm (maximum of 9 gpm) based on data obtained from the more recent East Ravine groundwater investigations (see Section 2.1.2).	What aspects of the East Ravine investigation provided the basis to conclude that the five East Ravine Extraction Wells will be adequate to “provide hydraulic capture of the Cr(VI) impacted groundwater … in the East Ravine bedrock”? What about the plume to the southern portion of the site which have not been fully characterized? It is not clear why the original estimate of 15 wells at 10 gpm has been revised to 5 at 5 gpm. Clarifying text should be added in this section. Additional East Ravine provisional extraction wells seem appropriate based on the original estimate, inherently difficult remedial clean up posed by bedrock fractures, and difficulty accurately modeling bedrock.	As stated in Section 2.1.2 of the BOD/60% Design Submittal, the East Ravine groundwater investigations have shown that "there is no evidence to indicate any sizable potential for development of groundwater in the bedrock, although locally, small yields may be developed from fractures". In an effort to balance the objectives of maximizing mass capture while minimizing the footprint of the remedial system, four extraction wells were proposed in the East Ravine area. An additional well, ER-6, was proposed at Site H, utilizing existing monitoring well MW-70BR-225, because elevated Cr(VI) groundwater concentrations were detected at this location and a relatively high groundwater extraction rate could be obtained. One provisional well (ER-5) has been identified to accommodate data to be collected in the southern portion of the site (Site K, near MW-72BR). Clarifying text to this effect will be added to Section 3.2.3.1. Up to six future provisional East Ravine Extraction Wells will be added as a contingency measure should additional extraction capacity be needed (see map included in **Attachment D**, at the end of this table). Potential locations for these wells will be selected during a later stage of the 60% BOD response-to-comment process considering both technical criteria and knowledge of sensitive areas.	Resolution dependent upon clarifying text to be added in the 90%. A site walk was conducted on October 28, 2013. PG&E, tribes, stakeholders, and agencies were invited to attend. Potential provisional well locations/ areas were described as areas along the general length of the old trails highway. The length of the road at interest was walked. PG&E should now proceed with its proposed modifications cited in the response to the left.			Comment resolved.	90% BOD Section 3.2.3. O&M Manual Volume 1 Section 2.1.

112	DTSC-32	3.2.3.1 Description. TCS Injection Wells, P.3-18	Results of the modeling effort indicate that the potential for westward flow from the TCS Injection Wells, and the resulting westward expansion of the plume, is sufficiently mitigated by the natural eastward flow gradient and the injection of fresh water at FW-2...	Actual monitoring will need to be conducted to the west to verify the modeling effort. This section should discuss or reference the monitoring that will be conducted to assess anticipated hydraulics and aquifer chemistry. PG&E should consider how best to monitor for potential westward expansion/ containment of the plume. Well installation west of the TCS injectors should be evaluated to ensure an adequate monitoring program is in place.	Agreed that monitoring should be conducted to ensure that the Cr plume is adequately controlled to the west of the TCS injections. Several lines of evidence will be used to evaluate groundwater flow and plume control in this area. First, groundwater elevations will be measured and the hydraulic gradients will be evaluated to see if the model predicted gradients and hydraulic control are realized. Second, analytical data will be collected from monitoring wells to the west of the TCS injections. Monitoring wells MW-10 and MW-38S/D have been specified to the west of the TCS as inner plume compliance wells (Table 2.1-2 of the Sampling and Monitoring Plan, Volume 2 of Appendix L) which are used to ensure that Cr(VI) concentration trends behave within expectations per Compliance DQO-2 (RAO 3) in Section 2.1 of the Sampling and Monitoring Plan. In addition, MW-9, located south of MW-10 and to the west of the TCS, will be added to the monitoring program network as an additional inner plume compliance well. Chromium concentration trends will serve as an indicator of whether the high concentration (several milligram per liter) plume in the vicinity of the	DTSC is considering the use of conservative tracers be added to TCS-1 and TCS-2 injection wells and monitored in western Bat Cave Wash monitoring wells. The 90% design should allow for tracers if other lines of evidence are inconclusive.			Comment resolved.	90% BOD Section 3.2.3. O&M Manual Volume 2 Sections 2.1 and 2.2.3.

			testing, the drawdown measured in the observation wells was negligible."		provisional wells were identified (see comment response #109 DTSC-30) in the event that additional extraction/hydraulic control is needed in the vicinity of the proposed bedrock extraction wells.					
115	DTSC-33	3.2.3.3 Uncertainties and Assumptions, Page 3-20	The TCS Recirculation Loop will be implemented and operated using an adaptive approach, similar to operation of the NTH IRZ system—data will be collected from select monitoring wells, and operations will be modified to optimize the remedy performance.	Due to the adaptive approach described, it would appear that additional provisional wells should be called out in the event they are needed.	Two provisional TWB Extraction Wells (TWB-3 and 4) were identified, along with additional provisional East Ravine Extraction Wells (see response to comment #109 DTSC-30). Provisional TCS Injection Wells were not identified as these wells are designed to accelerate the remedial timeframe by injecting carbon amended water into areas with elevated Cr(VI) concentrations. Operational rates of the TCS recirculation loop need to be controlled in order to prevent western migration of the plume. Additional language will be added to the 90% design discussing the need for flexibility to locate wells in the future as the remedial program evolves. Any modifications would be discussed with stakeholders prior to implementation.	During the Oct 2013 field visit, it was noted that additional/ alternate well locations might be possible north of TWB-3 (provided old roads were repaired and regarded). Also note comment #543 DTSC-152 discussing IRL-6 that might be used as an extractor and noting its location could be adjusted if necessary. Please note the above in the section and note that it provides some flexibility in adapting to uncertainties. Comment resolved pending review of 90% design.			Comment resolved.	90% BOD Sections 3.2.1, 3.2.2, and 3.2.3.
116	DOI-53	Section 3.2.4.1, Page 3-21	"The NTH IRZ contains significant lengths of extracted groundwater, carbon-amended water, and remedy-produced water conveyance pipelines."	It does not appear the CIP would address remedy-produced water conveyance pipelines. Please clarify.	The CIP system is also capable of operating in a closed loop through the main IRZ well backwash headers as depicted on Drawings I-04-02 and I-04-03 in Appendix D. The text of Section 3.2.4.1 will be amended to reflect this operational scenario.		Comment resolved pending review of 90% design.		Comment resolved.	90% BOD Section 3.2.4.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				problematic over the years that the remedy will operate.	while those used as integral components of a remediation system may be removed and re-installed periodically for well or packer maintenance. Packers used in remediation wells serve to isolate screened intervals and facilitate the distribution of varying quantities of carbon amended water to each screened interval individually, but long-term isolation is not a requirement. Therefore packers are ideal for use in remediation wells because there are opportunities to remove and maintain them, as necessary. During use, packer inflation pressures will be monitored by pressure instruments to ensure an adequate seal is maintained during injection operations. See response to comment #232 DTSC-103 for clarification on the use of packers in monitoring wells during the East Ravine investigation.					
133	DTSC-41	Figure 3.1-1	Conceptual Final Groundwater Remedy Cross-Section Locations	Please include iso-concentrations of the plume on the figure.	Plume iso-concentrations can be added to Figure 3.1-1 (and Appendix B Figure 6.4-2) with the consideration that there are variations in concentration vertically. Show the cumulative four-layer plume outline or to just generate four versions of this figure to display the plume distribution in each layer.	Please use the cumulative view on one figure and then use the cross-sections to show vertical distribution. Comment resolved pending review of 90% design.			Comment resolved.	90% BOD Figure 3.1-1 and Appendix B Figure 6.4-2.
134	DTSC-42	Figure 3.1-3	Conceptual Final Groundwater Remedy Cross-Section B-B’	Please provide additional wells north of IRZ-1 to fully address the lateral extent of the plume.	A review of historical data collected at MW-35-060 and MW-35-135, northernmost monitoring wells located adjacent to the proposed location of IRZ-1, indicates that Cr(VI) concentrations have oscillated at these wells but are generally below 32 ppb. The maximum Cr(VI) concentration observed at MW-35-060 was 35.8 ppb in March 2008, and the maximum Cr(VI) concentration observed at MW-35-135 was 37.8 ppb in December 2010. The concentration trends observed at MW-35-060 and MW-35-135 suggest that these wells define the edge of the Cr(VI) plume, and additional remediation wells installed to the north of IRZ-1 will provide negligible value for treatment. In addition, the simulated	The MW-35 cluster does not monitor the deep portion of the aquifer where PG&E’s cross-section B-B’ shows contamination to extend. It is requested that a deep well (e.g., greater than 300 feet bgs.) be installed in the vicinity of MW-35. An additional provisional well location to the north should be cited if this deep well encounters significant contamination. Comment resolved pending review of 90% design.			Comment resolved.	90% BOD Figure 3.1-3.

TABLE I-1

Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					hydraulic capture zone of the northern NTH IRZ wells extends more than 100 feet to the north past IRZ-1 in Layer 2 (see Figure 6.5-10 of Appendix B) and more than 300 feet to the north past IRZ-1 in Layers 3 and 4 (see Figures 6.5-11 and 6.5-12 of Appendix B, respectively). As noted by the DTSC, the MW-35 cluster does not monitor the deep portion of the aquifer. The northern extent of the Cr(VI) plume in the deep portion of the aquifer along the NTH is currently defined by TW-4. Cr(VI) concentrations at this well have consistently been below 32 ppb since 2007. Additional Cr(VI) concentration data, including data from the deep portion of the aquifer, will be collected during installation of IRZ-1 and monitoring wells A and B to further delineate the extent of the plume to the north. Based on the additional information, an additional well to the north of MW-35 may be determined to be necessary. In addition, PG&E proposes to install an additional monitoring well northwest of MW-35 for remedy compliance monitoring (see also response to comment #651 DTSC-199).					
135	FMIT-23	Figure 3.1.3		This conceptual final groundwater remedy cross section depicts the extent of the infrastructure that could be intruding into this culturally sensitive area during the remedy and possibly permanently depending on the well decommissioning processes used. This visually describes a major part of the significant impact to the TCP caused by the proposed remedy.	PG&E has reviewed the locations of four provisional NTH IRZ wells (IRZ-12, IRZ-14, IRZ-22, and IRZ-24) located below the mesas and has determined that these provisional wells could be moved to the east side of National Trails Highway. The proposed new locations/areas for these four wells were included on a map that was made available to the stakeholders, Tribes, and agency representatives who attended the October 28, 2013 site walk, and were also discussed during the November 5 TWG meeting (map is included in **Attachment D**, at the end of this table). In response to clarifications from the Tribes during the December 12, 2013 TWG meeting, PG&E evaluated moving all NTH IRZ wells to the east side of National Trails Highway. The results of the evaluation was presented during the February 11, 2014 TWG meeting prior to the 90%				PG&E evaluated moving all NTH IRZ wells to the east side of National Trails Highway, the results of the evaluation was presented at the February 11, 2014 TWG meeting (map is included in **Attachment D**, at the end of this table). PG&E understand that this comment is resolved.	90% BOD Figure 3.1-3

TABLE I-1

					design (map is included in **Attachment D**, at the end of this table).					
136	DTSC-43	Figure 3.1-4	Conceptual Final Groundwater Remedy Cross-Section C-C'	Please provide additional wells north of TWB-3 to fully address the lateral extent of the plume.	Originally, in the 30% Design Submittal, a well (MID-EX-1) was proposed to the north of TWB-3. However, this well was removed from the 60% Design Submittal due to constructability issues observed in the field: i.e., presence of multiple major gas pipelines, limitations on heavy equipment access, and evidence of significant erosion. In addition, although the intent of the TWB Extraction Wells is to accelerate capture/treatment of the portion of the Cr(VI) plume located immediately downgradient of the TCS, these wells are not intended to provide full capture/treatment. The portions of the Cr(VI) plume that are not within the simulated capture zone (e.g., to the north of TWB-3) are anticipated to pass through the NTH IRZ where they will be treated. The need and location of additional injection and/or extraction wells will be evaluated and considered as operational data is collected and system performance evaluated. This concept will be incorporated into the 90% design.	DTSC is concerned that, based on existing data, the highest chromium contaminant concentrations would be located between the compressor station and the MW-20 bench. Trying to attack the highest contaminant concentrations with this particular loop system seems beneficial. Keep note that IRZ well installation may better suggest where to locate these wells. Therefore a provisional well location/ alternative well location(s) should be based off the results of the IRZ installation and data collection. Can IRL-6 and/or IRL-7 also be utilized as extractors early on to focus on high chromium concentrations? PG&E and DTSC conducted a site walk on October 28, 2013. After viewing the area north of TWB-3, it was decided a well might be able to be cited in that area provided that dirt moving activities be conducted (e.g., repair former road from erosion, flatten/prep. site for drill rig). Therefore, DTSC requests that an additional provisional well be added to this area. Comment resolved pending review of the 90% design.			Comment resolved.	90% BOD Sections 3.2.1, 3.2.2, and 3.2.3.
137	DTSC-44	Figure 3.1-6	Conceptual Final Groundwater Remedy Cross-Section E-E'	Please provide additional wells north of IRL-6 to fully address the lateral extent of the plume.	Future provisional well IRL-7 is proposed to the north of IRL-6. Note that future provisional wells IRL-6 and IRL-7 were proposed as a contingency should monitoring indicate that cleanup is not progressing at the anticipated rate. These wells, located in the current central portion of the Cr(VI) plume, are designated as "late time" remedial wells that are intended to accelerate the remediation process once eastward migration of the Cr(VI) plume has occurred.	PG&E should consider the inclusion of some flexibility in the design document to allow IRL-6 to be moved a couple hundred feet to optimize remedy design based on data to be collected during remedy implementation. Also modify the design document to allow early startup of provisional wells IRL-6 and/or IRL-7 if determined necessary based on monitoring and operational data.			Comment resolved.	90% BOD Section 3.2.2.

					Additional remediation wells were not proposed to the north of IRL-6 due to constructability issues and access/right-of-way limitations associated with construction in the area between I-40 and the BNSF Railroad. The accessibility issues in this area were previously discussed during the January 9, 2012 briefing and project area site walk that was led by representatives of PG&E and attended by members and representatives of the Fort Mojave Indian Tribe and the Hualapai Tribe.	Comment resolved, see also comment #136 DTSC-43.				
Specific Comments – Sections 3.3 through 3.6										
138	DTSC-45	3.3.1 Freshwater Supply Sources, Pages 3-24 and 3-25	Use of an existing well avoids the disturbance and the uncertainty about quantity and quality of supply that would be associated with drilling a new well.	This sentence should be revised as PG&E indicates that additional characterization (and disturbance) of the HNWR-1 area is needed as there is uncertainty regarding the hydrogeology of the area and even some concern with the construction of the well. Additional characterization is to be collected through implementation of the freshwater work plan.	The cited sentence will be deleted as requested.	In light of PG&E's recent Arizona supply well findings expressed on November 4, 2013, DTSC requests that the cited sentence simply be deleted. PG&E now contends that the HNWR-1 well has questionable construction that would affect its operation and maintenance and the location does not appear as desirable geohydrologically when compared to Site B. PG&E has proposed to drill a new well at Site B. Potential disturbances for a California well would likely be similar to those for Arizona wells.			Comment resolved.	90% BOD Section 3.3.1.
139	DTSC-46	3.3.1 Freshwater Supply Sources, Page 3-25	Although geochemical modeling indicates that this arsenic will not migrate far from the injection points and will dissipate within a reasonable period of time after the completion of the remedy, the RWQCB, subject to its invitation for PG&E to seek review by the SWRCB, indicated that	The use of the term "within a reasonable period of time" is subjective. As the RWQCB and, therefore, DTSC did not find this to provide sufficient merit for injection above the MCL, this statement is therefore moot and may or may not be reasonable. It should be replaced with the estimated number of years that it will take for the arsenic to return to pre-injection conditions.	The State Board letter dated November 20, 2013 provides the Board's rationale and conditions for allowing injection of naturally occurring arsenic above MCL without pre-treatment. The letter also states that the arsenic water quality objective must be met within the earlier of 20 years after achieving the RAO for Cr or 20 years after ceasing injection of water containing naturally occurring arsenic above MCL. On this basis, the term "within a reasonable period of time" could be interpreted as "within approximately 20 years".	Comment resolved based on interpretation by the State Board's November 20, 2013 letter. PG&E should, however, revise the sentence to specify "approximately 20 years after injection ceases for the remedy."			Comment resolved.	90% BOD Section 3.3.1.

		Selection of Preferred Source, Page 3-26	injection exhibits high levels of naturally occurring fluoride.	indicated, "Water quality data at the area of injection exhibits elevated high levels of naturally occurring fluoride."						
145	DTSC-50	3.3.2 Evaluation of Freshwater Supply Sources/ Selection of Preferred Source, Page 3-26	It is also likely that the TDS of the water from a high capacity well would be greater than 3,000 mg/L, making it undesirable for injection into the less saline, upper portions of the aquifer at the Topock site.	What are the TDS limits for freshwater injection at the Topock site. Language contained here suggests that discharge limits should be below at least 3,000 mg/L for the upper portion of the aquifer. Discharge limits for all analytes injected into the aquifer are needed.	The cited text refers to possible water quality from a hypothetical well at Moabi Regional Park. It should be noted that HNWR-1 water has a fairly low TDS level of approximately 500 mg/L. As discussed in response to comment #67 DTSC-20, setting discharge limits is not appropriate for the remedy due to the mixing that is necessary in the treatment zone. It is anticipated that as the lower TDS freshwater is injected and mixed with the higher TDS water (greater than 3000 mg/L) from the middle and deeper portions of the receiving water, the resulting TDS in the receiving water will be lower after injection than that before injection of freshwater. Water quality including electrical conductivity (related to TDS) will be monitored in sentinel wells at the injection areas and elsewhere throughout the site during the remedial action.	See response to #67 above. Discharge limits for all analytes injected into the aquifer are needed. DTSC is referring to FW and IRL wells outside the plume boundary and not the IRZ line. Please refer to the existing discharge requirements for IM-3 injections as starting point. PG&E should attempt to protect the low TDS shallow zone during FW and IRL injections. Perhaps high TDS waters can be preferentially injected into lower zones via packer systems or dedicated injection wells.			Discussion between DTSC, DOI, RWQCB, and PG&E is ongoing to resolve this comment. This topic will be carried forward. Resolution of this comment will be included in the 90% design. PG&E will also work on items related to this comment as directed in the Agencies' direction letter dated April 4, 2014.	90% BOD Sections 3.2.2 and 3.3.3 O&M Manual Volume 1 Sections 2.1 and 3.1
146	DOI-63	Exhibit 3.3-1, Page 3-27, 2. Quantity of Water Available	"At the time of this writing, PG&E has conducted a longer-term constant rate extraction test at HNWR-1 . . . "	How long was the extraction pump test run?	This test was planned to be a 96-hour test but it was cancelled at the last minute because Southwest Water needed to postpone the shut down and monitoring of water levels in Topock-2/3, until a later time. PG&E plans to conduct this test as part of the FWIP.		Comment resolved pending review of the 90% design.		Comment resolved.	Not applicable

147	DTSC-51	3.3.2 Evaluation of Freshwater Supply Sources/ Selection of Preferred Source, Exhibit 3.3-1, Page 3-27	While this has negligible effects on the rate of Cr(VI) removal, it could be important if there were some objectionable characteristic in the injected water because it is likely that some of the injected water would be drawn back close to or possibly within Park Moabi by the end of the active remedial action.	The cited sentence is speculative and confusing and should probably be deleted or clarified. It would seem that water sourced from Park Moabi could not be "objectionable" to a well in Park Moabi. What is the basis for this comment? Was fate and transport modeling conducted to form a basis?	The sentence in question will be revised to read: "Although pumping freshwater from Park Moabi would have negligible effects on the rate of Cr(VI) remediation, there are two potential problems: 1) pumping more than about 60 gpm from a well or wells at Park Moabi poses a risk of upconing of high TDS water from depth and degrading water quality in the existing wells and 2) if high TDS water were pumped from Park Moabi and injected into the freshwater wells, it could be drawn back to the park over the course of the remedial action and degrade the water quality in the existing wells. (see Appendix J for further details)"	Comment resolved.			Comment resolved.	90% BOD Exhibit 3.3-1.
148	DTSC-52	3.3.2 Evaluation of Freshwater Supply Sources/ Selection of Preferred Source, Exhibit 3.3-1, Page 3-27	At the time of this writing, PG&E has conducted a longer-term constant-rate extraction test at HNWR-1 well to confirm the well capacity to meet the need of the remedy and other needs; results from this test will be presented when available.	Please include the date of the long term extraction test.	The long term extraction test was cancelled on short notice shortly after the 60% BOD was submitted because Southwest Water needed to postpone the shut down and monitoring of water levels in Topock-2/3, until a later time. PG&E plans to conduct this test as part of the FWIP, and summarized/ referenced in the 90% BOD.	DTSC concurs that the results from this test will need to be presented or summarized and referenced in the 90% BOD.			Comment resolved.	90% BOD Exhibit 3.3-1.
149	DOI-64	Exhibit 3.3-1, Page 3-29, 4. Implement-ability Considerations	"All new conditioning facilities or an arsenic treatment facility will require electricity and strong chemicals . . . "	What chemicals would be used that are classified as "strong"?	Strong chemicals would include oxidizing agent (e.g., calcium hypochlorite) and acids (e.g., sulfuric or hydrochloric acid). For arsenic/fluoride removal, a caustic (e.g., sodium hydroxide) would also be used. Text will be included in the 90% BOD to reflect this response.		Comment resolved pending review of 90% design. 		Page 3-31	Actions for Potential Problem – Well yield declines below the minimum required for optimal remedy operation	action. It is presumed that either over-drilling of the current HNWR-1 well site or re-drilling adjacent to the current site are both possible considerations for well replacement?	replacing wells that are no longer performing as design. In the case of HNWR-1, the screen is set inside the well casing and not welded or otherwise attached, so it could not be easily removed for over-drilling. If the screen couldn't be removed, it would likely be necessary to abandon HNWR-1 and drill a replacement well nearby.					
151	DTSC-53	3.3.2 Evaluation of Freshwater Supply Sources/ Selection of Preferred Source, Exhibit 3.3-2, Page 3-31		Suggest adding increasing river bank extraction to the Possible Operational Actions column on this table.	Increasing river bank extraction results in increased velocity across the IRZ line and across the floodplain. Increased groundwater flow velocity can potentially result in incomplete treatment of chromium in the IRZ and insufficient time for byproducts to dissipate between the IRZ and the river bank wells. This option will be added to the table, with the caveat that it could only be used to offset a marginal reduction in freshwater supply. The nominal aggregate riverbank well extraction rate of 150 gpm was the ideal rate for the remedial system design based on the groundwater flow and solute transport modeling. Sensitivity analyses conducted at a rate of 300 gpm riverbank extraction (Appendix B Section 10.3) indicates that small fingers of Cr(VI) progress past the NTH IRZ during the 18 month NTH IRZ off-cycle, although they are attenuated during the next 6-month NTH IRZ on-cycle. Additional steps such as increase NTH IRZ operational rates, activation of provisional NTH IRZ wells, reduction in the NTH IRZ off-cycle duration, or an increase in TOC injection concentrations can also be used to address potential Cr(VI) breakthrough along the NTH IRZ. Due to the limited amount of hydrogeologic data in the northern part of the floodplain where the aquifer thickens, flexibility was added into the riverbank extraction well design to allow for greater total extraction rates than the model currently projects would be optimal. An aggregate riverbank extraction rate of 500 gpm was estimated as a	Table 3.2-2 indicates that nominal river back extraction rates are 150 gpm. Maximum rates are stated to be a combined 500 gpm. This also relates to comment #839 DTSC-252. Is 500 gpm an excessive groundwater flow velocity? Is 500 gpm a realistic rate? If not, what is realistic? DTSC agrees with PG&E with respect to the risk associated with high extraction rates. This is one of the reasons that DTSC has requested additional contingency river bank extraction wells to manage possible breakthroughs or excess by-product generation. DTSC also agrees that extraction velocity adjustments would be an essential contingency measure for the remedy as well. Comment resolved.			Comment resolved.	90% BOD Exhibit 3.3-2. O&M Manual Volume 3 Table 2.3-1.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					reasonable maximum for the riverbank extraction wells in order to accommodate the potential for higher than expected transmissivity along the river bank. A model run was not conducted at a 500 gpm riverbank extraction rate. If the transmissivity along the river bank is higher than expected, the hydraulic influence of the river bank wells on the IRZ would be lessened and pumping rates from the river bank wells would need to be increased above the rates currently projected by the model to maintain hydraulic control. The groundwater flow and solute transport model will be updated based on data obtained during well installation and operation which will allow for the riverbank extraction well pumping rates to be refined.					
152	DTSC-54	Exhibit 3.3-2, Contingency Matrix for potential problems with HNWR-1	Well yield declines below the minimum required for optimal remedy operation Third bullet: Establish institutional control to prevent excessive drawdown from competing water users.	Possible contingency measures did not include the tie in of Topock 2 and 3 for added quantity of known quality water. Instead of seeking new well immediately, PG&E should design the system to allow Topock 2 and 3 water to be blended with HNWR-1. DTSC would not have jurisdiction in Arizona to limit or restrict water usage from users outside of PG&E's area of contamination. Restrictions may be within the jurisdiction of the Federal land owner or under jurisdiction of the Arizona state agencies. Furthermore, as a condition of approval, DTSC specified in the certified EIR that PG&E's remedy cannot interfere with existing water usage.	As discussed in response to comment #168 DTSC-63, PG&E will separate the freshwater supply and storage for the remedy and the Compressor Station. Topock-2/3 wells will continue to supply water for Compressor Station use via the existing 6-inch pipeline. Because of this separation of freshwater storage, the tie-in of Topock-2 and 3 wells will be eliminated in the 90% design. A tee and a valve will be added to the new 10,000-gallon freshwater storage tank for the remedy to allow for the flexibility of adding water from the TCS storage tanks as needed. Comment noted. As directed, PG&E fully intends to demonstrate compliance with EIR mitigation measure WATER-1, which is to proactively identify and mitigate potentially significant effects on local groundwater levels associated with proposed freshwater extraction wells. In addition, as directed, PG&E will also implement institutional controls (ICs) to protect the integrity and the effectiveness of the remedy in the short-term and long-term. To this end, PG&E is evaluating the need for and/or the scope of an IC at or near the HNWR-1 well to ensure adequate quantity of fresh water for	Okay.			Comment resolved.	90% BOD Figures 3.3-1, 3.5-1, and 3.5-3.

					remedy effectiveness (see Note 3 on Figure 5.1-1, page 211 of the PDF). In the event an IC is determined to be needed, PG&E will work with the appropriate agencies, land manager, and land owner to obtain the necessary IC.					
153	DTSC-55	Exhibit 3.3-2, Quality of water in freshwater well declines over time		DTSC has required PG&E to design the water treatment system so that it would be a contingency in event water quality would impact PG&E's ability to continue operation of the remedy. Construct and operate the water treatment system should be listed as a contingency.	PG&E complied with DTSC's direction in its December 31, 2012 letter and included a freshwater pre-injection treatment system in the 60% design. Therefore, the water treatment system was not a contingency in the 60% BOD. As discussed in response to comment #21 DTSC-2, PG&E will include a freshwater pre-injection treatment for arsenic only in the 90% and final designs as a contingency.	Comment resolved pending review of the 90%. Please ensure freshwater pre-injection treatment for arsenic is listed in Exhibit 3.3-2.			Comment resolved.	O&M Manual Volume 3.
154	DOI-66	Section 3.3.2, Page 3-32	"Most of the water produced by HNWR-1 is expected to come from the Colorado River . . . "	Several concerns were identified in Exhibit 3.3-1 regarding use of the Colorado River as a source of fresh water. These included susceptibility to future contamination, and the possibility of the presence and potential need to address emerging contaminants. Further describe how these concerns do not carry over to the use of wells located near Sacramento Wash/Topock Marsh.	Wells near the river do not pump river water directly. Groundwater travel time from the river to a well located at the distance of HNWR-1 well is likely many months to a few years. Depending on the transport properties some contaminants move much slower than the water. All contaminants are subject to dispersion and dilution between the river and a well. So if a contaminant is found in the river, there is ample time to stop pumping or institute additional monitoring before it shows up in a well near the river, and the concentration of the contaminant in the well is likely to be considerably less than in the river. Discussion of this will be made clearer in the text.		Comment resolved pending review of text addition.		Comment resolved.	90% BOD Section 3.3.2. O&M Manual Volume 2 Section 5.2.2.

		Assessment, Page 3-32, Paragraph 1 and Exhibit 3.3-3	Arizona and encompasses the Topock Marina area (see Exhibit 3.3-3). As shown in Exhibit 3.3-3, the majority of the property in this radius is undeveloped…	MTS-2, Sanders, Smith, PGE-9N, PGE-9S, New Topock Marina well, and monitoring wells MW-54 cluster, MW-55 cluster, and MW-56 cluster. Please also consider including Serrano and GSRV-2 especially if Site B were to be utilized instead of HNWR-1. Please clarify if any of these wells have been appropriately decommissioned and no longer exist at the surface. The source water assessment should focus on the developed areas that may have water impacts associated with them. Some research into the various waste ponds at the EPNG Mohave Compressor Station should be conducted and summarized in this section. Groundwater monitoring parameters should be selected and included in remedy monitoring that would be related to or unique to EPNG operations. Installation of monitoring wells associated with the waste ponds may be prudent. Summary of the monitoring well data related to former USTs at Topock Marina should be cited. Former Topock shops/gas stations (e.g., old garages) should be considered and appropriate monitoring parameters and monitoring wells should be selected and incorporated into the remedy.	Hand drawn sketches on some of the well records show an abandoned well between Topock 2 and 3. As far as PG&E knows, all of the other wells listed are still in existence and the figure will be modified to show them. Based on information in the ADEQ Topock Groundwater Study report, the ponds at the Mohave Topock Station were constructed in 2005 and are permitted units with leak detection systems. The ponds receive non-contact cooling water that was formerly directly discharged to the river. There is no reason to suspect that these recently constructed, RCRA permitted facilities receiving non-hazardous cooling water should represent a threat to water quality or require additional monitoring to be installed by PG&E. PG&E will request information from ADEQ regarding the former USTs at the Topock Marina. The UST site was closed by ADEQ, so it is not anticipated that it would continue to be a threat to groundwater quality in the HNWR well, which is over 2,000 feet away. The MW-55 cluster is located less than 100 feet from the former UST and directly between the UST and HNWR-1, so it should provide an adequate monitoring location to address this concern, or the concern about unknown historic sources in the Topock area. Additional information obtained will be summarized in the 90% design.					
157	DOI-68	Section 3.3.2, Page 3-32	"This dump consists of small area of rusty cans and other metal debris scattered on the land surface. . . . It is located adjacent to a flat area that may have housed a military or work crew	Is there any information about the dump area? Has any testing been done? Could this site represent a potential source for the elevated arsenic found in HNWR-1?	There is no information about the dump area and it does not appear to PG&E or DTSC to be a threat to groundwater. The text will be revised as follows (inserted verbiage shown in underline typeface, deleted verbiage shown in ~~strikethrough~~ typeface): "This area ~~dump~~ consists of ~~small area of~~ rusty cans and other metal debris scattered on the land surface…"		Comment resolved. 			encampment.”							
158	DTSC-57	3.3.2 Evaluation of Freshwater Supply Sources/ Selection of Preferred Source, Source Water Assessment, Page 3-32	Also within this radius is a former dump area which DTSC expressed concern about.	As existing DTSC representatives had no knowledge of the former dump site cited, the reference to DTSC should be deleted. After reviewing this item, DTSC visited the cited area in Arizona and it did not appear to be a significant threat to groundwater resources (Does PG&E believe it is a threat?). It is uncertain why it is being discussed in the document. DTSC is interested in any historical knowledge PG&E may have of this area. Please clarify.	The cited text and the rest of the paragraph will be deleted. The following text will be inserted in its place: “A question was raised in a public meeting about a rumored former “Topock Dump” that reportedly contained trash from local residents. PG&E was not aware of any such former dump. A member of the FMIT who has lived in the area for many years indicated that the area of debris and can scatter was the only “dump” that he knew of in the area and speculated that it might have been trash left from a railroad work camp. PG&E agrees that this debris does not appear to represent a threat to groundwater.” Because this area does not appear to be a dump, Exhibit 3.3-3 will be revised to describe it as a “debris area” rather than a dump. In addition, the word “dump” at the end of the next paragraph will be replaced with “EPNG Mojave Topock Compressor Station”.	Comment resolved pending review of replacement language in 90% BOD.			Comment resolved.	90% BOD Section 3.3.2; original text retained (but revised) to reconcile with RTC#157 DOI-68
159	DTSC-58	3.3.2 Evaluation of Freshwater Supply Sources/ Selection of Preferred Source, Source Water Assessment, Page 3-32, Paragraph 2 and 3.	Most of the water produced by HNWR-1 is expected to come from the Colorado River (via its partial diversion into Topock Marsh), although some will be derived from groundwater flowing down from the Sacramento Valley to the east (CH2M HILL 2012d). There are currently no monitoring wells in Sacramento Wash. The property	Include the basis for this statement regarding most of the groundwater coming from the river. What do stable isotope data from HNWR-1 tell us? Was modeling utilized to arrive at this conclusion? Is there enough (any) hydraulic conductivity data to make this statement? A simple assessment of the pictured 5-year radius of influence in Exhibit 3.3-3 suggests that half to a third of the groundwater might come from the east/northeast and not be sourced from the river (especially if you consider three dimensional flow). Geologic channels in the Sacramento Wash could alter this simple assessment. Please revise the statement to best relate to site conditions. Please also revise the monitoring well installation conclusion (See DTSC comment on 3.3.2 Evaluation of Freshwater Supply Sources/Selection of Preferred Source, Source Water Assessment, Page 3-32 Paragraph 1	The first sentence will be revised to read “Water produced by HNWR-1 is expected to be a mix of water recharged from the Colorado River and groundwater flowing down from the Sacramento Valley to the east (CH2M HILL 2012d).” Considering the close proximity of the well to the river and the larger volume of water available from river recharge, it is reasonable to assume that a large fraction of the water would come from the river, but there is currently insufficient data about the aquifer in the vicinity of HNWR-1 to quantify the relative fractions of water that would come from the river vs. from Sacramento Wash recharge. To be consistent, the first sentence in the next paragraph will also be revised as follows: “…~~the majority~~ a component of the water produced from HNWR-1 should originate from the Colorado River …”. Based on three available samples of	Comment resolved.			Comment resolved.	90% BOD Section 3.3.2. O&M Manual Volume 2 Section 5.2.2.

			upstream in Sacramento Wash is undeveloped for miles… Considering the lack of existing contaminant sources in the Sacramento Valley (Exhibit 3.3-3), the installation of monitoring wells in Sacramento Wash upstream of HNWR-1 for source water protection is not considered warranted…..	and Exhibit 3.3-3 above).	stable isotopes, the average concentrations of oxygen18 and deuterium in HNWR-1 are -10.2 per mil and -75.4 per mil respectively. This water plots in near the center of the “Isotopic Non-Industrial Signature” group shown on Figure 5-24a in Volume 2 of the RFI, and indicates an intermediate signature between the river and another signature represented by the ground water coming down Sacramento Wash. If HNWR-1 is pumped continuously, the isotopic signature could begin to shift as more river water is drawn into the well. This effect has been noted in response to IM-3 pumping, which has resulted in an increasing percentage of river water with time in wells near PE-1 (see Figure 6-21 in RFI Volume 2). See response to comment #160 DTSC-59 regarding the need for monitoring wells around the freshwater well.					
160	DTSC-59	Section 3.3.2, p.3-32, 2nd paragraph	Considering the lack of existing contaminant sources in the Sacramento Valley (Exhibit 3.3-3), the installation of monitoring wells in Sacramento Wash upstream of HNWR-1 for source water protection is not considered warranted.	DTSC disagrees with PG&E’s conclusion. DTSC believes that it would be prudent to understand the incoming water quality up gradient of the freshwater well over time to ensure that quality will meet the injection objective prior to detection at the production well. Advance knowledge will allow proper planning before issue arises at the well. Furthermore, because the area of draw down encompasses many potential users, it is also necessary to monitor possible changes in water quality conditions prior to impacts of nearby wells. DTSC requests that PG&E provide a robust monitoring system up gradient and down gradient of the fresh water well.	Even in areas where groundwater is a primary source of drinking water and potential contaminant sources are numerous (such as Phoenix, Tucson, and the San Fernando Valley) installation of monitor wells for an early warning system around a new production well is not a typical requirement. CH2M HILL is unaware of any municipality that is required to provide this level of monitoring for wells that are remote from any known sources of contaminants and directly serve water to their customers. In addition, the predictive value of data from a monitoring well at a distance from a pumping well is limited. In a radial converging flow field around a pumping well, any single monitor well represents only a small fraction of the total circle from which the flow converge at the pumping well. The concentration in a continuously pumped well represents an integrated sample of water coming inward to the well from all directions. Due to dilution in the radial flow field, the concentration in the pumped well could be much less than in a	In an effort to minimize additional well installations, it is proposed that existing wells be utilized to provide groundwater data that may provide value for source water protection. As the only known potential source of anthropogenic contamination in the vicinity would be from the Mohave Topock Station waste ponds, periodic analysis of Topock 2/3 well data should be included in the remedy operation and added to the 90% design. Wells Topock 2/3 are located between HNWR-1 and the Mohave Topock Station and capture water from a significant distance as compared to a dedicated monitoring well.			Comment resolved. PG&E will include periodic sampling of Topock-2/3 wells in the 90% assuming that the well owner will allow sampling of the wells.	90% BOD Section 3.3.2 (3rd paragraph from the bottom, last sentence). O&M Manual Volume 2, Section 5.2.2 (5th full paragraph, last sentence) PG&E will provide Topock-2 and 3 water quality data collected for water supply purposes as PG&E receives the information from Southwest Water.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					monitoring well located even a few hundred feet away. For a monitoring network to be able to accurately predict future concentrations in a pumped well, monitoring wells would need to be spaced sufficiently close so that they could begin to represent the average water quality coming into the pumped well from all directions. The number of wells required to accomplish this goes up geometrically with the distance from the pumped well. Using the equations provided for travel time to the well in Section 3.3.2, a robust monitoring network located far enough from the pumped well to provide reasonable early warning, (say a years' travel time), would need to monitor a circumference of about 7,500 feet. So even with relatively wide spacing of 1,000 feet between wells, this would require 7 new monitor wells. To dedicate this many monitoring wells for the purpose of monitoring a supply well that does not serve customers directly and is located in a relatively undeveloped area seems excessive and unwarranted, particularly in light of the need to control the total well count at the Topock site.					
161	DTSC-60	3.3.2 Evaluation of Freshwater Supply Sources/ Selection of Preferred Source, Source Water Assessment, Page 3-32, Paragraph 3.	The travel time of constituents in river water to a nearby well may take many years, depending on their mobility (CH2M HILL 2012d); therefore, river water quality is a good indicator and should be used for source water protection of HNWR-1.	It is requested that existing well locations (e.g., MW-54/55/56) be considered for periodic monitoring of river constituents/ source protection. Also clarify that the freshwater supply well will be periodically monitored for potential river contaminants.	The primary monitoring strategy for detecting contaminants in the river is to rely on samples of river water. Samples of wells near the river provide at best a diluted sample of what is in the river. Recharge to HNWR-1 is much more likely to come from the nearby Topock Marsh than from the main river channel, where MW-54 and MW-56 wells are located. There is continuous interchange of water in the marsh with the river, so there is no reason to expect a contaminant in the river would not be present in the marsh, or vice-versa. The MW-54 and 56 well clusters are outside the projected 5 year travel time from HNWR-1, so monitoring at these locations is of questionable value to predicting water quality changes in HNWR-1. The MW-55 cluster is between the Topock Marina and HNWR-1, PG&E agrees that	Comment resolved.			Comment resolved.	O&M Manual Volume 2 Section 5.2.2 (last paragraph) and Table 5.2-5.

					monitoring at this location could have some value in detecting contaminants originating from any sources in the small developed area around the marina and it will be included in the monitoring program. The proposed monitoring program for freshwater supply well(s) is provided in Exhibit 5.2-2 of the O&M Manual, Volume 2 (page 5-4) and includes constituents such as pesticides and herbicides that are more commonly found in surface water than in groundwater and may be present in the river.					
162	DTSC-61	3.3.2 Evaluation of Freshwater Supply Sources/ Selection of Preferred Source, Source Water Assessment, Page 3-32, Paragraph 3.	The river in the immediate vicinity of the site and downstream is monitored by the Metropolitan Water District of Southern California (MWD).	Please include the MWD monitoring stations on a figure so all will know where sampling is conducted with respect to the PG&E site and that it is appropriate.	PG&E received permission from MWD to include its monitoring stations on a figure in the Topock design report. Therefore, PG&E will include MWD monitoring stations in Figure 2.4-7 (Surface Water Monitoring Locations) in the 90% BOD.	Okay			Comment resolved.	90% BOD Figure 2.4-7.
163	CRB-1	Section 3.3.2, p. 3-37	*"most of the water produced by HNWR-1 is expected to come from the Colorado River (via its partial diversion into Topock Marsh), although some will be derived from groundwater flowing down from the Sacramento Valley to the east"*	The Board expects any new well to be drilled in compliance with state and federal laws. Although the draft BOD report indicates PG&E's intention to maximize re-injection of treated remedy-produced water to the groundwater basin and minimize consumptive use for the remediation project, any consumptive use at the project should be documented. The Board requests that PG&E document water usage information that includes the amount of water diverted and re-injected to groundwater at the remediation project site.	PG&E plans to document groundwater usage and has equipped extraction and injection wells with flowmeters and totalizers as shown on the P&ID drawings. Under the terms of its water right, PG&E will continue to report quantities of water pumped and injected during the operation of the remedy to the City of Needles, as administering agency for the Lower Colorado River Water Supply Project (LCWSP) water for non-federal entities (FEIR at page 4.12-1).					90% BOD Appendix D Drawings (e.g., E-02-01, I-01-01, M-01-01, etc.)

167	DOI-71	Exhibit 3.3-4, Page 3-35	Footnote b	The information in Footnote b regarding the freshwater injection wells seems inappropriate. Suggest deleting the footnote.	Footnote b is useful because it provides a cross-reference to the well design parameter tables in Section 3. Therefore, it is suggested that footnote b be retained and revised as follows: "See Table 3.3-1 for design flows related to Freshwater Injection Wells (FWs) and Table 3.2-2 for design flows related to Inner Recirculation Wells (IRLs)."		Comment resolved.		Comment resolved.	90% BOD Exhibit 3.3-4.
168	DTSC-63	Section 3.3.3, Design Basis for Freshwater Supply System, p.3-35	To accommodate potential future operational changes associated with the remedy while maximizing the use of existing facilities, the design incorporates the current freshwater supply system for the Compressor Station. The	Project demand should be first priority for the design and future operation of the freshwater source. PG&E should separate station operational needs from remedy. It is DTSC's expectation that the use of all infrastructure designed and constructed under DTSC's approval would be prioritized for remedy first and not PG&E's operational needs. Furthermore, DTSC has not evaluated, in the Certified EIR, the economic impacts to water purveyor by allowing PG&E to use the same fresh water source for operational needs.	The first priority for the freshwater stored in or flow from the existing storage tanks is fire protection for the Compressor Station and current water need at the Station, and that priority cannot be changed. To ensure first priority for remedy use and after further evaluation of the additional controls, instrumentation, and tank upgrades needed to be installed in the existing tanks in order to harmonize various demand for freshwater, PG&E will separate the freshwater supply storage for the remedy and the Compressor Station. A separate and smaller tank (10,000 gallons) will be installed inside the Compressor Station for remedy use only and will be supplied by the new freshwater	Comment resolved pending review of 90% design. Since this is a new change from the 60% BOD, PG&E should keep the agencies, Tribes, and other stakeholders informed of this proposal before the 90% BOD submittal.			Comment resolved.	90% BOD Figures 3.3-1, 3.5-1, and 3.5-3. PG&E discussed the design change related to the separation of freshwater storage and the location of the new 10,000-gallon remedy freshwater water storage tank, at the June 18, 2014 TWG meeting and the July 16, 2014 CWG meeting.

			compressor Station's current water need (approximately 110 gpm) is served by Topock-2 and -3 supply wells in Arizona; the fresh water is conveyed via a pipe crossing the Colorado River on the arch bridge.		supply source from Arizona (pending completion of the Alternative Freshwater Source Evaluation). Note that Topock-2/3 wells will continue to supply water for Compressor Station use via the existing 6-inch pipeline. The new 10,000-gallon tank is different from the proposed conditioned water storage tank and will be located near the planned Remedy-produced water conditioning plant (see proposed layout and tank specification in the technical memorandum titled "Addendum to the Freshwater Pre-injection Treatment System Design Basis", included in **Attachment F** at the end of this table). As for freshwater supply piping, PG&E will retain the existing 6-inch line to supply the Compressor Station.					
169	DOI-72	Section 3.3.3.2, Page 3-36	"Storage of fresh water is required to meet the flow demands to injection wells during extended supply well(s) shutdown and outage . . . "	How long of a shutdown can the system endure and meet flow demands before storage capacity is exhausted?	The existing freshwater storage capacity is 420,000 gallons. Per Exhibit 3.3-4, the injection flow for IRZ/FW wells ranges from 150 to 900 gpm, and the Compressor Station flow is 110 gpm, for a combined total of 260 to 1,010 gpm. At this combined flow range, the supply well(s) could be shut down for 7 hours to almost 27 hours before the storage capacity is exhausted. Note that if needed, injection flows can also be temporarily reduced to allow injection to continue for a longer time.		Comment resolved pending review of SOPs in 90% design.		Comment resolved.	This RTC is no longer applicable with the separation of freshwater storage between TCS and groundwater remedy. This essentially decouple the fire protection supply from freshwater injection. TCS will continue to supply fire protection water for groundwater remedy facilities. The new 10,000 gallon Remedy freshwater storage tank will supply the freshwater injection well FW-2. At the nominal and maximum flowrates of 50 and 100 gpm, FW-2 can be operated for 2-3 hrs with the freshwater supply well down. Note that if needed, injection flows can also be temporarily reduced to allow injection to continue for a longer time. Since the upland wells (FW-1 and certain IRL wells) receive freshwater directly from the supply well, they will not be operated if the supply well is down.

			River into California, the water pipeline . . . "	text.						
171	DOI-74	Section 3.3.3.2, Page 3-36	"An analysis of the fire protection system hydraulic performed at the 60% design stage suggested that there is adequate storage capacity to meet fire flow storage requirements that can be shared with the remedy, as long as there is sufficient supply . . . "	How long can injection wells operate during a shutdown before they are required to be shutdown to ensure ample water for fire protection?	The existing freshwater storage capacity is 420,000 gallons. Per PG&E's insurance company, the required fire flow for TCS is 900 gpm and duration is 60 minutes, which results in a total of 54,000 gallons. See also response to comment #428 FMIT-124 below for fire flow requirements for remedy facilities. If the storage tanks are completely full and the freshwater supply well(s) are down, the injection wells can be operated for 6 to 11 hours and still ensure ample water for fire protection for both TCS and remedy facilities. If a certain minimum level must be maintained in the storage tanks, the duration could be less (the control strategy will be included in 90% design). Note that if needed, injection flows can also be temporarily reduced to allow injection to continue for a longer time.		Comment resolved pending review of SOPs in 90% design.		Comment resolved.	This RTC is no longer applicable with the separation of freshwater storage between TCS and groundwater remedy. This essentially decouple the fire protection supply from freshwater injection. TCS will continue to supply fire protection water for groundwater remedy facilities. The new 10,000 gallon Remedy freshwater storage tank will supply the freshwater injection well FW-2. At the nominal and maximum flowrates of 50 and 100 gpm, FW-2 can be operated for 2-3 hrs with the freshwater supply well down. Note that if needed, injection flows can also be temporarily reduced to allow injection to continue for a longer time. Since the upland wells (FW-1 and certain IRL wells) receive freshwater directly from the supply well, they will not be operated if the supply well is down.
172	DTSC-64	3.3.3.1 Freshwater Supply Piping Network, Page 3-36, Paragraph 2 and 3.		For clarity, please indicate if the existing pipeline from Topock 2-3 will be removed along any of its existing length.	The entire length of the existing pipeline carrying water from Topock-2/3 is included in the 60% design. Final configuration of the pipeline including any modifications for remedy use will be included in the 90% design submittal.	Comment resolved pending review of the 90% BOD.			Comment resolved.	At this 90% design stage, the existing 6-inch freshwater pipeline from Topock-2 and 3 to TCS storage tanks will remain. See 90% BOD Exhibit 3.3-1, Evaluation Criteria #2, 3rd paragraph for additional details.
173	DTSC-65	3.3.3.1 Freshwater Supply Piping Network, Page 3-36, Paragraph 4.		Indicate if the freshwater piping, other buried piping, or other remedy components will require cathodic protection for protection against corrosive soils. Is so, please discuss and include the design. Suggest indicating the composition of the piping in these sections (believe it's all plastic underground after review of Appendix L, Volume 1, Section 5).	At the 60% design stage, the material of construction for belowground water pipes is plastic (HDPE), and for aboveground water pipes is steel (Schedule 40 steel with AWWA C205 cement mortar lining) or plastic (HDPE or CPVC). Steel pipe will have an exterior coating to prevent external corrosion. Based upon this design approach, no cathodic protection is required.	Okay, pending final material specification, including the composition of the exterior coating for the pipes.			Comment resolved.	90% BOD Exhibit 3.3-4 (Item: Water Pipe).
174	DTSC-66	3.3.3.2 Freshwater	…sharing of existing	It is not clear why this statement is needed. From a supply standpoint,	This statement will be deleted as requested.	Okay.			Comment resolved.	90% BOD Section 3.3.3.

179	DOI-76	Section 3.3.3.3, Page 3-38, Process Description		Please add a discussion of solids management (expected quantities, characteristics, handling, and disposition) to the section. Also, add information regarding solids management to Exhibits 3.3-5 and 3.3-6.	A discussion of solids management will be added to this section in the 90% BOD. As stated in response to comment #176 DTSC-67, Section 3.3.3.3 text in the 90% BOD will be revised to reflect an arsenic only treatment design as a contingency.		Resolved pending review of the 90% design.		Comment resolved.	90% BOD Section 3.3.3.4, last paragraph, last sentence. O&M Manual Volume 3, Appendix B, Section 5.2 (page 5, Wastewater and Solid Waste Generation).
180	DOI-77	Section 3.3.3.3, Page 3-38, Process Description	"This information will provide further clarification on the waste quantities and qualities . . . "	The chance of using the option to reinject regeneration wastewater into the IRZ seems remote, since it will contain elevated arsenic, fluoride, and salts relative to the untreated freshwater. Suggest deleting this option.	As directed by DTSC, PG&E will design an arsenic only freshwater pre-injection treatment system and this will be included in the 90% design as a contingency. Based on bench scale testing, PG&E proposes granular ferric hydroxide (GFH) as the adsorption media. This media is disposable and does not require regeneration. The cited text will be revised as follows in the 90% BOD: "<u>The majority (approx. 95%) of the backwash water generated will be recycled in the freshwater pre-injection treatment system leaving only about five percent of the backwash stream needing to be managed (this stream is not expected to have elevated As concentrations). The management options for backwash water include reuse in the cooling towers, discharge to the evaporation ponds, and/or truck to off-site permitted disposal facilities.</u>"		Comment resolved.		Comment resolved.	90% BOD Exhibit 3.4-3 (Footnote).
181	DTSC-70	3.3.3.3/3-38	Process Description	The proposed use of wastewater in the cooling tower or reinjection in the in situ reactive zone wells may present challenges in obtaining the quantity and quality diverted. Please provide specific water quality parameters required and viability for the proposed reuse of each said reuse.	Regarding water quality parameters required for reuse of wastewater in the cooling towers, NALCO (PG&E's current contractor for cooling tower chemistry) will review and sign off on any influent water prior to its use in the cooling towers. The Topock remediation team has and will continue to engage NALCO in the proposed reuse of conditioned remedy-produced water in the TCS cooling towers. At this time, this reuse option remains viable and will be carried forward into the 90% design. Regarding water quality parameters required for reinjection into the IRZ wells, PG&E understands that the comment pertains to requirements for protection of the IRZ wells from fouling. To that end, PG&E prepared a technical memorandum titled "Summary of IRZ Well Fouling at	DTSC understands that the water quality acceptable for use at the cooling towers rests solely upon PG&E and to some extent the RWQCB for the discharge water to the existing ponds. DTSC's objective is to ensure the protection of the water basin receiving the reused wastewater and that PG&E is operating in a manner that would safeguard the future use of the beneficial use aquifer. Although DTSC remains cautious due to injection well fouling issues experienced at Hinkley. DTSC will, however, withhold any further comments based on PG&E's assurance that they have thorough understanding of the chemistry associated with injection well design as			Comment resolved. 					Hinkley as it Relates to Re-Injection of Remedy Produced Water into IRZ Injection Wells at Topock" (included in **Attachment P** at the end of this RTC table). This technical memorandum summarizes IRZ well fouling experience at Hinkley and confirms that based on operational information collected to date at Hinkley, the effluent water quality requirements specified for conditioned remedy produced water at Topock are adequate and are protective against fouling of IRZ wells (see Exhibit 3.4-5 of the 60% BOD). This will be confirmed during remedy operation by the proposed sampling program for the influent and effluent of the conditioning system (see Exhibit 5.3-2 of O&M Manual Volume 2, Sampling and Monitoring Program). With the proposed protections, reinjection of conditioned remedy-produced water into the IRZ wells continues to remain viable and will be carried forward into the 90% design.	well as pending complete review of the compliance monitoring plan to be submitted with the 90% design.				
182	DOI-78	Exhibit 3.3-5, Page 3-39		From the Compressor Station Freshwater Storage Tanks, what percent of the water will be used for Compressor Station Use and what percent of the water will be directed to the pre-treatment system?	See response to comment #168 DTSC-63. Exhibit 3.3-5 will be revised to separate the freshwater supply storage for the remedy and the Compressor Station.		Resolved pending review of the 90% design.		Comment resolved.	90% BOD Exhibit 3.3-4 (see Freshwater Storage Capacity).
183	DTSC-71	Exhibit 3.3-5	To IRZ Wells from Backwash Tanks	Under what circumstance and chemical conditions can the backwash water be used in the IRZ wells? Although the remedy is operating under the CERCLA exemption from Waste Discharge Requirements, DOI as the administrating agency of the exemption must understand the substantive requirements for injecting the waste water stream into the ground. DTSC recommends PG&E and DOI to consult with the RWQCB to identify and include in the report. Alternatively, PG&E should consider removing injection of backwash water into the IRZ as a waste water management option.	Exhibit 3.3-5 will be revised to reflect an arsenic only pre-injection treatment system. The arsenic removal process is highly efficient enabling a high recycling rate (about 95%) of the backwash water, therefore, the volume of wastewater needing to be managed will be minimal. This volume of wastewater can be accommodated using management options such as cooling towers, TCS evaporation ponds and/or offsite permitted facilities. Therefore, the option of injecting backwash water (from freshwater pre-injection treatment) into the IRZ will not be necessary and therefore, will be removed.	Comment resolved pending review of the 90%.			Comment resolved.	90% BOD Exhibit 3.4-3 (see Footnote).
184	DTSC-72	Exhibit 3.3-5/3-39	Pre-injection Treatment Process Schematic	Please introduce pre-treatment chemical after the filters to save on overall dosage quantity as well as filter longevity. 188	DOI-80	Section 3.3.3.4, Page 3-41	"Injection wells invariably lose capacity over time."	Please mention the likelihood of adding additional injection wells to increase capacity based on the IM-3 experience.	After the most recent (June 2013) well rehabilitation work, the IM-3 injection wells have been operating near their original capacity. At this time, after almost 7 years of operation, the IM-3 injection wells have not required replacement. The water from IM-3 passes through a micro-filter and is almost completely free from suspended solids. Water to be injected into the FW and IRL wells during the final remedy will not be filtered. In addition, it is likely that bio-fouling will be a factor in the IRL wells where carbon may be added. Since the final remedy injection wells will be receiving water from a different source than the IM-3 injection wells, it is not appropriate to make projections based on IM-3 experience alone.	Okay. DTSC, however, understands that currently there are injection well fouling issues at Hinkley and would like PG&E to consider the lessons learned from similar operations and ensure appropriate responses are in place during O&M at Topock. 			the wells is planned to be continuous to aid in reducing the time to cleanup.	beyond identified plume boundaries.	reducing the time to cleanup <u>and provide hydraulic control to prevent migration of the chromium plume beyond identified plume boundaries</u>."					
190	DTSC-76	3.3.3.4 Freshwater Injection Wells, Page 3-41	The anticipated nominal injection flow rate per well ranges from 50 to 100 gpm, and the anticipated maximum flow rate is 100 to 200 gpm per well.	The section should clarify that freshwater is also being proposed to be injected at wells IRL-3 and 4 at a total of nominal flow rate of 300gpm.	PG&E suggests adding a reference to Exhibit 3.3-4 (pages 3-34 and 3-35) at the end of this sentence, rather than spelling out information for IRL-3 and IRL-4 only.	Okay.			Comment resolved.	90% BOD Exhibit 3.3-4 (Footnote a).
191	DTSC-77	3.3.3.4 Freshwater Injection Wells, Page 3-41	If the step testing indicates that the capacity of any injection well is less than three times the design flow rate, consideration will be given to installation of an additional well to ensure that sufficient injection capacity is available for the life of the remedy.	Consideration must also be given to installation of a new well should unexpected contamination be discovered. The potential for this to occur increases where characterization efforts are minimal. For instance, the FW-2 area is not as well characterized as the FW-1 area and might intersect the chromium plume. This issue also applies to other areas and the remedy document must account for these contingent wells. Conversely, wells targeting contamination may come up clean or low yield and need to be drilled in a new location to more efficiently extract contaminants.	Concur. There are numerous factors that will only become known after drilling and testing could affect the need for additional wells or the design of a well. The 90% design will contain a section describing an adaptive approach to well installation which will take into account the various factors that could cause a change in the number of design of wells as they are being installed and provide a process for decision making during the well installation phase.	PG&E should not be waiting to the 90% design to describe such an integral part of the evaluation for remedy design. DTSC will reserve our review of the adaptive approach when it is presented.			Noted.	Construction/ Remedial Action Work Plan, Section 3.1. 90% BOD, Section 3.6.3.
192	DTSC-78	3.3.3.4/3-41	Freshwater Injection wells	Please provide the rationale and basis for the requirement of one third the design flow for injection well replacement. It is recommended that empirical data as well as modeling may help to adequately ascertain the full hydraulic control of each well and the need for replacement.	PG&E suggested that, as a rule of thumb, new injection locations should have a sufficient number of wells to provide about 3 times the design capacity to provide adequate contingency for future decreases in injection flow (see response to comment #164 DOI-69). Because it is not known how much capacity will be lost over time, particularly in the IRL wells that may be subject to bio-fouling or fouling by iron and manganese from the floodplain, modeling would not be useful in establishing a threshold for excess capacity. The trade-off for not providing sufficient excess injection	What if the replacement well also does not exhibit 3 times the proposed capacity, will PG&E move to another well location? When will this stop? Comment resolved.			Comment resolved.	Not applicable.

TABLE I-1

					capacity during initial construction is the need for future downtime and intrusion to install new injection wells when existing wells are no longer able to provide sufficient capacity. PG&E believes a factor of three times the design flow is a comfortable margin of safety, however a smaller margin could probably be tolerated so long as there is recognition that it entails more likelihood of remedy down time and well installation in the future.					
193	DOI-81	Section 3.3.3.4, Page 3-42	"Well vaults will be equipped with removable covers . . . "	How many workers are required to remove a cover? Does it make since to use spring-loaded doors on the well vaults?	PG&E plans to have spring-assist lids on well and valve vaults. This feature will be shown in the 90% design. 194a	FMIT-28	Section 3.3.3.4	*Freshwater injection wells "During flow rate and capacity testing, injection wells need significantly greater actual capacity than design capacity. If well has low capacity, another well will be drilled to obtain greater capacity."*	What is the limit on this iterative approach? Could the result be too many large boreholes and greater destruction of	Please note that the reference text is incorrectly quoted in this comment. Section 3.3.3.4 states: "Injection wells invariably lose capacity over time. In order to last for the life of the remedial action, it will be necessary for the injection wells to have initial capacity significant greater than their design flow rates. If the step testing indicates that the capacity of any injection well is less than three times the design flow rate, consideration will be given to installation of an additional well to ensure that sufficient injection capacity is available for the life of the remedy." PG&E proposes that as a rule of thumb, initial injection capacity at each FW or IRL location should be approximately three times the design flow rate for that location. Any additional wells needed to achieve this capacity would be installed in the same area as the primary well. Well drilling at any one area would only continue until this target of three times the design capacity was reached. There is also a possibility that the design flow rates for individual well locations could be adjusted to allow for somewhat more injection in the higher permeability locations and somewhat less injection in the lower permeability locations. 194b	Hualapai-21 Chemehuevi-21 Cocopah-21 CRIT-21	Section 3.3.3.4	*Freshwater injection wells "During flow rate and capacity testing, injection wells need significantly greater actual capacity than design capacity. If well has low capacity, another well will be drilled to obtain greater capacity."*	What is the limit on this iterative approach? Could the result be too many large boreholes and greater destruction of the sacred landscape? Please explain the relevance of the cap on the number of wells and how that relates to abandonment of such underperforming wells under this scenario.	See response to comment #194a FMIT-28. The cap on number of wells was established in the EIR, in recognition of tribal sensitivity to activities that involved drilling or digging in the earth. If a well can be replaced in the original borehole, it does not increase the well count. Unless the new well encountered different geologic conditions and/or has significantly smaller capacity than the well it replaced, there would be no net change in the number of wells. If the new well has significantly smaller capacity, it may be necessary to replace an existing well with two wells under. In this case, each of these additional wells at each location would add to the well count. Clarify in the BOD text and indicate in the figure legend that there may be more than one well installed at the FW or IRL well locations initially to ensure sufficient capacity. Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
213	DTSC-87	3.4.2.2 Conditioning Page 3-46.	Under the management plan presented above, removal of dissolved constituents will not be required because the injected water quality will be similar to the aquifer water quality in/near the IRZ Injection Wells.	Treated injection water quality must be monitored at some level to ensure appropriate water quality is being injected into the aquifer. This paragraph should briefly discuss monitoring of the treated water and refer the reader to an appropriate monitoring section.	As discussed in Section 1.3 of the BOD (Organization and Content of BOD), this section of the BOD is intended to discuss the design basis and assumptions/ considerations (e.g., number/locations of wells, design flow rates), while Volume 2 of the O&M Manual is intended to address proposed sampling and monitoring during implementation (e.g., sampling frequency/ analytes). For clarity, it is recommended that a sentence be added at the very beginning of Section 3 to refer the reader to Volume 2 of the O&M Manual for sampling/monitoring details, instead of in the subsections.	Comment resolved.			Comment resolved.	90% BOD Section 3, Intro, 3rd paragraph.
214	DTSC-88	Section 3.4.2.2, p.3-46	In the event that the produced water is hazardous, permitted transportable treatment units could be used.	Since PG&E asserts that the proposed cleanup is conducted under the CERCLA permit exemption, this may not apply. However, substantive requirements for such operation would be required, such as record keeping, maximum air quality emission limitations, secondary containment, etc. PG&E should specify these applicable requirements.	Treatment could potentially be performed using a treatment unit operated exclusively at the Topock site, in which case the substantive requirements for a fixed treatment unit (FTU) operating under the Conditional Authorization (CA) permit tier would apply, or a transportable treatment unit (TTU) authorized to operate at multiple sites, in which case the substantive requirements for a transportable treatment unit (TTU) operating under the Permit By Rule (PBR) tier would apply. FTUs operating under CA must comply with all applicable requirements for hazardous waste generators. If treatment occurs in containers, all containers must have secondary containment, be in good condition, managed to prevent leaks, remain closed except when adding or removing waste, and meet hazardous waste labeling requirements. Hazardous waste containers must be inspected weekly. If treatment occurs in tanks the tanks must be equipped with secondary containment and overfill protection and must be labeled as containing hazardous waste. Hazardous waste tanks must be inspected daily and must undergo an integrity assessment by a California-licensed professional engineer (PE). The treatment unit must have written operating instructions and maintain a record of the dates,	Comment resolved pending review of SOPs in the 90% design.			Comment resolved.	Not applicable.

					concentrations, amounts, and types of waste treated, as well as a written inspection schedule and inspection log. FTUs operating under CA must also maintain a written closure cost estimate and must maintain a financial assurance mechanism if the closure cost estimate exceeds $10,000. Adequate security must be provided. A TTU operating under PBR must meet the following additional requirements in addition to those applicable to the CA tier. Additional records must be maintained, including a written waste analysis plan. Closure must occur pursuant to a written closure plan, and completion of closure must be certified by a California-registered PE.					
215	DTSC-89	Section 3.4.2.2, p.3-46, 1st bullet	The cutover from “early” stage to “later” stage is proposed to be defined through easily measured onsite water quality tests such as pH, turbidity, and conductivity.	This set of identified analysts is too limiting to ensure that it complies with substantive requirements for waste water injection.	This set of parameters is only intended for use in the field to differentiate between the dirtier (first flush) and the cleaner (second flush) water during well rehab events. As described in Section 4.2.2.3.5 of the O&M Manual Volume 1 (page 4-19), during well rehab events, turbid and/or discolored water (first flush) will be removed from the well until the water becomes clear and the well is relatively clean. All first flush water will be contained in temporary, portable tanks, tested, and managed in accordance the updated Figure 3.4-2 of the 60% BOD and Figure 6.1-2 of the O&M Manual Volume 1 (in response to comment #619 DOI-250).	Comment resolved pending review of the 90%.			Comment resolved.	O&M Manual Volume 1 Section 4.2.2.3.5 (page 4-18) and Figure 6.1-2. 90% BOD Figure 3.4-2.
				DTSC is unsure of the regulatory constraints associated with reinjection of waste, even if it is into the same contaminated zone. PG&E should conduct this analysis In the design and specify to reader and agencies for clarity and implementation.	As for reinjection of remedy-produced water back into treatment zone, please see response to comment #181 DTSC-70.	See response to comment #181

216	DTSC-90	Section, 3.4.2.2, p.3-46, last paragraph	Furthermore, contaminant migration to the river that could potentially affect water quality goals or beneficial uses does not occur during remedy implementation through groundwater extraction along the river bank.	This would only be true if there is full hydraulic capture of the water flow towards Arizona and the river, and that the remedy as proposed will not send mobilized by products through the IRZ. DTSC requests PG&E to include particle tracking for evaluation as part of the remedy design. Much of the conceptual remedy has changed since the CMS/FS, including elimination of the northern freshwater injection point, and changes in well locations. PG&E should use the particle tracking model to visually demonstrate the resulting flow lines for evaluation of the remedy's ability for hydraulic capture and verify the model through actual sampling during operation.	See response and resolution to comment #646 DTSC-197 regarding particle tracking. Figures for each layer were prepared and submitted to DTSC for review.	DTSC may still consider the evaluation of particle tracking for the future..			Flow field figures for Layers 1-4 were submitted to DTSC and DOI on December 30, 2013 (see **Attachment E**, at the end of this table). Per DTSC request, particle track figures for Layers 1-4 were submitted to DTSC on March 11, 2014 (see **Attachment R** at the end of this table). Particle tracking figures will continue to be included in the 90% Design document. Comment resolved.	90% BOD Section 3.1, Figures 3.1-1 through 3.1-7 90% BOD Appendix B, Figures 6.5-13 through 6.5-20
217	DTSC-91	Exhibit 3.4-4/3-47	Remedy-Produced Water Conditioning Process Schematic	Please provide the disposition of the water obtained as the result of the dewatering process.	The exhibit will be updated to show the water will be returned to the influent tanks for re-processing.	Okay.			Comment resolved.	90% BOD Exhibit 3.4-4. O&M Manual Volume 1 Section 2.3.
218	DTSC-92	3.4.2.2 Conditioning Page 3-48.	Exhibit 3.4-5 Influent solids loading Typical: 60 mg/L total suspended solids Estimated value consistent with Hinkley results.	With the higher TDS encountered at Topock, is it appropriate to always utilize Hinkley results? Should the suspended solids estimate be modified?	It is assumed that this comment addresses TSS, and not TDS. As discussed in Appendix F (pages F-7 to F-10), PG&E conducted a test at Hinkley to evaluate the effectiveness of regular backwashing on an IRZ well. At Topock, the IM-3 injection wells also undergo regular backwash. From a design standpoint, although Hinkley data does not reflect Topock specific conditions, it does show how the IRZ well performs with regular backwashing. Using IRZ backwash data for a design basis is more conservative and appropriate as it contains more suspended solids than IM-3 backwash. In addition, the IRZ backwash water also contains biomass.	Okay.			Comment resolved.	Not applicable
219	DOI-91	Section 3.5.1, Pages 3-49 and 3-50	"Secondary power supply will be power generated from small photovoltaic solar panels . . . "	The text refers to the placement of small photovoltaic solar panels at selected remote sites. Are these sites identified in the 60% Design or will they be identified in the 90% Design? Will solar panels encourage vandalism? Consider appropriate theft-prevention devices (locks, etc.) as necessary to ensure continued function of the secondary power supply.	These small solar panels will be identified in the 90% design. Theft-prevention devices and techniques commonly employed for remote sites will be considered and included as appropriate.		Comment resolved pending review of 90% design.		Comment resolved.	90% BOD Appendix D, Drawing E-16-01.

220	DOI-92	Section 3.5.2, Page 3-50		What safety operational alarms will be incorporated into the SCADA that will automatically notify personnel and shut down equipment/systems/operations as required?	At the 60% design stage, precise alarms and control logic have not been fully defined. Examples of safety alarm conditions that would shut down equipment/systems include, but not limited to the following: a) A high level condition in the ethanol storage tank causes an alarm that notifies the operator and tanker to discontinue filling the tank. As a precautionary safety measure, this condition will shutdown the carbon substrate hose pumps and close the downstream flow control valves. b) A high level alarm in the secondary containment pipe downstream of the ethanol tank would shut down the ethanol hose pumps and valves if a leak is detected, indicating a loss of ethanol from the primary pipe. c) A high level in an influent storage tank at the remedy-produced water tank farm causes an alarm that closes the upstream control valve to prevent overfilling. d) A level switch being triggered in any secondary containment (e.g., well or meter vault) would shut down any pumps and close valves associated with that pipeline in an attempt to isolate that portion of piping. An exhibit or table will be added to the O&M Manual, Volume 1 to list the alarm conditions.		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 1, Table 3.1-1 (Control Set Points and Approaches).
221	DTSC-95	Section 3.5.1, Electrical Power Supply and Distribution, p.3-50		Please note that the December 31, 2011 remedy decision letter from DTSC to PG&E states in condition 2 that PG&E shall obtain a 320 kW generator for the purpose of providing backup electricity at the site for remedy implementation. PG&E should include this condition into the design document.	PG&E will include a generator that meets the condition of approval in DTSC's January 31, 2011 remedy approval letter, in the 90% BOD. The generator will be located on PG&E parcel. The generator will be described in text and shown on maps.	Resolved. DTSC will review the complete electrical system as part of the 90% design. 			wells intended to characterize the plume. <u>However, the effort to obtain this data to determine screened intervals of remediation monitoring wells, which may be located in a plume undergoing active remediation, may not be warranted at all locations.</u>							
228	DTSC-101	3.6.1 Key Variables and Well Design Considerations, Page 3-55	However, the number of available boreholes is limited (DTSC 2011d). <u>No more than 60 boreholes can be installed for the construction of monitoring wells.</u>	DTSC based the number of wells on estimates provided by PG&E at a stage when the remedy was quite conceptual. While every effort should be made to minimize the total number of wells, if necessary, wells should be installed for an identified purpose and not be artificially bound by the specific well counts for the design. Please evaluate this section based on need and possible contingencies and not well count.	The EIR was developed to balance potential impacts of the remedy implementation, including impacts to cultural resources. As such, limitations were placed on the number of boreholes for remedial wells and monitoring wells. PG&E maintains that it is important to stay within these limitations that were specified in the EIR to preserve an appropriate balance between remedy implementation and minimizing impacts. With regards to the design of the monitoring program, the locations and number of monitoring wells were decided upon to provide the necessary density of data to meet the data quality objectives detailed in the Sampling and Monitoring Plan (Appendix L, Volume 2). The referenced text in Section 3.6.1 is specific to how monitoring well design influences the number of boreholes that will be needed. Section 3.6.2 provided an evaluation of several monitoring well design options and factors to consider in selecting a design, including the number of boreholes that will be required, well utility, and constructability and longevity. Use of monitoring wells that place multiple well screens within a single borehole will allow greater data density and vertical coverage while minimizing	Comment resolved pending review of the 90% design. 231	FMIT-31 Hualapai-23 Chemehuevi-23 Cocopah-23 CRIT-23	Section 3.6.2 p. 3-56 to 3-58	Well design options	Where the water table is within about 18 feet of land surface, a peristaltic or centrifugal pump might be used to collect water samples. With borehole size limitations, numerous zones could be sampled using tubes for sampling access, rather than submersible pumps in nested wells.	PG&E agrees that the use of small diameter pumping systems are beneficial when there are limitations on borehole diameter, multiple zones within one borehole must be monitored, and the depth to water is shallow. However, as detailed in Section 3.6.1 there are several other design variables that must be considered for the Topock site when determining the appropriate diameter of a monitoring well casing.			Comment resolved pending review of 90% design documents.	Comment resolved.	Not applicable
232	DTSC-103	3.6.2 Well Design Options, Page 3-57	Dual-screen Wells. This design has been used in two bedrock boreholes in the East Ravine area, and is also planned for many of the IRZ wells associated with the final groundwater remedy.	The section must discuss the failings of the packers in both of the two East Ravine wells and how PG&E plans to overcome those failure modes in the final design.	A specific reference to the failings of inflatable packers when used in East Ravine wells will be added to the "Constructability and Longevity" bullet for dual-screen wells. The failure mode observed in these wells is inherent in the design of inflatable packers. As detailed in this section, inflatable packers can be maintenance intensive and may require periodic replacement, which is not desirable for monitoring wells because the isolation of the two monitoring intervals is lost. This is a different operating condition than that of the remediation wells. Packers used in remediation wells	Response noted. However, DTSC may request that packers be utilized in monitoring wells, to be evaluated on a case by case basis.			Comment resolved.	90% BOD Section 3.6.2.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					serve to isolate screened intervals and facilitate the distribution of varying quantities of carbon amended water to each screened interval individually, but long-term isolation is not a requirement. Therefore, packers are ideal for use in remediation wells because there are opportunities to remove and maintain them, as necessary. See responses to comment #132 DTSC-40 for clarification on the use of packers in monitoring wells during the East Ravine investigation and #90 DTSC-25 regarding the types of packers included in the remediation well design.					
233	DTSC-104	3.6.2 Well Design Options, Page 3-57 and 58		Please add a section discussing the ability of the different well designs to accommodate pressure transducers. The flat gradients and continuously changing river stage make this a very important consideration for well design.	The need for monitoring wells to be able to accommodate water level transducers is identified in Section 3.6.1 as a design consideration (well utility). The text in Section 3.6.2 already speaks to the ability of each design to be scaled to accommodate required sample equipment. However, as requested, pressure transducers will be specifically identified in these sections (note that pressure transducers are already specifically mentioned for multi-level wells).	Okay.			Comment resolved.	90% BOD Section 3.6.2.
234	DTSC-105	3.6.2 Well Design Options, Page 3-58	Multi-level Wells. Multi-level well designs vary significantly by manufacturer, but many of them include elastomeric materials in the sealed intervals which may not be stable in the subsurface environment at the Topock site.	Please elaborate on the elastomeric materials used in some multilevel wells as it is not certain how this can affect Topock data collection efforts.	This statement was meant to highlight the fact, that based on site experience with the FLUTe liners, there may be a problem with some materials in the reduced environment of the bedrock or IRZ. PG&E does not have information on the specific properties of all the elastomeric materials used in the different multilevel samplers and many of these are likely proprietary. The statement will be expanded to read: "Multi-level well designs vary significantly by manufacturer, but some of them include elastomeric materials in the sealed intervals which may not be stable in the subsurface environment at the Topock site. <u>Based on experience with FLUTe liners in the East Ravine, it is recommended that testing be conducted prior to deployment of any multilevel system that contains</u>	Okay.			Comment resolved.	90% BOD Section 3.6.2.

Specific Comments – Section 5										
244	DOI-97	Page 5-1	"The SOB (DTSC 2011) stated that due to the incomplete evaluation of soil contamination . . . "	The in-text citation for DTSC 2011 is not listed in the Reference list section.	The letter "a" will be added after 2011.		Comment resolved.		Comment resolved.	90% BOD Section 5, 3rd paragraph.
245	DOI-98	Page 5-1, 1st bullet	Category 1 ICs	Based on current hydrogeologic understandings, should groundwater withdrawal usage by the private sector in the vicinity of the freshwater supply well(s) require an IC to protect quantity supply issues to the treatment program?	As indicated in Figure 5.1-1 (page 211 of the PDF), PG&E is still evaluating the need for and/or scope of an institutional control at and around HNWR-1 well, for the purpose of ensuring the quantity of freshwater needed for the remedy over its decades long operation. PG&E notes that policies for the management of surface uses and the use of groundwater on the HNWR are included in the 1994 Lower Colorado River National Wildlife Refuges Comprehensive Management Plan.		Comment resolved.		Comment resolved.	90% BOD Figure 5.1-1.
246	DOI-99	Section 5.1, Page 5-2		This subsection defines areas for future restrictions. If groundwater quality may be an issue in the future, does PG&E plan on performing a Wellhead Protection Study to ascertain where spills, leaks, chemical storage areas, etc., may impact the water quality upgradient of the freshwater supply well during operation in order to apply/seek any development restrictions?	The section titled "Source Water Assessment" on page 3-30 describes the approach taken to identify the wellhead protection zone around HNWR-1 based on Arizona guidance. Exhibit 3.3-3 shows the estimated radius of the wellhead protection zone There are no major sources of groundwater contaminants in this zone. PG&E does not propose to seek development restrictions for the purposes of wellhead protection. However, as indicated in Figure 5.1-1 (page 211 of the PDF), PG&E is still evaluating the need for and/or scope of an institutional control at and around HNWR-1 well, for the purpose of ensuring the quantity of freshwater needed for the remedy over its decades long operation. PG&E notes that policies for the management of surface uses and the use of groundwater on the HNWR are included in the 1994 Lower Colorado River National Wildlife Refuges Comprehensive Management Plan. 264	FMIT-40 Hualapai-29 Chemehuevi-29 Cocopah-29 CRIT-29	Table 6.1-1 p. 6-18	Noise-2d	It is not sufficient to manage communication with noise-sensitive receptors and concerning noise issues and complaints. There needs to be a meaningful and functional set of protocols for both communicating and resolving issues and complaints. Further, applicable noise standards need to be spelled out and the basis for their selection provided.	In conformance with requirements in the EIR MMRP, mitigation measure CUL-1a-8h (Protocols for the appropriate methods, consistent with mitigation measure Noise-3, to reduce auditory impacts) was developed as part of the draft CIMP with inputs from Tribes. The draft CIMP was submitted to the Tribes for review on July 8, 2013, and comments were received from Tribes on October 22, 2013. PG&E will review and discuss these comments with Tribes prior to submitting the draft CIMP to DTSC at 90% design. PG&E defers to DTSC on response to comment regarding the sufficiency of the requirements and applicable standards. The certified EIR lists the applicable noise standards for the remedy. Section C.11 of Appendix C contains the noise design criteria for the remedy.	See response to comment #261 FMIT-37.		Comment stands. Tribal concerns regarding noise may be different than applied regulatory standards. The tribes would like to continue a dialogue with the agencies to further clarify the nature of noise and vibration impacts. The FMIT requests to review the CIMP prior to the 90% design submittal.	This comment and the responses were discussed at the December 17-18, 2013 TWG meeting.	CIMP Noise Protocol CUL-1a-8h (the CIMP Is included as an appendix to the Construction/ Remedial Action Work Plan).
265a	FMIT-41	Table 6.1-1 p. 6-21	CUL-1a-10	Regarding certain (e.g., noise, aesthetics, etc.) impacts on the Topock Maze and the associated sacred area, the 60% BOD report states, as did the 30% BOD report, that "prevention of indirect impacts to the Maze will be incorporated into the design to the maximum extent feasible as determined by DTSC". Where is the process spelled out for such a determination by DTSC? Additionally, the Tribe does not consider such impact "indirect." They are direct impacts.	PG&E defers to DTSC as the language cited in the comment is copied verbatim from the certified EIR.	DTSC makes such a determination through oversight of PG&E's implementation of mitigation measure to avoid any identified archaeological sites. PG&E will also conduct pre-construction survey and if necessary follow CHPMP requirements for treatment if avoidance is impossible. Tribes will also be invited to the pre-construction survey.		The response only mentions archeological value and not cultural value. In addition, the response does not address the indirect vs. direct portion of the comment.	This comment and the responses were discussed at the December 17-18, 2013 TWG meeting.	Not applicable

The following text will be added to the last column of Table 6.2-1 for Item 14 after "Requirements in the PA and the CHPMP will be adhered to": "<u>These requirements include implementation of mitigation measures identified in the PA and the CHPMP and through ongoing consultation activities with the Tribes that will avoid, mitigate, or otherwise minimize adverse effects from the undertaking.</u>"		Comment resolved.		Comment resolved.	90% BOD Table 6.2-1 Item 17.
273	FMIT-42	Table 6.2-1		The Tribe disagrees with the conclusions regarding Item No. 39 (RFRA) and Item No 22 (AIRFA). There is no question in the Tribe's mind that the project burdens the traditional religious practices of the Tribe. The issue is not merely defined by physical access concerns. The Actions should more fully reflect the breadth of the statutes and the projects impacts on the Tribe. The Tribe is also concerned about Item No. 14 (NHPA). The Action described appears to be mostly about producing documents. Action should also focus on process inclusion of the Tribe. It should also reflect that Treatment Measures may evolve as the design evolves.	PG&E defers to DOI.		In specific reference to Item 39 (RFRA), the federal courts have held that the requirement not to impose a substantial burden on the exercise of traditional religious practices is violated "only when individuals are forced to choose between following the tenets of their religion and receiving a governmental benefit or coerced to act contrary to their religious beliefs by the threat of civil or criminal sanctions." Based on this judicial interpretation of the law, DOI has concluded that the groundwater remedy does not present a substantial burden on the exercise of traditional religious practices. However, DOI and BLM acknowledge that many of the Tribes feel that the remediation project does impact religious and cultural practices in the Topock area. One effort made to address this concern was DOI and BLM's development of the Tribal Access Plan to assure the Tribes of	Under further tribal review.	This comment and response were discussed at the February 11, 2014 TWG meeting.	Not applicable

							continued access to federal lands contained within the boundary of the APE. The provision of tribal access to property for religious, spiritual or other cultural purposes is consistent with both RFRA and AIRFA. DOI and BLM will continue to consult with the Tribes in an effort to identify and implement mitigation measures that will prevent or mitigate impacts on the ability of Tribal members to exercise traditional cultural and religious activities associated with the Topock area. The documents referenced under "Action", including the PA and the CHPMP, are the result of the ongoing consultation efforts with the Tribes and serve to memorialize the collaborative decisions made during these meetings.			
274	MWD-8	6.2-1, Table 6.2-1, Item No. 52	"There is no state MCL for Cr(VI)..."	This should read 'There is currently no state MCL for Cr(VI), although the California Department of Public Health has been ordered to propose an MCL for Cr(VI) by August 31, 2013. PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
276	DOI-114	Table 6.2-2, Item Number 4, Stipulation I(D) Page 6-72 And Table 6.2-3, Page 6-77		The compliance status addresses the stipulation in part. The language contained within this section specifies that “If adverse effects to such properties are unavoidable, PG&E, under the direction of BLM, will develop and follow procedures that reduce the possibility of inadvertent damage.” It is our expectation that proactive measures will be included in the Remedial Action Work Plan to reduce the potential for inadvertent damage, including those listed in Section 6.6.3 of the CHPMP.	Comment noted, although PG&E notes that it appears that this comment applies to Item No. 4 of Table 6.2-3 only and not Item No. 4 of Table 6.2-2, which relates specifically to restoration. PG&E will describe steps to prevent or reduce the potential for inadvertent damage in the Remedial Action Work Plan.		Comment resolved pending review of 90% design.		Comment resolved.	90% BOD Table 6.2-3 Item #4.
277	FMIT-43	Table 6.2-2		Stipulation 18. The Tribe believes that a solid draft plan and not merely an outline of the IM3 decommissioning and restoration plan should be produced prior to the groundwater remedy.	PG&E understands that the FMIT’s comment is focused on Section 8 of the Draft IM-3 Decommissioning, Removal, and Restoration Work Plan (“Draft Plan”), which sets forth a general approach for IM-3 Site restoration. In brief, Section 8 of the Draft Plan includes restoration guidelines (steps to be followed during restoration), elements of the restoration of habitat and revegetation and demobilization, and a draft annotated outline of a future more detailed, site specific IM-3 Restoration Plan. In coordination with the FMIT and other tribes, PG&E will develop a schedule for developing the more detailed Restoration Plan The schedule will be tailored to provide a timely plan with additional detail on the restoration process, and avoid delay so that restoration will commence shortly after decommissioning is completed. PG&E anticipates that some details of the restoration plan, in particular the amount of earthwork and earth movement involved in the restoration, will be deferred to the completion of decommissioning, so that PG&E and the Tribes can evaluate which approach may minimize further disturbance (and may minimize the amount of earth movement) while achieving the required restoration. PG&E believes that specific determination can best be made when the condition of ground surface is known, following the removal of the IM3 facilities.				In addition to discussions at the TWG, PG&E’s response was discussed with the FMIT, and revised in response to that discussion.	Draft IM-3 Decommissioning, Removal, and Restoration Work Plan, Section 1.1, last paragraph.

283	DTSC-114	Section 7.3.3, p.7-7, last paragraph	The downside of complete shutdown of the IM system upon final groundwater remedy start-up is that the hydraulic control exerted by the IM pumping would end. From a hydrogeologic perspective, this is not a significant concern due to the slow migration rate and the presence of the reducing rind.	Although the hydraulic gradient is flat, depending on the time of year, if the implementation is during the low river stages, the hydraulic movement would be significantly higher toward Arizona. Also, would PG&E's conclusion still be true with nine months of reductant injection at IRZ and minimum three months of freshwater injection? DTSC is concerned that this approach would allow a slug of Cr(VI) to be pushed towards Arizona, even if it is protective of river water.	Seasonal variations in river stage will result in localized variations in flow velocity but the long term trends will still be consistent with average flow velocities. PG&E's conclusion is still true with nine months of NTH IRZ operation and 3 months freshwater injection as Scenarios 1A (6 month NTH IRZ and 3 month freshwater injection) and 1B (12 month NTH IRZ and 6 month freshwater injection) bracket this timeframe. Even with the longer transitional operation times described in Scenario 1B, simulation results indicate that a slug of Cr(VI) will not be pushed towards Arizona and will still be within the simulated hydraulic capture zone of the River Bank Extraction Wells when they are activated. 					decision to decommission IM-3." (emphasis added).					
288	DOI-122	Section 7.6, Page 7-10	"Figure 7.6-1 shows a preliminary map of all temporary equipment staging areas and the yard, . . . "	According to the text, only a subset of the areas shown in Figure 7.6-1 would be used as staging areas. Recommend including a rectangle under the Notes for this figure depicting the area actually needed for staging, and identify the acreage. This information will be useful in evaluating selection of areas for staging.	Figure 7.6-1 has been revised to show acreage for the potential equipment staging and soil storage areas (see **Attachment G**, at the end of this table).		Comment resolved.		Comment resolved.	At this 90% stage, the full content of Section 7.6 (including Figure 7.6-1) has been incorporated into the Construction/Remedial Action Work Plan, where constructed related elements are presented in detail. See Section 4 and Figure 4-5 of the Construction/Remedial Action Work Plan for details.
289	DOI-123	Figure 7.6-1		Based on input from the Hualapai, Cocopah, Chemehuevi, Quechan, CRIT and Fort Mojave Indian Tribes, and considering the additional activity in the Refuge and adjacent to the Topock Maze, DOI requests that the BOR Quarry and former evaporation pond area no longer be considered as options for staging or soil storage during the groundwater remedy implementation. Additionally, BLM and San Bernardino County have discussed the potential use the OHV staging area within Park Moabi as a potential storage location for excess soil. PG&E has engaged with the County regarding the remedy and the use of similar areas around Park Moabi and should include this area as an option.	Figure 7.6-1 has been updated to remove the BOR Quarry and former evaporation pond area as options for staging or soil storage, and to add the OHV staging area within Park Moabi as a potential storage location for excess soil (see **Attachment G**, at the end of this table). In addition, the Old Gravel Pit/Current Paint Ball area was added as a potential soil storage area for evaluation.		Comment resolved pending review of 90% design.		Comment resolved.	At this 90% stage, the full content of Section 7.6 (including Figure 7.6-1) has been incorporated into the Construction/Remedial Action Work Plan, where constructed related elements are presented in detail. See Section 4 and Figure 4-5 of the Construction/Remedial Action Work Plan for details.
290	DTSC-115	Figure 7.6-1	Proposed staging areas, construction yard and access routes	Please note that environmental impacts have not been fully evaluated for the use of any staging areas outside of the final EIR project boundary.	The proposed staging areas are all located within the APE, and as noted in the EIR, the entire area of the APE was studied for impacts such as impacts to biological resources (see Final EIR exhibit 4.3-1 showing entire APE as biological study area) and impacts to cultural resources (see Final EIR exhibit 4.4-1 showing entire APE as cultural resources study area). The EIR states in the project description that staging areas would typically be located in areas that are already developed or disturbed, and that staging areas could be anywhere within the project area as shown in the EIR. (Final EIR, p. 3-21). All but three of the proposed staging areas are within the EIR project area. With respect to these three proposed staging areas, they are all located within the APE which was evaluated for impacts to biological	The proposed CEQA impact conclusion by PG&E may very well be appropriate; however, this formal analysis within the CEQA context for the three areas outside of the current project boundaries has not been conducted. PG&E's response is noted.		The Tribes request to be involved in any future cultural studies.	Comment and responses noted.	Not applicable.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					and cultural resources, and they consist of areas that have been previously developed or disturbed, consistent with the statement in the EIR project description. PG&E understands and anticipates that the use of these areas for staging would be evaluated as part of DTSC's CEQA evaluation of the final design. PG&E also anticipates that this review will demonstrate that the use of these areas does not involve new or substantially more severe environmental impacts compared to the evaluation in the Final EIR, given that the areas are previously developed or disturbed and have already been evaluated for impacts to cultural and biological resources.					
291	FMIT-44	Figure 7.6-1		The Tribe and PG&E appear to disagree about the timing of the DTSC-required restoration of the prior IM3 parking area. The Tribe believes that the directive from former DTSC Director Blevins remains in place, requiring the immediate restoration of that area. The settlement agreement between FMIT and PG&E could not override DTSC's direction. The Tribe objects to that area being proposed as a staging area in the design.	PG&E agrees with DTSC's interpretation that B.B. Blevins' March 8, 2005 letter regarding restoration of the staging area has been superseded by the settlement agreement between DTSC and the FMIT. In addition, the 2006 settlement agreement between PG&E and the FMIT, which addresses restoration of the IM-3 Site, also supersedes the prior direction in the 2005 letter. That settlement agreement states "upon decommissioning of the IM-3 treatment plant, PG&E will work in consultation with the Tribe to restore the IM-3 Site to pre-existing conditions to the maximum extent practicable, subject to the continued use of remedial facilities" and requires PG&E to consult with the FMIT regarding a plan for restoration of the IM-3 Site. (2006 Settlement Agreement § VII(A)(1).) The 2006 settlement agreement's provisions regarding restoration encompass the entire IM-3 Site, including the staging area. Section XII(H) of the 2006 settlement agreement expresses its intent to supersede other documents concerning the same subject matter: "This agreement supersedes all prior or written agreements, negotiations, discussions, understandings and representations between the Settlement Parties hereto and/or their respective counsel with respect	Comment noted regarding Tribe's objection to that area being proposed as a staging area in the design. See RTC #776 for related discussions of construction staging areas. DTSC wants to clarify its position regarding the March 8, 2005 Director Blevins' letter directing PG&E to meet certain timing deadlines for restoration of the IM3 staging area. DTSC believes that the 2006 Settlement Agreement between FMIT and DTSC supersedes Director Blevins' 2005 letter. Various sections of the Agreement, including paragraph V.M., that states that this "Agreement supersedes all prior oral or written agreements…between the parties hereto…." supports this position.			PG&E and the FMIT have discussed this comment and its response to the Tribe's comment.	Not applicable

					is however not warranted and not recommended. No changes are proposed.					
311	DOI-140	Appendix A-7, Ethnobotany Survey Report.	General Comment	Is Lycium considered an ethnobotanical or culturally significant? Anderson's desert thorn (Lycium andersonii) is only mentioned on page 2-1 as a component of the Blue palo verde woodland community, but is not listed as a plant in the EIR Appendix PLA. It produces edible berries and may have been used as a food source.	Culturally significant plants for the survey of culturally significant plants were those species that were included in Appendix PLA of the Final EIR. PG&E will survey for Lycium and include the survey results in the 90% BOD.		Comment resolved pending review of 90% design.		Comment resolved.	See the February 28, 2014 *Supplemental Ethnobotanical Plant Surveys for the PG&E Topock Compressor Station* included in Appendix A7 of the 90% BOD.
312	DOI-141	Appendix A-7, Appendix A: Target List of Culturally Significant Plant Species from Appendix PLA of the EIR with the Potential to Occur in the Project Area		Arrowweed is not identified as a plant of cultural significance in this report but it should be.	Comment noted. Surveys for culturally significant plants included only those species that were included in Appendix PLA of the Final EIR; Arrowweed was not included on this list. See response to comment #83 DOI-34. PG&E will survey for Arrowweed and include the survey results in the 90% BOD.		Add a footnote to Figure 2.4-11 noting that the tribes have recently (June 2011) stated that Arrow weed is an ethnobotanical plant. Comment resolved pending review of 90% design.		The following note will be added to Figure 2.4-9 and similar maps in the 90% BOD: "Tribes have stated that Arrow weed is an ethnobotanical sensitive plant (June 2011). Arrow weed however is not on the Appendix PLA of the FEIR. Arrow weed will be protected during construction as a mature plant under AES-1a".	See the February 28, 2014 *Supplemental Ethnobotanical Plant Surveys for the PG&E Topock Compressor Station* included in Appendix A7 of the 90% BOD.
313	DOI-142	Appendix A-7, Ethnobotany Survey Report. Section 2.1.2, Page 2-1	Tamarisk thicket is primarily found on the low sandy terraces adjacent to the Colorado River and Park Moabi Slough. This vegetation type is also found near the terminus of the larger ephemeral washes associated with the dissected terraces south of the Colorado River'. (Same text appears in the Final Floristic Survey Report, Section 2.1.2, page 2-1)	Athel tamarisk is described. There is no mention of Athel as an upland species, as found in the FWIP. These reports should be consistent.	The Ethnobotany Survey Report is currently being revised. There was an attempt by the botanists to differentiate species of tamarisk found at the site (Tamarix ramosissima and T. aphylla). T. aphylla can be found in floodplains - text in the report will be adjusted to reflect that it is not entirely confined to uplands.		Comment resolved.		Comment resolved.	See the January 15, 2014 *Topock Groundwater Remediation Revised Ethnobotany Survey Report* included in the Appendix A7 of the 90% BOD.
314	DOI-143	Appendix A7, Section 4.2, Page 4-1		The in-text citation for USFWS 2011 is not listed in the Reference section.	Comment noted. The in-text citation will be added to the reference list.		Comment resolved.		Comment resolved.	The January 15, 2014 *Topock Groundwater Remediation Revised Ethnobotany Survey Report* did not cite USFWS 2011;

										therefore, that citation is not included in the Reference list.
315	FMIT-48 Hualapai-34 Chemehuevi-34 Cocopah-34 CRIT-34	Append A7 Section 5.3 p. A7-5-3	*Additional floristic surveys will be completed in the spring of 2013 to focus on areas where culturally significant herbaceous plant species are most likely to be present within the Project Area.*	When will the results of the 2013 survey be incorporated into the previous plant surveys?	See response to comment #302 FMIT-47.			Comment resolved pending submittal of the Mature Plants Survey report.	Comment resolved. The revised Floristic Survey Report was submitted to DTSC and DOI on December 30, 2013. The revised report expanded on the previous plant survey report (which covers the 2011/2012 surveys), and included the Spring 2013 survey results of the freshwater evaluation areas in Arizona.	See the May 19, 2014 *Addendum to Mature Plant Survey Report for the PG&E Topock Compressor Station* included in Appendix A4 of the 90% BOD.
316	FMIT-49 Hualapai-35 Chemehuevi-35 Cocopah-35 CRIT-35	Append A7 Append-E of A7 (Avoidance and Restoration Plan for Significant Plant Species") P. A7-E-2	*Topsoil salvaged from short-term disturbance areas should be piled to no more than 4 feet high and stabilized to prevent loss during storage.*	It is not clear however how the 4-foot maximum depth was determined. Will surface soils stored at the bottom of a 4 foot stock pile be able to preserve the biological integrity of the soils for extended durations? It is requested that PG&E provide a technical memorandum outlining options for how the biological integrity will be ensured during short- and long-term soil storage.	The height of the stockpile was determined based on the ability of the stockpiled soil to maintain viable seeds and nutrients. The American Association of State Highway and Transportation Officials (AASHTO) developed The Compendium of Environmental Stewardship Practices in Construction and Maintenance <http://environment.transportation.org/environmental_issues/construct_maint_prac/compendium/ best practices/> which includes thousands of individual practices used by DOTs across the country. Through a peer review vetting process, a number of practices in the Compendium have been identified as Best Practices. In Chapter 4 Section 4.11.1 under Soil Management Practices, the maximum depth of soil stockpiles is recommended to be no more than 4 feet: "When stockpiling topsoil, mound soil no higher than 1.3 m (4 feet) high for less than 1 year. Cover to prevent soil erosion and contamination by weeds." (See attached PDF). However, a literature review of soil stock piling (Strohmeyer 1999) suggest that adverse effects may occur in soil stockpiles greater than one meter (3 feet) deep. Therefore the cited text will be revised to indicate the temporary topsoil stockpiles will not exceed a depth of 3 feet. This new specification for top soil			Comment resolved.	Comment resolved.	CIMP Appendix A (Mitigation and Monitoring Plan for Culturally Significant Plants), Section 2.3.1 2nd paragraph.

					storage will be incorporated into the 90% BOD. Based on the insignificant amount of top-soil anticipated to be stored, PGE does not believe that a technical memorandum is warranted.					
Specific Comments – Appendix A8 (Supplemental Baseline Sound Level Measurement Technical Memorandum)										
317	FMIT-50 Hualapai-36 Chemehuevi-36 Cocopah-36 CRIT-36	Append A8		There needs to be a narrative that explains how these baseline data will be used in any decision-making process(es), and as a part of Mitigation Measures NOISE-1, NOISE-2 or NOISE-3.	The purpose of the supplemental sound data (collected in 2012 and 2013) was to augment the then existing noise data set (collected during the EIR development period) which is comprised of data collected over a single 15-minute period in December 2008 at the short-term measurement locations in the FEIR (shown in Exhibit 4.9-2 as ST-1, ST-2, and ST-3). As with other existing environmental conditions (e.g., water quality, site topography, vegetation communities, etc.), the purpose of the data is to document site conditions prior to remedy implementation. In compliance with mitigation measure NOISE-1 and NOISE-2, PG&E has designated disturbance coordinators who will manage any project-related complaints. In addition, PG&E will comply with mitigation measure CUL-1a-8h, protocols to reduce auditory impacts as part of the future CIMP. The above noise data is available for use, if needed and as appropriate. See also response to TRC's (Charlie Schlinger) memorandum dated December 10, 2013, included in **Attachment H**, at the end of this table.	The noise data collected for the EIR was used to determine the threshold sound energy for the project. No additional decisions will be made based on the long term or short term survey results.		Comment resolved. Tribal concerns regarding noise may be different than applied regulatory standards.	Comment resolved. PG&E will insert the Appendix A8 RTCs at the end of Appendix A8.	Appendix A8 RTCs at the end of Appendix A8.
318	FMIT-51 Hualapai-37 Chemehuevi-37 Cocopah-37 CRIT-37	Append A8		A tabular inventory and map of noise source locations (inclusive of sound power levels, with time dependencies noted) is needed in order to assess the noise impact(s) of this project. There should be an inventory and map for each of the construction and operational periods.	Comment noted. This information will be provided at 90% BOD once the infrastructure locations/ alignment are settled. See also response to TRC's (Charlie Schlinger) memorandum dated December 10, 2013, included in **Attachment H**, at the end of this table.			Comment resolved pending review of the 90% design.	Comment resolved.	90% BOD Appendix D, Table D1-13.
319	FMIT-52 Hualapai-38 Chemehuevi-38 Cocopah-38 CRIT-38	Append A8		It is not clear whether and how the selection and specification of noise-generating equipment, such as transformers, above-ground pumps, and motors, etc., will utilize noise-restrictive criteria.	The majority of pumps and motors will be located either underground, inside a well, or inside an enclosure (e.g., building). Power supply equipment/backup generator also will be located inside enclosures or buildings. Placing pumps, motors,			Comment resolved pending review of the 90% design.	Comment resolved.	Not applicable

TABLE I-1

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					and power supply/ backup generators in these locations effectively minimizes the sound emissions. The remaining non-emergency above ground equipment is limited to transformers which are similar in size to the one already operating at IM-3, and communication/control panels. Selection of this equipment will be reviewed by the Noise Engineer for conformance with the noise design criteria (see Section C.11). See also response to TRC's (Charlie Schlinger) memorandum dated December 10, 2013, included in **Attachment H**, at the end of this table.					
320	FMIT-53 Hualapai-39 Chemehuevi-39 Cocopah-39 CRIT-39	Append A8		The important effect(s) of meteorological conditions on the long-range propagation of sound should be addressed.	Meteorological effects are most pronounced for elevated sources or very loud sources, particularly those with strong low frequency content (such as a train). The operational sources of noise associated with this project are primarily located within buildings or underground, therefore their sound emissions are minimized and are not elevated. This project does not utilize equipment which is known to emit high levels of low frequency noise (such as train engines or unsilenced simple-cycle combustion exhaust stacks). See also response to TRC's (Charlie Schlinger) memorandum dated December 10, 2013, included in **Attachment H**, at the end of this table. Below is PG&E's response to the suggested language to close this comment: 1. The methodology for noise measurement in Topock Project Sound Level Measurements Protocol complies San Bernardino County Code 83.01.080(a) – Noise Measurement, and the EIR. The County requirements include the use of a sound level meter that meets ANSI standard, Type 1 or 2, and use the "A" weighted sound pressure level with unit of measurement as dB(A). The dB(A) is the sound pressure level as measured on a meter using the A-weighting filter	DTSC recognizes that meteorological conditions generally have the potential to result in increased, or decreased, noise exposure at known sensitive receptors. CEQA requires lead agencies to consider whether a project would have a substantial permanent increase in ambient noise levels above levels existing without the project, or a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project. Here, construction noise for the project was appropriately identified as a potentially significant impact and mitigation measures were imposed in "Mitigation Measure NOISE-2: Project Generated Construction-Related Noise Levels". This issue will be considered further if needed based on the final design.		. See the following language in the Hualapai Tribe's letter (3/10/14) – Use the following language for closure of this comment: 1. Revise the noise measurement protocol in consultation with the Tribes. Specifically, the protocol needs to include the collection and archiving of noise measurements that include spectral content (noise level as a function of frequency, which consists of unfiltered and un-weighted, or un-averaged, raw data, aka band spectra), and noise recordings accompanied by a spoken or written narrative addressing what noise and sounds are being heard. 2. Following the above revised protocol, collect additional noise data during the summer and early winter of 2014. 3. Adopt the protocol for use on the project, going forward.	Written comments on the responses to this comment were received from the TRC (Charlie Schlinger) on November 15, 2013. PG&E provided a response to the written comment on December 10, 2013 (see memo included in **Attachment H**, at the end of this table). The TRC (Charlie Schlinger) presented draft proposed language to this comment at the February 11, 2014 TWG meeting. On March 10, 2014, the Hualapai Tribe provided a letter with language to close out the unresolved noise and vibration-related comments (see **Attachment H**, at the end of this table).	CIMP Noise Protocol CUL-1a-8h.

TABLE I-1

					network. Noise standards are expressed as Leq which is the equivalent energy level of a time varying signal over a given period of time, typically, 1, 8, or 24 hrs. Further, the EIR identified the applicable criteria as A-weighted. There is no technical or regulatory basis to revise the measurement protocol or to further clarify the existing sources. For the above reasons, PG&E believes that it is not necessary to collect additional measurements or noise recordings to be consistent with the EIR. However, PGE recognizes the importance of the area to the Tribes, and should a concern about the actual noise generated by remedy operations arise, PG&E will work with the Tribes, agencies, and stakeholders to thoroughly investigate and resolve the issue appropriately . 2 & 3. See response to #1 above.					
321	FMIT-54 Hualapai-40 Chemehuevi-40 Cocopah-40 CRIT-40	Append A8 p. 1 and Figure 1	*The sound measurement locations were selected near the short term measurement locations in the Final Environmental Impact Report (FEIR) (DTSC,2011).*(shown in Exhibit 4.9-2 as ST-1, ST-2, and ST-3) (see Figure 1)	The three sites, ST-1, ST-2 & ST-3, have quite different levels of background sound levels and time—distributions, but this is not discussed. The report as it stands provides practically no quantitative evidence about the nearby noise sources and their (expected/measured) spatial contribution to the background noise. Such information is crucial to properly analyze and understand the highly variable background noise which was measured across the three sites. Further, it is unclear as to why these sites were chosen. *"PGE asked for clarification of this comment prior to response. The following clarification of comment was obtained from TRC on October 17, 2013. Response addresses the clarified comment.* *It is unclear what the data entries included in Appendix A8 Tables (1 & 2) represent? It is assumed that these data represent averages of other numbers presumably numbers in the Appendices (C-H) of Appendix A8. Please confirm if this assumption is*	American National Standards Institute (ANSI) S1.4 Type 1 (precision) sound level meters were used to monitor ambient sound levels. The sound level meters were programmed to report the average (L_{eq}) and statistical sound level metrics (Leq, L50, and L90) at hourly intervals. The sound level meters continuously monitor the sound levels during each hourly interval and automatically calculate and report the average and statistical levels at the conclusion of the hourly interval. This process repeats continuously until the meters are manually turned off or the batteries are depleted and	A specific rationale for the selection of individual sites for noise measurements was not provided in the Groundwater Final EIR. Based on the locations of the monitoring locations, the following can be inferred: ST 1 was chosen for its proximity to Maze Loci A; ST 2 was chosen for its proximity to Maze Loci C; ST 3 was chosen for its proximity to residences and traffic intersection at Park Moabi; LT A was chosen to provide ambient noise data from I-40; and LT B was chosen to provide ambient noise data from the BNSF rail line. It can also be inferred from the text in the Final EIR that the five locations were identified in recognition of the existing noise environment associated with the site (i.e., the diversity of background sound levels that exist on the site) and the existing noise-sensitive land uses. Further, because		The Tribe was not involved in the selection of the sites in the FEIR and the 2012-2013 study. The Tribe also note that there is no noise monitoring plan. See the following language in the Hualapai Tribe's letter (3/10/14) – Use the following language for closure of this comment: 1. Revise the noise measurement protocol in consultation with the Tribes. Specifically, the protocol needs to include the collection and archiving of noise measurements that include spectral content (noise level as a function of frequency, which consists of unfiltered and un-weighted, or un-averaged, raw data, aka band spectra), and noise recordings accompanied by a spoken or written narrative addressing what noise and sounds are being heard. 2. Following the above	Written comments on the responses to this comment were received from the TRC (Charlie Schlinger) on November 15, 2013. PG&E provided a response to the written comment on December 10, 2013 (see memo included in **Attachment H**, at the end of this table). The TRC (Charlie Schlinger) presented draft proposed language to this comment at the February 11, 2014 TWG meeting. On March 10, 2014, the Hualapai Tribe provided a letter with language to close out the unresolved noise and vibration-related comments (see **Attachment H**, at the end of this table). Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				correct. In addition it is not clear what the numbers in Appendices C-H represent? Presumably, they too are "averages" of other numbers - these latter numbers probably being what was actually measured. Please provide additional detail that allows the reader to understand what was actually measured and for what duration(s). That is, what are the basic measurements for this baseline sound characterization, and what "averaging" methods were used to develop the tabular summary information? *Site selection is a critical matter when it comes to developing a baseline. In the case of noise on this project, 3 sites were selected, with very little basis/justification provided in the FEIR. (The initial response to comments for this comment goes a long way in providing some explanation, but it is not complete, as*	the meter automatically turns off. Appendices C through H present the data reported by the sound level meters in tabular and graphical format. The data in Table 1 is a summary of the data presented in Appendices C through H. Table 1 presents the maximum and minimum hourly Leq sound pressure level and corresponding wind speed for each monitoring location during both the daytime (7 a.m. to 10 p.m.) and nighttime (10 p.m. to 7 a.m.) periods for both the summer and winter monitoring events. For example, the data presented in Appendix C (ST-1, August 2012) was reviewed to identify the maximum and minimum L_{eq} during the daytime and nighttime periods. These maximum and minimum levels were summarized for in Table 1 along with the wind speed that occurred during those maximum and minimum periods for ST-1 during August 2012. Table 2 presents the same sound pressure level data that is in Table 1 alongside the data collected from the 2008 EIR (the wind speed which was reported in Table 1 was omitted from Table 2 to enhance readability of Table 2). Table 2 shows that the short-term data collected for the 2008 EIR is within the range of the longer-term data collected over both a summer and winter period. Had the 2008 EIR sound level data fallen substantially outside the range of that recorded during this longer term monitoring event, its reproducibility could have been questioned. This did not occur. That is, there was nothing anomalous or spurious occurring during the time the sound level data reported in the 2008 EIR was collected. These sites were chosen by the EIR preparer for noise measurements because mesas that generally shield noise sensitive receptors from full exposure of operations that were occurring when the EIR was prepared, exist between the compressor station and other portions of the project areas (see FEIR, page 4.9-5). Additional data	intervening topography exists between the compressor station and other portions of the project areas in the form of mesas that generally shield noise-sensitive receptors from full exposure of current on-site operations, multiple representative sites for ambient noise measurements were necessary. To accurately describe potential noise related impacts, the Final EIR used the ambient noise survey data from the individual locations to determine impacts to nearest sensitive receptors from the proposed project (i.e., the data collected for the three sites was not averaged). The normalization of the data described above, was conducted for individual sites only.		revised protocol, collect additional noise data during the summer and early winter of 2014. 3. Adopt the protocol for use on the project, going forward.		

TABLE I-1

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				ST-1 and ST-2 are indeed located on "mesa" tops (upland areas) and one, ST-3, is located down off of the "mesa", at a street intersection.) Please provide additional detail regarding what is it about these sites that is representative and meaningful when it comes to baseline noise measurements? Why are these locations appropriate for developing the baseline sound characterization? *The reporting in Appendix A8 is too clinical and terse; there are no more than a half-dozen sentences given to the discussion of results, mainly with an eye toward wind effects on noise measurements. While there are essential footnotes related to measured wind speed, which is highly relevant to noise measurements, there is no interpretation and discussion of the numerical values in Tables 1-2, or in the Tables in Appendices C-H in terms of individual site location and proximity to known noise sources, time of day, actual noise from these sources, season, atmospheric conditions, topographic conditions, or any other factor known to influence the measurements.* *There needs to be clear communication, in the design documents, of how these most recent noise data, together with the FEIR noise data collected in 2008, will be used as part of the project design.*	was collected in proximity to these sites in 2012 – 2013. Agencies, Tribes, and Stakeholders were informed of this selection as documented in the *Sound Level Measurements Protocol Technical Memorandum* (Appendix B to the 60% BOD Appendix A8). See also response to comment #322 FMIT-55/Hualapai-41. The *Sound Level Measurements Technical Memorandum* in Appendix A8 is intended to report the supplemental data collected during the 2012-2013 event. Since the existing site conditions (e.g., noise environment, topographic condition) are well documented in the FEIR, that body of information is intentionally not repeated in this technical memorandum. If helpful, additional references to the FEIR can be added to this technical memorandum. See responses to comment #317 FMIT-50/Hualapai-36 and #319 FMIT-52/ Hualapai-38, as well as TRC's (Charlie Schlinger) memorandum dated December 10, 2013, included in **Attachment H**, at the end of this table. For PG&E's response to suggested language to close this comment, see RTC #320.					
322	FMIT-55 Hualapai-41 Chemehuevi-41 Cocopah-41 CRIT-41	Append A8 p.1 and Photo 1 & 2		The 60% BOD Report Appendix A-8 noise measurement locations are reported to be "near" and "in proximity to" the certified EIR noise measurement locations. The meanings of these terms are ambiguous and need clarification. Why were the certified EIR noise measurement locations not used?	Precise GPS locations were not available for the locations used in the certified EIR. The 2012 – 2013 noise measurement locations were selected based on their suitability for a longer term noise measurement. All of these locations are within approximately 100 feet of the EIR noise measurement locations and are well within the same acoustical environment.			The Tribes were not involved in the selection of the sites in the FEIR and the 2012-2013 study. The Tribes also note that there is no noise monitoring plan.	This comment and response were discussed at the October 16-17, 2013 TWG meeting. Comment resolved.	Not applicable

324	DOI-145	Section 2.4, Page 7	"Specifically, this involves the simulation of native microorganisms through the delivery of a degradable source of organic carbon, . . . "	What types/species of microorganisms are present at the Topock site?	The pilot tests conducted at the Topock site demonstrated that the bacteria capable of generating the reducing conditions required for chromium reduction are present. The data generated in the pilot studies indicated that aerobic bacteria, denitrifiers, manganese reducers, iron reducers, sulfate reducers, and methanogens are present and were stimulated by the addition of lactate and ethanol at the site. Further analysis of which species of bacteria are present was not conducted and is not necessary to design or implement the remedy. A reference to where the pilot tests are discussed in Section 3 will be added to this section.		Comment resolved pending review of 90% design.		Comment resolved.	90% BOD Apdx B Section 2.4
325	DOI-146	Section 2.4, Page 8	"Note that the reduction of chromate is thermodynamically more favorable than the reduction of Mn(III/IV), Fe(III), and $SO4^{2-}$[S(VI)]; therefore, it is not theoretically necessary to achieve manganese-, iron-, or sulfate-reducing conditions in order to reduce Cr(VI)."	It has been reported that Cr(III) will oxidize to Cr(VI) in the presence of Mn(IV) oxides. Could this possibly occur at the Topock site? Please discuss.	The issue of re-oxidation of Cr(III) precipitated during in-situ remediation to Cr(VI) by manganese oxides was evaluated extensively as part of the Corrective Measures Study/Feasibility Study in conjunction with the Technical Working Group and members of the United States Geological Survey. The oxidation of naturally occurring Cr(III) to Cr(VI) is responsible for the natural background concentration of Cr(VI) in groundwater. This oxidation process is anticipated to convert Cr(III) precipitated by in-situ remediation. However, the rate and extent of oxidation is anticipated to be limited to background levels by two key factors: the limited solubility of Cr(III) and the lack of reactivity of the manganese oxides in an IRZ area. Thus, the conclusion of the analysis of the CMS/FS was that "The degree of reversibility of the Cr(VI) reduction reaction is expected to ultimately result in Cr(VI) concentrations at levels similar to ambient Cr(VI)" (Table 5.5 of the CMS/FS). A detailed analysis of this topic was presented in Appendix G, Section 7 of the CMS/FS. Text will be included in the 90% BOD		Comment resolved pending review of 90% design. 					constrained as deemed necessary in subsequent PEST runs.					
335	DOI-155	Section 4, Page 18, 1st paragraph	"Groundwater budget was developed from regional river gradient and estimates of precipitation recharge, subsurface inflow beneath major and minor washes, evapotranspiration, and subsurface outflow."	What data was used to calculate evapotranspiration? Was the data site-specific?	Presented in 2005 Groundwater Flow Model Update Report (Section 2.5.2). The evapotranspiration (ET) rate was not designed to correspond to published plant ET rates, but as a value averaged over nodal areas which consist of both bare soil along with plant growth. The value of 9.59e-04 ft/d was assigned to areas where plant growth is obvious from field conditions and aerial photographs. This value assumes a roughly 10-20% ground cover for each nodal area and average ET values published for several species typical to this region including Fourwing Saltbrush, Salt Cedar, Arrowweed, and Quailbrush (Mc Donald, Charles C., and Gilbert H. Hughes. 1968. *Studies of Consumptive Use of Water by Phreatophytes and Hydophytes Near Yuma, Arizona*. Water Resources on Lower Colorado River Salton Sea Area. USGS Paper 486-F, Washington, DC.; Gay, Lloyd W. 1986. Water Use by Saltcedar in an Arid Environment. p.855-862. In Karamouz, Mohammad., George R. Baumli, and William J, Brick. Water Forum '86: World Water Issues in Evolution. Volume 1. American Society of Civil Engineers, New York, NY.). An extinction depth of 10 feet was assigned, corresponding with the assumed average root depth. In active ET areas of the model domain (i.e., the southern floodplain, Bat Cave Wash mouth, Topock Marsh area) the plants are predominantly small and the water table is within several feet of land surface, so the 10-foot extinction depth is considered appropriate. In this model package, the maximum ET rate is applied only when the water table coincides with the ground surface. The rate decreases linearly to zero at the extinction depth. Therefore, all areas of the model in which the depth to water is greater than 10 feet have zero ET applied.		Comment resolved.		Comment resolved.	Not applicable

	Hualapai-43 Chemehuevi-43 Cocopah-43 CRIT-43	5.3.1 p. 24	Dissolution, Figure 5.3-1, calibration of the rate constant for manganese and arsenic reduction.	constants compare with literature sources?	constant for manganese oxide dissolution will be included in Appendix B in the 90% design. Specifically, the half-reactions included in the PHREEQC database that link manganese oxide reduction to organic carbon (ethanol) oxidation are as follows: MnO_2: $H_2O + 4 H^+ + 2 e^- = Mn^{+2} + 3 H_2O$ $2 CO_3^{-2} + 16 H^+ + 12 e^- = C_2H_6O + 5 H_2O$ This yields: $6(MnO_2{:}H_2O) + 10 H^+ + C_2H_6O = 6 Mn^{+2} + 13 H_2O + 2 HCO_3^-$ Far from equilibrium, the kinetic rate will be independent of the concentrations of the products (right side of the equation), and assuming that the manganese oxide concentration and pH does not change appreciably within the IRZ, the kinetic rate becomes first order with respect to organic matter concentration: $d[MnO_2]/dt = -k*C$ where k is the rate constant and C is the organic carbon concentration. The rate constant value after calibration was determined to be 2.48e-4 inverse days. Importantly, this rate constant is highly site-specific, as the manganese oxidation rate will vary according to the properties of manganese phases within the aquifer (including the exposed surface area, mineralogy, purity, and crystallinity of manganese oxides and oxyhydroxides at the site) as well as the organic carbon microbial oxidation rate, as based on site-specific observations from pilot testing. Accordingly, literature values of manganese oxidation rates will not be directly comparable; regardless, a discussion of literature studies of microbial manganese oxidation will be included in the 90% design.

The monthly monitoring frequency was specified, given the timescales required for transport of reagents from injection wells to dose response wells on the order of 1-2 months and establishment of a microbial population within the IRZ are on the order of weeks. As initial monthly samples are collected, the changes will be assessed and more frequent sampling will be conducted if necessary. This language will be added to Appendix L, Volume 2 for this portion of the sampling program.					
338	DOI-156	Section 6.2.1, Page 33	"The simulated mobile porosity of the aquifer is 12% of the total volume, with immobile porosity to be 28% of the total volume."	Was a sensitivity analysis conducted to deduce the effect of major model parameters on contaminant transport and, if so, how sensitive was the model to changes in the mobile porosity and immobile porosity values?	Sensitivity analyses were conducted during the calibration of the regional groundwater flow model (CH2M HILL 2005) and numerous sensitivity analyses were conducted and presented in the 60% BOD Appendix B (Section 10). Mobile and immobile porosity values were not addressed in the sensitivity analyses as these porosity values were determined during tracer injection tests conducted at the Site. With no changes in hydraulic conductivity or hydraulic gradient, the reduction in mobile porosity and an increase in immobile porosity would result in faster transport velocities, and slower velocities would occur with an inverse adjustment. Flexibility in components of the remedial design (well flow rates, provisional well locations, etc.) was integrated into the design to account for any variability encountered in the field.		Comment resolved.		Comment resolved.	Not applicable
339	MWD-11	Appendix B, 6.2.1, 3rd paragraph	"...with the immobile porosity to be 28% of the total volume." 	45 Cocopah-45 CRIT-45		*through reaction with dissolved oxygen in the aquifer. Manganese concentrations will attenuate via… reoxidation.*	migrate downgradient from the IRZ line towards the IRZ or riverbank extraction wells. How will dissolved oxygen be reintroduced into the aquifer for these reactions to take place? What will be the resulting pHs of the aquifer water? What will happen to all of the dissolved gases (CO2, H2(g), H2S, N2) that will be produced as part of the remediation?	outside of the IRZ and from the river. In more oxic portions of the aquifer, Fe(II) uptake will occur both through reaction with dissolved oxygen and by adsorption to/oxidation by Fe(III) minerals, forming mixed Fe(II)/ (III)-oxides. Dissolved oxygen and iron minerals in the deeper aquifer will mix and come into contact with groundwater coming in from upgradient. As iron minerals accumulate downgradient of the IRZ, this will continue to provide additional sorption capacity for manganese and arsenic. This process of attenuation of iron by sorption, rather than re-oxidation, is similar to the attenuation mechanism that is anticipated and that was modeled for manganese. Changes in pH and production of dissolved gases are not anticipated to be a concern based on the in-situ pilot test (ISPT) results as well as results observed at Hinkley and other sites. During pilot testing, no significant changes in pH were observed in monitoring wells, indicating that any pH changes caused by carbon consumption and subsequent redox/precipitation/dissolution reactions were adequately buffered by the aquifer solids. Dissolved gas concentrations generated within the IRZ are anticipated to be sufficiently low as to minimize formation of a gas phase within the aquifer. Given the relatively low carbon concentration used in pilot testing and specified in the design, any CO_2 generated will be at a low enough concentration that it will remain dissolved and be flushed through the IRZ over time. Further, pH buffering to circumneutral values will ensure that most of the inorganic carbon generated will be present as bicarbonate rather than dissolved CO_2. Formation of $H_2(g)$ and H_2S will be limited by controlling TOC concentrations to limit byproduct generation. Formation of these gases (as well as N_2 formation) was not an			in groundwater. Comment resolved pending review of the 90% design.

355	DOI-160	Figures 10.13-1 through 10.13-6		Recommend that the additional wells, IRL-6 and IRL-7, be identified in these graphics.	IRL-6 and IRL-7 will be labeled in these figures for clarification.		Comment resolved.		Comment resolved.	90% BOD Apdx B Figures 10.13-1 through 10.13-6
356	DOI-161	Section 10, Figures 10.1-1 through 10.15-4		Typically, the figures display the results of three sensitivity analyses for both Model Layer 2 and Model Layer 4. Variations in concentrations and flow rates are utilized to ascertain potential impacts to the remedial program (e.g., how sensitive is the model to changes). A review of the 109 drawings determined that there were minimal changes between the runs. For example, variations in TOC concentrations and groundwater withdrawal had little to no impact on the results. Please explain why there were minimal changes among nearly all the runs.	The fact that there were minimal changes between the simulated results in nearly all of the runs indicates that the majority of the parameters adjusted in the sensitivity runs had a low degree of sensitivity. However, a few of the runs indicated parameters of higher sensitivity (i.e., TOC concentrations, TOC/Cr(VI) trigger, manganese sorption/generation). Recognizing the difficulty in comparing the 109 drawings, a table summarizing the relative sensitivities of the 15 different sensitivity runs will be provided for the 90% Design Submittal. This will better illustrate the sensitivity of the various sensitivity runs to Cr(VI), manganese, and arsenic simulation.		Comment resolved pending review of 90% design. 357a	FMIT-67	Append B Section 2.3 Page 6,		The effect of this high range of TDS should be evaluated in the context of remedial system efficiency/performance. Was the dismissal of variable-density influence because of earlier evaluations that suggested it was not so important in affecting the plume migration? While this may be the case, current ASR technology suggests the anisotropy/layering and heterogeneity combined with density differences may strongly affect injection of freshwater of low TDS into a stratified density distribution based on reported orders of magnitude difference. The lower Cr(VI)-rich denser water may not be remediated with the assumption of uniform water density. The implication is that when the system starts up, and efforts are made to monitor, then adjust system performance, improvements to the system operating factors (i.e., flow rates, TOC injections, on/off durations etc.) may not be able to improve cleanup as predicted by the uniform density model predictions. Wells at this time will have been installed with little chance to improve spacing (which might need to be	Given the aquifer heterogeneity and vertical anisotropy, and the relatively high expected flow velocities within the system, advection-driven flows are expected to allow adequate horizontal flows to develop and be maintained at all depths between freshwater injection wells and riverbank extraction wells. See response to comment 384a. While it is acknowledged that effects of density-driven flow may occur, they are not expected. If however, effects of density are observed during remedy implementation (i.e. slower, or 'short-circuiting' of flushing within the deeper, more saline portions of the aquifer in areas some distance away from the injection wells), steps can be taken to mitigate these impacts. Potential steps include varying well flow rates over the entire screened zone, or packing off sections of upper screened intervals to increase flushing in deeper zones, effectively countering buoyant effects caused by density contrasts between injected freshwater and in-situ denser water. The 90% design will include a section describing in more detail how density effects will be			The FMIT transmitted a letter to DTSC/DOI regarding comments on modeling issues related to the 60% BOD on April 7, 2014. 359	FMIT-69 Hualapai-55 Chemehuevi-55 Cocopah-55 CRIT-55	Section 3.1.1p. 3-1	*In addition, the auto-calibration program PEST was employed torefine the calibration and to reduce the effects of uncertainty in each calibration target.*	How did PEST reduce uncertainty in each calibration target? How exactly did PEST refine the model calibration? A concern exists about how well the hydraulic aquifer parameters have been calibrated and how well-tested the distribution is, as implied by the complex distribution presented for each layer (i.e., Layers 2, 3 and 4 in Figures 4.5-2 through 4.5-4, respectively). Clearly no data points exist beneath the River, but the hydraulic property distribution is complex. The concern arises because the system is calibrated to existing “unstressed” conditions relative to what will happen when the operating remediation system stresses the system well outside of calibration, both in terms of changes to heads, but also in terms of flows into/out of the remedial area from external boundaries including the river and lateral boundaries, where little characterization (or conceptualization) has occurred. PEST was utilized to develop complex parameter distributions for hydraulic conductivity (as outlined in Section 3.2, in the Report “Groundwater Model Update Report, July 2005”). It	Text will be modified as follows: “*In addition, the auto-calibration program PEST was employed to refine the calibration ~~and to reduce the effects of uncertainty in each calibration target~~*”. PEST refined the model calibration because the first stage of the calibration was manual through a trial-and-error approach until an approximate match was achieved. The second stage then involved PEST where it was run numerous times with incremental parameter adjustments to reduce error variance (CH2M HILL, 2005). Based on the available data the groundwater flow model was calibrated against (a) long term average groundwater levels, (b) average monthly floodplain levels responding to fluctuating river levels, (c) short-term responses to pump testing events, and (d) plume development over time) the groundwater flow model was finalized and approved by DTSC for use in the CMS. The Kh:Kv ratios were refined with PEST as described in Section 3.2 of the Groundwater Model Update Report (CH2M HILL, 2005). PEST was only allowed to adjust parameters			The FMIT and the Cocopah Indian Tribe transmitted letters to DTSC/DOI regarding comments on modeling issues related to the 60% BOD on April 7 and April 9, 2014, respectively. 				is unclear whether the complex Kh:Kv ratios presented in Figures B-6 were determined through PEST. Given the importance and high uncertainty associated with the hydraulic conductivity values, both horizontally and vertically, it is surprising that a sensitivity analysis was not conducted to assess the full range of possible remedial system performance. Remedial systems are typically designed conservatively to allow for unexpected variances in field conditions during remedy implementation.	(including Kv) in the area of the floodplain, which shows up in Figure 8-6 as the oval shaped area of earth tone color. Outside the floodplain area, Kv was calculated as a thickness weighted geometric mean of the stratigraphic units assigned to each model cell. The complex pattern of geometric triangles in the areas of the model north and east of the Topock Site is an artifact of rounding of the Kv values to fit the color scheme of the figure. The values in the model actually vary just slightly above and below 10, causing the color scale to “flicker” between the lighter green for values less than 10 and the darker green for values greater than 10.. Adjustments in the riverbed conductance and evapotranspiration parameters led to little variation in calibration results indicating the low degree of sensitivity to these parameters in the calibration scenarios. As a result, these parameters were not adjusted during the PEST analysis. By contrast, the model was found to be much more sensitive to K and Kh/Kv, especially in the floodplain transient data calibration (matching changes in monthly average water levels over the course of the year and water level response during short-term aquifer tests). It is acknowledged that there is not a single unique solution for the calibration of the groundwater flow model, and variations in parameter values could produce similar calibration results. The hydraulic stress on the aquifer will be different when the final remedy is in operation than it was during the model calibration. The groundwater flow and solute transport model will be updated and recalibrated if significant differences from the current model construction are encountered with respect to hydrogeologic characterization or remedy performance. This will allow the model to be used as a tool to evaluate the performance and guide the operation of the remedial design

360	FMIT-70 Hualapai-56 Chemehuevi-56 Cocopah-56 CRIT-56	Section 3.1.1 p. 3-1	*This calibration procedure yielded a highly variable distribution of hydraulic conductivities to better reflect the local-scale geologic heterogeneities that characterize the natural system.*	Is this realistic considering the highly variable K configuration beneath the river with no supporting data? What should be done is to test a range of hydraulic properties beneath the river to see how much calibration and predictions change.	It is recognized that the complexity of K array beneath the river is not supported by data, however this array did result in some improvement of the match to calibration targets and the overall range of K is consistent with what has been measured. Despite the lack of hydraulic data beneath the river, the simulated K distributions represent an estimated interpolation of K values based on data collected in the vicinity of the river. Hydrogeologic interpretation is important in simulating areas where limited data are available. It is acknowledged that there is not a single unique solution for the calibration of the groundwater flow model, and variations in parameter values could produce similar calibration results. The hydraulic stress on the aquifer will be different when the final remedy is in operation than it was during the model calibration. The groundwater flow and solute transport model will be updated and recalibrated if significant differences from the conceptual site model are encountered with respect to hydrogeologic characterization or remedy performance. This will allow the model to be used as a tool to evaluate the performance and guide the operation of the remedial design after including the adjusted data. See response to comment 653 DOI-268. A section will be added to the 90% BOD report to describe model update procedures.			The FMIT and the Cocopah Indian Tribe transmitted letters to DTSC/DOI regarding comments on modeling issues related to the 60% BOD on April 7 and April 9, 2014, respectively. The letters are included in **Attachment S** at the end of this table.	PG&E's response has been revised to reflect ongoing discussions between PG&E and TRC (Bob Prucha). On April 7 and April 9, 2014, the FMIT and the Cocopah Indian Tribe transmitted letters regarding comments on modeling issues, respectively. PG&E will work with the Tribes and the TRC to resolve these comments and incorporate the resolution in the 90% design.	90% BOD Section 3.1.5

	Cocopah-59 CRIT-59		*the NTH IRZ line via the 24 NTH IRZ Injection Wells, resulting in a net flow of 0 gpm.*		impact on the cumulative injection rate. The NTH IRZ statement does not refer to elements of the Inner Recirculation Loop or freshwater injection. Text will be added to the 90% design to reflect this clarification.					
364a	FMIT-74	Section 3.2.1.1 p. 3-5	*Based on the results of groundwater flow and solute transport modeling, the current recirculation system configuration—injection wells spaced along the NTH IRZ line with extraction wells located at the ends and in minimal places along the line—will allow for adequate lateral dispersion of organic carbon while minimizing the potential for the extraction of carbon substrate or treated water.*	Were "adequate" lateral dispersion of OC and minimizing potential extraction of OC or treated water the only constraints? How were different optimization constraints considered or weighted to come up with the final configuration? For example, how were constraints (i.e., minimizing generation of secondary geochemical species or minimizing overall cleanup time) incorporated into the final remedy configuration? What are details related to defining the constraint for minimizing cleanup? Was it minimum time to minimize Cr(VI) conversion to Cr(III) within 30 years, for the entire plume, or was it total reduction in overall plume volume of Cr(VI) or Cr(III)? It is important to distinguish between them. What is meant by "in minimal places"?	The three optimization criteria are to minimize the remedial clean-up time of the Cr(VI) plume, minimize infrastructure, and minimize byproduct generation. These three optimization criteria were considered concurrently in the design of the remedy. A table of optimization criteria will be developed reflecting the remedial design specifications and parameters encountered during well installation and operation. In order to minimize the remedial clean-up time of the Cr(VI) plume (first optimization criterion listed above), the NTH IRZ should provide adequate lateral dispersion of carbon and minimize the potential extraction of carbon. The text "in minimal places" will be revised to "in the central portion of the NTH IRZ".			Comment resolved pending review of the 90% design. 370	FMIT-80 Hualapai-66 Chemehuevi-66 Cocopah-66 CRIT-66	Section 3.2.2.1 p. 3-12	*The expected total average extraction flow rate of these wells is 150 gpm, although flexibility will be provided to increase this flow rate to 500 gpm (see Table 3.2-2).*	How was 500 gpm determined? Is this enough to account for the cumulative effects of uncertainty in flows, transport, geochemical reactions etc?	The 500 gpm maximum was determined by increasing the nominal flow rate by more than a factor of three to provide hydraulic capture in the event that the regional volumetric flow rates are up to three times higher than anticipated. While this is unlikely, the flexibility was incorporated into the model for conservativeness. The 500 gpm maximum is more than adequate to account for uncertainty in flows. An additional model run at 500 gpm will be used to assess the implications of this maximum flow rate and the results will be accounted for in the O&M plan presented in the 90% design.			Comment resolved pending review of the 90% design. Comment resolution is pending review/okay by the Tribes.	
376	FMIT-86 Hualapai-72 Chemehuevi-72 Cocopah-72 CRIT-72	Append B Section 2.0p. 3	*For the Site, the conceptual model forms the single most important guide for the design and operation of the proposed remediation system, as it is the basis for the numeric modeling, comprised of groundwater flow and contaminant fate and transport that simulate the operation of the remediation system.*	This sentence (1st paragraph) says, the conceptual model represents the most important guide for design and operation of the proposed remediation system. As such, presenting a more detailed discussion of the conceptual flow, fate/transport and geochemical models, for the existing system AND for proposed remediation system (complete with injection/extraction, TOC etc) and how they relate to each other is critical for reviewers to appreciate all of the factors (and assumptions) that go into development of the complex models used as the primary tool to support design of the remediation system, and determine how it will be operated. Simple flow arrows typically included are not included (and should be included) on a diagram that depicts current/proposed conditions. A simple narrative here without supporting graphics is of only limited value. Previous documents have shown this information, but it is difficult to track down and see everything together in one piece that reflects current understanding and knowledge of how the system works.	Flow arrows/flow fields can be added to Figures 6.5-1 to 6.5-12 to better illustrate groundwater flow directions with respect to ambient flow conditions, active remedy flow conditions, and hydraulic capture of active extraction wells. A conceptual operational diagram will also be prepared and included in the 90% design to illustrate the source of extracted water and where it will be injected for each remedial element.			Comment resolved pending review the 90% design documents.	Comment resolved.	90% BOD Apdx B Sections 4 and 6.4
377	FMIT-87 Hualapai-73 Chemehuevi-73 Cocopah-73 CRIT-73	Append B Section 2.2 p. 5	*The saturated thickness of the alluvial aquifer is approximately 100 feet in the floodplain and thins to the south, pinching out along locations where the Miocene Conglomerate and igneous/ metamorphic rocks outcrop.*	Can the location of this point be indicated on a map? Isn't this where the rind also disappears and as such represents an important factor in the conceptual flow and fate/transport model?	Yes, this contact can be identified in a figure. The bedrock contact is evident with the abrupt change in hydraulic conductivity values in Figures 4.5-1 to 4.5-4 of Appendix B (60% BOD) but this contact can be clearly labeled in the 90% BOD.			Comment resolved pending review of 90% design.	Comment resolved.	90% BOD Apdx B Section 4.2

378	FMIT-88 Hualapai-74 Chemehuevi-74 Cocopah-74 CRIT-74	Append B Section 3.4.3 p. 15	*The relationship between TOC and manganese concentration is shown in Figure G13 of Appendix G of the CMS/FS, while Figure G14 of the CMS/FS shows the relationship for TOC and arsenic. In the solute transport model, these correlations are used as the basis for manganese and arsenic generation. Manganese and arsenic generation rates were calculated based on the average amount of byproduct observed in solution for TOC concentrations greater than 10 mg/L and less than 100 mg/L within the upland and floodplain ISPT datasets.*	Rather than use the Mn factor of 0.016, which appears to represent an average or best-case scenario, the range of concentrations of Mn vs. TOC should be considered in the design? Also, Figures G13 and G14 in the CMS/FS are derived from sites other than Topock (i.e., from page 33/45 in App G in CMS/FS it states *"Empirical data demonstrates this as shown in Figures G12, G13, and G14 which depict relative trends of iron, manganese, and arsenic versus total organic carbon (TOC) observed at several sites where large-scale, long-term IRZ remedies are currently being applied."*). Are these applicable to the particular geochemical conditions at Topock?	The basis for the relationship between organic carbon concentration and generation of dissolved manganese and arsenic is from the results of the in-situ pilot tests (ISPTs) conducted at the Topock site, both in the upland and floodplain. In the case of manganese, the base case was developed using the average concentration generated at organic carbon concentrations between 10 and 100 mg/L (as described in Section 3.4.3). Manganese is naturally present in Topock soil at higher concentrations than arsenic and therefore was detected at higher concentrations in the dissolved phase, as compared to arsenic, as a result of the application of organic carbon. Because of this, the arsenic generation rate is lower than that for manganese, and this rate is also based on the Topock ISPTs. Section 3.4.3 refers to Figures G13 and G14 in the CMS/FS because these show the relatively predictable trend in manganese and arsenic generation as related to organic carbon concentration. This predictable trend forms the technical basis for the development of generation rates for the Topock design; however the rates themselves are based on the Topock ISPT data and are therefore appropriate for the geochemical conditions at the Topock site. The sensitivity analysis captures a wide range of generation rates, and covers the range of manganese, arsenic, and TOC concentrations relevant to operation of the remedy. These points will be made clearer in Section 3.4.3 of Appendix B in the 90% Design Submittal. Text will be included in the 90% design directing the reader to the details of the manganese sensitivity analysis and summarizing the results of that analysis. 380	FMIT-90 Hualapai-76 Chemehuevi-76 Cocopah-76 CRIT-76	Append B Section 6.3 p.37	*A sensitivity analysis quantifies the impact that variations on model parameter values have on differences between Site observations and model predictions.*	This is not the standard definition of sensitivity analysis. ASTM standards for conducting a sensitivity analysis show there are there are two types: a) calibration sensitivity and b) predictive sensitivity. The Tribe recommends that both types of sensitivity analyses be performed.	The groundwater flow model was calibrated against (a) long term average groundwater levels, (b) average monthly floodplain levels responding to fluctuating river levels, (c) short-term responses to pump testing events, and (d) plume development over time. A solute transport model was adopted following the choice of remedy in the CMS, with the approved hydraulic model forming the basis of this model. Predictive sensitivity was applied to the solute transport model, since prediction of remedy success was made on the basis of concentration of Cr(VI) and COPCs A predictive sensitivity analysis was conducted using the solute transport model by varying multiple solute transport model parameters and observing the impact on Cr(VI), TOC, Mn, and As. A calibration sensitivity analysis is not applicable for the solute transport model as the full scale remedial design has not been implemented and therefore no data exists to calibrate the solute transport model against for future pumping conditions. Text will be added to clarify the basis for selecting the specific subset of possible parameters and remedial system operational rates evaluated				The comment was resolved verbally at the February 12, 2014 CWG. 					during this sensitivity analysis. The relative sensitivities of variables will be organized and summarized in a sensitivity table to better illustrate the degree of sensitivity, in addition to presenting the simulated solute transport modeling results at 10 and 30 years for Cr(VI), TOC, Mn, and As.					
381a	FMIT-91	Append B Section 6.3 p. 37	*However, various aspects of the Cr(VI) plume and behavior of manganese and arsenic were analyzed in detail with the solute transport model to determine an appropriate range of solute transport parameters to use for the predictive modeling.*	Is it possible to explain why there was no sensitivity analysis of flow conditions and their influence on the remedy? The sensitivity of flow conditions on the overall remedial system performance likely dominates the sensitivity of system response to other factors. It is important to know how to rank these factors, especially when the system is started up and future changes are needed. There are many factors that can be adjusted, or that may explain why the system might not perform as expected. Unexpected conditions of performance might be likely, given the relatively high number of factors and assumptions associated with model predictions (flows, fate/transport, geochemical processes etc). What is the sensitivity of screen depth, well placement, flow rates, especially when key parameters are adjusted? What is the sensitivity of K distributions (especially under river and surrounding known data areas - where it is assumed)? What about the riverbed conductance? Was local scaled-sensitivity analysis to determine and rank which parameters the flow, transport and geochemical reactions are most sensitive to ever performed or considered?	See comments 359 FMIT-69 and 360 FMIT-70. Variations in hydraulic conductivity would impact the volumetric flow through the aquifer which was evaluated by varying the remedial design flow rates (riverbank extraction well rates, freshwater injection well rates, and NTH IRZ well spacing and rates) in the solute transport model sensitivity analysis (Appendix B Section 10). Utilizing the data collected during installation and implementation of the remedial design would be more beneficial than basing the design operation on a theoretical sensitivity analysis. The remedial design components were designed through interpretation of the flow and hydraulic conditions from observed data. These remedial components were then simulated using the groundwater flow and solute transport model. With respect to the remedial design, the proposed remedial design layout would not change, but the implementation of provisional wells or variations in well injection/extraction rates can be adjusted. Variations in encountered hydraulic properties or overall system performance will be integrated back into the groundwater flow and solute transport model to determine the impact on the proposed remedial timeline. It is acknowledged that there is not a single unique solution for the calibration of the groundwater flow model, and variations in parameter values could produce similar calibration results. The hydraulic stress on the aquifer will be different when the final remedy is in operation than it was during the model calibration. The groundwater flow and solute				The comment was resolved verbally at the February 12, 2014 CWG. Comment resolved.	90% BOD Apdx B Section 6.3

	78 Cocopah-78 CRIT-78		*partition coefficient, manganese Freundlich constants, arsenic precipitation rate, manganese liberation rate, and arsenic liberation rate, a reasonable qualitative and quantitative fit to the observed data and flow conditions was obtained. In addition to varying the parameters for the constituents of concern, additional analyses were conducted to evaluate additional parameter impacts on the solute transport model. These parameters include the TOC injection concentration, the riverbank extraction well rate, and the NTH IRZ well spacing. The solute transport modeling sensitivity analysis is presented in Section 10.*		the parameters describing the generation/ attenuation of solutes included in the solute transport model (including TOC, Cr[VI], manganese, and arsenic) were included in the sensitivity analysis, and, therefore, this aspect of the sensitivity analysis is comprehensive. It is agreed that there is a degree of subjectivity and uncertainty associated with selecting sensitivity ranges. A more detailed discussion of the parameters adjusted and justification of the ranges will be presented in Section 10. For clarity, the text in Section 6.3 will be modified to include all adjusted parameters in the 90% Design Submittal. Specifically, the following text will replace the second and third paragraphs of Section 6.3: "Each of the solute transport parameters affecting the transport and dynamics of dissolved solutes was adjusted in the sensitivity analysis, including the chromium partition coefficient, manganese Freundlich constants, arsenic precipitation rate, manganese and arsenic liberation rates, TOC half-life, and TOC-based chromium precipitation trigger. Each of these parameters was adjusted within a range encompassing anticipated values. For some parameters, the ranges were informed by a geochemical assessment of how site-specific variations in water quality affect the parameter of interest (see the geochemical sensitivity analysis described in Section 9.2), while for other parameters, sensitivity ranges were harder to constrain. In these cases, the ranges were chosen to be sufficiently wide (from at least +/- 50% to over an order of magnitude in some cases) to more than encompass any reasonably-anticipated values, given that the values chosen are site-specific and based on pilot test observations. Parameter ranges and results are described in more detail in Section 10. In addition to solute transport parameters, engineering design			issues related to the 60% BOD on April 7 and April 9, 2014, respectively. The letters are included in **Attachment S** at the end of this table.	On April 7 and April 9, 2014, the FMIT and the Cocopah Indian Tribe transmitted letters regarding comments on modeling issues, respectively. PG&E will work with the Tribes and the TRC to resolve these comments and incorporate the resolution in the 90% design.

			deviations intemperature and salinity) were not simulated because these will have a negligible impact onsystem flows and the remedy design when compared to the natural heterogeneity of the aquifer.	Water Investigation, Feb 11, 2009, pages 6-33 to 6-37) This evaluation ONLY considered effects of density on plumemovement, not on effectiveness, efficiency or potential problems with the remediationsystem. Page 107 to 108 in Groundwater Modeling in Arid and Semi-Arid Areas edited by Howard S. Wheater, Simon A. Mathias, Xin Li discusses density effects on injection for ASR.The report should present an analysis supporting dismissal of density/temperature effects.What are the temperature effects on piped in freshwater injected over entire screened zone/aquifer? (see Revised Final RCRA Facility See also http://www.deepdyve.com/lp/elsevier/variable- density-modelling-of-multiple-cycle-aquifer- storage-and-NSsvy8c4T2 for variable density effects on cyclic ASR effects of heterogeneity and anisotropy (vert:horz). Review of 2009 CH2M HILL report suggests complex lateral heterogeneities and variable vertical anisotropy complicate this picture but WERE NOT considered in evaluating density effects on remediation system simulations. Available literature (and FEFLOW) suggest this should be considered, even if it is conceptual. This alone could cause considerable variation in predicted flow, transport, and geochemical predictions.	*multiple cycle aquifer storage and recovery (ASR): Importance of anisotropy and layered heterogeneity in brackish aquifers*) supports the conclusion that advective flow will likely be dominant over density driven flow in the vicinity of the Topock freshwater injection wells in most instances, though it is still possible. The paper presents a formula for calculating the Mixed Convection Ratio, M $\left(M = \frac{2\pi rB}{Q} Kv \left(\frac{\rho - \rho 0}{\rho 0}\right)\right)$. When M is much less than one, advective flow is dominant. When M is greater than 1, density driven flow has more influence. The value of M varies with distance from the well and several other parameters. Using the formula provided in the paper, the mixed convection ratio M was calculated for the two freshwater wells, FW-1 and FW-2. For this calculation, it was assumed that the water temperature was 85 degrees F and that the TDS of the injected freshwater would be 450 mg/L. The nominal injection rates from the 60% design were 100 gpm at FW-1 and 50 gpm at FW-2. The TDS of the water in the aquifer at the injection wells was estimated based on highest TDS values from nearby deep zone wells. The values of M calculated at the distance of the next nearest injection well to the freshwater well in question. The parameters used in the calculations are shown in the tables included in **Attachment I**, at the end of this table. For both FW-1 and FW-2, M is less than 1 out to the radius of the nearest other injection well, indicating that advective flow will dominate over density driven flow within this radius. At greater distances from the freshwater wells, density-driven flow starts to have more influence in the deep aquifer, but at these greater radii the flow will be influenced more by the IRL wells than by the freshwater wells. Density difference is one of several factors that could adversely affect the flushing efficiency in some areas of the site. Low permeability zones and preferential groundwater flow			letter is included in **Attachment S** at the end of this table.	On April 7, 2014, the FMIT transmitted a letter regarding comments on modeling issues. PG&E will work with the Tribe and the TRC to resolve these comments and incorporate the resolution in the 90% design.

					paths are other factors. It is anticipated that there will be areas where flushing occurs faster than projected, and other areas where it occurs slower than projected. After several years of operations, areas where flushing efficiency is lacking will start to become apparent. One of the reasons for designing injection and extraction wells with excess capacity above the design flows is to have flexibility to adjust pumping and injection rates to optimize flushing of the plume to the IRZ. If density-driven flow impacts are observed to occur during remedy implementation (i.e. slower flushing of deeper, more saline portions of the aquifer in areas some distance away from the injection wells), steps can be taken to help mitigate these impacts. Potential steps include varying well flow rates or packering off sections of the screened intervals to manage density effects. The 90% design will include a section describing how density effects could be mitigated, should they occur.					
384b	Hualapai-80 Chemehuevi-80 Cocopah-80 CRIT-80	Append B Section 11.0p. 73	*Note that density dependent flows (resulting from potential deviations intemperature and salinity) were not simulated because these will have a negligible impact onsystem flows and the remedy design when compared to the natural heterogeneity of the aquifer.*	The report should present an analysis supporting dismissal of density/temperature effects. 385	FMIT-95 Hualapai-81 Chemehuevi-81 Cocopah-81 CRIT-81	Text is from “Groundwater Model UpdateReport, July 2005”,page 2-8	*The model requires three parameters for each river node: water surface elevation, riverbed elevation, and riverbed resistance (the inverse of permeability). Riversurface elevations were assigned throughout the model domain using average elevation of themain Topock site measuring point (I-3) and historical average river gradients between I-3 and the USGS gauging station in Topock Gorge, between I-3 and the RRB station at theupstream end of the site, and average gradient north*	What are effects of these assumptions (or associated uncertainty), especially the ”riverbed resistance”, on remedial system performance?Were these ever tested? The resistance as calculated here does not seem to correlate well with the thickness of the rind. Does it need to?	The simulated water surface elevation was based on average site measuring point data and historical average gradients and is therefore directly correlated with observed river stages. The riverbed elevation is an approximate representation of the river profile and would not have a significant impact on the remedial system performance as it remains in model layer 1. Riverbed resistance was evaluated during the calibration of the groundwater flow model and through the implementation of PEST it was observed that riverbed resistance was a relatively insensitive parameter. Riverbed resistance is dependent on the riverbed thickness and the model layer structure. By contrast, the rind is defined by geochemical properties, specifically reducing conditions prevalent in shallow-medium depth groundwater wells surrounding the river and the porewater of the river itself and the rind extends beyond the riverbed into the floodplain. Therefore the riverbed resistance does not necessarily correlate with the rind. The effects of changing riverbed conductance on the projected performance of the river bank wells has not been tested in the model. It should be noted that the river bank wells are not intended to be screened in the shallow zone, so they won’t be drawing water directly from the area immediately adjacent to and below the river. The amount of			The FMIT and the Cocopah Indian Tribe transmitted letters to DTSC/DOI regarding comments on modeling issues related to the 60% BOD on April 7 and April 9, 2014, respectively. 			of the site from USGS maps. The riverbed elevation wascalculated by assuming a triangular bed profile with a maximum depth of 20 feet decreasing to zero at the banks. Riverbed resistance is defined as the sum of:(1) riverbed thicknessdivided by its vertical hydraulic conductivity and (2) half of Layer 1 thickness divided by its vertical hydraulic conductivity.		water the wells draw from the river will be affected by both the river bed conductance and the Kh/Kv ratio of the sediments between the well screen depth and the river bottom, and Kh/Kv ratios surrounding the wells. Additional data to evaluate these parameters will be generated as the river bank extraction wells are installed and tested. The model will be updated, re-calibrated if necessary, and new long-term predictions made as these new data become available. A section will be added to the 90% BOD report to describe model update procedures.					
386	FMIT-96 Hualapai-82 Chemehuevi-82 Cocopah-82 CRIT-82	Section 3.1.4 p. 3-3	*Numerous iterations of the remedial system layout and operational strategy were then considered and simulated in order to arrive at an optimized remedial approach and to account for uncertainties in the model predictions.*	The document should present a summary of layouts and operational strategies and how were these used to 'optimize' the remedial approach. How were these used to account for uncertainties in model predictions specifically?	Considerable flexibility was incorporated into the remedial design by including provisional well locations and ranges in well rates in order to account for uncertainties in the model predictions. A table of optimization criteria will be developed reflecting the remedial design specifications and parameters encountered during well installation and operation.			Comment resolved pending review of 90% design. 			cycling patterns (i.e., duration of active operation versus shutdown), carbon substrate amendment injection concentrations, and reinjection destinations…		duration of active operation versus shutdown), ~~carbon substrate amendment injection concentrations,~~ and reinjection destinations. <u>Solute transport model parameters were also adjusted including carbon amendment injection concentrations, carbon decay rates, Cr(VI) partition coefficient, manganese generation/ attenuation rates, and arsenic generation/ attenuation rates."</u> <u>Relative sensitivities of each of the parameters/ conditions evaluated with the model will be tabulated to further illustrate the results of the sensitivity analyses and will be included in the 90% design submittal.</u>					
388a	FMIT-98	Section 3.1.4p. 3-3	• *Reduce the anticipated remedial time frame for effective capture and treatment of the Cr(VI) plume;* • *Minimize the necessary remediation infrastructure (i.e., total number of new well locations) or "footprint" of the remedial system; and* • *Minimize the impact of potential byproducts (i.e., arsenic and manganese.)*	After reviewing the document, it appears these are only three of other important optimization criteria. It is highly recommended that all of these be compare within a table where their relative priorities (importance) can be shown in deriving the final "layout" and "operational strategy" for the remedial system. What are the specific "performance metrics" for optimization? For example, what does the model suggest is the optimum time to reduce the plume volume (or Cavg for Cr(VI)) to some small remaining percentage of existing mass? Were the optimization (or sensitivity) runs designed to only qualitatively determine things like well locations, rates, cycling etc? It does not seem very quantitative. Is this because the overall modeling objectives are somewhat vague? Review of Appendix B - does not show a very clear optimization strategy. In fact, it appears to be confused with a limited sensitivity analysis that only assesses remedial design performance by adjusting remediation system-specific boundary conditions individually (and not in combination). It would be more useful to conduct a sensitivity analysis to evaluate remedial system performance due to the combined effects of remediation system BCs with uncertain model parameters, or model BC unrelated to	These are still the three core criteria for the remedial design. All three are directly related and need to be balanced during remedy design and implementation A table of optimization criteria will be developed reflecting the remedial design and operation specifications and parameters encountered during well installation and operation. Performance metrics will be developed as part of this table. A subset of possible boundary conditions and solute transport model parameters were varied individually to assess their direct impact on the simulation results. Relative impacts of individual parameters could be masked by simulating combinations of flow and solute transport parameters (and boundary conditions). Conclusions can still be drawn on combined impacts based on sensitivity simulation results where only individual parameter/boundary conditions are adjusted. The relative sensitivities of adjusted inputs will be summarized in a sensitivity table to better illustrate the degree of sensitivity, in addition to presenting the simulated solute transport modeling results at 10 and 30 years for Cr(VI), TOC, Mn, and As. The adjusted inputs will be arranged by type (i.e, flow parameter, transport parameter, boundary condition,			The FMIT transmitted a letter to DTSC/DOI regarding comments on modeling issues related to the 60% BOD on April 7, 2014. 392	FMIT-102 Hualapai-88 Chemehuevi-88 Cocopah-88 CRIT-88	Append B Section 1.2 p. 1	This appendix describes the results of six major components of the modeling study at the Site:	The flow, solute transport and fate associated with the natural and remedial operation flow systems is complex. The conceptual and numerical modeling of these processes is equally complex. It is standard practice to include flow charts of showing how previous regional modeling fit in with local-scale models, how the flow model feeds into the transport and the geochemical models, and then how sensitivity and uncertainty analyses/ model validation are conducted. This is recommended to help technical reviewers convey these concepts to other less technical people. It will also be useful for conveying how future updates would be conducted (i.e., what aspects of modeling). Much of the fate/transport modeling for example, depends on flow modeling. Ultimately the modeling should support complex decisions.	A flow chart will be developed and included in the 90% design submittal to show the relationship of the regional groundwater flow model, the geochemical model, and the solute transport model, and the associated uncertainties and sensitivities. 			heterogeneity in the aquifer by establishing a variable hydraulic conductivitydistribution across the groundwater flow model domain during thecalibration process.		interpretation is important in simulating areas where limited data is available. Given that the simulated K value distribution agreed with the hydrogeologic interpretation and resulted in a well calibrated groundwater flow model, this is the best baseline to conduct the solute transport modeling. While varying the K distribution may impact the calibration and predictions, the baseline run would still be the ideal version to utilize minimizing the need for a detailed sensitivity analysis.					
395	FMIT-105 Hualapai-91 Chemehuevi-91 Cocopah-91 CRIT-91	Append B Section 4.4 p. 20	Boundary Conditions	Typically recharge and evapotranspiration are discussed in this section. In the CH2M HILL document titled "Groundwater Model Update Report, July 2005", Maximum ET rates appear to have been set at 0.42 in/yr. This seems exceptionally low for max ET rate. Statewide estimates in this area likely exceed this by at least 2 orders of magnitude. The implication of underestimating this rate is that under the non-stressed calibration conditions more groundwater likely discharges into the river nodes rather than ET nodes adjacent to the river. The problem with this is that during remedial system operation, when the system gets stressed beyond the "calibration state", the predicted dynamics and water balance associated with aquifer-river interactions and aquifer-ET interactions will be wrong. See http://www.twdb.texas.gov/publications/reports/contracted_reports/doc/2004483535_UT_BEG.pdf for published examples of annual maximum ET rates and a review of ET simulations in MODFLOW. Time-varying Cr data presented at the TWG meeting, July 18, 2013, showed annual cyclicity of shallow Cr concentrations. Is it the variation in ET rates that concentrates Cr during warmer months? If so, is this accounted for in the models? The calibration of the transient groundwater flow model (MICROFEM) appears to be based on varying river stage and ET rates based	During the calibration process, it was observed that evapotranspiration was not a sensitive parameter in the groundwater flow model. The MODFLOW/MT3D flow model utilized the average ET rate directly from the regional groundwater flow model and it was held constant to represent long-term steady state conditions. Because of the depth of the water table throughout most of the model domain, the ET rate is specified as zero at the extinction depth specified to be 10 feet. The active areas are predominantly in the flood plain and to the south near the bedrock where the aquifer pinches out and are consistent with the narrow bands of observed vegetation. During remedy operation ET would likely remain the same or decrease due to hydraulic stresses in the floodplain. From a volumetric approach, implications for an ET value that is too low would mean that more water would discharge to the river to achieve flow balance in the system. This may require increased flows at river bank extraction wells than anticipated. During installation/testing and model updates, this will be further evaluated to see if the ET module parameters in the groundwater flow model need to also be updated under this new state of stress.				The comment was resolved verbally at the February 12, 2014 CWG. Comment resolved.	Not applicable

				on the Consumptive Use Program 2005 data - but it is unclear how 0.42 in/yr was scaled to match this data. What did the long-term transient MODFLOW/ MT3D flow and fate/transport simulations with the new remedial system design and operation presented here assume for maximum ET rate and its variation in time? What are implications if it is too low?						
396a	FMIT-106	Append B Section 5.1p. 21	Geochemical and Reactive Transport Code Selection *Batch simulations were performed with the geochemical modeling software PHREEQC…"*	How sensitive are the PHREEQC geochemical reactions to seasonal variations in injected water temperatures? Would external air temperature variations affect above the extracted groundwater temperatures associated with piping from the freshwater source?	All of the geochemical reactions considered are sensitive to temperature to a minor extent. The average temperature of groundwater at the Site is approximately 25°C, which is the temperature at which the geochemical calculations were run. While water temperatures are expected to change slightly during travel through the pipelines and tanks, the temperature changes will be readily buffered as the water is injected back into the aquifer so that the actual temperature change within the aquifer will be so small that the effects on geochemical reaction rates and equilibria will be negligible. Any variations in solute transport parameters as a result of temperature fluctuation are well-bracketed by the sensitivity parameter ranges already considered in Section 10. With respect to the freshwater injection, modeling will be updated in the 90% design to account for differences in temperature between the source water and the injection sites. It is, therefore, predicted that any increase in Mn(II) concentration in the river will be orders of magnitude below detection,*	Isn't this also true for Cr and As? Does this address the RAO regarding prevention of impacts on the Colorado River water?	The simulated results indicate that Cr(VI) is reduced and hydraulically captured and will not impact the Colorado River. Similarly, simulated byproduct arsenic generation in the floodplain remains below 5 ppb and will not impact the Colorado River. This addresses the RAO regarding the prevention of impacts to the Colorado River.			Comment resolved.	Comment resolved.	90% BOD Apdx B Section 8.2

			particularly after oxidation within the hyporheic zone.							
401	FMIT-111 Hualapai-97 Chemehuevi-97 Cocopah-97 CRIT-97	Append B Section 9.2 p. 58	*The sensitivity range considered in the solute transport model sensitivity analysis, therefore, adequately accounts for uncertainty and variability in groundwater chemistry, as well as additional uncertainty/ variability in sorption site concentration.*	All model parameters, boundary condition assumptions, and conceptualization uncertainties need to be assessed along with uncertainties in groundwater chemistry.	Uncertainty is inherent in any mathematical representation of a natural system. It is acknowledged in the groundwater flow and solute transport models that a more detailed uncertainty analysis would confirm this uncertainty. The proposed design and range of operation were based on the calibrated groundwater flow model, the predictive solute transport modeling and sensitivity analysis, available characterizations, and professional judgment.			The FMIT and the Cocopah Indian Tribe transmitted letters to DTSC/DOI regarding comments on modeling issues related to the 60% BOD on April 7 and April 9, 2014, respectively. The letters are included in **Attachment S** at the end of this table.	PG&E's response has been revised to reflect discussions between PG&E and TRC (Bob Prucha). On April 7 and April 9, 2014, the FMIT and the Cocopah Indian Tribe transmitted letters regarding comments on modeling issues, respectively. PG&E will work with the Tribes and the TRC to resolve these comments and incorporate the resolution in the 90% design.	90% BOD Apdx B Section 11
402	FMIT-112 Hualapai-98 Chemehuevi-98 Cocopah-98 CRIT-98	Append B Section 10.0 p. 59	Solute Transport Model Sensitivity Analysis	The sensitivity of model transport results performed here does not consider effects of the many complex flow parameter/boundaryconditions. Can the same conclusions about adjustments to design/operation factors (i.e., well spacing, TOC injection concentrations, etc.) be made given the uncertainties associated withflows? Is it always possible to conclude the design is conservative and operations can always be 'tweaked' to meet objectives? If multiple factors/parameters/boundary conditions had been adjusted within reasonable ranges simultaneously, rather than individually, would the conclusions be the same? There are many parameters and factors influencing the overall remedial system performance. Because the modeling tools are the primary tools used to define the design and operation of the system, it is recommended that all flow, transport, and geochemical parameters and boundary conditions, and all design and operation factors	The groundwater flow model utilized to conduct the solute transport modeling represents a reasonable calibration to the available data. It is admittedly not the only possible combination of parameters that could result in an acceptable calibration. The uncertainty in model predictions is accounted for by providing flexibility in the design flow rates and well locations. This design flexibility is based on the solute transport modeling and sensitivity analysis, professional experience, and the hydrogeologic characterization of the site. Adjustment to groundwater flow model parameters will change flows through hydrogeologic units differently, but adjusting individual remedial design injection/extraction well flow rates within stated ranges is expected to allow the system to meet stated objectives. A section will be added to the 90% BOD report to describe model update procedures.			Suggest it is better to use a range of calibrated model inputs (flow) and transport inputs (possible range) to simulate a range of possible outcomes. The FMIT and the Cocopah Indian Tribe transmitted letters to DTSC/DOI regarding comments on modeling issues related to the 60% BOD on April 7 and April 9, 2014, respectively. The letters are included in **Attachment S** at the end of this table.	PG&E's response has been revised to reflect discussions between PG&E and TRC (Bob Prucha). On April 7 and April 9, 2014, the FMIT and the Cocopah Indian Tribe transmitted letters regarding comments on modeling issues, respectively. 				be compiled and kept separate. Given the complexities of the flow/transport system, when initial observed system performance starts to deviate from what was simulated, knowing which parameters, or factors to adjust will be essential. The impression here is that they are not distinguished, nor fully tested. It is difficult to see how the model(s) won't be required to be updated frequently, at least early on, especially with any adjustments to the design or operation. Every adjustment would require long-term projections to make sure that none of the modeling objectives (or metrics) are problematic. This doesn't seem possible using just field observations.						
403a	FMIT-113	Append B Section 10.13 p. 71	Intermediate Recirculation Well Sensitivity *In order to optimize the performance of the remedial design….*	How many simulations were conducted and what were the performance metrics, or optimization criteria/targets?	Numerous simulations were conducted with changes in well locations, well rates, well operations, and TOC concentrations. The optimization criteria were to accelerate the remedial timeframe while preventing Cr(VI) migration past the NTH IRZ, hydraulically capturing the existing floodplain Cr(VI) impacts, and minimizing byproduct generation. A table of optimization criteria will be developed reflecting the remedial design specifications and parameters encountered during well installation and operation. Performance metrics will be developed as part of this table.			Comment resolved pending review of 90% design. 			byproducts.	simultaneously varies parameters an amount that preserves calibration and provides a probability associated with predictions. Typical methods are Monte Carlo, GLUE, Linear, etc.). See http://www.nrc.gov/reading-rm/doc-collections/nuregs/contract/cr6805/cr6805.pdf b) Only a select number of parameters were evaluated in the sensitivity analysis. It is unclear whether those parameters adjusted in the analysis represent ones the system response is most sensitive to. A complete table showing which parameters were adjusted, by how much, the basis for the adjustments and quantifiable results is needed. c) Were model results from each sensitivity run evaluated to ensure that specified parameter adjustments still produced results within calibration? Calibration was performed against several datasets (page 18, p. 1, AppB) including short-term pumping tests and monthly water level response to river-levelfluctuations. Were these re-evaluated with parameter adjustments in the sensitivity analysis to ensure sensitivity results are still valid within the calibration solution space? d) It is unclear what basis is used for specification of parameter adjustment amounts. This can be very subjective and can lead to meaningless output if results lie outside of calibration target values. Can specific calibration target values/tolerance be provided? It is not uncommon to vary hydraulic conductivity by an order of magnitude (a factor of 10), but each parameter should only be adjusted by an amount commensurate with its likely range. e) Parameter adjustments appear to have been only varied individually vs. in combination. The concern here is that although the system	practical exercise. b) The parameters varied for the solute transport model represented the major parameters utilized in the solute transport model as well as the remedial components. The sensitivity analysis details were presented in Section 10 of Appendix B, but they will be tabulated and organized by type for clarity. c) The calibration was conducted for the groundwater flow model prior to the integration into the solute transport submodel. Subsequent sensitivity analyses conducted using the solute transport model involved ranges in solute transport parameters and remedial component operation. d) Parameter variation was described in Section 10 of Appendix B, but they can be tabulated for clarity. e) Solute transport model parameters were varied individually to assess their direct impact on the simulation results. Relative impacts of individual parameters could be masked by combining sensitivity				resolution in the 90% design.

				might have responded one way with one input adjustment (i.e., IRZ well location spacing), with an adjustment of another input such as injection/extraction well flow rates, or hydraulic conductivity values, results would likely be different.	runs. However, conclusions can still be drawn on combined impacts based on the individual sensitivity analyses.					
407	FMIT-117 Hualapai-103 Chemehuevi-103 Cocopah-103 CRIT-103	Append B Section 12.0p. 74	*During installation and implementation of the remedial design, the additional hydrogeologic and groundwater quality data can be utilized to update the groundwater flow and transport models to improve their effectiveness as evaluation tools.*	The details of how this will be done should be included. It is highly recommended that the flow model be updated and verified as new wells are completed and hydraulically tested. This way, it would be possible to revise any remaining well locations if needed.	See response to comment #653 DOI-268. There are several checkpoints during remedy implementation when the groundwater flow and solute transport model update will be evaluated, including during installation, after system start-up, and during remedy operation. During the installation phase the model will be updated, if the data collected during construction significantly contradict the current model construction. For example, if large variations in saturated aquifer thickness, bedrock extent, permeability, chromium distribution, etc. are measured compared to what has been modeled to date, the model would be updated and re-run. The regional model would be updated first, then imported into the fate and transport submodel before transport runs are conducted. During remedy well testing and system start-up, information will be gathered about achievable flow rates for the remedy wells and system as installed and actual hydraulic gradients. That information will be fed back into the model and additional predictions will be made. As remedy operation progresses, the observed data will be used to better calibrate the model and generate updated predictions of future performance. In particular if actual data collected contradicts geochemical or solute transport results, the model will be updated and predictive scenarios will be re-run. A section will be added to the 90% BOD report to describe model update procedures.				The comment was resolved verbally at the February 12, 2014 CWG. Comment resolved.	90% BOD Apdx B Section 12
Specific Comments – Appendix C (Design Criteria), Attachment C (Geotechnical Analysis) and Attachment E (Fire System Analyses)

419	FMIT-119 Hualapai-104 Chemehuevi-104 Cocopah-104 CRIT-104	Attach C		A friction angle of 38 degrees, used for fill and alluvial materials in the slope stability analyses, seems high in comparison to friction angle values presented in Exhibit C.1-1. The Modified Proctor maximum dry densities are at the high end of what could be expected (but they are not impossibly high, given that the material is well- graded (poorly-sorted) and contains minimal clay). Some consideration needs to be given to the friction angle of in-situ material versus the friction angle of compacted laboratory specimens tested in direct shear, assuming that we are concerned with slope stability of natural slopes vs. the stability of constructed slopes compacted to 90% of Modified Proctor maximum dry density.	The friction angle of 38 degrees used in the slope stability analysis should not be compared to the friction angles in Exhibit C.1-1 because the values are for different soils in different locations. The friction angles used for slope stability analysis are based upon a geotechnical investigation conducted in 2009 at AOC 4 on the southwest side of the station. The friction angles shown in Exhibit C.1-1 are based upon a geotechnical investigation conducted in 2004 for the Interim Measures No. 3 site on the north side of I-40 and approximately 3,000 feet from AOC 4. The design considered the difference in friction angle for in-situ soil versus remolded soils. This is demonstrated in Exhibit C.4-1 where different design friction angles are presented for compacted fill and native soil (App. C).			Comment resolved.	Comment resolved.	Not applicable
420	FMIT-120 Hualapai-105 Chemehuevi-105 Cocopah-105 CRIT-105	Attach C	Geotechnical Summary	It may be appropriate to consider the effect of partial saturation on apparent (ephemeral) cohesion in the granular site soils, especially as it relates to slopes maintainable during construction. Site soils may appear to be capable of greater slope stability when partially-saturated, versus their stability when dry.	PG&E does not consider the effects of partial soil saturation on soil strength to be important for this site for the conditions anticipated during construction or for the life of project.			Comment resolved.	Comment resolved.	Not applicable

426	FMIT-122 Hualapai-107 Chemehuevi-107 Cocopah-107 CRIT-107	Attach E	Fire System Analyses	This technical memo has no stated source or date.	Source and date will be added to Attachment E in the 90% design submittal.			Comment resolved pending review of the 90% design documents.	Comment resolved.	90% BOD Appendix C Attachment E
427	FMIT-123 Hualapai-108 Chemehuevi-108 Cocopah-108 CRIT-108	Attach E	Fire System Analyses	The analysis doesn't explicitly consider NPSH requirements for either fire pump. NPSH criteria for the Allis Chalmers electric-motor-driven fire pump are provided but are illegible, and no criteria are presented for the ITT A-C diesel- motor-driven fire pump.	The net positive suction head (NPSH) available for the fire service pumps is 96.4 feet at design flows. The required NPSH for either of the pumps is not readily available from the manufacturers. However, cavitation is not expected to be a problem. Required NPSH values can vary from 2 to 30 feet. Even allowing for a 30% buffer and assuming required NPSH is 30 feet, the available NPSH should not be higher than 39 feet (30 * 1.30), which is significantly less than the 96.4 feet available. If cavitation was a problem, it should have been evident from annual pump testing.			Comment resolved.	Comment resolved.	Not applicable

TABLE I-1

Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
428	FMIT-124 Hualapai-109 Chemehuevi-109 Cocopah-109 CRIT-109	Attach E	Fire System Analyses	For an industrial facility mixing flammable liquids, the required fire flow seems low.	Please note that the volume of ethanol within a building during normal operations is less than 4 gallons (Including the pumps and piping). The following fire flow required was provided to the design team by PG&E's insurance company: a) MW-20 bench: 363 gpm sprinkler flow (1210 sq ft of 0.3 gpm/sq ft) plus a 500 gpm hose allowance for a fire hydrant. b) TW bench - 144 gpm sprinkler flow (480 sq ft of 0.3 gpm/sq ft) plus a 500 gpm hose allowance for a fire hydrant. It should be noted that extinguishing a fire in a sprinklered building requires on the average approx. 8% of the volume of water to extinguish a similar blaze in a similar, unsprinklered building. This is because the fire is quenched with water before it can accelerate out of control.			Comment resolved.	Comment resolved.	Not applicable
Specific Comments – Appendix D (Engineering Plans/Drawings)										
429	FMIT-125	General		There is no notation on the plans (i.e., in "General Notes" or elsewhere) indicating that the area is listed on the National Register of Historic Places, eligible for listing on the National Register as a Traditional Cultural Property and/or a sacred place and that all workers are subject to sensitivity training before working in the field. Such notations should appear on all plans to underscore the nature of the project area and demonstrate a commitment to cultural sensitivity. The plans may be the only project document some workers have contact with.	Workers will participate in site orientation and training on cultural/ historical resources sensitivity that will be provided at the project initiation meeting, to be held at the Topock Compressor Station. Site orientation will stress that all site activities will be conducted in a respectful manner. PG&E believes that this training should address the FMIT's concerns in this comment. However, the following text will also be added to the General Notes: "The project area is eligible for listing on the National Register as a Traditional Cultural Property and/or considered a sacred place by area American Indian Tribes; all workers are subject to sensitivity training before working in the field."			Comment resolved.	Comment resolved.	90% BOD Appendix D Drawing C-00-01.
430	DOI-167	G-10-01		The schematic includes a discharge line from pump PMP-205 going to the "Influent Tank Farm". This discharge line should be going to "Influent Tanks", since the location is already in the Influent Tank Farm.	This call out will be changed to show the pump returning fluids to the Influent Tanks.		Comment resolved.		Comment resolved.	90% BOD Appendix D Drawing I-11-04.

			Produced Water	3.3.3.3 page 3-38 in the process description for consistency.	revised to be pH 6.5 in accordance with the Drawing G-12-04.					
432	DTSC-130	Appendix D Page G-12-03	Process Schematic for Freshwater Pre-Injection Treatment System	Please introduce pre-treatment chemical after the filters to save on overall dosage quantity as well as filter longevity. In addition, please consider the possible use of hydrochloric acid to save in amount used and efficiency.	See responses to comment #184 DTSC-72 and #185 DTSC-73. Hydrochloric acid was considered. However, since sulfuric acid is currently used for conditioning cooling makeup water, it is proposed to be used in the freshwater pre-injection treatment system to take advantage of the economy of scale.	Okay.			Comment resolved.	90% BOD Exhibit 3.3-6.
433	DTSC-131	Appendix D Page G-12-03	Process Schematic for Freshwater Pre-Injection Treatment System	The proposed use of wastewater in the cooling tower or reinjection in the in situ reactive zone wells may present challenges in obtaining the quantity and quality diverted. Please provide specific water quality parameters required and viability for the proposed reuse of each said reuse.	See RTC #181 DTSC-70.	Noted. See RTC #181 DTSC-70.			Comment resolved.	Not applicable
434a	FMIT-126	Append D1 “C”-Drawings		Based on the information presented in Appendix D-2 (C-Drawings), in deciding to place nearly all utility (water, electrical, fiber-optic, etc.) services below ground, the designers apparently gave no consideration to Tribal preferences or to an earlier-stated tribal preference to have that infrastructure placed above-ground, thereby minimizing earth disturbance. Above ground piping also appears supported in at least certain areas by the draft GeoArchaeological Report	See response to comment #8a FMIT-3. The Tribe’s comments expressing a preference for aboveground facilities were noted and considered. While PG&E recognizes the Tribe’s expressed preference, the facilities are proposed below ground because that is consistent with the analysis in the EIR. (See, e.g., EIR, Vol. 2, at 1-6.) Placing facilities aboveground creates potentially significant aesthetic, O&M, and safety impacts. Further, while aboveground utilities may reduce earth disturbance to some extent, aboveground facilities would still require earth disturbance for foundations, vaults, and other supporting equipment. PG&E believes that the proposed 60% design represents the most appropriate design in the Topock site setting while incorporating the Tribes’ preferences to the extent practicable, is most protective of remedy infrastructure, most O&M friendly for the decades-long life of this remedy, and most consistent with the certified EIR. The draft geoarchaeological report (July 2013) presents results from the geoarchaeological assessment of the Project Area, and ranks locations where sediments have the highest,				This comment and response are being discussed as part of the evaluation of aboveground piping alternatives (#1 DOI-1, #8a FMIT-3, and #8b Hualapai-3/ Chemehuevi-3/Cocopah-3/CRIT-3).	The 90% design complies with the Agencies’ directive on aboveground/ belowground pipeline infrastructure in the April 4, 2014 letter titled *“Directives on Outstanding Issues of the Response to Basis of Design Report/ Intermediate (60%) Design Comments for PG&E Topock Compressor Station Remediation Site”*.

TABLE I-1

				(July 2013).	intermediate, lowest, or no potential to contain buried archaeological resources. As discussed at the August 20, 2013 TMU meeting, this ranking is relative rather than absolute – higher potential does not mean that archaeological materials are likely to be encountered, but rather the stratigraphic unit with this designation is more capable of containing buried archaeological materials than other units. Therefore, the potential ranking only represents relative probability and does not predict actual locations of buried archaeological materials or suggest preferred locations for aboveground vs. belowground piping and utilities.					
434b	Hualapai-110 Chemehuevi-110 Cocopah-110 CRIT-110	Append D1 "C"-Drawings		Based on the information presented in Appendix D-2 (C-Drawings), in deciding to place nearly all utility (water, electrical, fiber-optic, etc.) services below ground, the designers apparently gave no consideration to Tribal preferences or to an earlier-stated tribal preference to have that infrastructure placed above-ground, thereby minimizing earth disturbance.	See response to comments #8a FMIT-3 and #434a FMIT-126.				This comment and response are being discussed as part of the evaluation of aboveground piping alternatives (#1 DOI-1, #8a FMIT-3, and #8b Hualapai-3/ Chemehuevi-3/Cocopah-3/CRIT-3).	The 90% design complies with the Agencies' directive on aboveground/ belowground pipeline infrastructure in the April 4, 2014 letter titled *"Directives on Outstanding Issues of the Response to Basis of Design Report/ Intermediate (60%) Design Comments for PG&E Topock Compressor Station Remediation Site"*.
435	FMIT-127 Hualapai-111 Chemehuevi-111 Cocopah-111 CRIT-111	Append D1 Sheet C-00-01 "General Notes"	*"3. No excavated material shall be stored on site except as approved by owner"* *4. Dispose of unusable excavated materials at no additional cost to the owner"*	This project has very specific requirements regarding all soil excavated at the site. These "general notes" while typical of most construction projects are inappropriate for this project. The contractor should be referred to the specific documents detailing soil handling for this project. Additionally, the procedure under development for handling displaced soils needs to be referenced.	Comment noted. These notes will be revised to state: "Management of displaced soils shall be in accordance with the Soil Management Plan (Volume 4 of the O&M Manual) and the Management Protocol for the Handling and Disposition of Displaced Site Materials (Appendix B of the Soil Management Plan)."			Comment resolved.	Comment resolved.	90% BOD Appendix D Drawing C-00-02.
436a	FMIT-128	Append D1 Design Drawings ("C"-drawings)		**SEE EXHIBITS I to IV submitted with these comments:** Construction of pipe sections A & H, as presented in the 60% BOD report (see Exhibit I) will involve considerable soil excavation, surface disturbance, soil testing, soil transport, soil processing and, possibly, soil storage in an extremely culturally sensitive area. An alternative approach, with much less excavation and surface disturbance,	See response to comment #1 DOI-1 and pipeline evaluation matrix (see **Attachment A**, at the end of this table).			The FMIT provided the tribe's assessment and comments on the alternative pipeline routings. The Tribe's comment letter is included in **Attachment A**, at the end of this table.	Information presented in DOI's pipeline evaluation matrix and associated visualizations were discussed with the agencies, Tribes, and stakeholders at the November 19-20, 2013 TWG meeting. Tribes' response was presented at the December 17-18, 2013 TWG meeting and subsequently provided in a draft technical memorandum from TRC (Charlie Schlinger) to	The 90% design complies with the Agencies' directive on aboveground/ belowground pipeline infrastructure in the April 4, 2014 letter titled *"Directives on Outstanding Issues of the Response to Basis of Design Report/ Intermediate (60%) Design Comments for PG&E Topock Compressor Station Remediation Site"*.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				and consistent with already-stated Tribal preferences, is as follows: Obtain 12 kV power from the City of Needles and step it down to 480 V near IM-3 using a dedicated transformer. This would require coordination and possible partnership, with the City of Needles, as they are planning an upgrade of the line capacity, at least as far as the Pirate's Cove development. Distribute the 480-V power to the planned (and possible contingency) IRL & FW wells using conventional above-ground power lines and poles, with a nominal spacing of100-150 feet. See Exhibit II. This approach to the electrical supply would possibly eliminate the need for step-down transformers at each major point of use. Alternatively, if line losses at 480 Vare too high, or if other constraints dictate, distribute the 12 kV power on above-ground power lines and poles, and step down the voltage at each major point of use. Also, pole mounts of transformers could be considered. Use wireless SCADA (Supervisory Control and Data Acquisition) communication technology (which is highly developed) instead of fiber optic technology for monitoring and control, or hang fiber optic cables using the electrical power poles. The wireless approach would require aerial antennas for communication with the project control center. Construct water lines in a manner similar to existing above-ground IM water lines or the existing above-ground freshwater water Topock Compressor Station supply line (exposed pipe). See Exhibits III & IV for two possible above- ground waterline location alternatives (Alternatives I & II) for pipe sections A & H. This differs from the design in the 60% BOD report in that almost all utility infrastructure would be above-ground. Along limited portions of pipe sections A & H, as needed, the above-ground water lines could/may need to be placed in an above-ground concrete box. Along limited portions of the pipe section A, aerial bridge crossings (such as the one presently					PG&E, DTSC, and DOI/ BLM dated Dec 17, 2013 (also included in **Attachment A**, at the end of this table). A site walk was held on Dec 27, 2013 to further discuss the piping options. Representatives from DOI, FMIT, Hualapai Tribe, Chemehuevi Tribe, TRC, and PG&E participated in the site walk. A presentation was made by TRC (Charlie Schlinger) at the January 23, 2014 TWG meeting (presentation materials are included in **Attachment A**, at the end of this table). Additional analysis was performed by PG&E on Segments 1 and 2 of Pipeline A, and presented at the February 11, 2014 TWG meeting. Presentation materials are also included in **Attachment A**, at the end of this table.

				sections of dual-wall pipe. This overall approach would greatly reduce the excavation volume required, though the electrical, water and SCADA / communication infrastructure would be visible and subject to vandalism or other physical damage. In addition, limitations on vehicular access to the little-used portion of old Route 66, between Park Moabi Road on the west side and National Trails Highway on the east, could be explored, e.g., with gated access on each end and with pedestrian access allowed, for the period of remedy operation. We believe that the east and west ends of Route 66 have apparently been signed for several years to discourage access by the public. This action, which would require agency buy-in, would reduce objections associated with the use of above-ground infrastructure. As part of the communication system, cameras could be installed for monitoring. The Tribes request that this Utility Alternative be studied and presented as part of the CEQA process. NOTE: Exhibits I-IV show approximate locations only.						
437	FMIT-129 Hualapai-113 Chemehuevi-113 Cocopah-113 CRIT-113	Append D1 Design Drawings ("C"-drawings)		Construction of pipe sections B1 & B2 as presented in the 60% BOD report, will require considerable excavation and corresponding surface disturbance. An alternative design is as follows. Utilize above-ground water piping (as is presently done). The 12 kV service along pipe section B1 could be done using above-ground (aerial) distribution on conventional poles, or, per the design, with a minimal trench.	See response to comment #1 DOI-1 and evaluation matrix (see **Attachment A**, at the end of this table).				Information presented in DOI's pipeline evaluation matrix and associated visualizations were discussed with the agencies, Tribes, and stakeholders at the November 19-20, 2013 TWG meeting. Tribes' response was presented at the December 17-18, 2013 TWG meeting and subsequently provided in a draft technical memorandum from TRC (Charlie Schlinger) to PG&E, DTSC, and DOI/ BLM dated Dec 17, 2013 (also included in **Attachment A**, at the end of this table). 									PG&E participated in the site walk.	
438	FMIT-130	C-05-06 C-07-10		Power and communication Node 5 is currently designed to be constructed due north of IRL-3's well and meter vault. The node is approximately ~15'-20' north of the vaults and on top of a crest (~12'-15') above the well vaults. Construction of this Node will cause a great disturbance to the surrounding land, and its current construction location will create a visual eye sore with the surrounding area. Redesign to reduce impacts should be sought.	In response to this comment, Node 5 will be relocated down the slope on a flat spot to be created by earthwork. As a result, all equipment will be spread out laterally along the road (about 100 feet) to ensure adequate space for O&M (see figure in **Attachment J**, at the end of this table). Drawing C-05-06 will be revised to reflect this detail. The proposed relocation will remain the same if the aboveground option is selected for piping. Under either proposal piping between the relocated equipment and IRL-3 will be underground.			Comment resolved pending review of the 90% design.	Comment resolved.	90% BOD Appendix D Drawing C-05-06.
439	FMIT-131	C-05-06		Pull Boxes PBX-D5C and PBX-T5C sizes do not match between C-05-06 and E-00-08. Also the pull boxes are very large, in respects to the amount of fiber optics running through them. What can be done to reduce size?	Size of the pull boxes will be updated in the 90% drawings.			The issue will be revisited pending the decision of aboveground vs. belowground piping.	PG&E will update the size of pull boxes in the 90% design and submit for review and comment.	90% BOD Appendix D Drawings C-05-06 and E-00-08. As noted, PG&E is evaluating options to optimize Node 5 footprint.
440	FMIT-132	C-02-01		Pull Boxes E and C are on the North side of the existing dirt road, while the FW-1 vaults are on the south side. Is it necessary to split the pull boxes from the well vaults, disturbing both sides of the road?	The pull boxes were located on the north side because of space constraint on the south side of the road and to avoid having to shutdown IM-3 injection during construction. Further, future maintenance and repair would be more difficult and less safe due to a lack of space if the pull boxes and well vaults were both located on the same side of the road (see figure in **Attachment J**, at the end of this table). Drawing C—02-01 will be revised to reflect this detail.			Comment resolved pending review of the 90% design.	Comment resolved.	90% BOD Appendix D Drawing C-02-01.
441	DTSC-132	Appendix D Page C-05-01 and C-05-02	IRL-4 Access Road Site Plan	Please combine the plan and profile if possible for ease of use in design and construction.	Comment noted. PG&E will evaluate the possibility of combining the cited plan and profile drawings as requested, and will include in the 90% design.	Response noted. Comment deferred to 90%.			Noted.	90% BOD Appendix D Drawings C-05-01 and C-05-02. The possibility of combining these drawings was evaluated. For clarity and ease of use in construction, these drawings will remain as two separate drawings.
442	FMIT-133	C-05-03 C-05-05 C-07-10		Currently IRL-2 location is of great concern. The disturbance to the local area during construction and after during monitoring will have heavy impact to the Maze both physically and visually. As previously mentioned in meetings between FMIT and PG&E, FMIT recommends further rigorous evaluation of an alternative locations	In response to this comment, PG&E evaluated what would be required to relocate IRL-2 closer to the road. Taking into consideration the Southwest gas ROW, the remedy piping corridor, and the space required for drilling and O&M of this well, PG&E will need to cut into the bank of the road on the north side			The Tribe would like to see visualizations of both options and further discussion prior to the 90% design.	This comment and response were discussed with Tribes at the December 12, 2013 TWG meeting, and the December 27, 2013 site walk. The requested visualization of IRL-2 was provided on December 17, 2013 and included in **Attachment J** at the end of this	90% BOD Appendix D Drawings C-05-03 and C-05-05.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				closer to the road adjacent to the main pipeline.	and install a retaining wall to prevent slough off or caving (see figure and visualization in **Attachment J**, at the end of this table). PG&E does not recommend IRL-2 be relocated due to the required amount of earthwork and associated disturbance, as well as the construction challenges on a slope.				table. In response to the Tribes' preference for no additional cuts would be made into the banks on either side of the roadway, IRL-2 location will remain as proposed in the 60% design.	
443	DTSC-133	Appendix D Page C-07-17 and C-07-18	Pipeline Plan and Profile	Please provide a reference and detail for the above ground supports.	Please see drawing C-07-67 for aboveground supports. PG&E will evaluate the aboveground supports in the 90% design.	PG&E's proposal for above ground support appears excessive for non-hazardous water.			PG&E will evaluate the aboveground supports in the 90% design.	Not applicable because this portion of Pipeline B (formerly Segment B4) was brought underground. See Appendix D Drawings C-07-28, -29, and -103 (Segment B2).
444	FMIT-134	C-07-02 C-07-54		Pipeline J - Purpose of this Line? It is taking water from the RAW line before it is treated. (Two lines from raw water line with isolation valves).	Pipeline J is the main trunk connecting Pipeline B, the freshwater supply pipeline from the Arizona wells, to the FW and IRL wells in the uplands. This allows for direct pumping from the supply well(s) to the injection wells, and reduces electricity use. See also drawing G-00-06 (blue line). In the event that pre-injection treatment of freshwater supply is needed, all freshwater would first be pumped to the treatment system at the Compressor Station via Pipeline B. The treated freshwater would then flow to the uplands injection wells, along the Station access road following Pipeline F (see drawing C-07-01 for key map). The pipes will be installed if the contingency action is required. At the time the construction is complete, isolation valves will be closed on Pipeline J to prevent untreated freshwater from flowing to the injection wells.			Comment resolved pending review of 90% design documents.	Comment resolved.	Not applicable
445	DTSC-134	Appendix D Page C-07-74, Detail C12	Trench Sections	Please provide the footing design for the pipe support.	The pipe support referenced was designed to be anchored into the rock surface that was expected to be located directly under the road bed. Subsequent investigation has revealed that it may be possible to place the pipe in a more traditional trench. This will be evaluated during the 90% design process and presented in the 90% Design Submittal.	Ok pending review of 90%. However, PG&E should consider minimizing footprint and infrastructure in respect for the Tribal sensitivity of the area.			Comment resolved.	90% BOD Appendix D Drawing C-07-109
446	FMIT-135	C-08-01 S-06-06		Currently there are four new structures planned for the Transwestern Bench area. The carbon	PG&E disagrees with the assertion regarding the level of ground disturbance. Field inspection and			Comment resolved. The Tribe requests that details be presented prior to submittal	Comment resolved.	90% BOD Appendix D Transwestern Bench 08 Drawings

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				amendment building and carbon storage tanks will be built on the south side of the decon pad, 25-30 ft of undisturbed ground will have to be leveled for construction. Construction of the new storage building, on the west side of the decon pad, will require cutting into a ~15'-20' undisturbed hillside, and the construction of a retaining wall. Lastly, the new two story maintenance facility is extremely large, and will also require that undisturbed areas are disturbed for construction purposes. What can be done to reduce this level of landform disturbance?	historical account of excess fill materials from TCS construction used at the TW Bench indicate that the footprint of the carbon amendment building and carbon storage tanks is located in primarily fill materials. The maintenance facility would require a cut of about 5 feet into the hillside. However, as discussed in response to comment #26 DTSC-4, in order to reduce the infrastructure on the TW Bench, PG&E is evaluating an option of moving some functions originally intended to occur at the TW Bench - training, conference room, library, laboratories, maintenance, and storage – to a location at Park Moabi. Concurrently, PG&E is evaluating a revised layout of the potential remaining functions at the bench. PG&E will keep the agencies, Tribes, and stakeholders informed of PG&E's proposal regarding location and layout prior to the 90% design submittal.			of the 90% design. The Tribe further requests that PG&E verify that the excavation will be limited to actual fill materials.		(i.e., Function Code 08 Drawings)
447	FMIT-136	C-02-01 C-05-03 C-05-05 C-05-06 C-07-09 C-07-10 C-07-11 C-07-12 C-07-13 C-07-14		With IM-3 remaining potentially operational until after the final groundwater remedy is up and running, is it possible to construct and install the groundwater remedy's wells, injection pipeline, trenching, and conduit (See Referenced Sheets) while the IM-3 components are still in place? The proposed locations for the new remediation components are in the exact same locations as the old IM-3 system. Is there enough room to construct and install the new system around the old, without being forced to disturb an even greater area? Can any of the existing IM-3 components at these locations be decommissioned consistent with whatever need has been identified for maintaining the IM-3 treatment plant?	Yes, it is possible. Construction approaches will be included in the forthcoming Construction/Remedial Action Work Plan. All efforts will be made to minimize the amount of disturbance during construction. PG&E understood that the second question in the comment to ask if partial decommissioning of the IM-3 infrastructure can be done as part of construction of the full-scale remedy. The response to this question is partial decommissioning of the IM-3 infrastructure cannot be done. Additionally, note that the criteria for decommissioning IM-3 are specified in the 2012 Settlement Agreement between DTSC and the FMIT. In accordance with the agreement, the decommissioning plan will not recommend decommissioning of the IM-3 facilities until the Plume Control Criteria are met and DTSC determines that the groundwater remedy is achieving plume control, DOI determines that the remedy is operational and functional, and DOI concurs with DTSC's determination to decommission IM-3. The settlement agreement also provides,				PG&E and the Tribe discussed this comment and response at the December 17-18, 2013 TWG meeting.	Construction/Remedial Action Work Plan Section 3.

					however, that “DTSC' s determination of Plume Control . . . must be made concurrent with or after DTSC's OPS determination, unless DTSC in its lawful discretion, decides that decommissioning of IM-3 can occur prior to DTSC's OPS Determination; and DOI must concur with DTSC's decision to decommission IM-3.”					
448	FMIT-137	C-07-69 C-07-70 C-07-71 C-07-72		With pipelines being placed in open air concrete trenches, has pipeline expansion and contraction been taken into account for the total length of trenching required?	Pipeline expansion/ contraction has been accounted for. Two different methods will be shown in the 90% design – expansion joints or pipeline anchors (provided at 200 foot spacing or at each joint whichever is closer).			Comment resolved.	Comment resolved.	90% BOD Appendix D.
449	DTSC-135	Appendix D Page M-02-02	Freshwater Injection Well Construction Details	Please note that the text prescribes stainless steel continuous wrapped well screens as opposed to the provided louvered screens in the notes section. Please correct accordingly based on the final proposed well screen chosen.	The details of the wells design are still being developed. The text in Section 3.3.3 will be expanded to more fully describe the well design for each type of well and the drawings will be made consistent with the text at the 90% design.	Okay			Comment resolved.	90% BOD Section 3.3.3.
450	DTSC-136	Appendix D Page M-02-02	Freshwater Injection Well Construction Details	Please provide a neat cement seal between the annular space of the inner and outer well casings.	The space between the conductor casing and the inner casing will be sealed by the wellhead flange. Not clearly shown on the drawings included in the 60% BOD is the sanitary seal at the top of the inner casing. This type of construction provided for in California State Well Standards Bulletin 74-81 (see Figure 5b in the attachment to the RTCs). Drawings on Sheets M-02-01 and M-02-02 will be revised to more clearly show the seal on the inner casing. The FW Injection wells are being constructed in this way to allow for the possibility of reconstructing the wells by pulling the inner casing, removing the clogged gravel pack and the inner few inches of the borehole wall, and reconstructing the well in the original borehole. If successful, this could allow for reconstruction of an injection well without the need to drill another borehole. The ability to successfully pull the inner casing in an old well where the gravel pack may be cemented by mineral precipitates is uncertain, however this method of well construction is proposed to allow for that possibility. If neat	Comment resolved pending review of the 90%. Also consider bentonite seals for saturated zones.			Comment resolved.	90% BOD Appendix D Drawing M-02-02.

TABLE I-1

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				IRL-series wells. Can butterfly valve in injection line between FCV and FCA be eliminated, seems like extra component given butterfly valves at entrance and exit of vault. Also consider swapping FCV and flow meter to minimize potential for FCV to introduce flow disturbance prior to flow meter.	vault dimensions are identified on M-05-05. As part of the 90% design, PG&E will review this to evaluate whether the vault length can be reduced by taking out one valve. Since this change will occur on the smaller FW pipe, it is unlikely to change the required length for the larger RW pipe.			documents.		considered and an evaluation was conducted as indicated in the response. Results from the evaluation indicate that all valves are needed and need to kept for maintenance purposes.
454	FMIT-140	E-00-21		Node 5 communication panel located near IRL- 3 is 90"x36". Can the panel size be reduced?	PG&E will evaluate a smaller panel size (up to 18" shorter in height) and propose a final panel size in the 90% design, after important design details such as aboveground vs. belowground piping and conduits have been settled.			The issue will be revisited pending the decision of aboveground vs. belowground piping.	PG&E will evaluate a smaller panel size and propose a final panel size in the 90% design for review and comment.	90% BOD Appendix D E-00-21. At this 90% stage, Node 5 communication panel is designed to support all remedy communications in the uplands related to planned wells FW-1, IRL-1 to 4, and future provisional wells IRL-5 to 7. This eliminates the need for additional equipment for future provisional wells and the associated disturbance with installation of the equipment. The panel size is appropriate for this type of installation and intended use at Topock. PG&E will continue to seek ways to reduce the panel size while balancing the need for and the ability to properly maintain the equipment over multiple decades.
Specific Comments – Appendix E (Draft Specifications)										
455	DOI-168	Part 3, Division 1, Section 01 11 00, Part 1, 1.01, B, 1		The Summary of Work includes installation of 51 new remedy wells. Section 3 of the main text identifies installation of the following remedy wells; 24 NTH injection, four NTH extraction, five river bank extraction, four IRL injection, two TWB extraction, five ER extraction, two TCS injection, and two FW. This accounts for a total of 48 wells (not including provisional wells). Please review and clarify.	Comment noted. The Summary of Work will be revised at 90% stage to reflect the well count at 90% design.		Comment resolved pending review of 90% design.		Comment resolved.	A summary of borehole count is provided in Tables ES-2A and 2B of the 90% BOD. The Summary of Work will be prepared after the design is finalized.
456	DOI-169	Part 3, Division 1, Section 01 11 00, Part 1, 1.01, B		Suggest revising the Summary of Work to include more specific language regarding facilities and design components to be constructed. It is not clear that all design elements are incorporated as currently written (i.e., see Exhibit 3.5-1, truck loading/unloading stations, central maintenance and storage buildings are not discussed in the work summary).	Comment noted. The Summary of Work will be updated at 90% stage.		Comment resolved pending review of 90% design.		Comment resolved.	The Summary of Work will be prepared after the design is finalized.

		03 30 00 Page 15-16	Materials C. Admixtures	underground concrete vaults carrying high voltage conduits are to be marked with red-dyed concrete. However no specific product is provided for technical review. General information available for underground concrete dyes indicate that electrical concrete envelope shall contain red dye at 8 lbs. per cubic yard of concrete. Based on this standard concentration it is concluded that significant amounts of this dye will be used as part of the remediation system design and could be potentially released into the subsurface. The 60% BOD report provides no recommendations on the specific product that will be used or environmental safety requirements for this dye. It is requested that PG&E provide information on the specific dyes that will be used and ensure that the selected dyes have been adequately characterized for environmental hazards (i.e. aquatic toxicity, persistence and bioaccumulation) and for use in this sensitive area.	33 00 (Cast-In-Place Concrete), contains information about the pigments that may be used to color the electrical duct banks. General pigment characteristics are specified in Article 2.01.C.1. More detailed pigment characteristics are specified in Article 2.01.C.9. That Article also specifies requirements by referencing reputable widely-used nationally-recognized product standards. PG&E believes that the specified properties in the subject specification align our goals with the Tribes' goals in terms of using sustainable products to meet the objectives of the project. It is not standard practice to specify a specific pigment product during design because the engineer cannot know all of the other products that will be in the concrete mix. As a result, the designer cannot determine compatibility and may accidentally specify a product that reacts with other materials in the mix and adversely affects concrete performance. It is standard practice to specify material requirements for the pigments as done in the subject specification section. This allows the construction contractor to propose and submit a concrete mix with compatible products. It also allows the construction contractor to propose more innovative products that may not have been available or known at the time of design. The contractor's proposed products will be submitted for review and approval before use per Article 1.04.A.1.c.5. Although Article 2.01.C.9 does mention electrical duct banks, the subject specification section does not appear to mention underground concrete electrical vaults. It is an industry best practice to color underground concrete electrical duct banks to improve safety; however, PG&E is not aware of colored concrete being used for underground vaults. PG&E agrees to provide pigment information to the tribe, if requested when it becomes available.			review of 90% design documents.

				place significant load on the bridge compared to a water-filled 12- inch-diameter water line? Also, why is there no reference analysis provided for the bridge in its existing condition?	conditions as a reference analysis.			Comment resolved.		
471	FMIT-146 Hualapai-119 Chemehuevi-119 Cocopah-119 CRIT-119	Append G AECOM report Sect. 6.0		In section 6.0 (Conclusions) of the AECOM report, reference is made to a section 7.0, said to contain recommended modifications. There appears to be no section 7.0.	See attached Drawing #481620, Change #1 (Erection Plan, Colorado River Highway Bridge Topock-Milpitas Main 300) for recommended modifications for compliance with current wind/horizontal loading requirements (included in **Attachment K**, at the end of this table). This drawing will be added to the report as Section 7. PG&E Gas Transmission, as the entity responsible for the pipe bridge within PG&E organization, is leading the discussion with Kinder Morgan regarding modifications to the arched bridge. Any follow-on pipeline bridge improvement project will be a Gas Transmission project. Consistent with current practice, PG&E will keep the agencies, stakeholders, and Tribes informed of Gas Transmission projects in the Topock area.			Comment resolved pending review of the 90% design.	Comment resolved.	90% BOD Appendix G.
Specific Comments – Appendix H (Updated Cost Estimate)										
472	FMIT-147	General		The first paragraph is unclear about whether PG&E is asserting that the remedy cost increase is attributable to addressing stakeholder comments. Please clarify and explain the relevance of this assertion if the cost increase was otherwise required to comply with ARARs or other statutory requirements. Also, please explain on page 10 of the estimate why certain mitigation measures are excluded from the estimates.	Cost increase is primarily attributable to more engineering detail and changes between the 30% and the 60% designs. Some of the changes are in response to stakeholder (including agency) comments, for example the addition of As/F pre-treatment facility. Specific cost increases (or decreases) can be found in Table H-1, with text explanations in Table H-2. As detailed in those tables some of the larger cost increases include: • Monitoring wells: The monitoring well network was modified which resulted in larger and deeper wells. A pre-drilling field program and expanded testing was added. In addition, well construction materials changed to more expensive material. • Arsenic/fluoride treatment plant: Construction and			Comment resolved pending review of the 90% design.	Comment resolved.	90% BOD Appendix H.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					operation/maintenance were added due to concerns about water quality in the HNWR-1 well. An alternative to treatment is still under consideration, but DTSC directed that treatment of parameters above CA MCLs be included in the 60% design. • Power source: Specifics were added regarding the source and distribution of power for the operation of the remedy as information became available. • Certain mitigation measures (listed in Appendix H) were excluded from the 60% design cost estimate for various reasons, including judgment that the costs were minimal relative to overall project costs (disturbance coordinator, tribal access plan), or because these items were not estimable at the time (TRC), or because the costs are embedded within design and operation (noise mitigation). Certain costs that were not estimable at the time of the 60% design, may be estimable at 90% design, and, if so, will then be included in the cost estimate. Text will be added to the 90% design to clarify that the changes in cost estimates are based on various factors including technical, stakeholder, and agency inputs.					
473	MWD-16	Appendix H/ Table H-1	Construction Cost Estimate	Construction cost of As/F Freshwater treatment is estimated at $9.5 million (nearly 9% of overall construction cost). Does the estimated O&M cost ($6.8 million per year) in Attachment C Table 1 include O&M costs for the pre-injection treatment system, including chemical costs?	The estimated annual O&M cost for the pre-injection treatment system for arsenic and fluoride in Attachment C Table 1 (page 3397 of the 60% BOD) is $1.16M. The estimated cost included chemicals as well as labor, maintenance, and materials.				Comment resolved.	90% BOD Appendix H.

		Page 4								
477	DTSC-142	Appendix H, Cost Resources, 5th bullet	National Electrical Contractors Association – Labor Unit Manual and published list pricing discounted 30% for electrical materials	Please provide rationale on the 30% discount applied.	The 30% discount for electrical materials is based upon professional experience and conversations with vendors regarding discount for bulk purchase. Note that the 30% discount did not apply to any of the generation equipment.	DTSC discourages use of discount rates unless it is backed up by vendor estimates. Pursuant to EPA's guide for cost estimate (EPA 540-R-00-002 OSWER 9355.0-75), "If possible, more than one vendor quote should be obtained. Quotes from multiple sources can be averaged, or the highest quote can be used in the cost estimate if the collected quotes seem to be at the low end of the industry range."			DTSC's input are noted for the 90% cost estimate.	90% BOD Appendix H.
478	DTSC-143	Appendix H, Major Assumptions, p.6	HDPE pipe installation and fusing will be done at night for the next day of work.	This is contrary to PG&E's design statements that night work is not anticipated. Please explain.	Pipe installation will be done during daytime hours. Pipe fusing can be done at night and to do so could significantly reduce the construction schedule. If such work is proposed for the night time, PG&E will take all possible steps to reduce lighting (shrouding and shielding temporary lights) and duration. All night time work will be performed in compliance with the approved mitigation measures.	If this is PG&E's plan, it is recommended that all statements associated with night work are consistent within the design document.			Comment resolved.	90% BOD Appendix H.
479	DTSC-144	Appendix H, Major Assumptions, p.7	Startup is 6 weeks.	Please define start up and how this effects costs.	The startup task entails pre-commissioning and commissioning tasks for the Remedy system. Pre-commissioning includes confirming all electrical, mechanical, and controls equipment are installed properly so that the system is accepted as complete following construction and startup can be begin. Equipment testing during this phase includes such things as motor rotation tests, control loop checks, and valve actuation. Any defects found during this phase will be corrected and checked prior to accepting the system. Commissioning includes testing the entire system on both a subsystem level (e.g., individual well or carbon dosing system) and the entire system to verify operational sequences and alarms work properly using clean water to the maximum extent possible. Any system defects are repaired and checked prior to accepting the commissioning phase. A testing phase using contaminated	Comment resolved pending review of the 90% design.			Comment resolved.	90% BOD Appendix H.

Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					groundwater, known as groundwater commissioning, would normally be the next step, but this step was not included in the estimate as the procedures had not been defined for the 60 percent design. Once a groundwater commissioning procedure is prepared (start-up procedures will be included in the 90% design) this step can be estimated. The time of six weeks is based upon the best estimate of time at the 60% design stage. The quality of the engineering/ specifications with input from the owner with incorporation of the owner input and design requirements into a comprehensive QA program will determine the true time and cost of startup. Price impacts are based upon how the risk is contractually distributed among the various vendors and subcontractors. For instance, if startup and testing is a time and materials/expense activity, cost will increase if the startup time exceeds six weeks. If startup time is based upon a lump sum performance based scope of work, the cost may remain the same. The time and pricing implications can be better examined when the class 1 estimate is priced because the design plan set and specifications will be more definitive (i.e., complete design, functional description, schedule).					
480	DTSC-145	Appendix H, Description of Construction Work	Process trench spoil, assuming 100% will be used as bedding/backfil l	Did estimate take into consideration the large volume of soil that may require storage, care and maintenance for an extended period of time? What cost assumptions were used for the soil?	Not enough information regarding the anticipated volumes, storage locations, and details regarding maintenance protocols for excess soil was available at the time of the 60% design cost estimate. Therefore, it was assumed that all of the soil generated would be re-used on-site. This information will be updated in the 90% design cost estimate. DTSC's input are noted for 90% cost estimate.	PG&E is currently considering specific locations for soil storage from the construction phase of the project. Cost estimate should be consistent with PG&E's proposal for the quantity of soil estimated for storage.			Comment resolved.	90% BOD Appendix H.
481	DTSC-146	Appendix H, Excluded Costs		Why did PG&E exclude these costs, especially mitigation measures that will be required for the life of the project?	See response to comment #472 FMIT-147. DTSC's input are noted for 90% cost estimate.	DTSC would like to see a rationale for each item that is excluded from the cost estimate in the 90% design. Please note that all costs, even			Comment resolved.	90% BOD Appendix H.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

						minimal costs should be included.				
482	DOI-175	Appendix H, Attachment C, Page 2	References	The following item is included in the Reference list but is not referenced in the text: CH2M Hill 2011.	Noted. Will include in the 90% design submittal.		Comment resolved.		Comment resolved.	90% BOD Appendix H.
483	DTSC-147	Appendix H, Attachment C, Table 1	Arsenic and Fluoride Treatment Plant – Comment: Facility O&M and assumes minimal waste need to be transported off-site	According to PG&E's Sustainability Summary Metrics of 3/29/2013, PG&E estimated Liquid Waste Truck Trips to range from low of 500 truck trips to high of 1,833 trips for AA technology. See also comment on Appendix M, 4.0 Summary of Ongoing Bench-scale Testing Results, Wastewater Generation, Page 4 below. Please explain why this assumption is used for cost estimate.	The reference text assumes the wastewater could be managed using a range of management options similar to those identified for remedy produced water. The assumption was made based on preliminary bench testing results. Note that PG&E will remove the arsenic and fluoride treatment system, and include an arsenic only freshwater pre-injection treatment system, in the 90% design as a contingency.	PG&E's response suggests that the Sustainability Summary Metrics as published is misleading since the design document considered another set of management options. The cost estimate must consider the higher of the range of options that are consistent with the design. PG&E cannot publish in a summary metric of needing up to 1833 truck trips and yet not consider it for cost estimate. DTSC understands that the 90% design will contain different technology and that the cost estimate will be updated.			Comment and response noted.	90% BOD Appendix H.
Specific Comments – Appendix I (Response to Comments on Draft 30% BOD Report)										
484	DOI-176	Appendix I	General Comment	The references in this Appendix need to be reviewed, as there seems to be some in-text citations missing, as well as some discrepancies with the corresponding References list.	Comment noted. Cross references will be verified.		Comment resolved.		Comment resolved.	This Appendix.
485	FMIT-148	General		Where the final two columns (final comment resolution and where responses are reflected in the BOD report) are blank, how is the reader to interpret the status of the comment? For example, is it being carried forward to the final design document for resolution? Is there any schedule for resolution, either by date or program event? Also, some of the Final Comment Resolution Boxes do not appear to "match" the DTSC or DOI responses to the 30 % design comment (i.e., Item 303). This makes the tracking of comments difficult and the matrix of limited utility. How will this be resolved in the final design documents?	In that case, it means that the comment has been resolved and there is no need for modify the cited text/tables/ figures in the next iteration of the BOD. For the 90% BOD, in such case, PG&E proposes to put "Comment Resolved" under the Final Comment Resolution column and "Not Applicable" under the "Where responses are reflected in the BOD report" column. PG&E welcome suggestions from the Tribe to assist with its tracking of the comments and use of the matrix.			Comment resolved.	Comment resolved.	90% BOD Appendix I.
486	FMIT-149	Items 25 & 183		By letter dated March 15, 2012, to DTSC and DOI, the Tribe communicated that its legal counsel had not provided any non-confidential communications to PG&E	PG&E fully responded to all of the Tribe's comments on the 30% BOD (See Appendix I in the Intermediate Basis of Design Document.) When responding to the Tribe's comments,				PG&E and the FMIT have discussed this comment and the response.	Not applicable

TABLE I-1

Response to Comments on Basis of Design Report/Intermediate (60%) Design

Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				on the 30% BOD and did not authorize PG&E to communicate or represent the Tribe's position in any regard. This should be noted in respect to PG&E's responses on these and other items in the 30% BOD. Please refer to and incorporate the Tribe's position on Items 25 and 183 as they are set forth in that letter.	PG&E did not in any way indicate that its response to the Tribe represented the Tribe's position. PG&E's responses to comments represent PG&E's understanding and good faith effort to answer comments. PG&E continues to understand based on the Tribe's May 15, 2012 letter to DTSC and DOI (the comment appears to have the wrong date) that the Tribe's comments regarding the East Ravine area and electrical transformers were not intended "to criticize the completeness of the FEIR nor to request additional mitigation measures." (Letter from the Tribe to DTSC and DOI (May 15, 2012) at p. 5). Accordingly, PG&E's response that the Tribe's comments on items 25 and 183 references to mitigation measures refers to measures from the EIR and does not need to be amended.					
487	FMIT-150	Item 27		PG&E's response/the intermediate BOD narrative does not respond to DOI's comment. Also, the Tribe believes it is disrespectful for PG&E to try and place modern development in the same paragraph and same context as the Tribe's religious and cultural history/values. These should be separated in the final BOD. Also, please strike statement that Tribe "considers" the area sacred; the area IS sacred to the Tribe. Finally, did the language that was struck at the end (what appear to be general project protocols to minimize impacts) get moved elsewhere and if so where?	**<u>Proposed revision to the RTC is below in bold/underlined:</u>** DOI's comment recommended that Section 1.1 "be revised to discuss project history and a new section or subsection be added to address the cultural significance, cultural and historic resources and ecological resources, including the ACEC and the HNWR." PG&E's response to this comment and its revisions reflected in the 60% BOD directly address DOI's comment by adding further information regarding project history to Section 1.1. "Background" and by adding subsections further addressing Cultural and Historic Resources and Ecological Resources. In response to the FMIT's request that discussion of modern development be separated from the Tribe's religious and cultural history/ values. PG&E will include the discussion of the historic-era features and archaeological resources in a separate paragraph from the discussion of the Topock Maze. Text will be changed as follows: "[t]he Topock site and adjacent lands are contained within a larger			The FMIT requests that the stricken language be inserted into the 90% BOD.	PG&E and the FMIT have discussed this comment and the response. PG&E is awaiting a response from the FMIT on the text options that PG&E presented.	90% BOD Executive Summary. 90% BOD Section 1.1.1.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					geographic area that is ~~considered~~ sacred to ~~by~~ the Fort Mojave Indian Tribe and to ~~by~~ other Native American Tribes." **<u>PG&E proposes either of the following sentences in lieu of the above revision:</u>** **<u>"The APE for the Topock site is contained within what the FMIT and other Native American Tribes have identified as a larger area of traditional and cultural importance."</u>** **<u>OR</u>** **<u>"The Tribes have stated that the APE is contained within a larger geographic area that is sacred to the FMIT and other Native American Tribes."</u>** Finally, the language that was stricken at the end of Section 1.1 (in response to 30% design comments #27 DOI-13 and #30 HA-3c) was not moved elsewhere, instead it was replaced with language stating that impacts to cultural resources will be minimized by implementing mitigation measures in the EIR, PA and CHPMP, and in consultation with the Tribes throughout the design process.					
488	FMIT-151	Item 27		PG&E's response/the intermediate BOD narrative does not respond to DOI's comment. Also, the Tribe believes it is disrespectful for PG&E to try and place modern development in the same paragraph and same context as the Tribe's religious and cultural history/values. These should be separated in the final BOD. Also, please strike statement that Tribe "considers" the area sacred; the area IS sacred to the Tribe. Finally, did the language that was struck at the end (what appear to be general project protocols to minimize impacts) get moved elsewhere and if so where?	The FMIT has confirmed that comment FMIT-151 is duplicative of comment FMIT-150. See response to comment #487 FMIT-150.				Comment resolved.	Not applicable
489	FMIT-152	Item 53		The Tribe is concerned about DTSC's statement that it "continues to be concerned with the efficacy of the remedy." It seems to the Tribe that DTSC has approved this particular remedy and would be surprised if DTSC would approve a remedy it did	PG&E defers to DTSC.	DTSC's statement is in regards to the acknowledgement of the complexity of the proposed remedy in context to the sensitivity of the surrounding landscape. The technology presented is sound,		Review in progress.	This comment and responses were discussed at the December 17-18, 2013 TWG meeting.	Not applicable

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				not think would work or be effective. What does this statement mean to DTSC?		however, there are constraints that would limit PG&E's ability to refine the remedy, or respond as they would in a typical remedial enhancement; for example, installing additional injection wells in response to recalcitrant areas. Nevertheless, as included in the original statement, "PG&E has been able to provide reasonable logic to all concerns raised. DTSC will continue to carefully evaluate and monitor PG&E's proposal throughout the design, construction and implementation process."				
490	FMIT-153	Item 63		Is PG&E's proposal to incorporate possible use of an infiltration gallery in Bat Cave Wash into the soil RFI/RI Work Plan mean that potential aspects of the groundwater remedy are now being proposed to be combined with the soil remedy? What are the potential CEQA ramifications of this? Please note that the Tribe objects to such an infiltration gallery in this especially culturally sensitive area.	As stated in the response to comment #72a FMIT-21, the concept of an infiltration gallery in Bat Cave Wash was included in the design documents as an option to manage remedy-produced water. This option is not being further evaluated in the design at this time. If PG&E proposes to evaluate this option further in the future, PG&E will discuss the option at that time, and will seek further input from the Tribes during the Soil CMS/FS development and review. Text will be added to the 90% BOD to reflect this response.			Comment resolved.	Comment resolved.	90% BOD, Footnote to Exhibit 3.4-2 90% BOD, Appendix F, Footnote to Table F-5
491	FMIT-154	Item 65		Why would the 20-foot setback requirement not apply to the Arizona remedy infrastructure? Why would the rationale for such requirements differ on each side of the River?	PG&E defers to DTSC as the 20-foot setback requirement is set forth in the EIR mitigation measure AES-2a.	DTSC's understanding of PG&E's response to the referenced comment is that there will not be any substantial vegetation removal along the riverbank for any infrastructure proposed in the Arizona side of the river. Therefore, set back in Arizona side of the river is not applicable based on current design.		Response noted.	Noted.	Not applicable
492	FMIT-155	Item 71		The Tribe appreciates DOI's response that additional consultation "provides the framework needed to address cultural values of religious and spiritual significance." The Tribe would like DOI to provide it with a timeframe for that consultation that	PG&E defers to DOI.		BLM has conducted formal Section 106 consultation with the Tribes early in the remedial design process on both the 30% and 60% design documents	Response noted.	Noted.	Not applicable

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				will be adequate to the need and not push that important and long-awaited consultation to the very end of remedy design or when insufficient time will remain for those necessary discussions.			and will consult on the 90% design documents when they become available. DOI and BLM have had several formal, face-to-face consultation meetings with the Tribes on the CHPMP (bi-monthly), the 30% design documents (March 8, 2012) and 60% design documents (May 23rd 2013 & July 9, 2013) as well informal discussions at the TWG meetings. We will continue to engage in consultation on the design throughout the remainder of the resolution and review of the 90% design package. DOI will continue to coordinate as much as possible with the tribes to allow for sufficient time for consultation.			
493	FMIT-156	Item 119		The Tribe feels that PG&E's generalized comment is not fully responsive. The Tribe would like to understand the specifics of where cultural resource constraints may affect design and operation. As noted elsewhere, the Tribe also would like to understand the different design options relative to tribal cultural resources.	Section 6 of the 60% BOD (Table 6.1-1) presents a summary of actions taken or being performed under each EIR mitigation measure, which includes specific examples of how the 60% design incorporated cultural considerations and Tribal inputs, e.g., the use of field reviews in siting infrastructures, eliminating the BCW trenching, relocating wells in the upland, and reducing the number of transformers/ siting transformers aboveground. More recent examples of how cultural resources consideration was incorporated into the design are: 1) the relocation of monitoring well I in the uplands to a location further away from cultural resources, 2) the proposed relocation of certain provisional IRZ wells and associated infrastructure from the west side to the east side of NTH at the request of the Tribes, and 3) the current evaluation of relocating well IRL-2 closer to the road. Regarding alternative design options, please see response to comment #1 DOI-1 for aboveground vs.			Comment resolved. Please provide similar examples moving forward.	Comment resolved.	Table 6.1-1 of the 90% BOD includes specific examples of how the 90% design incorporated cultural considerations and Tribal inputs, e.g., CUL-1a-10. 90% BOD Executive Sumamry Section ES.3, last paragraph, contains examples of actions taken to avoid new remedy infrastructure on the FMIT parcel.

							the groundwater. Institutional controls will remain in place for the duration of the remedy until RAOs are achieved."			
Specific Comments – Appendix J (Freshwater Supply Technical Memorandum and Response to Comments)										
496	FMIT-159	General Comment		The Tribe submitted comments on earlier versions of the FWIP. These should be addressed along with DTSC's and DOI's comments.	PG&E had provided responses to all comments received on the FWIP (2013) prior to finalizing the work plan. These responses are documented in Attachment A of the FWIP. Additional comments were received from FMIT on the Final FWIP, and those were reviewed by DTSC/DOI prior to FWIP implementation. In addition, PG&E also provided responses to all comments received on the Freshwater Supply Technical Memo (2012), these are documented in Appendix J of the 60% BOD.			Comment resolved.	Comment resolved.	Not applicable
497	FMIT-160	DTSC Comment 10		PG&E states that it purchased water from the owners of the Topock 2 and 3 wells. Were there any other users or purchasers of water from these wells during the time period referenced in the comment? Does PG&E still buy water from this source and if so, for what purpose?	These wells are currently owned by the Southwest Water Company. The wells were previously owned by the City of Needles and by Burlington Northern Santa Fe Railroad. PG&E continues to purchase water from these wells for industrial uses at the Topock Compressor Station. PG&E is aware that the Topock Marina facility used water from these wells prior to its demolition a few years ago, but does not have any further information about other users or purchasers. 533	DOI-206	Section 5, Pages L5-1 and L5-2		The following are on the Reference list but are not referenced in the text: CH2M HILL 2011k, CH2M HILL 2012f, and CH2M HILL 2012. Should these items be removed from the Reference list?	See response to comments #515 DOI-194 and #519 DOI-197: Item 2011k will be revised to 2011d and Item 2012f will be revised to 2012a. No changes are proposed for Item 2012.		Resolved.		Comment resolved.	O&M Manual Main Text Section L5.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
Specific Comments – Appendix L – Volume 1: Operations and Maintenance Manual										
534	DOI-207	Volume 1	General Comment	Without detailed SOPs and equipment O&M Manuals, the O&M Plan is more of an overview of operations. It is understood that these documents will be provided in the 90% Design.	Comment noted. PG&E looks forward to inputs from and discussions with the agencies, Tribes, and stakeholders on the information presented in the Draft O&M Plan, as that will inform and shape the details that are forthcoming in the 90% design.		Comment resolved.		Comment resolved.	Detailed SOPs are included in Appendix B of O&M Manual Volume 1 and Appendix A of O&M Manual Volume 2. Select equipment manuals are included in Appendix A of O&M Manual Volume 1.
535	DOI-208	Volume 1	General Comment	Will all pumps and valves be labeled with ID numbers in the field, thereby allowing operators to cross reference information and drawings within the O&M manual to equipment in the field?	Yes. The following text will be added to the second paragraph in Section 2.0: "<u>All pumps and valves will have steel identification tags attached to the device to enable operations personnel to identify equipment and cross-reference information within the O&M manual and drawings.</u>"		Comment resolved.		Comment resolved.	O&M Manual Volume 1 Section 2.
536	FMIT-163	Section 1		The plan should set out how CEQA requirements will be met when changes occur during the decades-long operation of the remedy, and how the Tribe will participate in that review.	As operation of the project proceeds, PG&E will continue to implement the adopted mitigation measures, which include multiple requirements for Tribe monitoring, outreach, and coordination during operation of the remedy, including the protocols for continued communication and tribal communication to be set forth in the CIMP that is required pursuant to Mitigation Measure CUL-1a-8. It is PG&E's understanding that changes generally will not require a further CEQA review process unless there is a discretionary project approval that triggers such a review. Absent such a new future project approval, the CEQA review process will have been completed, and tribal participation will be pursuant to the Mitigation Measures including the CIMP. If there is a new discretionary approval based on some change in the remedy, however, it is PG&E's understanding that DTSC would evaluate the proper CEQA document for any such required new approval, and the form of that document will depend on the nature of the new approval. PG&E understands that DTSC as lead agency would follow the required CEQA procedures according to the type of document to be prepared.	In addition to CEQA requirements for public involvement, DTSC will continue to work collaboratively with the Tribes through established Consultative Work Group meetings as well as early communication with the Tribes pursuant to the 2006 settlement agreement. DTSC will work with the Tribes and the CTF, a subgroup of the CWG, to clarify the relationship between CEQA and the environmental investigation and cleanup process for the public, stakeholders, and the Tribes.		This is an open issue that will be carried forward to the 90% design.	This is an open issue that will be carried forward to the 90% design.	Not applicable

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
537	DOI-209	Section 2.1.1.1, Page 2-2	"Dual screen extraction wells will be constructed with a dedicated pump for each well screen with the intervals separated using a pneumatic packer."	Will the dual screen extraction wells share the same riser pipe? If not, the text should specify that each screen will have a dedicated riser pipe.	It is anticipated that the dual screen extraction well pumps will have dedicated riser pipes. Section 2.1.1.1 will be revised to reflect this.		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 1 Section 2.1
538	DOI-210	Section 2.1.1.1, Page 2-2	"Conveyance piping from extraction well IRZ-23 to the main groundwater conveyance header will be double-contained and include leak detection instrumentation at low points."	The significance of well IRZ-23 should be for clarification purposes. Leak detection should also be considered for the connection between conveyance pipeline and the main header.	The concrete trench containing piping for IRZ-23 will slope to the low points and, therefore, to the leak detection instruments. The IRZ-23 conveyance line exits double-containment in the carbon amendment room at the MW-20 bench, a room that already includes leak detection equipment.		Comment resolved.		Comment resolved.	Not applicable
539	DOI-211	Section 2.1.1.1, Page 2-2		What casing material will be used for the extraction wells? Will cathodic protection be required?	Well construction details, including casing material and corrosion protection measures, are included in the 60% BOD Report, Section 3.2.5.1. Text will be included in the 90% BOD to reflect this response.		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 1 Section 2.1
540	DTSC-151	Appendix L O&M Plan Volume 1 2.1.1.1 NTH IRZ Extraction Wells Page 2-2	Conveyance piping from extraction well IRZ-23 to the main groundwater conveyance header will be double-contained and include leak detection instrumentation at low points.	Include the rationale for double containment and leak detection in this pipe segment and not others.	As described in Appendix C, Section C.5.1, conveyance pipelines will be single-walled unless the pipe is used to convey: 1) groundwater or remedy-produced water that exhibits the hazardous waste characteristic; or 2) concentrated carbon substrate. In these cases, double-walled piping will be used. Based on these criteria and anticipated remedy operations and groundwater concentrations, double-walled piping is included for conveyance associated with extraction wells IRZ-23, TWB-1, TWB-2, future provisional extraction well IRZ-40, IRL-4 remedy-produced water, and certain piping at the MW-20 Bench and Transwestern Bench Carbon Amendment Facilities.	Okay	Comment resolved.		Comment resolved.	Not applicable

541	DOI-212	Section 2.1.1.3, Primary Carbon Amendment, Metering, and Control Equipment, Page 2-3	"A sample port and pressure gauge located downstream of the static mixer will be used for monitoring purposes."	Will a sample port be made available before carbon amendment is applied for sampling purposes?	Sample ports are located at each individual well for sampling purposes but are not included in the carbon amendment room prior to the static mixers. A sample port upstream of the static mixer will be included for collecting TOC samples for diagnostic purposes.		Comment resolved.		Comment resolved.	O&M Manual Volume 1 Section 2.1
542	DOI-213	Section 2.1.1.3, Primary Carbon Substrate Storage, Page 2-3	". . . , with secondary containment around the nozzles and connections as required by regulation and/or best practices."	If ethanol is the substrate of choice, it is presumed that the requirements for storage in fire rated, impact-resistant tanks with secondary containment would be instituted at the site. Please clarify the notation for containment around "nozzles and connections".	Ethanol storage tanks are specified as both fire-rated and impact-resistant with integral secondary containment. "Nozzles and connections" refers to portions of the ethanol filling and withdrawal system that are not immediately adjacent to the tank. This may include tanker hose connections at the tanker offload bays and piping connections inside the carbon amendment buildings.		Comment resolved.		Comment resolved.	Not applicable
543	DTSC-152	Appendix L O&M Plan Volume 1 2.1.2 Inner Recirculation Loop, Page 2-4	Three provisional Inner Recirculation Loop Injection Wells (IRL-5 through IRL-7,[1] see Figure 2.1-1). [1] IRL-6 may alternatively be considered as an extraction well with extracted groundwater re-injected into the other IRL injection wells.	Discuss or reference the section describing the basis for these provisional wells and criteria that would be used to trigger installation. Same issue for all provisional wells.	The basis for adding provisional wells is provided in the Sampling and Monitoring Program, Appendix L, Volume 2, Section 2. In particular, the basis for adding IRL provisional wells and the criteria used to trigger installation are discussed in Volume 2: Sampling and Monitoring Plan (Section 2.2.2; see also Figure 2.2-4). References to the appropriate sections of the Sampling and Monitoring Program (Volume 2) will be added throughout this section of Volume 1 in the 90% Design Submittal. Additional language will be added to the 90% design discussing the need for flexibility to locate wells in the future as the remedial program evolves. Any modifications would be discussed with stakeholders prior to implementation.	As suggested after the October 2013 site walk, DTSC would prefer PG&E to propose a wider area for contingency wells instead of specific dots on a map. Please include text that conveys this message as well. Comment resolved pending review of the 90% design.			Comment resolved.	O&M Manual Volume 1 Section 2.1
544	DOI-214	Section 2.1.2.1, Page 2-4	"The River Bank Extraction Wells are currently anticipated to be constructed with 8-inch diameter well casing, . . . "	Provide the anticipated type of well casing material. Is cathodic protection required?	Well construction details, including casing material and corrosion protection measures, are included in the 60% BOD Report, Section 3.2.5.1. Text will be included in the 90% BOD to reflect this response.		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 1 Section 2.1

545	DTSC-153	Appendix L O&M Plan Volume 1 2.1.2.2 Inner Recirculation Loop Injection Wells, Page 2-5	Water captured by the River Bank Extraction Wells will be amended with carbon substrate if the Cr(VI) concentrations are greater than 32 micrograms per liter (µg/L). The Sampling and Monitoring Plan in Volume 2 of this O&M Manual presents the monitoring plan for collecting and evaluating analytical data to determine whether or not carbon amendment will be required according to this criterion.	Injection criteria should be developed for constituents other than just chromium. What if the riverbank water contains elevated constituents (e.g., nitrate, selenium, molybdenum, etc.). What is the desired TDS level sought for injection and what is the TDS discharge limit? How much TDS will be added via addition of amendments (ethanol/lactate) or via conditioned water?	Remedy pumping and injection will be operated so that the extent of elevated concentrations of COPCs at the completion of the remedy does not extend beyond the current extent of the chromium plume. Management of the COPCs will not necessarily require carbon addition to the IRL, and setting discharge limits for injection could impede the efficient operation of the remedy. Therefore, COPC-based criteria for carbon addition have not been developed at this time. TDS limits for IRL injection are not necessary. This is because the selected remedy relies on the ability to inject water in order to mix water throughout the treatment zone, therefore, setting discharge limits is inconsistent with the selected remedy. The influent TDS and constituents of TDS will be monitored and addressed if found to be affecting well performance. Lactate and ethanol will be converted to biomass and bicarbonate alkalinity, a constituent of TDS. Sodium, the counter ion to lactate, would also contribute to TDS. However, other processes, such as precipitation of carbonate minerals, will reduce TDS within the IRZs. TDS concentrations over time were measured during the floodplain pilot test, and concentrations declined over the course of the study.	See response to comments 38, 145, and 181. Please explain the highlighted statement.			Discussion between DTSC, DOI, RWQCB, and PG&E is ongoing to resolve this comment. This topic will be carried forward. Resolution of this comment will be included in the 90% design. PG&E will also work on items related to this comment as directed in the Agencies' direction letter dated April 4, 2014.	Not applicable
546	DTSC-154	Appendix L O&M Plan Volume 1 2.1.2.2 Inner Recirculation Loop Injection Wells, Page 2-5	Below-grade piping between the IRL-4 valve and well vaults will be installed in double-contained piping with leak detection instrumentation at low points.	Briefly include the rationale for double containment and leak detection in this pipe segment and not others (or is the sentence a little unclear). Please clarify.	The following text will be added: "<u>Due to the steepness of the access road, secondary containment is included between the valve/ meter vault and the well vault. A sump pump and concrete containment vault is included near the well vault to capture and recover fluids emanating from a release. This approach also improves safety during operations and maintenance. For example during well maintenance, fluids can be pumped from the well directly into a temporary portable tank located near the meter vault located outside the ravine. This approach eliminates the need to haul a tank into the ravine.</u>"	Okay.			Comment resolved.	O&M Manual Volume 1 Section 2.1

					based on information in the final design.					
553	DTSC-155	Appendix L O&M Plan Volume 1 2.2.1.2 Components, Page 2-9	To allow for these wells to supplement the HNWR-1 well, if needed, the existing 6-inch diameter pipeline from Topock-2 and -3 wells will be retrofitted for connection to the new 12-inch pipeline in Arizona.	It is recommended that the existing 6-inch line be connected to the new 12-inch line during construction of the new line. A valve can also be installed to open the 6-inch line if the Topock 2-3 water source is needed for compressor station operations.	Comment noted. PG&E will take the suggestion into consideration in the 90% design. Topock-2 and -3 wells will be connected to the new 12 inch pipeline in Arizona.	Comment resolved.			Comment resolved.	This RTC is no longer applicable as the freshwater storage for remedy and TCS is now separate. Topock-2 and -3 wells will not be connected to the 12-inch freshwater pipeline.
554	DOI-220	Section 2.2.1.3, Page 2-9		Please provide additional explanation of the operation of Topock-2/-3 based on line pressure. Are the Topock-2/-3 wells expected to be operational on an intermittent basis or only when flow rates drop below required levels at the HNWR-1 well?	The operation scheme for freshwater supply will be determined at the 90% design, after further information is learned on the primary well from implementation of FWIP. Barring this forthcoming information and the final design details, it is more likely that the Topock-2/3 wells would be operated when flow rates drop below required rates in the primary supply well.		Comment resolved pending review of 90% design.		Comment resolved.	This RTC is no longer applicable as the freshwater storage for remedy and TCS is now separate. Operation of Topock-2 and -3 wells will not be tied to operation of the remedy freshwater supply well (HNWR-1A).
555	DOI-221	Section 2.2.2, Page 2-9		The in-text citation for DTSC 2012 is not in the Reference list, and needs to be added.	The in-text citation will be added to the Reference list.		Comment resolved.		Comment resolved.	O&M Manual Volume 1 Section 8
556	DOI-222	Exhibit 2.2-2, Page 2-11		The notes indicate the wastewater could be blended with conditioned remedy produced water. This is not mentioned in Appendix M. There are four types of wastewater generated by pre-injection treatment; backwash, regeneration, rinse, and neutralization. Appendix M indicates only the neutralization waste stream has been considered as a candidate for the cooling towers and IRZ wells. Are all these streams candidates for blending, or just the neutralization stream?	No, not all cited waste streams are candidates for blending. Exhibit 2.2-2 will be revised to reflect an arsenic only treatment system.		Comment resolved.		Comment resolved.	O&M Manual Volume 1 Exhibit 2.2-2.
557	DTSC-156	Appendix L O&M Plan Volume 1 2.3 Remedy-produced Water Management, Page 2-13		It is requested that this introduction section include brief discussion of the estimated volume of waste water generated. Perhaps the volumes can be included in Exhibit 2.3-1.	The volumes from Table F-1 (Appendix F) will be shown on Exhibit 2.3-1.	Okay. Please note that the O&M Plan should be a standalone document to be used on site after design and construction are complete.			Comment resolved.	O&M Manual Volume 1 Section 2.3, 1st paragraph.

558	DOI-223	Section 2.3.2.4, Page 2-15	"Alarm conditions include the following: . . . "	There is no mention of high level alarms on the frac tank.	This section refers to the control system for the piping system, not tanks. Alarm conditions associated with the frac tank is in Section 2.3.1.4 (page 2-14, 3rd paragraph).		Comment resolved.		Comment resolved.	Not applicable
559	DTSC-157	Appendix L O&M Plan Volume 1 2.3.2.4 Control System, Page 2-15	For direct buried pipe segments, potential leaks will be monitored by measuring backwash pump discharge pressure and flow rates.	This method of leak detection seems less desirable, especially for slower leaks. What other alternatives exist? Please also remind the reader how often direct burial is proposed.	The following text will be added: "<u>In addition, annual pressure testing of these segments will be performed as routine operation. This will apply to over 60% of the 13,400 feet of piping sections with remedy produced water pipes</u>."	Based on current proposal, it is possible that slow leaks would not be detected for up to one year? Perhaps the use of double wall piping and moisture sensors would be more effective.			Response noted and will be considered in the 90% design.	O&M Manual Volume 1 Section 2.3.2.4.
560	DTSC-158	Appendix L O&M Plan Volume 1 2.3.3.2 Components, Page 2-16	• Future coagulant feed tank and pump system • Future dewatering aid supply system	Please discuss (or reference the appropriate section) the reference to "future" unconditioned water storage components.	PG&E is evaluating the feed systems for coagulants and dewatering aids (e.g., metering pumps, piping, and small storage containers), and will provide additional information at the 90% design. These systems are anticipated to fit in the current footprint of the remedy-produced water conditioning plant and the influent water tank farm.	All systems anticipated must be specified and fully designed for construction if PG&E anticipate their use. Anything not fully designed cannot be supplemented into the remedy without a separate decision process. Comment resolved.			Comment resolved.	O&M Manual Volume 1 Section 2.3.3.2.
561	DOI-224	Section 2.3.3.2, Page 2-17	"The Conditioned Water Storage system includes the following major components: • Remedy A-side conditioned water tank farm • Conditioned water tank.. "	For clarity, indicate that the 2nd bullet – Conditioned water tank refers to the Remedy B-side conditioned water tank.	The suggested change in text will be made.		Comment resolved.		Comment resolved.	O&M Manual Volume 1 Section 2.3.3.2.
562	DOI-225	Section 2.3.4.3, Page 2-18	"The Remedy A-side conditioned water tanks supply conditioned water to the IRZ wells . . . "	The text indicates the Remedy A-side conditioned water will be pumped across the Station. Does this refer to the TCS? Also, why would it need to be pumped considering the amount of elevation head between the conditioned water tanks and the MW-20 bench frac tank? Discuss the management of Remedy B-side conditioned water.	Correct, "Station" refers to the TCS. The Remedy A-side conditioned water tank farm is located at a ground elevation of about 609 feet and must move the water up to the main part of the Station located at about 626 feet elevation. Management of the Remedy B-side conditioned water is described in the last paragraph of Section 2.3.4.3 (page 2-19). Primary use for the		Comment resolved.		Comment resolved.	Not applicable

					conditioned water is cooling tower makeup, and secondary use is re-injection to IRZ wells.					
563	DOI-226	Section 2.4, Page 2-19	"The power system will be transmitted at 480 VAC to 12K VAC along the pipeline corridors . . . "	It is stated in the text that power cables can be buried in accordance with National Electrical Safety Code 30 to 36 inches below grade, or as deep as 48 inches. Indicate what is proposed for the remedy electrical power.	In general, the 60% design proposes a minimum depth of 18 inches for buried low voltage power (up to 480volts) and 36 inches for buried medium voltage power. If required to avoid conflict(s) with other utilities, power conduits may have to go deeper -- typical vertical separations from pipes could be 6-12 inches. The field effort to resolve conflicts where remedy utilities cross foreign utilities will help determine the precise depths of buried utilities, and this information will be incorporated into the 90% design. In some cases, options exist to bury power conduits at a shallower depth, e.g., through the use of concrete encasement.		Comment resolved pending review of 90% design.		Comment resolved.	90% BOD Section 3.5.1 O&M Manual Volume 1 Section 2.4
564	DTSC-159	Appendix L O&M Plan Volume 1 2.4 Power Supply and Distribution, Page 2-19	Secondary power supply will be power generated from small photovoltaic solar panels at various locations such as the Central Maintenance Facility at the Transwestern Bench and at select remote well locations.	Why not put solar panels on most/all new remedy buildings? Why only select structures?	The reference text does not preclude solar panels from being considered for other remedy structures. PG&E is evaluating solar panels for all remedy buildings, and will include in 90% design as appropriate. Text will be included in the 90% BOD to reflect this response.	Okay.			Comment resolved.	90% BOD Section 3.5.1 O&M Manual Volume 1 Section 2.4
565	FMIT-165	Section 2.4		The burial depths for voltage vary. What is the proposed depth? How much of this system is in areas classified as sensitive in the geoarchaeological report?	In general, the 60% design proposes a minimum depth of 18 inches for buried low voltage power (up to 480volts) and 36 inches for buried medium voltage power. If required to avoid conflict(s) with other utilities, power conduits may have to go deeper. See also response to comment #563 DOI-226. Text will be added to the 90% BOD. See attached map showing an overlay of the 60% design on the layer showing sediment ranks from the geoarch report (see **Attachment L**, at the end of this table). As discussed in the response to			Comment resolved pending review of the 90% design. The Tribe notes that the CIMP is not yet completed as of 12/17/13.	Comment resolved.	90% BOD Section 2.4.

		Recirculation, Page 3-1	target flow rates as specified in Table 2.1-1. However, actual flow rates may vary in the field.	become available. A schedule to conduct this update(s) should be included in the design document. A schedule to assess the accuracy of the groundwater flow and transport model over time should also be prepared.						
569	DOI-229	Section 3.1.3, Page 3-3		Because there is a single header feeding all of the north (or south) NTH IRZ injection wells, adjustments to the flow of any one well to add additional carbon reduces the flow at some or all of the other wells, as the extraction well flow rate is fixed. Although it is not proposed that there be individual lines from the carbon amendment system at the MW-20 Bench to all the injection wells, it seem that system adjustments, including carbon injection rates, to achieve optimum carbon dosing will be tricky at best.	PG&E does not anticipate the need to routinely implement the dosing of specific quantities of carbon substrate to wells on an individual basis. However, if certain wells within the north or south branches of the NTH IRZ require supplemental substrate injections, provisions have been included for dosing immediately at the well vaults. An SOP for this operation will be included in the 90% Design Submittal. Text will be included in the 90% BOD to reflect this response.		Comment resolved.		Comment resolved.	O&M Manual Volume 1 Section 3.1
570	DOI-230	Section 3.1.3, Page 3-3	"The target carbon load will be based on the extracted groundwater flow rate of each individual well and the target in-situ carbon concentration. As summarized in Section 2.1.1.4 and detailed in the Sampling and Monitoring Plan in Volume 2 of this O&M Manual, carbon substrate amendment concentrations, frequency, and duration will be adjusted based on analytical groundwater data and injection well performance data."	Will carbon concentration analyses be performed at the site or off-site at a laboratory?	All analyses associated with sampling events identified in the Sampling and Monitoring Plan (Appendix L, Volume 2) will be performed by an off-site analytical laboratory. However, additional supplemental sampling may be performed that will include on-site field analyses, including total organic carbon (TOC) analysis. PG&E is currently in the process of testing bench procedures for on-site TOC analysis with site groundwater. If these procedures are to be implemented, details will be added to Appendix L in the 90% Design Submittal, including analysis SOPs and references at appropriate locations in the document.		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 2, Section 7.1

581	DTSC-169	Appendix L O&M Plan Volume 1 4.1.1.1 Well Capacity, Page 4-2	Water level logging with the level probes should begin 1 to 2 weeks prior to startup so that background water level trends can be evaluated.	This section should make reference to deconvolution methods that will be utilized to evaluate water level data at the site. The remedy design document will need a section dedicated to discussion of the deconvolution technique. Don't recall seeing discussion of it elsewhere.	It is not anticipated that deconvolution would normally be used to evaluate water levels or well performance. Water level evaluations will rely on averaging over a period of time to damp out river fluctuations, similar to what is done now to monitor water levels in response to IM-3 pumping. Specific capacity or injectivity can be measured without the need for deconvolution because the water level change in the pumping or injection well is large compared to the river influence. Deconvolution has only been used in the past to analyze results of short term aquifer tests, which are not planned in conjunction with routine well maintenance discussed in this	Consider the need for assessment of hydraulic influence at the margins of pumping/injection (e.g., where it may be desirable to show containment or hydraulic effect. While this does not seem the appropriate section, it does seem that it might be used for the project and must be included in the project tool box. Comment resolved pending review of 90% design.			Comment resolved.	See Section 3.1.1.5 (Well Testing) of the Construction/Remedial Action Work Plan.

			met and the capacity is not fluctuating. It is expected that this will be done during the first month to few months of the system being commenced.		startup of the system. Frequency of well performance evaluation over the duration of the remedial action will be monthly, as shown in Exhibit 4.1-3.					
585	DTSC-173	Appendix L O&M Plan Volume 1 4.1.1.3 Video Survey, Page 4-2	Once testing is complete, and all equipment is removed from the well, a baseline video survey will be conducted on select wells to support diagnosis of future well problems.	List the wells that will definitely be surveyed by video. Also include a list of wells that might be surveyed and those that are not planned on being surveyed.	The second sentence of Section 4.1.1.3 will be revised as follows (underline typeface is added text, ~~strikethrough~~ typeface is used for deleted text): "Once testing is complete, and all equipment is removed from the well, a baseline video survey will be conducted on ~~select wells~~ all remediation wells to support diagnosis of future well problems.	Okay.			Comment resolved.	O&M Manual Volume 1 Section 4.1
586	DTSC-174	Appendix L O&M Plan Volume 1 4.1.1.4 Water Quality Sampling, Page 4-3	Exhibit 4.1-1 a Parameters will be collected during baseline monitoring, and may not be collected at later sampling dates.	It is requested that the analytes with footnote "a" be samples two or three times to establish an early, more, representative baseline. This section should clarify that the sampling pertains to maintenance issues and that conventional plume and remedy effectiveness monitoring are detailed in other volumes. Similar revision should be applied to section 4.1.2.3 Water Quality Monitoring on page 4-6.	Footnote "a" applies to analytes scheduled for baseline assessment of IRZ injection wells. All IRZ injection wells will be installed in areas of similar hydrogeologic condition, and the baseline analytical results for all IRZ wells will be evaluated together to determine if any of the data points appear to be anomalous or representative of a condition not observed at other IRZ locations. The text will be revised to state that two baseline samples will be collected to establish the baseline condition. A third baseline sample will be collected if it is necessary to confirm the baseline condition should a given data point appear anomalous. It is assumed that the two baseline samples will be collected approximately one month apart; however, the time between samples might be shortened if determined necessary to ensure that the collection of these samples doesn't delay startup of the system. Changes to the duration between samples will be discussed with the agencies prior to implementation. The following statement will be added to the beginning of Sections	The table needs revision. It is not clear that footnote "a" applies to IRZ injection wells. Sampling the IRZ injection wells two or three times is requested for establishing a representative baseline. Hydrogeochemical conditions should be understood prior to start up. PG&E must ensure this does not delay system start up. Please revise. Put this in a more appropriate water quality sampling section if necessary. Comment resolved.			Comment resolved.	O&M Manual Volume 1 Section 4.1

					4.1.2.3: "Water quality monitoring in this section pertains specifically to the assessment and tracking of well performance. Water quality monitoring for the purposes of plume monitoring or remedy performance are detailed in other volumes."					
587	FMIT-166 Hualapai-120 Chemehuevi-120 Cocopah-120 CRIT-120	Append L-Vol 1 Section 4.1.1.4 p. 4-3	Exhibit 4.1-1	Please specify what sampling frequencies and statistics will be used to establish baseline conditions for the Biological and Geochemical Analytical Monitoring Parameters indicated in the notes to this table.	Sampling frequencies are detailed on Exhibit 4.1-3. A single sampling round is proposed for establishing baseline conditions. Biological and geochemical data will be collected to evaluate potential agents causing well fouling as water is being injected. In general, baseline data, collected before continuous extraction and re-injection begins, are not as useful for understanding well performance issues as trends in water quality (extracted and re-injected) over time. Trends in water quality can be correlated with changes in well performance. Therefore, no statistical analysis is planned for evaluation of well performance.			Comment resolved pending review of 90% design documents.	Comment resolved.	Not applicable
588	DOI-233	Exhibit 4.1-3, Page 4-5		Please explain why many of the monitoring parameters in this exhibit are not recommended for the IRZ injection wells.	Biological and Geochemical sampling, biological activity tests, and MFI: The changes in chemistry and bacteria in the IRZs will be dominated by the reducing conditions generated by the addition of ethanol and is well understood (i.e. biomass, reduced metals, sulfide, and alkalinity concentrations will increase). Measuring these changes will not provide insight into the causes of fouling, which are known to be due to biological growth and precipitation of iron sulfide and carbonate minerals and therefore these measurements are not specified. Sand Content: sand may cause well clogging. The source of sand would be extraction wells where the water for re-injection is sourced, not the from the injection wells themselves. Therefore, sand content measurements were specified for extraction wells rather than IRZ injection wells.		Comment resolved pending review of the 90% design.		Comment resolved.	Not applicable

593	FMIT-167 Hualapai-121 Chemehuevi-121 Cocopah-121 CRIT-121	Append L-Vol 1 Section 4.1.2.1 p. 4-6	*The demotion/ promotion of the performance color code will result in consideration for routine maintenance frequency changes (see Exhibit 4.2-1 in Section 4.2.1, Routine Maintenance). For example, if the capacity of a given well drops below 85 percent, the well will be coded as yellow and potentially undergo more frequent maintenance or rehabilitation until the capacity is improved.*	Please provide additional detail on how well capacity will be determined. For example is capacity based on one time measurements or statistical averages? Also how will reduced efficiencies be determined? This is of importance as it will be used to drive the possible decision for increases in well rehabilitation frequencies or determine the need for well replacements, both activities which will lead to increased field presence and associated impacts.	Well performance will be tracked in the same way it has been tracked for the IM-3 injection wells. The specific capacity or injectivity will be estimated based on measurements of flow and water level when the well is first put into service. These measurements are made after the well has been pumping or injecting for a sufficient time to allow water levels to stabilize. The flow rate divided by the drawdown (or "drawup" in an injection well) provides a measure of the specific capacity or specific injectivity in the well. The specific capacity/injectivity values will be plotted on a graph. If the line on the graph shows the average specific capacity or injectivity has decreased to 85% of the original value, the well will be coded as yellow.			Comment resolved pending review of the 90% design.	Comment resolved.	Not applicable
594	DOI-237	Section 4.1.2.2, Page 4-6	"1. Visual Inspection. The aboveground discharge/ supply pipe, . . . "	The applicability of ARAR 47, (Exemption of Superfund remedial action activities; use requirements; definition), to visual inspections is unclear. ARAR 48, (well construction standards; remedial measures), specifies that "all well construction, replacement, deepening and abandonment operations shall comply with the rules adopted pursuant to this section". Please provide specific citation of the applicable rules regarding well inspections.	The comment is correct that ARAR #47 does not apply to well inspections. ARARs #48 and #98 pertain to well construction standards but not with inspections per se. The intent for including these two ARARs is to recognize the well standards and that the wells will be inspected to meet the requirements of these standards. If helpful, the cited text can be revised to remove the reference to ARARs as follows: "The aboveground discharge/supply pipe, valves, gauges, meters, well seals, well pads, vaults, and flanges should be inspected for visible leaks and damage ~~per the following~~		Comment resolved. 601	DTSC-179	Appendix L O&M Plan Volume 1 Injection, Page 4-14	Chemicals may be added from the well head for wells with short screens.	If reagents are going to be poured down the well from the top of casing, clarify if it will be necessary to remove the concentrated reagent from the sides of the well (e.g., prior to collecting a representative sample from the rehabilitated well). DTSC recommends that a tremie pipe always be used.	Agreed. The text will be revised to say (inserted text shown in underline typeface, deleted text shown in ~~strikethrough~~ typeface): "Chemicals should be added through a tremie pipe from the well head in ~~for~~ wells with short screens"	Okay. Change may to will or should.			Comment resolved.	O&M Manual Volume 1 Section 4.2
602	DOI-240	Section 4.2.2.3.4, Page 4-15	"● Phosphoric acid has no particular advantage over other acids except for sulfate salt removal (Smith 2007) except the ability to dissolve iron and manganese compounds."	This sentence appears incomplete. Please consider that the Smith article further recommends that the shock method of treatment be used to remove sulfate minerals instead of using phosphorus-containing chemicals, noting that residual phosphorus can act as a nutrient and actually boost regrowth. Phosphorus-containing material also promotes algal and cyanobacterial growth in surface waters.	The first sentence will be revised as follows (inserted text shown in underline typeface, deleted text shown in ~~strikethrough~~ typeface): "Phosphoric acid has no particular advantage over other acids in the ability to dissolve iron and manganese compounds except for sulfate salt removal (Smith 2007) ~~except the ability to dissolve iron and manganese compounds~~." It is agreed that phosphoric acid appears to have several drawbacks, as noted in the discussion, but it may still be useful in some specific situations so it should be included as an option.		Comment resolved.		Comment resolved.	O&M Manual Volume 1 Section 4.2
603	DOI-241	Section 4.2.2.3.4, Page 4-15	General comment	This section is very generic. Please include a discussion of chemicals used for well rehabilitation at the Hinkley site, including information on what worked, what did not work, and any unforeseen complications. Also, please include text explaining that addition of hypochlorite can result in formation of trihalomethanes via reaction with soluble organics. Use of hypochlorite solutions should be avoided at Topock because of the high TOC content in the injection wells.	Lessons learned from the Hinkley operations have been incorporated into the O&M plan for Topock. The following details will be added to the text in the 90% design, "At Hinkley, hydrochloric acid was initially used for IRZ well cleaning and resulted in well screen corrosion. To date a phosphoric acid (NuWell 120 and a biodispersant (NuWell 310) have been used with success on IRZ, clean water injection and extraction wells. A variety of materials comprise the various well screens at the Hinkley site and include low carbon steel, copper bearing mild steel and stainless steel. No corrosion has been detected during post chemical cleaning video logging." Text will also be included in the 90% BOD regarding the use of chlorine based products and the formation of trihalomethanes.		Comment resolved pending review of the 90% design.		Comment resolved.	O&M Manual Volume 1 Section 4.2

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
604	DOI-242	Section 4.2.2.3.6, Page 4-21	"While the original capacity may never be restored, reasonable rehabilitation results are roughly 75 percent of the baseline value."	What is the source of the 75 percent value, experience or scientific literature?	The 75% is a rough estimate based on experience with well rehabilitation at multiple sites. The sentence will be revised as follows: "While the original capacity may never be restored, experience with multiple wells at other sites suggests that successful ~~reasonable~~ rehabilitation ~~results~~ ~~are~~ can often restore roughly 75 percent of the baseline value."		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 1 Section 4.2
605	DTSC-180	Appendix L O&M Plan Volume 1 4.2.2.5 Well Replacement, Page 4-22	If it is determined after further evaluation and discussions with agencies that a replacement well is warranted and that the most suitable location to achieve the well objective is within 200 feet of the original well location, well replacement will proceed under the scope of this O&M Plan.	The 200 foot criteria appears arbitrary and should be deleted. Suggest replacing "200 feet" with "the area" in the cited sentence. This is requested since the well in question is being removed since rehabilitation will not allow it to function properly any further. If moving the replacement well 245 feet, for example, makes the best technical sense, then DTSC requests that the well and the associated disturbance be situated so that it will provide valuable data for the longest amount of time. Of course, this is assuming the new area poses the same level of disturbance and concerned tribes have the opportunity for input.	Agree. Text changes will be made as suggested. PG&E notes that if the new well is in the same geologic conditions as the well it replaced, there would be no net change in the number of wells (see FEIR, Page 3-26).	Okay.			Comment resolved.	O&M Manual Volume 1 Section 4.2
606	FMIT-169	Section 4.2.2.5.		The Tribe appreciates the comment that well replacement is the least desirable option to achieve the given objective of the well. New wells cause impacts to this cultural area. Exhibit 4.2.7 indicates that over 50 years, each well can expect to be replaced. This means twice as many wells intruding into the landscape. Did the groundwater FEIR analyze that impact? If so, please cite to the pages. If not, please identify what process will be applied to evaluate the impacts of ongoing replacement.	The impacts of well replacement have been evaluated in the FEIR - Note 2 in Table 1-1 (page 1-4) states "Replacement wells were estimated to be 10% of the wells per year". This means up to 11 replacement wells per year (10% of 110 new remediation wells [excludes replacement wells]) were factored in the CEQA analysis over a 30-year life of the remedy, a total of 330 replacement wells. The assumptions in the O&M Plan (Exhibit 4.2-7) are environmentally more conservative than the FEIR when it comes to well replacement (up to 110 replacement wells), so the level of replacement set forth in the O&M plan is within what was			Comment resolved. 611	DOI-245	Section 5.1, Page 5-1	"During operation of the CIP loop, all of the groundwater extraction pumps will be de-energized . . . "	Obviously an acid is being used to dissolve scale if pH stabilization is the criterion for maintenance completion. Because it is dependent on the strength of the acid and amount of scale, pH stabilization may or may not be an indicator that all scale has been dissolved. Therefore, pH stabilization would likely not be a good criterion for removal of biological growth. Please provide additional discussion to clarify the maintenance process.	Depending on the nature of any biological films or mineral scale that may develop in the pipelines, as well as the final reagent solution selection, there may be multiple potential criteria for assessing pipeline flushing completion. Additional discussion, including an SOP for this process, will be included in the 90% Design Submittal.		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 1 Section 5.1
612	DTSC-183	Appendix L O&M Plan Volume 1 5.1 Clean-In-Place (CIP) System, Page 5-1	The CIP solution will then be mixed in the reagent day tanks and pumped through the pipelines and into the receiving tank.	The section should be expanded to discuss what a "CIP solution" might contain similar to the section on well maintenance chemicals. Section 3.2.4 briefly discusses this, yet one would expect this section to contain more detail.	An exhibit listing potential CIP chemicals will be included in the 90% Design Submittal. An SOP for this process will be included in the 90% Design Submittal. See also response to comment #119 DTSC-34.	Okay.			Comment resolved.	O&M Manual Volume 1 Exhibit 5.1-1.
613	DTSC-184	Appendix L O&M Plan Volume 1 5.2 Maintenance and Repair of Plastic Pipe (HDPE), Page 5-2		As Section 2.3.2 (Conveyance of Unconditioned Remedy-produced Water) identifies conveyance pipeline pigging stations and cleanouts, these pipeline maintenance components should be described in detail in this section.	These elements will be included in the 90% design and added to the O&M Plan.	Okay.			Comment resolved.	O&M Manual Volume 1 Section 5.4
614	FMIT-170 Hualapai-122 Chemehuevi-122 Cocopah-122 CRIT-122	Append L-Volume 1 Sect. 6.1.1 p. 6-1	Expected Waste Streams	Please indicate where backwash and well rehabilitation waste water will be stored during the characterization step prior to the final disposal of this water.	It may be necessary at times during the remedy to hold wastewater for characterization prior to final disposal. Temporary portable tanks will be used to hold the water for this purpose. As discussed in response to comment #96a FMIT-25, portable tanks are not anticipated to be "installed" at wellheads for semi-permanent use. Clarification will be included in the 90% design documents.			Comment resolved.	Comment resolved.	O&M Manual Volume 1 Section 6.1
615	DOI-246	Section 6.1.3.1, Pages 6-3 and 6-4	General comment	This section needs to clearly state that the remedy-produced water conditioning plant is not designed for the treatment of RCRA and non-RCRA hazardous waste due to the presence of chromium and arsenic, and/or as a result of low pH (<2).	The following text will be added to the end of the 1st paragraph: "The conditioning plant is not designed for treatment of RCRA and non-RCRA hazardous waste."		Comment resolved.		Comment resolved. 616	DOI-247	Exhibit 6.1-2, Page 6-4		For completeness, include Remedy A-side or Remedy B-side conditioning (or no conditioning) under the Management Plan column.	Text will be added as suggested.		Comment resolved.		Comment resolved.	90% BOD Exhibit 3.4-3 O&M Manual Volume 1 Section 6.1 Exhibit 6.1-2.
617	DOI-248	Exhibit 6.1-2, Page 6-4	Exhibit 6.1-2 and Figure 6.1-1	It seems that the chemicals used in the CIP may be similar to the chemicals used in well rehabilitation. Explain why CIP wastewater is not handled similarly to first flush well rehabilitation water.	The following text will be added at the beginning of footnote a: "Prior to transferring the spent solution to the remedy-produced water conditioning plant, the solution will be allowed to settle and precipitate solids prior to pumping to the conditioning plant."		Comment resolved.		Comment resolved.	90% BOD Exhibit 3.4-3 O&M Manual Volume 1 Section 6.1 Exhibit 6.1-2.
618	DOI-249	Exhibit 6.1-2, Page 6-4	Exhibit 6.1-2 and Figure 6.1-2	The third waste management option for first flush well rehabilitation water needs clarifying information to address the following points: • Why does the water need to be filtered before sending it to the conditioning plant, since the main purpose of the conditioning plant is the removal of solids? Based on Figure 6.1-2, it appears the concern focuses on whether the wastewater is a hazardous waste due to the presence of chromium and arsenic. Are pre- and post-filtration testing for chromium and arsenic to be performed at the TWB lab? • Because first flush rehabilitation water may be high in soluble chromium and arsenic even after filtration, and could also contain residual oxidants, it does not seem prudent to process this water through the conditioning plant and reinject it at the IRZ. Perhaps this method should not be an option.	If pumped through the pipelines could cause obstructions to form or accumulate solids at low points. It is better to remove the solids near the point of generation. If testing is needed, it would be performed at the onsite lab located in the Central Maintenance Facility. (see also response to comment #210 DOI-89). This method is appropriate because some arsenic will be removed through filtration/ neutralization and any remaining dissolved arsenic will be similar in concentration to the reduced environment within the IRZ. Any soluble Cr(VI) that remains will be immobilized by the IRZ.		Comment resolved.		Comment resolved.	Not applicable
619	DOI-250	Section 6.1.3.1, Page 6-4	Figure 6.1-2	Suggest including the following revisions for clarification: • Top Row – After "To Off-Site Disposal or Treatment Facility" add the phrase "as a RCRA or non-RCRA hazardous waste" • Rows 2 and 3 – Add As < 5mg/L to the boxes showing Cr < 5 mg/L • Indicate the effluent from the conditioning plant goes to the IRZ injection wells (if this concept is still viable)	See updated Figure 6.1-2 (**Attachment M**, at the end of this table). Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
			flow rates, injection parameters, and potentially well locations. This monitoring program provides a plan for data collection, interpretation, and guidance for adapting operations as the remedy is implemented.							
633	FMIT-171 Hualapai-123 Chemehuevi-123 Cocopah-123 CRIT-123	Append L2- V2 1.2.2 p.1-2		The adaptive management concept is useful as it allows data to continually benefit and refine the operation of the system as the data is collected. Is there also a concept of modifying the monitoring program based on knowledge gained as the remedy is operated? If so, what would be the means of communicating possible changes in the monitoring program?	Yes, it is anticipated that the monitoring program may need to be refined as information is gained during remedy construction, start-up, and routine operation. As indicated in Section 2, including footnotes to Tables 2.1-2 and 2.1-3, the sampling program will be re-evaluated after two years of operation. However, modifications to the sampling program may be recommended sooner based on the results of monitoring within the first two years. Changes to the monitoring program will either be included within the quarterly monitoring report as recommendations for future monitoring ("Section 6: Recommendations" section; see Exhibit L2.2-4 in Appendix L), or included within a separate proposal submitted to the agencies. This section will be updated with a reference to Section 6.5 (Reporting). Section 6.5 will be expanded in the 90% Design Submittal to discuss how proposed changes to the monitoring plan and proposed operational adjustments will be communicated.			Comment resolved pending review of 90% design.	Comment resolved.	O&M Manual Volume 2 Section 2

					As detailed in Section 6.5 and Section L3.3 and Exhibit L2.2-4 of the Main Body of Appendix L, quarterly reports will be submitted with sampling results, interpretation of the results and an interpretation of progress toward RAOs.					
635	DTSC-191	Appendix L O&M Plan Volume 2 2.0 Monitoring Goals and Data Quality Objectives, Page 2-1	• Problem statements and decision statements (Section 2) • Inputs to the decisions and study area boundaries (Sections 3 and 4) • Decision rules (Section 2) • Limits of decision errors and optimization of design for data collection (Sections 3 and 4)	It is not clear what sections (in parentheses) are being referenced in the cited text. This is an issue in other sections of this volume. Please clarify/revise throughout the entire volume if appropriate. For example, Section 3.0 discusses Remedy Compliance Monitoring and does not mention decision error or study area boundaries.	In the 90% design, the text throughout the volume will be revised to use the DQO language (problem statement, study area, etc.) to clarify how each of these are defined in the referenced sections.	Okay.			Comment resolved.	O&M Manual Volume 2 Sections 2.1, 3.1, and 4.2
636	DTSC-192	Appendix L O&M Plan Volume 2, Compliance DQO-1 (RAO 2) Page 2-1	RAO 2 will be satisfied during remedy operation by the in-situ treatment of Cr(VI) in groundwater; the treatment will minimize and prevent Cr(VI) and Cr(T) from reaching the Colorado River.	This section should acknowledge that in-situ will not be able to clean up the downgradient chromium contamination in the floodplain during startup of the remedy and that enhanced floodplain and river monitoring should be conducted during startup until river bank extractors are turned on and running and properly affecting hydraulics in the area.	The following text will be added to this section: "During initial start-up of the NTH IRZ prior to operation of the River Bank Extraction Wells, Cr(VI) in the floodplain downgradient of the NTH IRZ will not be treated. Modeling results indicate that operations of the NTH IRZ during this period are protective of the Colorado River—i.e., the Cr(VI) plume does not migrate a significant distance in the floodplain during start-up, and the portion of the plume located downgradient of the NTH IRZ does not migrate past the capture zone of the River Bank Extraction Wells. To verify these predictions, quarterly sampling of the NTH IRZ downgradient monitoring well network and the river sampling locations will be conducted, as indicated on Table 2.1-2."	Comment resolved.			Comment resolved.	O&M Manual Volume 2 Section 2.1
637	DTSC-193	Appendix L O&M Plan Volume 2, Compliance	Although RAO 2 is specifically intended to address Cr(VI),	First, it should be clarified in the text that since river chromium concentrations are generally not detected, remedial system operations	The underlined text will be added to the first sentence of the second paragraph under this DQO: "If Cr(VI), arsenic, or manganese	Okay. 		DQO-1 (RAO 2), Page 2-1	the IRZ by-products arsenic and manganese will also be monitored. The surface water quality criteria for Cr(VI) is 11 µg/L and 150 µg/L for arsenic (Source: Table 2 of the Record of Decision [ROD], ARAR #3, Federal Water Pollution Control Act. 33 USC 1251-1387, 40 CFR 131.38).	would be modified should any chromium (or byproduct or COPC) start to be detected in the river that was attributable to remedy operations. It appears the DQO in Table 2.1-1 captures this issue for chromium, arsenic and manganese. Recommend adding the chromium plume co-constituents nitrate, selenium, and molybdenum to this DQO as, like arsenic and manganese, will be monitored as part of river protection.	concentrations increase in surface water samples, or are detected at locations that were previously non-detect, and are attributable to the Topock site, operational changes will be implemented per the process control decision rules outlined in Section 3." Surface water sampling for COPCs is specified in Section 5.1 of the Sampling and Monitoring Plan (Volume 2 of the O&M Manual).					
638	FMIT-172 Hualapai-124 Chemehuevi-124 Cocopah-124 CRIT-124	Append L2- V2 2.1 p. 2-1, last para	*If Cr(VI), arsenic or manganese concentrations increase in surface water samples and are attributable to the Topock site…*	Pilot test data indicate that the potential for increases in byproducts is greater with the concentration of the carbon amendment applied. If successful treatment of Cr(VI) in the IRZ requires significantly higher amendment concentrations than originally anticipated, would there be an increase in the frequency of monitoring for possible byproducts?	The monitoring frequencies proposed in the Sampling and Monitoring Plan are not dependent on the concentrations of carbon used. Rather, they were designed to adequately monitor the response to carbon amendments regardless of what the response may be based on time for changes to occur due to reaction and transport. Although byproduct concentrations may increase with higher amendment concentrations, byproduct generation rates and transport times will still be adequately assessed with the proposed monitoring schedule.			Comment resolved pending review of 90% design documents.	Comment resolved.	Not applicable
639	DOI-259	Section 2.1, Page 2-2	Tables 2.1-2 and 2.1-3	Recommend adding a column providing the model layers that are monitored for each well. This would be useful in evaluating the vertical as well as the horizontal monitoring coverage provided by the wells.	Columns indicating screen intervals and model layers intersected by screened intervals for each monitoring well will be added to Table 2.1-2 in the 90% Design Submittal. This information will likely not be added to Table 2.1-3 in order to avoid redundancy and complexity in the table.		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 2 Section 2.1 O&M Manual Volume 2 Table 2.1-2
640	DOI-260	Section 2.2, Page 2-2	General comment	The text and Figure 2.2-2 make reference to Table 2.2-1 for anticipated time frames for Cr (VI) attenuation to assist in evaluating the need for operational changes. Many of these ranges are relatively wide so they do not have much utility as a decision criterion. Please clarify.	The timeframe ranges for Cr(VI) attenuation will be re-assessed based on model results and tighter timeframes provided in the 90% Design Submittal. The narrower ranges will provide a more meaningful basis for assessment of operational changes.		Comment resolved pending review of 90% design.		Comment resolved. 			attenuation arises.							
645	DTSC-196	Appendix L O&M Plan Volume 2, NTH IRZ DQO-1, Page 2-3		The section summarizes the overall approach. Please add references to text (pages/sections), figures and tables so that the details (e.g., sampling points, frequency, constituents) of the sampling can be understood quickly. Ensure this is addressed for all DQO summaries.	References to relevant sections of Appendix L, Sections 3 and 4 (including references to sampling frequency tables and decision rule figures) will be added to the text for each DQO in the 90% Design Submittal. These references will also be provided in DQO Table 2.1-1, as indicated in the response to comment #671 DTSC-211. In addition, a figure will be prepared for NTH-DQO-1 to show sampling locations for the 90% Design Submittal.	Okay.			Comment resolved.	O&M Manual Volume 2 Sections 2.1, 2.2.1, 2.2.2, and 4.2.8 O&M Manual Volume 2 Table 2.1-1
646	DTSC-197	Appendix L O&M Plan Volume 2, NTH IRZ DQO-2, Page 2-3		DTSC requests that a detailed assessment of the monitoring program layout (selected wells) be conducted and documented in the design document. First, the vertical dimension of aquifer monitoring should be assessed and documented. It is suggested that cross sections along the NTH and shoreline be prepared showing monitoring well screens in relation to extractors and injectors (this should be done for all monitoring programs/subprograms). The chromium plume should also be placed on these cross-sections. Particle tracking (both outside and inside the plume), as was done in the 30% design, must be carried forward to assist in assessing program adequacy. If additional wells are needed, they should be called out along with the basis for adding the well. As example of this assessment, DTSC notes a likely problem with monitoring in the vicinity of IRZ-37 and IRZ-39. First, wells MW-23-060/080 are contaminated by grout and should be replaced if they cannot be rehabilitated. Well MW-21 is a very shallow well (it monitors the top 9 to 10 feet of the aquifer) and exhibits unusual/poor hydraulics as noted via muted pressure transducer data responses. Well MW-22 is a very shallow (11 feet deep) hand dug well completed in saline water (~20,000 ppm TDS) that monitors the top five feet of the aquifer. It would seem	Information on the vertical coverage of monitoring was presented in Table 3.6-1, which provided information on saturated thickness and potential number of monitoring well screens and lengths. As requested in this comment, cross-sections with monitoring well intervals posted for each monitoring program will be prepared and included in the 90% design (also included in **Attachment Q**, at the end of this table). Regarding particle tracking: particle flow paths are representative of a particle of water, while the solute transport model incorporates the behavior of the byproducts. Transport modeling is a superior tool for assessing remedy performance and designing the monitoring program. However, simulated flow fields will be provided to illustrate the simulated groundwater flow directions (included in **Attachment E**, at the end of this table). The flow fields are consistent with the simulated hydraulic capture zones presented in Appendix B, Section 6.5 and Figures 6.5-9 to 6.5-12. See response to comment #672 DTSC-212 in regards to MW-23. The saturated thickness of the aquifer is relatively thin in the area of MW-21 and MW-22 (i.e., approximately 10 feet). Thus, it is	Cross-sections for vertical layout: Comment resolved pending review of the 90%. However, the cross-sections should be provided prior to the 90% to allow for accelerated review/assessment of the monitoring programs. Particle tracking: Note: Figures for each layer should be prepared for the 90% design document. Early submittal requested as above. DTSC is concerned that the chemistry and water level data from MW-23 may not be representative due to grout contamination. Standard practice for well construction is to avoid grout contamination due to adverse impacts such as causing dissolved metals to precipitate from solution. Grout could certainly seal bedrock fractures and adversely impact hydraulic data as well. It may turn into a significant research project to assess the worthiness of the data from MW-23 cluster for hydraulic data and chemistry (e.g., every constituent sampled from this			Comment resolved. Per DTSC request, particle track figures for Layers 1-4 were submitted to DTSC on March 11, 2014 (see **Attachment R** at the end of this table). DTSC will continue to assess the monitoring program and provide any further input.	O&M Manual Volume 2 Table 2.1-2

TABLE I-1

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				that at a minimum, a deeper well is needed in the vicinity of MW-22 to monitor potential escape of contamination in the vicinity of the bedrock/alluvial interface. DTSC will continue to assess the monitoring programs after the requested information has been provided.	anticipated that shallow wells, such as MW-21, will be sufficient to monitor groundwater in this area. At the location of MW-22, a deeper boring and replacement monitoring well will be constructed if the alluvium is deeper in that area. The basis for the monitoring well locations is provided in this Appendix in Sections 3.1 and 4.2.1. MW-21 is designated an NTH dose response well. The general scheme for monitoring of the NTH IRZ was to place dose response monitoring wells in approximately half of the spaces between injection wells, and new monitoring well clusters were proposed in those locations. The placement in every other space allows for data collection along the full extent of the IRZ, balancing data density with infrastructure requirements. In places where existing wells were already present that could supplement the network, such as MW-21, the existing wells were added into the program. However, because multiple NTH IRZ dose response wells, staggered throughout the NTH IRZ line, have been identified for inclusion in the monitoring program, the removal of MW-21 from the monitoring program is not anticipated to result in a significant monitoring gap. For example, proposed monitoring well G will suffice as a dose response well for the southern portion of the NTH IRZ line.	well) and the data would need to be flagged appropriately. The well has certainly been compromised as evidenced by grout contamination (high pH) during well construction/ reconstruction. DTSC regards MW-23 as a significant monitoring point based on historical data (e.g., high chromium data) as well as its current isolated location with respect to the river and remedy components. DTSC requests that the wells be rehabilitated and replaced if rehabilitation fails to remove grout impacts. Aquifer thickness: DTSC is unsure of the actual aquifer thickness in the area based on data contained within existing PG&E reports and is a topic of concern. Aquifer thickness near MW-21 (along the end of the road) should be assessed during installation of IRZ 35, 37, and 39 and Well G. Aquifer thickness near MW-22 is not certain. Figure 2-3 and 2-4 of the RFI Volume 2 Addendum suggest if may be on the order of 30 to 50 feet and should be thicker than at Well G - saturated thickness of 32 feet (see Table 3.6-1). A deep exploration boring is requested at or near MW-22 to assess aquifer thickness. A well should be constructed at the bedrock/alluvial contact if the alluvium thickens as depicted in RFI figures. MW-21: DTSC concurs that proposed new Well G should suffice for dose response monitoring in the immediate area and that MW-21 can act to supplement shallow monitoring.				
647	DTSC-198	Appendix L O&M Plan Volume 2, NTH IRZ DQO-2, Page 2-3	Cr(VI): the presence or absence of Cr(VI) in groundwater will also serve	Add some cautionary text that the lack of chromium does not necessarily mean that treatment is occurring or that the area is not important. Fluctuations in chromium concentrations as the plume is	The following text will replace the last sentence in the second paragraph under the NTH-DQO-2 discussion: "It is important to note that, although Cr(VI) concentrations will be used as a line of evidence for	Okay. 			as a direct indicator of whether Cr(VI) treatment at a given location is occurring or necessary.	extracted and injected and pushed around should not be unexpected. Simple fluctuations in river stage can make chromium disappear for months only to return later. As with any assessment, multiple lines of evidence should be gathered and evaluated.	establishment of a treatment zone, decreases in dissolved Cr(VI) alone in the short-term are not necessarily a definitive metric for treatment. Multiple lines of evidence will be used to evaluate the establishment of the treatment zone, including the following:"					
648	FMIT-180 Hualapai-131 Chemehuevi-131 Cocopah-131 CRIT-131	Append L2- V2 Sect 2.2 p. 2-3	*Once the system operations are verified, sampling frequency will be reduced to quarterly or semi-annually…*	If sampling is reduced to semi-annual, one option to consider is to collect a subset of the data on alternating time periods, such that half of the wells are monitored each quarter. This provides some data each quarter without increasing the overall monitoring.	PG&E agrees that this is a good suggestion. The following text will be added to this paragraph in the 90% design submittal: "Once the system operations are verified, sampling frequency will be reduced to quarterly or semi-annually. If semi-annual monitoring is proposed, sampling events may be performed on a quarterly basis, with half of the injection well vaults sampled on alternating quarters. This would ensure that information on the system is collected quarterly, even if any given injection vault would only require semi-annual sampling."			Comment resolved pending review of 90% design documents.	Comment resolved.	O&M Manual Volume 2 Section 2.2.1
649	DOI-265	Section 2.2.1, NTH IRZ DQO-2, Page 2-4	"Selection of a carbon substrate with slower degradation rates could increase the distribution distances."	Please provide examples of carbon substrates that have slower degradation properties.	More complex substrates, such as whey and molasses, tend to have slower degradation properties. 				capture. This location might also be used to monitor effects of freshwater injection. A back up location could be cited at the old Workman's resort area.						
652	DOI-267	Section 2.2.1, NTH IRZ DQO-5, Pages 2-5 and 2-6	"These operational adjustments, including the shutdown of any given injection or extraction well, would be coupled with an assessment of the strength of the IRZ and Cr(VI) treatment in that area per NTH IRZ DQO-2."	Will an analysis be performed to ascertain what impact, if any, shutting down an extraction or injection well will have on the capture zone?	Such an analysis will be performed with groundwater modeling prior to shutting down an extraction well. After shutting down such wells, lines of evidence will be used as part of the plume control assessment required under IRL-DQO-3 and IRL-DQO-4, including water level data, chromium concentration data, and modeling, as described in Section 4.3, Volume 2 of the O&M Manual (Appendix L), pp. 4-6 through 4-10.		Resolved.		Comment resolved.	Not applicable
653	DOI-268	Section 2.2.2, IRL DQO-1, Page 2-6	"Observed hydraulic gradients will be compared to anticipated gradients as simulated with flow modeling that will be periodically updated as field data are collected."	When does PG&E plan on updating the computer model runs to reflect existing conditions under full remedial systems operations?	There are several checkpoints during remedy implementation when the groundwater flow and solute transport model may be updated, including during installation, after system start-up, and during remedy operation. During the installation phase the model may be updated, if the data collected during construction significantly contradict the current CSM. For example, if large variations in saturated aquifer thickness, bedrock extent, permeability, chromium distribution, etc. are measured compared to what has been modeled to date, the model would be updated and re-run. The regional model would be updated first, then imported into the fate and transport submodel before transport runs are conducted. During remedy well testing and system start-up, information will be gathered about achievable flow rates for the remedy wells and system as installed and actual hydraulic gradients. That information will be fed back into the model and additional predictions will be made. As remedy implementation progresses, the observed data will		Comment resolved.		Comment resolved. 					become more useful than model predictions and the modeling will be relied on less heavily. If actual data collected contradicts geochemical or solute transport parameters used in the modeling, it may be appropriate to update and re-run the model simulations.					
654	DTSC-200	Appendix L O&M Plan Volume 2, IRL DQO-1, Page 2-6	The process for evaluating the development of hydraulic gradients to facilitate Cr(VI) plume flushing is illustrated on the right-hand side of the flow diagram in Figure 2.2-4.	Figure 2.2-4 seems to only tie hydraulic assessment with anticipated chromium concentration trends. A separate hydraulic only assessment should be included in the figure/rule.	To assess whether the plume is being adequately flushed by operation of the IRL, Figure 2.2-4 has two branches on the right side of the flowchart. The first branch (Box 22) is for the case where it is early in remedy operations and not enough time has passed for Cr concentration changes to occur. Under this condition, the hydraulic gradient (i.e., water level) data will be evaluated and used with the model to evaluate whether the gradient is consistent with the desired remediation timeframe, as the commenter suggests is appropriate. To clarify, Box 23 will be revised to state: "Evaluate whether hydraulic gradients to facilitate flushing of the plume have been established, recalibrating the model with water level data, and projecting remedial timeframes as needed." Further into remedy implementation, changes in Cr concentrations are anticipated and evaluation of the concentrations becomes more important than the hydraulic gradient, as shown on the branch of the flowchart starting in Box 24. If Cr concentrations are not changing as anticipated, but the gradient is within expectations, action and adjustment still need to be made: this is why concentration trends become the more important indicator to evaluate as the remedy progresses.	Okay.			Comment resolved.	O&M Manual Volume 2 Figure 2.2-4
655	DTSC-201	Appendix L O&M Plan Volume 2, IRL DQO-1, Page 2-6	Observed hydraulic gradients will be compared to anticipated gradients as simulated with flow modeling that will be	Ensure that anticipated gradients for this and all DQOs are included in the 90%. Will specific well pairs be established similar to IM-3 hydraulic monitoring?	Remedy performance monitoring includes periodic assessment of the hydraulic gradient across the site via analysis of water levels measured in site wells. Water level contour maps, which take into account water levels measured in all wells relevant to the portion of the aquifer being assessed, will be used as the	In addition to what is proposed, gradient pair monitoring at critical areas should be developed and included in the 90%.			PG&E will work on items related to this comment as directed in the Agencies' direction letter dated April 4, 2014.	O&M Manual Volume 2 Sections 2.2.2, 2.2.3, and 4.3.3

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
			periodically updated as field data are collected.		preferred method for assessing the hydraulic gradient. These maps are preferred over strictly well pair assessments because they are the result of the spatial integration of multiple water level data points. As discussed in Section 4.3.3.1 of the Sampling and Monitoring Plan (Appendix L, Volume 2), such contour maps will be constructed similarly to the maps presented in past quarterly and annual groundwater monitoring reports for the site. Thus it will not be necessary to establish specific well pairs to assess gradients. The 90% document will include a discussion of how the hydraulic control assessment will be performed using the multiple lines of evidence approach, and how the assessment will be an iterative process, consistent with the USEPA guidance document (2008). Also, a discussion will be included to show how the assessment might be summarized (i.e., in a table), illustrating conclusions from each of the lines of evidence used, with overall conclusions regarding hydraulic control, uncertainties and data gaps, and recommendations for future action. This discussion will be presented as an expansion of Section 4.3.4 of the Sampling and Monitoring Plan (Appendix L, Volume 2).					
656	DTSC-202	Appendix L O&M Plan Volume 2, IRL DQO-2, Page 2-6	If the carbon amendment system is active, data will be collected from the IRL injection dose response monitoring wells, listed in Table 2.1-2 and shown on Figure 2.2-1, to evaluate Cr(VI) treatment and by-product generation.	As the IRL wells screen the entire aquifer, it is requested that the neighboring CW wells be fitted with shallow zone monitoring wells. Cross sections of this area (and all critical areas) with remedial components displayed are requested. A deep well at MW-14 should be evaluated to determine if it would provide valuable hydraulic data (the deeper zone is contaminated in this portion of the plume so it would seem that monitoring that zone would be more important).	To strike a balance between data collection and minimizing monitoring well infrastructure, the monitoring network was designed to provide representative data throughout the remedial systems. In the case of the inner recirculation loop injection system, multi-depth monitoring wells were proposed near 2 of the 4 injection wells, i.e. proposed monitoring wells I, J, P and Q near IRL-1 and IRL-4, which are designated as outer plume compliance monitoring wells (Table 2.1-2). The preliminary design for I, J, P and Q includes 4 screen intervals to provide vertical coverage across the saturated thickness (Table 4.3-1). Additional monitoring wells with multiple screen intervals are also	Comment resolved.			Comment resolved.	Not applicable

					be provided to illustrate the simulated groundwater flow directions (included in **Attachment E**, at the end of this table). The flow fields are consistent with the simulated hydraulic capture zones presented in Appendix B Section 6.5 and Figures 6.5-9 to 6.5-12.					
660	DTSC-204	Appendix L O&M Plan Volume 2, IRL DQO-3/4, Page 2-7	Figure 2.2-5 14. Is Cr(VI) in the shallow unit controlled?	Change 14. to "Is Cr(VI) and/or byproducts in the shallow unit controlled?" Clarify in text and figure the need for hydraulic assessment of water level data to ensure appropriate capture/control is occurring. Also, discuss the need for additional extractors both shallow and deep (e.g., located between existing RB wells). Provisional well locations have not been called out.	As stated in Section 3.2.2.1 of the BOD/60% Design Submittal, the objectives of the River Bank Extraction Wells include: to control potential migration of Cr(VI) located downgradient of the NTH IRZ and to control byproduct migration in the deeper portion of the aquifer. Byproduct concentrations generated in the shallow unit are anticipated to be within the range of the naturally-occurring reducing rind that adjoins the Colorado River and therefore would not represent any additional threat to the river or be a target for capture. This is supported by the simulated solute transport results, which indicate that byproduct concentrations (manganese and arsenic) generated from the NTH IRZ are within the range of naturally occurring shallow manganese and arsenic concentrations in the floodplain. Shallow river bank extraction could have negative hydraulic impacts to the reducing rind. However, the shallow riverbank extraction will be added to the contingency plan as a potential option to address shallow byproduct concentrations significantly above naturally occurring concentrations and Figure 2.2-5 will be edited accordingly. Decisions on appropriate implementation of this contingency measure will be made based on evaluations of the water quality in the floodplain and/or the river, and of the remedy during implementation, weighing the need for capture with the potential negative impacts on the rind and remedy operations. Details of the hydraulic control evaluation are provided in Section 4.3 of this Volume (Volume 2 of the O&M Manual). A reference to this section will be added to Figure 2.2-5.	The figure needs to be revised to ensure that byproduct concentrations generated in the shallow unit are looked at and are within acceptable limits (i.e. naturally occurring concentration). If they are greater, then the figure should mention potential contingencies including bringing shallow river bank extractors online. Hydraulic control assessment: Concur with adding to figure. Add main applicable points if possible. Concur with Response to Comment 100 regarding provisional River Bank Extraction Wells.			Comment resolved. 					With regards to the need for additional extractors, see response to comment #100 DTSC-27. In addition, the River Bank Extraction Wells are designed with two screened intervals to allow for groundwater capture from both the shallow and deep units, if necessary. The shallow screens will be isolated from the well pump unless the need to pump in the shallow unit proves necessary.					
661	FMIT-176 Hualapai-128 Chemehuevi-128 Cocopah-128 CRIT-128	Append L-Vol 2 Section 2.1 p. 2-7	*IRL – DQO 5: The naturally occurring reducing rind will be monitored for changes in water quality.*	Which specific wells are intended to provide the data to monitor the reducing rind?	Generally speaking, the greatest emphasis will be placed on shallow monitoring wells within the NTH IRZ downgradient and riverbank extraction monitoring well networks (listed in Table 2.2-1), particularly those that fit the operational definition of the reducing rind as described in this paragraph and Appendix B, section 2.3. As is noted in the text, however, the entire monitoring data set (including historic data for existing wells and wells occurring outside of the reducing rind) will be considered when assessing reducing rind impacts. This will be necessary to provide the proper context on any apparent impacts for a given well in the network. For example, water quality may be highly variable in any given monitoring well in the floodplain, particularly when the flow regime is changed. Accordingly, changes in concentrations of redox parameters in any given well over a short timeframe may or may not be indicative of overall impacts to the reducing rind. This will need to be assessed within the context of the entire dataset. A discussion of these factors and a reference to Appendix B will be included for IRL DQO-5 in the 90% design submittal. 			multiple lines of investigation will be evaluated to understand the data trends. The presence and effectiveness of the engineered reducing zone will also be considered when evaluating changes to the natural reducing zone. If broad changes to the reducing conditions occur, further investigations may be warranted.	adequately characterized the potential impact?	the 90% design submittal: "The types of additional investigations conducted will be dependent on the nature of the observations. These additional investigations may include (but would not be limited to) supplementary groundwater sampling for additional analytes and/or increased monitoring frequency, installation of provisional wells, and/or sampling of aquifer solids and solid-phase analyses." Whether or not riverbank extraction will be shut down will be situational and will depend on the certainty of the data, the rate at which the reducing capacity of the rind may be decreasing, and the need for on-going operations of the riverbank extraction for hydraulic control. This is consistent with the adaptive operations approach.					
663	DTSC-205	Appendix L O&M Plan Volume 2, TCS DQO-1, Page 2-8	To evaluate treatment of Cr(VI) in groundwater beneath the TCS, data will be collected from the TCS Recirculation Loop dose response monitoring wells, listed in Table 2.1-2 and shown on Figure 2.2-1.	Include a dose response well for TCS-1. Can existing well TW-1 be utilized? Wells in Bat Cave Wash should be added to the TCS loop monitoring to ensure westward migration of the plume/byproducts is not occurring.	**Additional TCS-1 Dose Response Well:** In an effort to strike a balance between data collection and number of monitoring wells/ boreholes, a dose response well was proposed at only one of two of the injection wells for the TCS injection system. Including another dose response well in this area, where the injection wells are just approximately 300 feet apart, was not considered as valuable as the inclusion of multiple dose response wells in other areas, for instance along the NTH IRZ line where the injection wells cover a distance of approximately 3,000 feet. Well TW-1 was considered as a potential dose response well, but was originally not included in the program given that it has a screen length of 100 feet and was considered too long to provide useful information on reagent distribution and treatment from the approximately 40 to 50 foot long screen intervals of the TCS injection wells. TW-1 will be included in the 90% design monitoring program as an additional dose response well for	DTSC is alright with utilizing one dose response well provided TCS-1 and TCS-2 will always receive the same quantity and quality of injected water. If there is needed flexibility for varying the flow rates or quality of water received, then it would seem that separate dose wells are needed. During discussions with DTSC, PG&E indicated that they would check further into utilizing TW-1 with low flow monitoring methods. Regardless, attempts to use TW-1 should be included in the 90% and if it fails to provide valuable data, it could be dropped from the network in the future and replaced if necessary. Bat Cave Wash Wells- TCS Loop. Concur with proposal including adding byproducts to the three wells. How will this issue be linked in text/ table to know how to asses this item as part of monitoring? 				added midway between ER-2/ER-3 and ER-3/ER-4. These wells/boreholes could potentially be converted into extractors if needed in the future.	requested locations will not lead to a conclusive assessment of hydraulic control. All of the monitoring wells (specifically wells at locations MW-62, MW-63, and MW-72 which are located in the proximity of the proposed extraction wells) as identified as East Ravine Extraction Monitoring Wells on Table 2.1-2, Vol. 2 O&M Manual, will be used in conjunction with the proposed extraction wells to assess hydraulic control by employing the lines of evidence, including water level data, chromium concentration data, and modeling, as described in Section 4.3, Vol. 2 O&M Manual, pp. 4-6 through 4-10.	is effective. Modeling is less valuable in the fractured bedrock setting. Comment resolved.				
669	DTSC-209	Appendix L O&M Plan Volume 2, Freshwater DQO-1, Page 2-8		The DQO will need to be modified to address the freshwater water quality criteria needed for injection (including input from the State Board). Discharge limits for a wide suite of constituents (metals/general minerals/TDS) should be developed for freshwater injection. The section will also need to identify wells for monitoring arsenic impacts around injection points should the State Board allow elevated arsenic to be injected into the aquifer. A distal outboard monitoring well has not been identified for FW-2 injection.	On November 20, 2013, the State Water Resources Control Board issued a letter regarding remedy requirements associated with injection of groundwater containing naturally occurring arsenic. A new DQO will be added to the 90% design in this freshwater injection section to include: the monitoring required by the State Board letter, to verify modeling results; and the actions specified should arsenic exceed water quality objectives at 150 or 225 feet. Additional specifications on freshwater water quality are not necessary, were not established by the State Board, and will not be included in the DQOs.	DTSC notes that the State Board letter was responding to an inquiry from PG&E on the injection of water with natural arsenic above California MCL. The absence of discussion regarding other constituents should not be considered a waiver to not consider other constituents that may be injected into the subsurface. Also, see response to comments 38, 145, and 181.			Discussion between DTSC, DOI, RWQCB, and PG&E is ongoing to resolve this comment. This topic will be carried forward. Resolution of this comment will be included in the 90% design. PG&E will also work on items related to this comment as directed in the Agencies' direction letter dated April 4, 2014. 			addition of provisional IRZ wells) will be implemented per the process control decision rules.							
672	DTSC-212	Table 2.1-3		Include the following wells on the table: Outside Plume: MW-16[1], MW-17[1], MW-18, MW-22, MW-48, MW-62-190, MW-68BR-280, MW-72BR-200, OW-03S, OW-03M, OW-03D Inside the plume: MW-09, MW-24A, MW-60BR-245, MW-70-105, MW-70BR-225, 1 Consider utilizing as background/regional control well. Indicate why all PT wells/well clusters (PT1 through 9 including PTI wells) were not utilized. Same for not using any TW wells (TW-1 through TW-5). What purpose do these wells serve? Can wells PGE-7BR or PGE-8 be utilized for the remedy in any fashion? Update all tables to indicate if an outside plume well was historically contaminated (e.g., MW-14, MW-30-050, MW-31-135, MW-34-080, MW-35-060, MW-36-090, MW-39-050, MW-39-060, MW-39-070, MW-39-080, MW-47-055, MW-50-095, MW-58BR, MW-62-190). This list will hopefully grow over time and monitor remedy success and will also alert the reader to anticipate potential rebound, etc., in the future. Add an identifier to the Outside Plume wells in the “Currently-Anticipated Timeframe for Cr(VI) Concentration Changes” column that have had historic contamination, but are now clean. Assess if this should affect sampling frequency and make appropriate changes to sampling frequency. Note: Wells MW-23-060 and MW-23-080 have not recovered from grout contamination (elevated pH) and should be replaced if well rehabilitation measures do not improve the issue. Confirm the number of wells at	Monitoring wells MW-22, MW-48, MW-62-190, MW-68BR-280, and MW-72BR-200 will be added to the Outside Plume monitoring well network. Monitoring wells MW-09, and MW-60BR-245 will be added to the Inside Plume monitoring well network. The need to establish background or regional control with wells that are very far upgradient of the project, such as MW-16, MW-17, MW-18, and cluster OW-03 is not clear. Periodic sampling of these wells may be proposed in the future as the need arises, but specification of routine sampling of background/regional control wells is not currently necessary. MW-70-105 is included as an Outside Plume well. This well is screened in Model Layer 1 and does not exhibit Cr(VI) impacts, and therefore will remain in the Outside Plume well network. During final remedy construction, MW-70BR-225 will be converted into extraction well ER-6. As directed by the agencies, a deeper borehole is needed at this location to delineate the vertical extent of elevated Cr(VI) concentrations. As discussed with DTSC on November 21, 2013, in lieu of drilling an additional well, the additional characterization may be accomplished by deepening the existing MW-70BR-225 borehole. Depth-specific samples will be collected from the deepened borehole to assess Cr(VI) concentrations in permeable fractures encountered in the deeper portion of the borehole. After the	Outside: Okay Insider: Okay, but add MW-70-105 to inside as it is contaminated (see quarterly report). Control Well: Concur, but indicate how long it will take for injected water to reach these outer wells. Provide particle tracking figure to support this issue. Do make sure these wells are sampled during a baseline event prior to remedy start up. ER-6: Please recall that a deeper well/extension is required at this location.			Comment resolved. 				location MW-45-095 (a & b wells) and the purpose of each and that tables appropriately reference them. Confirm in the table if well MW-53S is not operational (and any other inoperable wells). The current well designation for MW-58BR should be used noting that DTSC will likely request modification of the current well design. Same for MW-64BR. MW-70-105 is incorrectly identified as a clean, outside the plume well. Based on Q2, 2013 PMP/GMP report, this well contains Cr(6) at elevated concentrations. Please revise.	deeper characterization is complete (i.e., concentrations of Cr(VI) is not detected or are observed to decrease with depth), the MW-72BR-225 borehole will be converted to extraction well ER-6, screened to capture the elevated Cr(VI) concentrations observed shallower in the borehole and any additional zones of elevated Cr(VI) concentrations found in the deeper section. Most PT well clusters and MW-24A were not included in the monitoring program because these wells were influenced by pilot testing. Since pilot test activities created strong and persistent reducing conditions in the vicinity of these wells, they cannot be used with confidence to track Cr(VI) migration as a result of field implementation activities. Exceptions include those PT wells that were not influenced by pilot testing, including the PT-5 cluster, PT-9 cluster, and PT-8D, which have been retained in the monitoring program. The PT wells will be included in the table for periodic sampling. TW-1 has a 100-ft screen interval, which limits its usefulness in the monitoring program. See response to comment #663 DTSC-205. TW-2S/D, TW-3D, TW-4, and TW-5 will be considered for inclusion in the monitoring program as compliance and IRZ dose-response wells. PGE-7 will be added to the monitoring program. PGE-8 will be monitored in the short term for remedy effects. If there is no effect, then PGE-8 will be removed from the program unless it is yielding good information and can be retrofitted like PGE-7. The table will be modified for the	PT Wells/MW-24A: DTSC to confirm current condition. Sample to study byproduct persistence. Also plan to sample some of these wells after they rebound to baseline. TW-1: Attempt to use this well as a dose response well and inside the plume well. It is highly contaminated, even with its long screen. Other TW wells: Concur. PG&E-7/8: Monitor both periodically at beginning to confirm no changes/ effects from remedy implementation. Sample less frequent over time. Formerly contaminated wells:

					90% Design Submittal to include information on whether outside-plume wells were historically contaminated. Although it is not anticipated that this will have an impact on sampling frequency, the sampling frequency will be assessed based on this information. For the MW-23 nested wells, rehabilitation options to improve pH will be evaluated and implemented, as appropriate. The effects of pH on parameters specified in the monitoring program for this location will also be evaluated. If these evaluations indicate that the well is not suitable for the specified monitoring program, the installation of replacement wells in a new borehole in the vicinity of the existing MW-23 wells will be considered. As requested by DTSC, monitoring well acceptance criteria will be included in the 90% design (O&M Plan Volume 1, Section 4, Well Maintenance and Decommissioning) such that the potential pathways to monitoring well maintenance, reconstruction, or replacement is clear. The conditions that will be addressed include well collapse (preventing sample collection or compromising water quality), screen damage (resulting in elevated turbidity and/or sanding problems), and the effects of grout intrusion (resulting in abnormally high pH values). There are two casings at MW-45-095 (A and B). However, both wells are screened in the exact same interval, and only MW-45-095A is currently being sampled. Specifically, MW-45-095B is a smaller diameter well in which a ZIST sampling system was tested. MW-45-095B is considered inactive. These details will be included in Table 2.1-2, with only 095A included in Table 2.1-3.	Concur. MW-23: Do not concur. See DTSC response to cited comment. Need to develop well quality criteria and well maintenance flow chart. MW-45-095 Cluster: Concur.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					It is correct that MW-53S is not operational. A note to this effect will be added to the table. The comment regarding maintaining the current well designations for MW-58BR and MW-64BR has been noted. Currently, as approved in the first quarter of 2013, packers have been removed and single zone micro-purge sampling is being performed at 165 ft in MW-58BR and at 255 ft in MW-64BR. Due to the timing of the 60% Design Submittal, inside- versus outside-plume monitoring wells were assigned based on fourth quarter 2011 monitoring results. All inside/outside-plume assignments (including MW-70-105) will be reassessed based on the latest available data for the 90% Design Submittal.	MW-53S: Okay. MW-58BR and MW-64BR: Noted. Comment resolved pending review of the 90% design.				
673	DTSC-213	Appendix L O&M Plan Volume 2, Table 2.1-3	Currently-Anticipated Timeframe for Cr(VI) Concentration Changes	Clarify and define the referenced column heading in the table and some locations in the text where this table is referenced. The heading is not clear if it is referring to the arrival time of treated water at which point a change in concentration is anticipated or actual time to cleanup Cr(6) to less than 32 ppb. Some flood plain wells that one would expect to have a shorter cleanup duration are listed with a significant timeframe under this column (e.g. MW-34-100 has 20-30 years listed, MW-36-100 lists 2-10 years) These duration does not appear to correspond to model simulation for Cr(6) reduction.	The column headings in Table 2.1-3 and Table 2.2-1 will be changed for consistency to read "Currently-Anticipated Timeframe for Cr(VI) Concentration Decreases," and additional detail will be added to the text in Sections 2.1 and 2.2 where the tables are referenced. The timeframe ranges for Cr(VI) attenuation will also be re-assessed based on model results, and tighter timeframes provided in the 90% Design Submittal.	What are the anticipated changes between 60% and 90% that would cause PG&E to reconsider timeframe in 90%? Please clarify what defines a “decrease” (one ppb, 100 ppb, an order of magnitude, or ????). Clarify that this decrease is not necessarily the cleanup goal. For clarity, what’s the point of the column? Comment resolved pending review of 90% design.			Comment resolved.	O&M Manual Volume 2 Sections 2.1, and 2.2.1 O&M Manual Volume 2 Table 2.2-1
674	FMIT-179 Hualapai-130 Chemehuevi-130 Cocopah-130 CRIT-130	Append L2- V2 2.1 & 4.2 Table 2.1-3 &Table 4.2.1		Table 2.1-3 has the symbol “T” for wells that may be monitored continuously with a transducer, however, none of the compliance/monitor wells appear to have transducers planned. Some or all of the IRZ wells may have transducers installed (e.g. bot p. 3-7). Is there any plan to collect water level data from any of the compliance wellsmore frequently than quarterly? Might there be value in collecting	As the commenter notes, the monitoring wells selected for transducer locations are listed in Table 4.2-1 and Section 4.2.7. The groups of wells listed for transducers in Table 4.2-1 are locations where significant changes in water levels are anticipated. The wells in these groups overlap substantially with the wells, both inside and outside of the plume, that have been specified in the compliance monitoring program,			Comment resolved pending review of the 90% design. Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				water level data more frequently (monthly? bi-weekly?) from a subset of monitor wells during remedy startup and duringthe first remedial cycle? Such data may aid in refining the GW model in evaluating lithologic heterogeneities and response of the system. Section 4.2.7 does indicate wells Q, P, S andothers may have transducers. And Table 4.2.1 indicates that some wells in various categories may have transducers.	resulting in a comprehensive set of continuous water level data. To help clarify this point, a column will be added to Table 2.1-2 in the 90% Design Submittal indicating which monitoring wells will be outfitted with transducers.					
675	FMIT-173 Hualapai-125 Chemehuevi-125 Cocopah-125 CRIT-125	Append L2- V2 2.1 Figure 2.1-1	Figure of compliance monitoring well network.	This figure does not show IRZ18, which appears to have been added during the modeling exercise due to potential breakthrough. (e.g. Append B, Fig. 6.4-2) With the addition of IRZ-18, does this impact the location of planned compliance well "D"?	The inclusion of IRZ-18 in Appendix B, Figure 6.4-2 was an error. IRZ-18 is still a future provisional well location and was not included in the modeling runs. The figure will be corrected in Appendix B for the 90% Design Submittal. See also response to comment #345a FMIT-61. The locations of IRZ-17 and IRZ-19 depicted in Figure 2.1-1 represent the most current planned locations. Based on these positions, the location of compliance well "D" is appropriate. If IRZ-17 and IRZ-19 are shifted based on future discussions, the location of compliance well "D" will also be reconsidered. Note that several of the IRZ Injection Well locations (including IRZ-17 and IRZ-19) may change based on ongoing discussions between PG&E and stakeholders. The 90% Design Submittal (including Appendix B and Appendix L) will be updated to reflect the finalized NTH IRZ well locations.			Comment resolved.	Comment resolved.	O&M Manual Volume 2 Figure 2.1-1
676	FMIT-178	Figure 2.1-3		Do the wells have to go inside the area between the extant lobes of the Maze? This area is extremely culturally-sensitive and the lack of discovered artifacts in this area does not mean that it is not culturally significant and is related to, and a part of the adjacent areas. Every effort should be made to avoid and minimize infrastructure in this area.	It is assumed that this comment refers to monitoring well "I", in particular, and was perhaps written prior to resolution of the location for this proposed monitoring well in July. See also response to comment #707a FMIT-182. A site walk was held on July 30, 2013 to see the options for relocation of monitoring well "I". During the site walk, the group visited the area of the westernmost alternative location. After walking the area and considering the alternatives, the group decided that: (1) a location approximately 45 to 50 feet south-southeast of the original location proposed during the July			Comment resolved pending review of the 90% design and relocation of well "I" based on site walk with the Tribes.	Comment resolved.	O&M Manual Volume 2 Figure 2.1-3

					2013 TWG meeting was acceptable to stakeholders; and (2) while this location was more physically constrained than the original location, it likely provided sufficient room for construction. The easternmost alternative location was also discussed, but the group agreed that the westernmost alternative location was preferred from both a technical and stakeholder perspective. PG&E documented the discussions and satisfactory resolution of concerns in a letter to the FMIT and the Hualapai on August 30, 2013.					
677	DOI-261	Section 2.2, Figure 2.2-2	Decision Diamond 3	It seems the questions posed should have the same answer in order to move forward with the decision, i.e., indicate “AND” and not “OR”.	In this case "OR" is the appropriate decision point. If TOC or dissolved iron is present, then the conditions for chromium reduction are being provided and operations should continue. It is possible that Cr and iron would be present and Cr(VI) would be greater than 32 ppb because complete reduction has not yet occurred. If that is the case, then operations would still continue in the same manner.		Comment resolved.		Comment resolved.	Not applicable
678	DOI-262	Section 2.2, Figure 2.2-2	Decision Diamonds 16 and 18	Inclusion of both diamonds seems unnecessary. Also, it is not clear how the decision logic flows to these two decision diamonds. The decision diamonds could be deleted and Note 2 expanded to discuss using the Contingency Plan when short and long term modifications are ineffective. The Contingency Plan (Table 2.1-1) does not appear to provide more information than what is given in this diagram.	**Flowchart** Boxes 16 and 18 deal with two different issues: incomplete chromium treatment versus unanticipated migration of byproducts. The actions that would be taken to address these two issues are different, and so they were included as two separate branches of the diagram. The flowchart includes actions that are currently foreseen to potentially be needed to adapt the operations for various issues. Note 2 indicates that actions beyond those that are currently contained in the flowchart may be considered and implemented. Consequently, it is difficult to expand upon the list at this stage (i.e., in advance of knowing what conditions will occur that will not be covered by the current list of actions). **Contingency Plan** The Contingency Plan—referred to in Box 19 of the flowchart—provides two potential measures that may		Comment resolved. 			sampling points in the East Ravine.							
685	DTSC-216	Appendix L O&M Plan Volume 2, 3.1 Monitoring Locations, Anticipated Concentration Changes, and Timeframes, Page 3-2		Site characterization efforts in the past focused on delineating the perimeter/extent of contamination that emanated from the PG&E Topock Compressor Station. As a result, the core of the plume was not well characterized. The core of the plume (where the greatest concentrations of contaminant mass occur) is an important component of the remedy as it will need to be aggressively "attacked" as part of the cleanup effort. Failure to identify the plume cores can lead to very extended cleanup timeframes as well as remedy failure. Suggest adding wells to characterize plume core. Perhaps the TWB-3 area and northeast of IRL-6. Are locations between I-40 and the railroad inaccessible to monitoring well drill rigs?	See also responses to comment #136 DTSC-43 and #137 DTSC-44. PG&E has considered the installation of additional wells to the north of TWB-3/northeast of IRL-6. However, due to constructability issues observed in the field (e.g., presence of multiple major gas pipelines and evidence of significant erosion) as well as access/right-of-way limitations associated, for example, with construction in the area between I-40 and the BNSF Railroad, these locations were dropped from consideration. Note that future provisional wells IRL-6 and IRL-7 were proposed as a contingency should monitoring indicate that cleanup is not progressing at the anticipated rate. These wells, located in the current central portion of the Cr(VI) plume, are designated as "late time" remedial wells that are intended to accelerate the remediation process once eastward migration of the Cr(VI) plume has occurred.	Okay. Comment resolved. See response to #136 DTSC-43 and #137 DTSC-44 to confirm well location constraint issues raised and related items.			Comment Resolved.	Not applicable
686	DTSC-217	Appendix L O&M Plan Volume 2, 3.2 Sampling Analytes and Frequencies, Page 3-2	Water level measurements will be collected at all locations on a quarterly basis for comparison against groundwater flow model predictions. The frequency of water level collection will be re-assessed after the first two years of operation. These results will be used to measure hydraulic gradients and directions as lines of	More detailed discussion of water level measurements and groundwater flow determinations must be presented in the design document due to the flat gradients and ever changing river stage. How many water level monitoring wells will be fitted with pressure transducers? Where are the critical locations for water level measurements based on anticipated modeled flows?	Comment noted. See response to comment #674 FMIT-179 and Hualapai/Chemehuevi/Cocopah/CRIT -130. The network of monitoring wells selected for transducer locations was described in the text in Section 4.2.7 and Table 4.2-1. To further clarify this network, a column designating transducer locations will be added to Table 2.1-2 in the 90% Design Submittal. A discussion of these continuous water level measurements will be added to the text in Section 3.2. See also response to comment 655 DTSC-201.	The response appears adequate pending review of the revised section 3.2. Also, see response to comment #655 DTSC-201.			See response to comment #655 DTSC-201	O&M Manual Volume 2 Section 3.2

			evidence in the assessment of hydraulic plume control, as discussed in Section 4.4.							
687	DOI-275	Section 4.0, Page 4-1	General Comment	It is anticipated that up to two years may be required in order to make the necessary adjustments to extraction and injection wells and chemical dosage in order to achieve routine operations. During this start-up period, will performance monitoring be more frequent than what is shown in Table 4.2-1?	It may take two years to bring the components of the remediation system on-line, sequentially, as outlined in the proposed transition plan in Section 7.3.2 of the main body of the 60% BOD. The monitoring frequencies specified in Table 4.2-1 are for each component of the system and would be implemented as each component is brought on-line, as detailed in Note 5 of the table. This plan does provide for increased sampling frequencies during start-up of individual components. For example, the sampling frequency for the NTH IRZ dose response wells is high (i.e., monthly) during the first year of implementation, which is anticipated to include 6 months ON and 6 months OFF as specified in the table. Higher sampling frequencies are also anticipated for the extraction wells during the first few months of operation, as specified in the table.		Comment resolved.		Comment resolved.	Not applicable
688	DOI-276	Section 4.0, Table 4.2-1		Note 2 is not identified in the table.	Note 2 will be removed from the table and references to notes will be corrected in the 90% Design Submittal or added to the table.		Comment resolved.		Comment resolved.	O&M Manual Volume 2 Table 4.2-1

			the solute transport model is refined."							
690	DOI-278	Section 4.1, Pages 4-1 and 4-2	TOC, Arsenic, Iron and Manganese sections	Will isopleth maps be developed in order to assess individual chemical concentration distributions, and also to compare concentration trends to earlier model runs?	Concentration maps for byproducts (iron, arsenic, and manganese) will periodically be prepared to compare concentration distribution with baseline data and model predictions. Color dot maps or concentration shading will be used to illustrate the distribution, rather than isopleths. Isopleths would be difficult to construct given the elevated concentrations of these constituents in the reducing rind. Concentration maps are less useful for TOC and are not planned; the distribution is expected to be limited to the dose response wells. Text will be included in the 90% BOD to reflect this response.		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 2 Section 4.1
691	FMIT-181 Hualapai-132 Chemehuevi-132 Cocopah-132 CRIT-132	Append L-Vol 2 Section 4.1 p. 4-2	*Although arsenic concentrations are expected to increase due to IRZ operations, arsenic is expected to attenuate rapidly outside of the IRZ footprint. In NTH IRZ dose response wells, concentrations are expected to be between 2 and 10 µg/L, with a maximum of 15 µg/L.*	Are these expected arsenic concentrations based on known arsenic concentrations in HNWR-1?	The expected arsenic concentrations provided in this section for the in situ areas were based on organic carbon concentrations rather than known concentrations in HNWR-1. The 60% design assumed that water from HNWR-1 would be treated for arsenic; these assumptions will be updated in the 90% design if that changes.			Comment resolved pending review of 90% design documents.	Comment resolved.	O&M Manual Volume 2 Section 4.1
692	DTSC-218	Appendix L O&M Plan Volume 2, 4.2 Sampling Locations, Analytes and Frequencies, Page 4-3		Requested cross-sections and particle tracking should be provided to DTSC so that the proposed Process Control Monitoring Program can be properly assessed.	Cross-sections will be produced to show monitoring well screens and chromium plume delineations (included in **Attachment Q**, at the end of this table). Per discussions during the TWG and subsequent calls with the agencies, simulated flow fields will be provided to illustrate the simulated groundwater flow directions (included in **Attachment E**, at the end of this table). Transport	Okay, DTSC is still evaluating the flow field diagrams and will reserve comments for now. DTSC will utilize the flow fields and cross-sections to assess the Process Control Monitoring Program.			Per DTSC request, particle track figures for Layers 1-4 were submitted to DTSC on March 11, 2014 (see **Attachment R** at the end of this table). DTSC will continue to assess the monitoring program and provide any further input. See response to RTC #683	90% BOD Appendix B, Figures 6.5-13 through 6.5-20 90% BOD Section 3.1, Figures 3.1-1 through 3.1-7

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
			2008 (USEPA 2008).		*into the design as an active extraction well, what impact would this have on the capture zone? Has this been modeled?* IRZ-40 has not been simulated as an active extraction well. While it may produce a small simulated capture zone, due to the relatively thin saturated aquifer thickness in this area, only a limited sustainable rate would be achieved at this location. IRZ-40 would provide more benefit as a provisional carbon amended injection well in order to address potential Cr(VI) impacts in the aquifer. Also see response to comment #109 DTSC-30 with respect to additional extraction wells in the East Ravine area. **SPECIFIC COMMENT (DOI ATTACHMENT D TO DOI-281):** *Step 3 – Defining the capture zone within the field does include utilizing observed drawdown values within monitoring wells in response to pumping. How will PG&E factor in fluctuations of groundwater elevation in response to changes in river elevation to document drawdown within each monitoring well?* Monitoring studies at the site have shown that water levels in monitoring wells located near the river fluctuate in a sinusoidal pattern with a frequency of approximately one day. Wells closest to the river exhibit a daily fluctuation magnitude of between 1 and 2 feet per day (compared to a daily river stage fluctuation of up to 3 feet). However, this oscillation does not prohibit assessment of longer-term trends. To do this, a smoothed curve—representing a median water level elevation for any given day—will be created, and will serve as the source for the drawdown values used in assessment of groundwater gradients. The use of transducers in monitoring wells will allow for this method to be used. **SPECIFIC COMMENT (DOI ATTACHMENT D TO DOI-281):** *Step 3 – Please explain how PG&E will develop groundwater contours; hand*

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					contouring or computer based contouring? If computer based, what software is anticipated to be used? When using water level data at extraction wells, will well inefficiency and well losses be taken into consideration in order to more accurately state water levels at extraction points? Does PG&E have piezometers located adjacent to each extraction well location? Hand contouring will be performed to generate water level contours for mapping. For water level values at extraction points, well efficiency effects will be considered. First, step tests will be performed at some extraction wells. Such test data will then be used to estimate well efficiency and, thus, a corrected water level will be calculated. Second, in lieu of having piezometers immediately adjacent to extraction wells (in order to address the borehole count restrictions), piezometers will be installed within the filter pack (outside of the extraction well casing) in some wells, and the difference between the water levels in the piezometer and in the extraction well casing during pumping will also aid in proper correction for well efficiency effects. **SPECIFIC COMMENT (DOI ATTACHMENT D TO DOI-281):** *Step 6 – How does PG&E plan on performing Step Six (Interpret actual capture based on Steps 1-5, compare to target capture zone, assess uncertainties and data gaps)? What data, analysis, modeling, and graphic presentations does PG&E plan on using to interpret actual capture and comparing these results to the targeted capture zones?* PG&E intends to present an assessment of plume control by using the available lines of evidence as discussed in Section 4.3 of the Sampling and Monitoring Plan (Appendix L, Volume 2). These lines of evidence are consistent with the USEPA (2008) guidance. This assessment will be presented in a way consistent with the recommended approach as outlined					

TABLE I-1

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					in the USEPA (2008) guidance document, pp. 26-29. Cr(VI) plume control will be assessed by: interpreting, to the extent possible, the extent and magnitude of hydraulic impact; assessing uncertainties and potential data gaps; and, evaluating the need to reduce or increase extraction rates.					
700	DTSC-221	Appendix L O&M Plan Volume 2, 4.3.2 Definition of the Target Capture Zone in Conjunction CSM and RAOs, Page 4-7	Based on this RAO, the objective of hydraulic capture of Cr(VI) in groundwater at the site is to protect the designated beneficial uses of the Colorado River.	The capture zone discussion appears to be applied to protection of surface water. It would appear necessary to include capture zone assessment to protect groundwater resources (e.g., prevent migration of chromium or byproducts to the east of the river bank line). The text should be expanded to discuss this issue.	The design of the river bank extraction system applies to both the river and groundwater beyond the river bank line. The extent to which plume control is required at various portions of the site can be defined by the RAOs and the DQOs for the selected groundwater remedy (RAOs are found in Section ES.2, 60% BOD Report, p. vii.; DQOs are found in Section 2, Draft O&M Plan, Volume 2, pp. 2-1 through 2-9.). The two RAOs relative to plume control are as follows. • RAO 2: Prevent or minimize migration of Cr(T) and Cr(VI) in groundwater to ensure concentrations in surface water do not exceed water quality standards that support the designated beneficial uses of the Colorado River (11 ug/L Cr[VI]). • RAO 4: Ensure that the geographic location of the target remediation area does not permanently expand following completion of the remedial action. RAO 4 will be added to section 4.3.2. The six DQOs relative to plume control are as follows. • NTH IRZ DQO-3: By-product generation and migration from the NTH IRZ must be controlled. • NTH IRZ DQO-4: Extraction on the north end of the NTH IRZ will be conducted to control Cr(VI) with the NTH and river bank extraction systems. • IRL DQO-3: Control migration of Cr(VI). • IRL DQO-4: Control the migration of by-products in the deeper units.	The section needs to be revised to clarify that capture zones will also be applied to protection of the groundwater basin as a resource.			PG&E will work on items related to this comment as directed in the Agencies' direction letter dated April 4, 2014.	O&M Manual Volume 2 Section 4.3.2

					• TCS DQO-2: TCS Recirculation Loop Transwestern Bench Extraction Wells will be operated to remove Cr(VI) mass from the high concentration area in the vicinity of the TCS and control migration toward the East Ravine. • TCS DQO-3: East Ravine Extraction Wells will be operated to remediate Cr(VI) and control migration towards the river.					
701	FMIT-186 Hualapai-136 Chemehuevi-136 Cocopah-136 CRIT-136	Append L2- V2 4.3.3 p. 4.7 & Sect 4.3.3.4 p.4-9	*There are a number of methods or tools available to access plume control. Each of these methods is considered a separate line of evidence.*	Tracer testing is listed under 4.3.3 as one of the methods to assess plume control. However, on page 4-9, the text indicates that of all the “lines of evidence” listed, tracer testing was eliminated. It is confusing to list this as a “line of evidence” and then eliminate it later in the text. It would be clearer to just leave this element off the initial list, and include a discussion of this and any other methods that were considered and discarded as a separate paragraph(s).	The discussion that is referenced was designed to provide a comprehensive list of available methods and tools generally known to the profession as well as mentioned in the USEPA guidance. This will be clarified in the 90% design to satisfy the comment.			Comment resolved pending review of the 90% design.	Comment resolved.	O&M Manual Volume 2 Section 4.3.3
702	MWD-18	Appendix L, Draft O&M Manual, Section 4.3	Hydraulic Control Evaluation/ Capture zone analysis	For the 90% design report, this section should include a specific approach that will be used to confirm capture zone effectiveness over time. Due to the various stresses that will be placed on the aquifer over time due to the turning on and off of injection and extraction wells and natural stresses (such as changes in river stage, flooding of Bat Cave Wash, or seismic activity), various metrics should be established for these different time periods that meet plume treatment criteria and are shown to be protective of the Colorado River.	Sample collection will be coordinated with the transient water level data collected using the transducers, and sample timing may be adjusted to better reflect water quality variability as a function of seasonal variations in river stage and corresponding groundwater level changes.				Comment resolved.	O&M Manual Volume 2 Section 4.3.3
703	MWD-19	Appendix L, Draft O&M Manual, Section 4.3.3.1	Capture zone analysis	The use of river stage measurements compared to groundwater levels will be misleading because as the river stage declines in the winter months, there is a lag in the groundwater response, and the result would indicate flow towards the river. For the IM, a gradient between paired wells was used to assess capture. A similar metric should be developed for the planned remedy for times of high and low river stages.	See response to comment #699 DOI-281 for gradient assessments related to river stages and corresponding fluctuations of groundwater levels. See response to comment #655 DTSC-201 with regard to hydraulic gradient assessments.				Comment resolved.	O&M Manual Volume 2 Section 4.3.3

704	DOI-282	Section 4.3.2, Page 4-7	"The current extent of Cr(VI) concentrations in groundwater that exceed 32 ug/L, the regional background concentration, is illustrated in Figure 2.1-1."	Do the combined outlines of both isopleths of Cr (VI) concentrations above 32 ug/L represent the horizontal capture zone that PG&E is targeting?	No. The proposed remedial design is not intended to provide complete hydraulic control of the Cr(VI) footprint defined as >32 ug/L. The remedy design is a combination of in situ groundwater treatment and hydraulic control, and is intended to remediate the Cr(VI) plume through implementation of IRZs as well as the hydraulic control in specific areas. While some portions of the Cr(VI) >32 ug/L will be captured by extraction wells, the remedy is designed to treat remaining Cr(VI) >32 ug/L that may not be hydraulically controlled. Thus, the Target Capture Zone (the term from USEPA, 2008) is not all Cr(VI) >32 ug/L but rather portions of the plume that are not reduced by the IRZ, including: (1) where Cr[VI] is >32 ug/L within the flood plain and to the east of the planned IRZ wells; (2) where Cr[VI] >32 ug/L is within the bedrock in the East Ravine area; and (3) where byproducts are at concentrations above natural levels within the deeper portion of the unconsolidated alluvium beneath the flood plain.		Resolved.		Comment resolved.	O&M Manual Volume 2 Section 4.3.2
705	DOI-283	Section 4.3.3.1, Water Level Pairs/Three-Point Gradient Analysis, Page 4-8	"This line of evidence (water level pairs/three-point gradient analysis) will be used to the extent allowed by the locations of the monitoring wells."	In the event that additional wells are required to more accurately reflect the gradient analysis, does PG&E plan on installing the additional wells?	The currently proposed monitoring network was designed to strike a balance between adequately describing the hydraulic gradients needed to assess hydraulic control objectives while minimizing infrastructure and honoring the well counts in the FEIR. If data gaps become apparent during initial data collection and evaluation, PG&E would use monitoring wells remaining within the well count to fill the data gap.		Resolved.		Comment resolved. 			1a-20, PA and CHPMP mitigation measures.							
708	FMIT-183	Figure 4.2-1		The Tribe objects to the conclusion in the legend that the proposed location does not create any direct physical impact or effect on the Topock Maze as it is manifested archaeologically. First, the Tribe questions the accuracy of the statement. Is this conclusion supported by recent filed studies and reports, including the draft geoarchaeological report? Second, the statement can mislead a reader into thinking that the well a) has no direct impact on a tribal cultural resource (it does) and b) has no indirect and cumulative effects on cultural resources (it does). Such legends need to be corrected throughout the BOD. Have the drafters of these documents been included in the required sensitivity training?	See response to comment #84a FMIT-22. Further, the drafters of the document are sensitive to the Tribe's viewpoint. The wording in the legend is intended to refer to similar language in the EIR.				PG&E's response was discussed with the FMIT, and revised in response to that discussion.	Not applicable
709	DTSC-222	Appendix L O&M Plan Volume 2, 5.0 Other Sampling and Monitoring, Page 5-1		A program to sample domestic/private water wells in the area should be added to this section. The objective of the program should be to evaluate potential effects the remedy could impart to private wells both chemically and hydraulically. Baseline values should be established for each well prior to system startup and then sampled periodically throughout the remedy. Wells such as the new Marina well, Sanders, Smith (abandoned?), Topock2/3, and the Park Moabi wells should be included at a minimum and possibly wells associated with the EPNG station and private Arizona wells to the north.	It is PG&E's understanding that EIR mitigation measure WATER-1 is intended to proactively identify and mitigate potentially significant effects on local groundwater levels associated with freshwater extraction wells. PG&E plans to demonstrate compliance with WATER-1 using computer simulations – information from the forthcoming pumping test at HNWR-1 (as part of FWIP) which includes measurement of water levels at nearby wells, will be used in this demonstration. It is unclear how the program suggested in this comment is different from WATER-1 from the perspective of *"evaluate potential effects the remedy could impart to private wells ….. hydraulically."* At this time, PG&E is aware of one private well (Sanders) located within the area where gradients may be significantly altered by pumping from HNWR-1 on the Arizona side of the Colorado River that may supply drinking water. A recent windshield reconnaissance in Sept 2013 showed the Smith well with both piping and power disconnected. PG&E will try to	The program requested should evaluate potential effects the remedy might impart to private wells both chemically and hydraulically. Hydraulic assessment could include monitoring water levels of the monitored wells over time to see if remedy related effects are noted. Additionally, the hydraulic pumping for monitored wells should tie into the model to most accurately depict flow fields. Infrequent monitoring will suffice (e.g., baseline and then every two or three years with options to modify frequency based on better understanding of actual flow dynamics and chemical transport after the remedy progresses.) Wells located in the vicinity of the remedy should be included (e.g., Topock Marina, Sanders, Smith) to ensure the viability of the wells are not jeopardized by the remedy. Topock 2/3 data collected for			Comment resolved. PG&E will implement the monitoring program as directed assuming well owners will allow sampling of their wells. Details will be included in the 90%.	90% BOD Section 3.3.2 O&M Manual Volume 2 Sections 5.2.2 and 5.4

					make contact with the residents to determine if the Sanders well is still used for drinking water. Topock-2/3 are public supply wells that are monitored regularly under the Safe Drinking Water Act. It is unclear why the installation of another pumping well nearby should trigger additional monitoring beyond that which is already mandated by their use as public supply wells. As for the other AZ wells mentioned in the comment, based on information in the ADEQ Topock Groundwater Study, the wells at the Mohave Topock Compressor Station (MTS-1 and MTS-2) supply water that is not suitable for drinking and is used in cooling towers and restrooms. These wells are approximately 5,000 feet from the HNWR-1 and Site B locations. The direction of the gradient at MTS is not projected to change significantly due to HNWR-1 or Site B pumping. The nearest well to the north is GSRV (also known as RPGS), which is currently not in use. Gradients will remain southerly in this area with HNWR-1 or Site B pumping. Based on communications with the Topock Marina owner, PG&E understands that the new Marina well produces salty water (specific conductance 15,000 to 18,000) that is not suitable for drinking or irrigation, and therefore, will be used only for fire protection. It is not clear whether the existing 4" well at the Marina will remain when the Marina completes the planned new production well. If not, ongoing sampling the new production well could be problematic from a water management standpoint -- the purge water is likely too salty to discharge to the ground or to the river and the purge volume will be large due to the expected large diameter and depth of the well (286 feet). While PG&E does not see a technical merit for an ongoing monitoring program of these wells, PG&E agree that a baseline data set could be beneficial. Therefore, PG&E will research the logistics associated with sampling these wells and report back to the	supply purposes should suffice provided it can be provided to agencies DTSC assumed PG&E would continue to monitor the Park Moabi wells and would include them in the private well program. RPGS/GSRV-2 should be monitored more for assessing potential effects to the Arizona fresh water pumping well (same for MTS-1 and MTS-2) in an effort to minimize installation of new wells.

					agencies. As for the California side of the Colorado River, PG&E has been collecting and reporting baseline data from the Park Moabi wells.					
710	DTSC-223	Appendix L O&M Plan Volume 2, 5.1.1 Sampling Locations, Page 5-1	This monitoring network is designed <u>to</u> track COPC concentrations in areas where they are currently elevated as well as areas where they may be transported during the remedial action.	DTSC concurs with the overriding basis for the COPC monitoring captured in the cited sentence. However, detailed review of well locations and sampling frequencies will be conducted after DTSC receives requested particle tracking information (including 5 year tick marks). It is requested that a separate COPC monitoring table be assembled that distinguishes between elevated COPC wells and downgradient wells (as well as other pertinent information such as analytes and frequency). Modifications/corrections will be requested. For example, Figure 5.1-2 illustrates that wells MW-66-165, MW-67-185, MW-67-225, and TW-1 have the highest selenium concentrations across the entire site, but none of them are included for selenium monitoring according to Table 2.1-2. Similar issue for nitrate.	PG&E has prepared a separate COPC monitoring table and revised its format with input from DTSC to provide more information about which wells have elevated concentrations of COPCs and to include wells where nitrate will be sampled for process control monitoring (see **Attachment N**, at the end of this table). This table will be included in the 90% design.	Comment resolved.			Comment resolved.	O&M Manual Volume 2 Section 5.1.1
711	DTSC-224	Appendix L O&M Plan Volume 2, 5.2 Monitoring of Freshwater Source (HNWR-1), Page 5-2	A detailed discussion of the desired water quality for injection is included in the 60% BOD Report (Section 3.3, Freshwater Supply and Storage).	As noted in comments on section 3.3, a detailed discussion of the desired water quality for injection do not currently exist. Discharge limits should be established for all analytes that will be injected into the aquifer. Please revise Section 3.3 to contain the required information. It's good to see that an analyte list was developed in Exhibit 5.2-2.	See responses to comment #145 DTSC-50 and #181 DTSC-70.	Response noted. See responses to comment #145 DTSC-50 and #181 DTSC-70.			Discussion between DTSC, DOI, RWQCB, and PG&E is ongoing to resolve this comment. This topic will be carried forward. Resolution of this comment will be included in the 90% design. PG&E will also work on items related to this comment as directed in the Agencies' direction letter dated April 4, 2014.	O&M Manual Volume 2 Section 2.2.2
712	DTSC-225	Appendix L O&M Plan Volume 2, 5.2 Monitoring of Freshwater Source (HNWR-1), Page 5-2	The naturally occurring arsenic concentration in Well HNWR-1 ranges from 15 to 16 µg/L, below the site background concentration of 24.3 µg/L.	Indicate that the arsenic background concentration cited is a regional value and that the area of injection contains arsenic at lower concentrations below MCLs. This is the very reason that a separate decision by the State Water Resources Board is needed for the proposed water injection from HNWR-1.	The sentence will be revised to read: "The naturally occurring arsenic concentration in Well HNWR-1 ranges from 15 to 16 µg/L, below the regional background concentration of 24.3 µg/L <u>but above the concentration in existing wells near the freshwater injection area.</u>"	Okay, provided requested edits are incorporated.			Comment resolved.	O&M Manual Volume 2 Section 5.2

715	FMIT-187 Hualapai-137 Chemehuevi-137 Cocopah-137 CRIT-137	Append L-Vol 2 Section 5.1 p. 5-2	*Monitoring frequency for the inorganic suite will be quarterly for the first year of operation, switching to semiannual in subsequent years.*	The HNWR-1 well will be pumping at least 600 gpm of water and will be injected into upland areas that have low metal concentrations associated with local groundwater. It is therefore suggested that the sampling frequency of this water be greater than quarterly to ensure that contamination of this upland groundwater not occur. During start up a monthly sampling frequency is suggested and monthly sampling continued during periods of heavy water usage.	PG&E agrees that more frequent sampling of the freshwater well during the initial startup could provide more confidence in the stability of the water quality and agrees to revise the sampling frequency to monthly for the first 6 months followed by quarterly, assuming that the water quality is generally stable at that time. If the water quality appears to be changing rapidly, monthly sampling would be continued beyond the first 6 months. It is not anticipated that the freshwater flow rate would be varied on any regular basis, however if there was a future reconfiguration of the remedy that caused a significant increase in freshwater pumping rate, the need for additional sampling frequency would be evaluated based on the data available at that time. Text will be updated in the 90% BOD to reflect this response.			Comment resolved pending review of 90% design documents.	Comment resolved.	O&M Manual Volume 2 Section 5.2.1

This is assumed, and SOP-A11 will be updated with the recommended language.		Comment resolved.		Comment resolved.	O&M Manual Volume 2 SOP A-11
728	Hualapai-138 Chemehuevi-138 Cocopah-138 CRIT-138	Append L-Vol 2 Section 7.1 p. 7-2	CrVI samples should be preserved using added basic solution, raising the pH so that no CrVI reduction would occur, and standard operating procedures from the 60% design report (SOP-L1 and – A6) are cited.	Samples for analysis of CrVI by colorimetric method using Hach DR4000 (as shown in SOP-L1) should not be preserved with the basic solution (NaOH), and should be analyzed within 24 hours of collection. The diphenylcarbohydrazide method adds an acidic reagent buffer, which brings the sample down to about pH = 2. Interferences in the method include high pH; therefore, addition of the basic preservative would create interferences in the analytical method. Another method for CrVI analyses (EPA 218.6 using ion chromatography) does allow for	SOP-L1 is applicable for process samples within IM3 treatment plant – the NaOH solution is used for SC-201B or 300A samples which are water that have been treated using ferrous chloride. SOP-L12 is applicable to groundwater samples analyzed in the on-site lab. In SOP-L12, field filtered samples are used to analyze for Cr(VI) and no preservative is added. EPA method 218.6 is the method used by the commercial laboratories and Appendix B Section 4.1.3 (the Topock QAPP addendum) requires every groundwater sample to have a matrix spike analyzed to ensure			Comment resolved.	This comment and response were discussed with the Tribes and TRC at the November 5, 2013 TWG meeting. Additional written comments were also received from TRC (Win Wright) on November 18, 2013. PG&E provided written responses to the additional comments on December 9, 2013 (see **Attachment O**, at the end of this table). TRC (Win Wright) presented final information at the February 12, 2014 TWG meeting (see additional info to **Attachment O**).	Not applicable

				sample preservation using the basic preservative; however, this method is not described in the 60% SOP's. Bench tests and matrix spikes could be done to determine the accuracy and precision of CrVI analyses given different pH's and carbon concentrations.	accuracy. See also response to TRC's (Win Wright) memorandum dated December 9, 2013, included in **Attachment O**, at the end of this table				Comment resolved.	
729	FMIT-188 Hualapai-139 Chemehuevi-139 Cocopah-139 CRIT-139	Append L-Vol 2 Section 7.1 p. 7-2	Cr(VI) samples should be preserved using added basic solution, raising the pH so that no Cr(VI) reduction would occur, and standard operating procedures from the 60% design report (SOP-L1 and –A6) are cited.	Many of the groundwater samples collected will have elevated carbon concentrations. As soon as a water sample is pumped from a well, reactions can be accelerated due to changes in dissolved oxygen and temperature, and Cr(VI) reduction could take place in the sample bottle, possibly giving a false reading. Even if a basic preservative is added, Cr(VI) reduction is known to occur in natural high pH waters. Bench tests and matrix spikes could be done to determine the accuracy and precision of Cr(VI) analyses given different pHs and carbon concentrations.	For groundwater samples, an inline filter is situated at the tip of the hose/ tube directly before the sample enters the pre-preserved sample container. Very little oxygen is introduced during the process and in fact, oxygen actually reacts with Ferrous iron inhibiting/slowing the reduction of Cr(VI) to Cr(III). Once the sample container is full the container is capped, placed in a zip-lock bag and placed on ice in a cooler. Reducing the temperature (ground water temperature is generally in the mid 80°F – 90°F) of the sample slows down any possible chemical or biological reactions. In addition the buffer solution (specified by EPA method 218.6) is not just for raising the pH but is designed to stop any reaction that might be occurring and provides a 28 day holding time.			Comment resolved.	This comment and response were discussed with the Tribes and TRC at the November 5, 2013 TWG meeting. TRC (Win Wright) presented final information at the February 12, 2014 TWG meeting (see additional info to **Attachment O**). Comment resolved.	Not applicable
730	Hualapai-140 Chemehuevi-140 Cocopah-140 CRIT-140	Append L-Vol 2 Section 7.1 p. 7-2	Field analyses of unstable constituents	Dissolved sulfide analyses may not be necessary for routine monitoring; however, sulfide measurements help to describe geochemical end products and electron acceptors. In addition to sulfide, the IRZ will generate hydrogen gas, and it is known that H2(g) is explosive. Collection and analysis of end-products could help verify geochemical modeling results.	Hydrogen sulfide will be periodically monitored in the on-site lab as a means to monitor subsurface conditions and understand how the process of reducing the Cr(VI) is progressing. The formation of hydrogen gas is not anticipated to be an issue. When in-situ treatment was first being introduced as a treatment for ground water contamination, the fear of excess hydrogen gas being produced at explosive levels was common. However, over time it has been shown that although hydrogen gas is produced it is not typically produced at explosive levels. Extra care needs to be taken in cases where hydrogen gas and hydrogen sulfide can displace the air such as confined spaced (e.g., well vaults)			Comment resolved pending review of 90% design documents. 731	FMIT-189 Hualapai-141 Chemehuevi-141 Cocopah-141 CRIT-141	Append L-Vol 2 Section 7.1p. 7-2	*Preservation and analysis of samples, unpreserved FeII samples can be transported for lab analyses.*	Oxidation of Fe(II) to Fe(III) is on the order of hours to days. Samples for Fe(II) concentration need to be analyzed immediately, or preserved using hydrochloric acid (HCl), then analyzed within a couple of days of sample collection. Samples for dissolved sulfide (S(II)) cannot be preserved, and need to be analyzed as soon as possible after sample collection. It is widely known that iron colloids can pass through a 0.45 micrometer filter (e.g. in water from turbid or muddy wells); therefore, turbid samples should be flagged. Protocols for turbid samples could include use of smaller filter sizes (e.g., 0.2 micrometers).	For Ferrous iron, a sample is treated with 1, 10-phenanthroline (HACH packet) at pH 3 to 3.5. Molecules of the phenanthroline chelate each atom of ferrous iron to form an orange-red complex. The colored solution obeys Beer's law; (concentration is proportional to the color intensity and is independent of pH as long as the pH is between 3 and 9. A pH between 2.9 and 3.5 ensures rapid color development in the presence of an excess of phenanthroline. The HACH packets are designed to acidify and provide the phenanthroline needed for the reaction, so adding additional HCl would drive the pH below the desired pH needed for the analysis and cause erroneous results. Samples should be field filtered, stored on ice or in a refrigerator and analyzed the same day as collection. Because the reaction is specific to ferrous iron, ferric iron colloids do not react with the phenanthroline.			Comment resolved.	This comment and response were discussed with the Tribes and TRC at the November 5, 2013 TWG meeting. 739	DOI-299	Appendix B	General Comment	Please address several questions related to river sampling procedures: • Will field data include river clarity, weather conditions, and river stage data? • Will the boat be anchored and the engine turned off prior to sampling? • Should bottom sediment be disturbed during sample preparation in the field, will time be allotted for settling to occur?	These topics are addressed in SOP-A4 as follows: • The field sheets do include weather conditions. One of the parameters is turbidity so clarity is recorded. River depth is also recorded at each location prior to sampling; no other river stage data is recorded in the field. • The boat is always anchored, but the engine is not always turned off in case there is an issue of dragging during the course of sampling. For this reason, ambient blanks are collected as a QC measure. In addition, the motor is always downstream of the sampling location since the boat is always pointed upstream. There is typically heavy boat traffic on the river so the motor is left running at all times as a safety precaution in case emergency avoidance action must be taken. • Sediments are generally not disturbed as the river water is typically traveling at 8-9 miles per hour. There are typically little to no sediments due to the speed of the river current. The river bottom is typically		Comment resolved.		Comment resolved.	Not applicable

741	DTSC-232	Appendix L O&M Plan Volume 2, Appendix B, 3.4 Additional QC Steps for Hexavalent Chromium in Select Floodplain Well Samples, Page 3	In addition to the QC steps discussed in Section 3.3, the additional QC steps outlined in this section will be followed during sampling of a) monitoring wells located in the floodplain that are currently non-detect (or detected at less than 5 parts per billion) for Cr(VI), and b) future floodplain wells as determined by the CH2M HILL project chemist. The applicable floodplain wells are listed in Exhibit 3-2. As water quality changes, the list of wells in Exhibit 3-2 will be reviewed periodically (initially on an annual basis) and updated as applicable.	Include the rationale for requiring additional QC steps in select floodplain wells. Note that wells MW-21 and MW-55 are not necessarily floodplain wells.	As an additional QC step, extra containers and equipment blanks (EBs) are collected to help determine the source for any possible anomalous results found in the listed wells. All the wells located near the river (specifically those around the active reducing zone) are susceptible to colloidal suspension of chromium which can cause a high variability between the Cr(T) and Cr(VI) results. The special EBs are collected to eliminate the possibility of cross contamination between the wells (i.e., to verify that carry over is not occurring). The MW-55 and MW-21 wells are not necessarily in the floodplain, but are located in areas “near” the river where the “normal” results are either non-detect or low concentrations. In the event results are “detected” higher than normal or where the Cr and Cr(VI) concentrations differed more than is considered normal, PG&E works to determine the likely causes and provide the analysis in the report where the results are reported.	Isn’t this true of most wells? Need to elaborate Seems like this should apply to all site wells with low level detections (less that ~5-10 ppb). Comment resolved.			The additional QC steps were put into place due to the sensitive nature of the sample locations, where low level detections could have large implications if shown to be correct. The additional QC steps are of little use for wells in the uplands where slight differences of a few ppb are of less concern, especially where the sample concentration is less than the background concentration. At the same time, samples with concentrations greater than 10 – 15 ppb can have sufficient variability within the analytical methods to exceed the possible influence from contamination sources or colloidal suspension concentrations. This discussion will be incorporated into the 90% design document. Comment resolved.	O&M Manual Volume 2 Apdx B Section 3.3

742	DTSC-233	Appendix L O&M Plan Volume 2, Appendix B, 3.5 Additional QC Steps for Cr(T) and Cr(VI) — River Samples, Page 4	For surface water sampling events; three analyte-specific sample containers will be collected from each sample location for both total chromium (Cr[T]) and Cr(VI). The laboratory will analyze the initial sample aliquot; if that result is considered “suspect” (any detected concentration in the river will be considered suspect), an additional aliquot of the original sample will be reanalyzed along with an aliquot from each of the additional sample volumes for comparison purposes.	“Suspect” detections should also be reported with qualifier for trend analysis in standard reports.	Three containers are collected and provided to the laboratories for cases of unexpected detects in the initial analysis. When a “suspect” result is initially obtained by the laboratory, the laboratory performs analyses on all sample containers in an attempt to determine if the initial result is correct or if it is a laboratory “artifact” (contaminate). In either case, the laboratory will report the result determined to be the most accurate, and that is the result that is validated and reported to the agencies. To date, all the “suspect” or anomalous results have been related back to a contamination issue in the laboratory. PG&E will work with the laboratory to ensure a more detailed case narrative is provided whenever an anomalous result is encountered.	Shouldn’t this be included in laboratory exception report? DTSC is requesting that “Suspect” detections also be reported with qualifier for trend analysis in standard reports. PG&E shall comply with the Agency directive letter dated April 4, 2014 with regards to sampling methodology and data reporting. Comment resolved			Comment resolved. Specific Comments – Appendix L – Volume 3: Contingency Plan										
748	DTSC-235	Appendix L, Volume 3, Section 1.0 Introduction		Category A under FMEA should not only be limited to attainment of final RAO. PG&E should define short term goals and process to monitor for attainment of these short term goals. Nonattainment should then trigger corrective actions through contingency planning. These short term goals should be specified in 60% design contingency planning (e.g. by production formation that is not dissipated or reverted in expected time frame according to model, undesirable or unexpected changes in geochemical quality of water in injection, extraction and production wells).	Unacceptable remedy performance (Category A) of the FMEA is defined as "Remedy does not meet RAOs, cleanup goals, design objectives, or otherwise perform as required," which is inclusive of shorter term performance objectives. The Sampling and Monitoring Plan (Appendix L, Volume 2) establishes detailed performance metrics to ensure that the system is meeting the short term performance objectives of (1 establishing the NTH IRZ while controlling byproduct generation, (2) establishing hydraulic control as needed for Cr[VI] and byproducts in the deep zone of the aquifer, and (3) flushing of the	See response to comment #38 DTSC-6. 					plume. Operational flowcharts for obtaining these goals are provided in the Sampling and Monitoring Plan. The flowcharts also specify contingency measures when adaptive operations are not sufficient to meet the performance objectives.					
749	DTSC-236	Appendix L, Volume 3, Section 1.0 Introduction	Causes of potential failures are mitigated in the design process, in adaptive operations, and/or in corrective action/ contingency response planning.	PG&E places heavy emphasis on adaptive operations to mitigate potential failures as can be seen in many of the FMEA tables that refers back to the O&M plan and sampling plan. DTSC is concerned that the range of operational adjustments may not be sufficient to mitigate the need for contingencies. For example, based on current design, there are only very limited numbers of additional wells that can be installed before reaching the total 170 well count, as PG&E install injection wells near the boundary of the plume at IRLs, the concentrations for Cr6 or other key compounds may not be below background, would that difference change the assumption of the predicative model, and how much latitude would PG&E have to move the IRL injection wells? What would PG&E do then?	Based on available data, PG&E anticipates that the proposed IRL locations (IRL-1 through IRL-4) are outside of the baseline hexavalent chromium plume (i.e., as defined by the 32 ppb background concentration). If, during the installation of these wells, it is identified that the hexavalent chromium plume extends further to the northwest in these areas than currently understood, PG&E would consider several alternatives. Alternatives that could be considered include well relocation, amendment of water injected into the IRL well with TOC to enhance hexavalent chromium treatment within the immediate vicinity of the well (if concentrations are near 32 ppb), or other alternatives. A contingency plan will be included in the Construction/Remedial Action Work Plan.	Comment resolved pending review of the 90%.			Comment resolved.	Construction/Remedial Action Work Plan Sections 3.2 and 5.
750	DTSC-237	Appendix L, Volume 3, Section 1.0, Category D	Changes (such as visual impact) that necessitate re-opening the EIR process.	DTSC would not be "re-opening the EIR process." The proper procedure would be to consider the additional CEQA impacts that have either not been identified or with a condition that was not anticipated. Either case, it would not be re-opening a CEQA decision, but to conduct additional CEQA analysis based on new information received.	Comment noted. PG&E understands that under CEQA, DTSC would determine whether new information meets any of the conditions listed in Public Resources Code section 21166. Text in the referenced section will be revised in the 90% design to reflect the above CEQA process.	Comment resolved.			Comment resolved.	O&M Manual Volume 3 Section 1 and all FMEA tables.

					should the adaptive procedures in Volumes 1 and 2 not achieve the remedy objectives. The following DQOs listed in Table 2.1-1 of the Sampling and Monitoring Plan (Appendix L, Volume 2) specify the decision rules for evaluating plume control and the adaptive operations framework that will be implemented if this evaluation indicates that plume control is not adequate: NTH IRZ DQO-4, IRL DQO-3, IRL DQO-4, TCS DQO-2, and TCS DQO-3, as outlined on the flowchart figures that are referred to in Table 2.1-1 for each DQO. Operational adjustments and activities listed in the flowcharts include, but are not limited to, increasing flow rates or altering the flow balance of the system, and bringing provisional wells on-line. See also response to comment 655 DTSC-201.					
753	DOI-307	Table 2.1-1, Conveyance (General)		In Table 1.0-1, Category E effect is not defined for severity level 4, yet for the release from the conveyance pipeline, it is defined. For the failures with severity level 2, none of the categories are checked which is inconsistent with Table 1.0-1. The rationale appears to be due to the low likelihood of the event, but likelihood is a different criterion. The logic in Table 1.0-1 as applied to the Section 2 tables needs clarification.	PG&E will clarify the application of Table 1.0-1 (Appendix L, Volume 3) in the 90% submittal.		Resolved pending review of the 90% design.		Comment resolved.	O&M Manual Volume 3 Section 1 O&M Manual Volume 3 Table 1.0-1
754	DTSC-238	Appendix L, Volume 3, Table 2.1-1	Release from conveyance pipeline	DTSC notes that only limited sections of the pipeline will be double walled. Furthermore, human observation of slow leaks with below ground pipes are unlikely. DTSC recommends a more robust leak detection system throughout the conveyance pipeline. PG&E must log all occurrences of these failures (leaks, fouling, clogging, and releases to wells, etc.), identify remedial measures taken and conduct periodic evaluations (i.e. 5 year reviews) to determine if a change in design would be necessary based on frequency of occurrence. This approach should be applied to all potential failures and detailed in periodic remedy performance reports	As described in Appendix C, Section C.5.1, conveyance pipelines will be single-walled unless the pipe is used to convey: (1) groundwater or remedy-produced water that exhibits the hazardous waste characteristic or (2) concentrated carbon substrate. In these cases, double-walled piping will be used. Double-walled pipe segments will include appropriately designed leak detection systems. Additionally, pipeline segments installed within belowground concrete trenches will be designed with leak detection at low points. Conveyance system maintenance Standard Operating Procedures will be provided in the 90% Design Submittal and will include maintenance, inspection, and logging	Okay, please also see comment #559 DTSC-157.			Comment resolved.	O&M Manual Volume 3 Table 2.1-1

				to be submitted to agencies.	procedures. O&M Manual Exhibit L2.2-3 provides the preliminary communication framework, including communication of potential releases. As described in Appendix L, Volume 3, Table 2.1-1, PG&E is taking several measures in the design and planned operations to mitigate potential leaks, releases, or other failures of the conveyance pipelines. Should leaks, releases, or other failures be identified during remedy implementation, potential improvements will be evaluated at that time.					
755	DOI-308	Table 2.1-1, Remediation Wells (General)	"Extraction Well Failure."	Is it possible for the water in the Colorado River to overflow its banks to the extent that it would impact the River Bank extraction wells?	As indicated on Page 10 of Table 2.1-1 under "Flooding", remedy infrastructure has been designed to be located outside of the ordinary high water mark and 100-year floodplain to the extent possible. The proposed River Bank Extraction Well locations are outside of the ordinary high water mark and 100-year floodplain. It is therefore not considered likely that Colorado River flooding would impact River Bank Extraction Well operation.		Resolved.		Comment resolved.	Not applicable
756	DOI-309	Table 2.1-1, NTH IRZ	"Extraction of organic carbon and/or significant byproducts."	Treatment of extracted river bank groundwater to remove carbon and byproducts should equate with all unacceptable conditions being checked.	PG&E does not anticipate that treatment of extracted river bank groundwater will be required, and this potential is being mitigated in several ways through the design and planned operations, as described in Table 2.1-1. If these efforts are not successful and treatment is required, it is expected to have a significant cost increase (i.e., unacceptable condition) as defined in Table 1.0-1. However, although treatment is considered undesirable, it would not be expected to cause unacceptable conditions A, B, D, or E as defined in Table 1.0-1. No changes to Table 2.1-1 are proposed.		Comment resolved.		Comment resolved.	Not applicable
757	DTSC-239	Appendix L, Volume 3, Table 2.2-1, Remedy produced water management system	4. Poor Quality Water to Wells: presence of scaling ions or high pH water	PG&E states that one mitigation in design is to "add conditioning units, if needed." Are these contingency designs currently included in remedy produced water conditional plant? If not, addition of units in future will likely trigger additional CEQA evaluations.	To facilitate CEQA evaluation of the 90% design, PG&E will include general information on contingency conditioning units to address scaling ions (primarily manganese, iron, magnesium, and calcium) in the 90% design. This information will include unit description and estimates of footprint, chemical use, electricity use, and waste generation.	Okay pending review of the 90% design.			Comment resolved.	O&M Manual Volume 3 Section 2.2 and Appendix A.

TABLE I-1

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
758	FMIT-190	Table 2.2-1		This chart is also troubling as it lists Re-Opening of EIR as a type of "Unacceptable Condition." It is the Tribe's view that more flexibility should be given regarding this potential: if there are alternate designs, methods, mitigation that could reduce impacts/effects to cultural resources but might reopen the CEQA or other process, they should be analyzed on their merits - not potentially summarily rejected by PG&E or the agencies because it could reopen an EIR, etc. Please clarify if DTSC's position is that re-opening of an EIR, etc., no matter the context, is an unacceptable condition and if so, the basis for DTSC limiting its future discretion in this manner regardless of future circumstances. The chart also lists "Significant Cost Increase" as a type of "Unacceptable Condition." Please clarify if DTSC's position is that cost increases to the PRP, is an unacceptable condition. Do DTSC and DOI agree with the PRP on what a "significant" cost increase is? Might that metric not change under different circumstances and contexts? Again, what is the basis for the agencies limiting their lawful discretion in the future based on cost alone, which is only one criterion under the law for making decisions under applicable law and ARARs?	This chart has factors that PG&E's engineers consider as they design the remedy. With respect to DTSC's position, PG&E defers to DTSC. PG&E's understands this entry on the chart as intended to indicate that one of the design parameters is consistency with the remedy that was selected based on the EIR, and avoiding the need to redo or reopen the EIR process. PG&E recognizes that DTSC will review the final design in compliance with CEQA. PG&E likewise defers to DTSC and DOI for their position on the cost effectiveness factor. From PG&E's perspective, cost effectiveness is one of the evaluation criteria required by RCRA and CERCLA in the CMS/FS process. In the CMS/FS, the selected remedy was scored medium for cost effectiveness, other alternatives that received a similar score have an estimated cost of $7M to $41M more than the selected remedy (see Table 5-7, page 5-85). Therefore, for the purpose of contingency planning for the remedy, PG&E defines potential causes for the remedy to increase in cost by more than $10M to $50M as conditions that need further agency discussion to allow PG&E to consider the most cost effective options for preventing a failure event.				PG&E's response was discussed with the FMIT, and revised in response to that discussion.	Not applicable
759	FMIT-191	Note 1		Note 1 is unclear as to whether the described trucking is within or outside of the groundwater EIR scope. Please clarify.	The 60% design includes an automated backwashing and conditioning system that, when operated as designed, will minimize the amount of trucking needed during O&M. The design is consistent with the certified EIR. For clarity, Note 1 will be revised as follows: "Anticipated annual remedy-produced water volume is 7.6 million gallons (MG) per year. With provisional wells this volume could increase to 10 MG per year. The automated backwashing and conditioning system has been designed to accommodate this range	For Note 1, PG&E cited Section 3.5.3, Operation and Maintenance of the project. The FEIR assumed that there will be periodic maintenance activities associated with the remedy that would require additional vehicular traffic. Although the FEIR did not specifically consider the contingency generated vehicular traffic, the FEIR did consider the cited level of traffic as part of the project.		Comment noted.	Noted.	O&M Manual Volume 3 Table 2.2-1.

					of anticipated volume of wastewater. If the system functions as designed, the amount of trucking needed during O&M would be minimal, and within the range analyzed in the certified EIR (see Section 3.5.3, page 3-26)."					
760	DTSC-240	Appendix L, Volume 3, Table 2.3-1, Freshwater Supply	Possible Contingency Measures	PG&E did not acknowledge DTSC's requirement for PG&E to include a pre-treatment plant as contingency. Instead, PG&E specifies seeking other sources of freshwater. DTSC would clarification from PG&E on possible additional freshwater locations that have not already been considered by PG&E in the current Freshwater Implementation Plan. Also, PG&E identifies provision of "alternate water supply for affected water users" as a contingency for freshwater pumping causing effects on water quality or capacity in nearby wells. **This is beyond the terms of DTSC's approval of the proposed remedy.** DTSC's approval is conditioned on PG&E's operation not impacting nearby wells.	PG&E interpreted DTSC's direction in the 12/31/12 letter as to include a pre-injection treatment system in the 60% design for actual remedy implementation, and not as a contingency. Therefore, the system was not included in the "Possible Contingency Measures" column in Table 2.3-1. However, as directed by DTSC (#21 DTSC-2), PG&E will design an arsenic only freshwater pre-injection treatment system and this will be included in the 90% design as a contingency. PG&E only listed possible contingency measures in Table 2.3-1, but did not develop these measures. At this time, PG&E has not considered additional locations outside of those included in the Alternative Freshwater Source Evaluation. This possible contingency measure will be deleted.	Okay. DTSC notes the length of time it has taken to site and evaluate the current site B alternative freshwater source location and cautions that this contingency measure may be lengthy. Furthermore, it is DTSC's interpretation that PG&E should test and monitor for conditions that may impact quality, not just quantity, of water to nearby wells.			Comment resolved.	O&M Manual Volume 3 Table 2.3-1 and Appendix B.
761	DTSC-241	Appendix L, Volume 3, Table 2.4-1, Power Supply	Utility or generated power supply failure	As part of DTSC's remedy approval condition, PG&E is required to "rent or otherwise obtain a single new primary 320 kW generator, of similar make and model of the existing generator (Isuzu Model 6WG1X), for purposes of providing backup electricity when needed at the site for implementation of the approved project." (see remedy approval letter to Yvonne Meeks, January 31, 2011)	Text under the column titled Mitigation-Design will be clarified as follows: "Interconnection to other source(s) of generated electrical power, connection point to <u>dedicated</u> portable generator".	Okay.			Comment resolved.	O&M Manual Volume 3 Table 2.4-1.
762	DOI-310	Table 2.5-1	General Comment	What are the potential consequences if alarms do not signal the SCADA system?	For the SCADA to not get alarms, it would mean that there was a loss of communications which results in loss of status, control, and alarms. In this system, individual wells and other loads do not operate on their own and must be connected to the main SCADA for instruction. Therefore, if communications are lost, systems are shut down. The system design includes layers of protection against such consequences that will be		Comment resolved pending review of 90% design.		Comment resolved.	O&M Manual Volume 3 Table 2.5-1.

					described in more detail in the control systems narrative planned for inclusion in the 90% design. In general, the following elements are included in the design: • Motors and valves go to safe positions following failure. • Local devices are controlled by local PLCs. • The SCADA will continuous monitor to verify signals are being received. • The SCADA will also confirm (every 1 to 3 minutes) and verify that there are no alarm conditions that should cause a device to be turned on or off.					
Specific Comments – Appendix L – Volume 4: Soil Management Plan, including Appendix A Groundwater Remedy Implementation – Baseline Soil Sampling and Analysis Plan										
763a	FMIT-192		General comment	It is requested that PG&E evaluate the use of displaced soils for the development of a soil/plant nursery in place of or in addition to the use of stockpiles. This approach would provide habitat for displaced seeds and plants and would better ensure that the biological integrity of the soil is maintained over potential long-term storage. If the development of a nursery is decided to not be a viable option it is further requested that the rationale behind the decision be clearly provided to the Tribe.	Salvage of topsoil during installation of linear utility features is a common practice for PG&E and will be done where the proposed excavation will occur in areas where undisturbed topsoil may be present. In such areas the upper 4 inches of soil will be carefully removed and placed near the excavation. The remaining sub-soil will then be excavated and stored separately from the topsoil. Following the installation of the pipe and backfilling of the trench the topsoil will be replaced over the trench. Therefore, there will be no need for long-term storage of undisturbed topsoil. As for the rest of the excavated soils that are not undisturbed topsoil, these desert soils in general are low in nutrients and organic matter and soils such as these that have been subject to disturbance typically lose a large percentage of the available nutrient supply and important soil biota. Therefore there is no ecological benefit associated with the salvage of soils from existing disturbed areas and such soils would not be suitable for the establishment of a native plant nursery. Additionally, one of the primary goals of the remedy design is to avoid and minimize disturbance to special-status plants, and therefore a careful analysis of the 60% design			Comment resolved. 					was conducted to determine areas where the impacts to culturally significant annual plants may occur. Based on the analysis, it was determined that less than one percent of the proposed pipeline will be located in undisturbed habitat. It was therefore determined that the amount of impacts to native vegetation does not warrant the need for an onsite nursery. PG&E does not believe that a nursery, based on using unsuitable displaced site soil is a viable option.					
763b	Hualapai-142 Chemehuevi-142 Cocopah-142 CRIT-142		General comment	It is requested that PG&E evaluate the use of displaced soils for the development of a soil/plant nursery in place of, or in addition to, the use of stock-piles. This approach would provide habitat for displaced seeds and plants and would ensure that the biological integrity of the soil is maintained over long-term storage. If the development of a nursery is decided to not be a viable option it is further requested that the rationale behind the decision be clearly provided to all stakeholders. 764	FMIT-195	Section 1		First paragraph is unnecessarily vague about when PG&E will receive approval to decommission and remove the IM3 system. The recent settlement between the Tribe and DTSC sets forth specific criteria for the decommissioning of the IM-3 treatment plant. A specific even milestone should be established for the determination of whether those criteria have been achieved. It should also be revised to reflect that displaced soil can be a project resource, particularly regarding the plant technical report which acknowledged the value of the duff, etc., for restoration.	The second sentence of the first paragraph will be revised as follows: "~~At some point during the implementation of the groundwater remedy, PG&E would receive~~ In addition, after receipt of approval from DTSC, with DOI's concurrence, PG&E will decommission and remove the Interim Measures No. 3 (IM-3) Groundwater Extraction and Treatment System (referred to herein as the "IM-3 system")." Regarding the use of displaced soil as a project resource, see response to comments #763a FMIT-192, #763b Hualapai-142, and #774 FMIT-193/Hualapai-143.			Review in progress. 768	DOI-314	Section 2.2 Page 2-2	General Comment	There is no mention of how soil that is not in or near Soil RFI/RI Investigation Areas will be characterized and managed. Although Section 1 indicates this soil will be placed back in the excavation without characterization or otherwise used in the APE, excess soil used in the APE may require testing. This is of particular concern with excess excavated material from roadways.	Please see response to comment #765 DOI-311. The first paragraph of Section 2.2 will be revised as follows (inserted verbiage shown in <u>underline</u> typeface, deleted text shown in ~~strikethrough~~ typeface): "Soil ~~in or near Soil RFI/RI Investigation Areas that are~~ in the vicinity of the groundwater remedy system expected to be displaced will be pre-characterized following the Groundwater Remedy Implementation—Baseline Soil sampling and Analysis Plan (Baseline SAP), included as Appendix A of this document." The first sentence of the second paragraph will be revised as follows: "<u>Representative sample profile results</u>, existing soil samples, and knowledge of the area history will be used to evaluate waste classification for displaced soil that has not been pre-characterized." The first sentence of the fourth paragraph of Section 2.2 has been revised and a sentence has been added: "The waste characterization samples <u>collected within or near Soil RFI/RI Investigation Area</u> will be analyzed for applicable Soil RFI/RI Investigation Area analytical suite presented in Tables 1.2-1 and 1.2-2. <u>The samples collected outside areas of known or suspected contamination will be analyzed for PAHs and lead.</u>"		Comment resolved.		Comment resolved.	O&M Manual Volume 4 Section 2, 2.2, 2.3, 2.5, 3, and 3.1.1
769	DOI-315	Section 2.2 Page 2-2	"Soil in or near Soil RFI/RI Investigation Areas that are in the vicinity of the groundwater remedy system . . ."	The first sentence indicates that soil in or near Soil RFI/RI Investigation Areas that are in the vicinity of the groundwater infrastructure will be pre-characterized. Later in the paragraph, the text states that there will be construction and O&M activities in or near Soil RFI/RI Investigation Areas that have not been pre-characterized. Why would soil not be pre-characterized and thus require special management considerations? Although drill cuttings from deep borings may be the appropriate course of action, this	Soil in the vicinity of the groundwater remedy infrastructure will be pre-characterized prior to construction, as stated in response to comment #768 DOI-314. The latter part of the paragraph discusses construction and O&M activities that could occur post-construction of the remedy as part of routine O&M, which is not part of the pre-characterization presented in Appendix A of Volume 4. In addition, pre-characterization of soil in the vicinity of groundwater remedy infrastructure will not be possible in		Comment resolved.		Comment resolved.	O&M Manual Volume 4 Section 2.2

			one discrete sample per 55-gallon DOT drum or at least one composite per ten drums,… .”		· For one drum, one discrete sample will be collected from the drum. The sample will be collected from the center of the drum from at least 12-inches below the surface of the soil. · For 2 to 10 drums, one discrete sample will be collected from each drum and composited into a single composite sample. · For more than 10 drums, one composite sample will be collected for every 10 drums. · For each roll-off bin, one four-point composite sample will be taken from the roll-off bin. Samples will be analyzed for applicable Soil RFI/RI Investigation Area analytical suite presented in Tables 1.2-1 and 1.2-2. Analytical results will be screened according to the procedure listed in Section 2.4 to classify the soil for handling, storage, and disposal purposes.”					
773	DOI-319	Section 2.4, Page 2-4		It should be noted that clay found in significant volumes will be set aside for special handling.	A significant amount of clay is not expected to be encountered during the installation of the groundwater remedy infrastructure. The predominant geology at the site consists of alluvial fan deposits on top of sloping bedrock, which is not the geologic environment where clays form. Shallow soil across the site consists mostly of weathered bedrock, sands, and gravel. However, consistent with the special handling procedures requested by the Hualapai Department of Cultural Resources for displaced clay material generated from clay beds (this does not include clay-containing sediment mixtures, only clay beds), PG&E will notify the agencies and Tribes in the event clay bed material is encountered and separated for storage on 100% cotton muslin (dye free) for future disposition. The following text will be added to the first paragraph in Section 2.4 (inserted verbiage shown in <u>underline</u> typeface: “Non-hazardous clean displaced soil will be stockpiled at the work site, if practicable, and recorded in an inventory as described in Section 5.0. 774	FMIT-193 Hualapai-143 Chemehuevi-143 Cocopah-143 CRIT-143	Sect. 2.4 p. 2-4 and Section 3.1	*Non-hazardous clean displaced soil will be stockpiled at the work site, if practicable, and recorded in an inventory as described in Section 5.0. Clean soil that was removed from trenches or excavations will be reused as backfill into the same trench or excavation area, if practicable.*	Suggested storage for displaced soils that are not hazardous wastes currently include roll-off bins, drums and stockpiles. It is important however to note that much of this stored soil will be returned to the landscape once final project specific soil risk values have been established. If any of this stored soil is replaced on the surface with the anticipation of supporting re-vegetation efforts, it is important that the biological integrity of the duff (top layer) is preserved during storage. For example as stated in Appendix E of Appendix A7 (Ethnobotany Survey Report): "In order to mitigate for annual species, such as chia or golden suncup, one should either collect and store seed prior to the disturbance	PG&E agrees that proper management of topsoil is important. As discussed in response to comment #763a FMIT-192, salvage of topsoil during installation of linear utility features is a common practice for PG&E and will be done where the proposed excavation will occur in areas where undisturbed topsoil may be present. In such areas, the upper 4 inches of soil will be carefully removed and placed near the excavation. The remaining sub-soil will then be excavated and stored separately from the topsoil. Following the installation of the pipe and backfilling of the trench the topsoil will be replaced over the trench. Therefore, there will be no need for long-term storage of undisturbed topsoil. 			Clean soil that cannot be immediately used as backfill may be reused in other areas within the APE, or stockpiled for future reuse within the APE.	and to re- seed post-construction or salvage the topsoil (3-4 inches) where construction or disturbance will take place and store that soil until after construction. Topsoil salvaged from short-term disturbance areas should be piled to no more than 4 feet high and stabilized to prevent loss during storage. It should be re-spread during site rehabilitation as an initial procedure following construction. These measures will preserve a portion of the existing seed bank through construction. In short-term disturbance areas, the existing seed bank present in the topsoil has advantages over subsequently sown seed in that it is pre-conditioned to the soils environment.”	As for the rest of the excavated soils that are not undisturbed topsoil, as discussed in response to comment #763a FMIT-192, these desert soils in general are low in nutrients and organic matter and soils such as these that have been subject to disturbance typically lose a large percentage of the available nutrient supply and important soil biota. Therefore, PG&E does not propose to conduct any specific actions related to protecting biological integrity while these soils are being stored. Further detail will be provided in the 90% design.					
775	DOI-320	Section 2.5, Page 2-5	“The volume of displaced soil in and near Soil RFI/RI Areas from the decommission-ing and removal . . . “	Consideration should be given to storing soils from the IM-3 decommissioning and sampling activities in the local vicinity of IM-3.	Based on September 18 TWG discussion, areas in the local vicinity of IM-3 treatment plant were included in the updated Figure 7.6-1 and the Potential Soil Storage Location Evaluation Matrix (see **Attachment G**, at the end of this table).		DOI defers to PG&E and the FMIT regarding soil storage locations in this area.		Topics related to the draft soil matrices and updated map showing soil storage and construction staging areas (updated Figure 7.6-1) were discussed at various 60% RTCs TWG meetings. Updates to the matrices and map were made as a result of these discussions. The latest version is included in **Attachment G**, at the end of this table. 783	DOI-327	Section 3.1.2, Page 3-2	“RCRA and non-RCRA Hazardous Soil. If it is necessary to temporarily stockpile soil classified as RCRA or non-RCRA hazardous waste . . . “	Further describe the situations necessitating stockpiling of RCRA and non-RCRA hazardous waste/soil rather than storing the material in roll-offs or drums. It is the agency’s preference to minimize stockpiling of RCRA and non-RCRA hazardous soil and material that exceeds screening criteria to the extent practicable. Further information should be provided on how wind and water erosion or infiltration will be addressed for hazardous waste/soil.	Stockpiling of soil RCRA and non-RCRA hazardous waste/soil is not planned. It is anticipated that all soil that is above soil screening levels will be placed in roll-off bins or similar containers. In the unlikely event that soil with contaminant concentrations above screening levels is stockpiled, best management practices described in Section 3.1.2 will be employed to prevent wind and water erosion.		Comment resolved.		Comment resolved.	O&M Manual Volume 4 Section 3.1.2.
784	DOI-328	Section 3.1.3, Page 3-3	“The bins will be covered and inspected at a specified frequency.”	Specify a proposed inspection frequency (as noted in Section 3.4).	Inspection frequencies are listed in Section 3.4. Weekly for containers storing hazardous waste, and monthly for containers storing non-hazardous waste. A reference to Section 3.4 will be added to the subject bullet.		Comment resolved.		Comment resolved.	O&M Manual Volume 4 Section 3.1.3

					response to Comment #765 DOI-311. Although some of these metals may not be present in influent and effluent at significant concentrations, obtaining baseline concentrations of all these metals in soil will allow PG&E to definitively assess potential affects to soil associated with the operation of the groundwater remedy. Therefore, the baseline soil samples will be analyzed for Title 22 metals because it includes all of the metals listed above, and is cheaper than analyzing for the individual metals. A summary of this rationale will be included in the 90% BOD.					
800	DOI-344	Appendix A, Section 2.2, Page A-4	"If the baseline soil sample location is within a Soil RFI/RI Investigation Area, the sample will also be analyzed . . . 801	DOI-345	Appendix A, Section 2.3, Page A-4	"A number of new monitoring wells are proposed (at the 60% design stage) to be installed to support the groundwater remedy system."	Information in this section conflicts with the sample strategy presented in SMP Section 2.2 regarding drill cuttings. Furthermore, a sample at 1 foot bgs is not representative of the cuttings generated at depth. Please resolve.	The sampling strategies listed in Section 2.2 of the SMP and Section 2.3 of the Baseline SAP serve two different purposes. The sampling strategy listed in Section 2.2 of the SMP is to characterize drill cuttings from the installation of wells for reuse, storage, or offsite disposal of the soil. The sample strategy listed in Section 2.3 of the Baseline SAP is to assess baseline conditions in areas where the monitoring wells will be installed to allow PG&E to definitively assess potential affects (e.g., incidental spills during sampling) to soil from the monitoring well. 					table) will replace the existing technical memorandum in Appendix M in the 90% BOD.					
817	DTSC-242	Appendix M, 1.0 Introduction, Page 1	… arsenic removal to concentrations less than the federal and California maximum contaminant level (MCL) of 10 micrograms per liter (µg/L) and fluoride removal to concentrations less than the California MCL of 2 milligrams per liter (mg/L)….	Attaining a goal of 2 mg/L for fluoride is futile as higher concentrations already exist in the area where fresh water will be injected. Please revise here and throughout the memorandum. A realistic treatment goal should be sought for fluoride.	As discussed in response to comment #145 DTSC-50, water quality in the proposed injection area exhibits elevated levels of naturally occurring fluoride. Fluoride concentrations in both HNWR-1 and the exploratory borehole at Site B are similar that in the proposed injection area. Therefore, treatment to remove fluoride is not needed pursuant to California standards, and hence, setting a treatment goal for fluoride is not needed. See also response to comment #21 DTSC-2.	PG&E should develop a background value for fluoride at the injection locations so that the injection standard for fluoride can be appropriately set. See response to comment #21 DTSC-2.			Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
818	DTSC-243	Appendix M, Page 1	This information is based on ongoing studies and will be updated as additional bench-scale testing results become available, and as the detailed design/optimization efforts progress (target completion in summer 2013)	Please provide the update to agencies as soon as possible. 823	DTSC-246	Appendix M, 4.0 Summary of Ongoing Bench-scale Testing Results, Page 3	From a water quality perspective, the average concentration of arsenic and fluoride in the Topock Background Study was 12.3 µg/L and 3.8 mg/L, similar to that in HNWR-1 (CH2M HILL, 2009).	It is not understood why a comparison to regional background values are being made and, therefore, it is recommended that the cited sentence be deleted. It would seem more appropriate to cite the HNWR-1/Topock2-3 data because that is the water subject to testing and evaluation. The cited 12.3 average for regional arsenic appears to be in error. The mean and median regional background values for arsenic from the CH2M HILL 2009 Background Report (Table 2-13) are 5.9 and 5.5 ug/L respectively, and are not close to the 12.3 ug/L average cited. Average values were not summarized in the Background Report. The cited fluoride average of 3.8 mg/L also appears to be in error. Tables 2-10 and 2-12 of the Background Report indicate that the maximum mean and median fluoride concentrations are both 4.0 mg/L. Topock-2 well had the second highest fluoride concentration in the whole background well population. Based on the Background Report it would be more fair to say that HNWR-1 is mining some of the highest arsenic and fluoride bearing waters in the region. Please also recall that elevated water temperatures occur at the Topock-2 well area suggestive of hydrothermal activity.	"Topock Background Study" was cited in error in the reference text, the correct citation should be Topock-2 well. The cited average concentration of arsenic and fluoride are correct, and can be found in Tables 2-9 and 2-10, respectively, in the 2009 Background Study Report.	Please replace the cited text with the following: "From a water quality perspective, the average concentration of arsenic and fluoride in the Topock 2 well was 12.3 µg/L and 3.8 mg/L, similar to that in HNWR-1 (CH2M HILL, 2009). The Topock Background Study (CH2M HILL, 2009) indicates that these are some of the highest arsenic and fluoride concentrations in the region."			Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
824	DTSC-247	Appendix M, 4.0 Summary of Ongoing Bench-scale Testing Results, Page 3	The groundwater sample was processed continuously through the column, and the treated water was sampled and analyzed for arsenic and fluoride until breakthrough (defined as at least 70 percent of the average influent concentration).	For completeness, please indicate what volume(s) were utilized during these tests.	See attached technical memo for information on arsenic-only pre-injection treatment system ((included in **Attachment F**, at the end of this table. See Section 4, 3rd paragraph of the tech memo).	Comment resolution pending review of technical memo provided.			Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
825	DOI-362	Section 5.1, Page 4	"Groundwater will be pumped and conveyed from the HNWR-1 well and the current TCS source wells (Topock-2 and -3) to the existing TCS storage tanks."	Since the groundwater is near neutral with a relatively high redox potential, the ongoing studies (see Introduction) should examine treatment effectiveness without pH adjustment and hypochlorite addition. If not required, removal of the treatment processes would reduce capital and operating costs.	Industry research and practice indicates the treatment process is most effective under oxidizing and slightly depressed pH conditions.		Comment resolved.		Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
826	DTSC-248	Appendix M, 4.0 Summary of Ongoing Bench-scale Testing Results, Wastewater Generation, Page 4	Assuming that regenerating a vessel after 1,500 bed-volumes will meet the treatment goals, the number of media regenerations per year is estimated to be 70 per in-service vessel at the maximum flow rate of 900 gpm and 35 per in-service vessel at the nominal flow rate of 450 gpm. Based on	The section should also comment on anticipated waste generation volumes if only arsenic is treated. With AA it would appear to be a quarter less than that for fluoride treatment. Since section 5.6 indicates ferric hydroxide would be selected for arsenic, its associated waste generation should be discussed.	See attached technical memo for information on arsenic-only pre-injection treatment system ((included in **Attachment F**, at the end of this table. See Section 5.4 of tech memo).	Comment resolution pending review of technical memo provided.			Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.

			these frequencies, the range of wastewater generated could be in the millions to tens of millions of gallons per year; therefore, it is critical to optimize the process and system design to minimize the amount of wastewater generated.							
827	DTSC-249	Appendix M, Treatment Effectiveness and Time to Breakthrough, Page 4	Figure 1 (located at the end of this memo) shows concentrations of arsenic and fluoride in treated water versus the number of bed-volumes of groundwater passed through (one bed-volume is equivalent to the amount of adsorptive media in the column).	Figure 1 was not easy to quickly comprehend. Perhaps a legend could be applied to the figure that repeats what is stated in text for each run. Also, it is not certain if AA-FS50 is plotted. Conclusions regarding fluoride treatment effectiveness and waste generation issues will need to be revised after a more reasonable fluoride treatment goal is established. For example, a very different conclusion would be derived for a fluoride target goal of 4mg/L (see Figure 1 of the memorandum)	See response to comment #816 DOI-359. See response to comment #817 DTSC-252, PG&E does not believe that fluoride treatment is warranted.	Comment resolution pending review of technical memo provided. Also see response to comment #21 DTSC-2.			Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
828	FMIT-197 Hualapai-146 Chemehuevi-146 Cocopah-146 CRIT-146	Section 5.1 p. 4	Groundwater will be pumped and conveyed from the HNWR-1 well and the current TCS source wells (Topock-2 and -3) to the existing TCS storage tanks. Water will be pumped from these tanks and will be injected with hypochlorite	Will chlorine residual affect remedy performance and carbon dosing?	This depends on residual levels. PG&E is evaluating dechlorination steps to remove residual chlorine from the treated freshwater. Dechlorination is often accomplished by addition of 1) ascorbic acid, 2) calcium thiosulfate, or 3) hydrogen peroxide (chemical reactions are shown below). Ascorbic acid (vitamin C) and calcium thiosulfate work by breaking the hypochlorous acid into hydrochloric acid and water. Hydrogen peroxide works by breaking the hypochlorite ion to form chloride ion, water, and oxygen.			Comment resolved pending review of the 90% design.	Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.

833	DOI-366	Section 5.4, Page 6	"Grab samples will be collected periodically and tested in the sample room . . . "	What testing procedures and equipment will be used to test for arsenic?	An SOP for arsenic testing will be developed and included in O&M Manual Volume 1, for submittal at 90% design.		Resolved pending review of the 90% design.		Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
834	DOI-367	Section 5.6, Page 7	"As previously mentioned, the FWPTS will be designed to achieve a safe, efficient, and sustainable operation . . . "	The text describing disposable granular ferric hydroxide as the treatment technology of choice for arsenic removal only should reference Appendix A, and Appendix A should provide the evaluation leading to this conclusion.	See attached technical memo for information on arsenic-only pre-injection treatment system (included in **Attachment F**, at the end of this table).		Resolved pending review of the 90% design.		Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
835	DTSC-251	Appendix M, 5.6 Design Philosophy/Uncertainties in Design, Page 7	For example, if fluoride treatment is not required, the treatment process would change to using disposable granular ferric hydroxide media (rather than regenerable AA), using the same treatment vessels described above. The resulting change would eliminate the need for the regeneration steps and regeneration-related equipment and chemicals. The building and outdoor tank area could be reduced in size.	Disposable ferric hydroxide treatment should be fully developed for the 90%/100%, even if only as a contingency. Figures similar to Figures 2 through 5 should be prepared for this treatment method within this memorandum.	Yes, as stated in response to comment #21 DTSC-2, PG&E will include a freshwater pre-injection treatment for arsenic only in the 90% and final designs as a contingency. Figures similar to Figures 2 through 4 were prepared and included in the attached memo (included in **Attachment F**, at the end of this table). Note that there was no Figure 5 in Appendix M in the 60% BOD.	Comment resolved.			Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
836	DOI-368	Section 7.0, Page 8	References	The following item is in the Reference list but is not referenced in the text: CH2M HILL 2013.	Comment noted. This has been corrected in the attached technical memorandum.		Comment resolved.		Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
837	DOI-369	Table 1		Because the text discussion focuses on arsenic and fluoride, all of the other data in the table can be deleted. Arsenic and fluoride data for Topock-2/-3 needs to be added, as it is a secondary source of water.	See Table 1 in the attached technical memo (included in **Attachment F**, at the end of this table).	As this may be the only current place where HNWR-1 data are presented, retention of the data is suggested.	Resolved pending review of the 90% design.		Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
838	DOI-370	Table 2		A goal of <1,000,000 gallons/year of wastewater is three to five times less than rates shown in Exhibit 3 and Table 4. Please explain the difference in values or correct if this is an error.	This value will be revised to reflect an arsenic-only pre-injection treatment system (see Table 2 in the attached technical memorandum, included in **Attachment F** at the end of this table).		Resolved pending review of the 90% design.		Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
839	DTSC-252	Appendix M	Table 2, Page Tables-7 Minimum Groundwater Injection Flow Capacity 75 gpm	Re. Freshwater treatment: Minimum flow rates are not discussed much in the 60% design. Briefly, what is the basis and how might the remedy utilize the lower flows. Won't it affect cleanup time? PG&E should provide analysis of startup injection rates, and propose parameters (decision tree) requiring increase or decrease in injection rate.	Please see Exhibit 3.3-4 of the 60% BOD for the basis of the design flow rate. The minimum flow for freshwater pre-injection treatment system was set to be same as the minimum freshwater injection flow from groundwater modeling (for details on basis of the modeled flow rates and ranges, see Section 3.3.3.4 of the BOD, as well as Appendix B). Information regarding the potential low flow range scenarios will be included in the 90% BOD. The cited 75gpm will be corrected to 150gpm (see Table 2 in the attached technical memorandum).	Comment resolved pending review of the 90% design.			Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
840	DOI-371	Table 4		The table is difficult to interpret. Recommend the following modifications: • The stream # should reference Figure 2 (Flowchart). • A heavy solid line should be inserted across the table between Wastewater Volume and Nominal Flow, highlighting the maximum flow conditions and nominal flow conditions values. • Include one more column (7d) to represent the flow to the IRZ/cooling towers, and the neutralization flow it receives, (if this is true). The final disposition of neutralization wastewater flow is not discussed in the text or identified in Exhibit 3 or Table 2, but is inferred in Figure 2 and Table 4. Please revise for clarity.	Please see Table 4 in the attached technical memorandum for an arsenic-only pre-injection treatment system (included in **Attachment F**, at the end of this table).		Comment resolved pending review of the technical memorandum.		Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.
841	DOI-372	Figure 1		Data for AA-F550, Fluoride and Arsenic, are not displayed.	The horizontal axis scale was inadvertently reduced so the AA-FS50 results were not visible. As this figure pertains to As/F system, it will not remain in Appendix M of the 90% BOD and therefore it will not be revised.		Comment resolved.		Comment resolved.	See the *Addendum to the Freshwater Pre-injection Treatment System Conceptual Design Basis* included as Appendix M of the 90% BOD.

849	CRIT-147	Cover Letter		To that end, CRIT is particularly concerned about two issues: first, the implications of recently located cultural resources on the ground surface, since, as of that time, those surface resources were unrecorded, and outside the apparent delimited preservation zones marked on Project resource protection maps. The import of this discovery is obvious, but nonetheless, disconcerting. It points to constant vigilance - by all concerned - as the only sure method of minimizing needless impacts to what is, for area Tribal members, a most sacred site.	The Tribe's comment and concerns are duly noted. As part of the project implementation, PG&E is committed to comply with all mitigation measures in the PA and CHPMP as well as in the certified EIR, which will result in the avoidance, minimization, or mitigation of potential impacts on cultural resources in the Area of Potential Effects and the project area, to the extent practicable. A number of the mitigation measures in the PA, CHPMP and EIR address discoveries of archaeological or historic resources. For example, a pre-project archaeological survey field verification will be conducted prior to any ground-disturbing activities (CHPMP, Stipulation 7.1.2). A Qualified Cultural Resources Consultant will be retained to observe ground-disturbing activities and will request the participation of tribal monitors during those activities, to ensure that historically significant resources are avoided to the maximum extent feasible (EIR CUL-1b/c-4). Further, all protocols in the future CIMP (EIR CUL-1a-8) will be followed during implementation to reduce the potential for impacts on historical resources within the project area, and to help preserve the values of and access to the Topock Cultural Area for local tribal users. Additionally, the CHPMP includes a Discovery Plan that provides procedures to be followed in the event that previously unidentified archaeological or historical resources are encountered during implementation of the Project. Also, consistent with current site practice, Agencies, Stakeholders, and Tribes will be invited to the site for a project initiation meeting to discuss various cultural sensitivities associated with the work activities.					90% BOD Section 6 Tables 6.1-1 through 6.2-3. Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				move and store masses of soil on-site or elsewhere is still an active area of concern for CRIT. While we understand the safety concerns of above-ground facilities, and the visual impacts that they will engender, it remains our strong preference to thousands of feet of deep, wide, destructive trenches in the Project area. CRIT has had recent, very disagreeable experience with excavations presumed to pose little or no risk to Tribal cultural resources. These excavations were undertaken by fully-qualified investigators with the best intentions, and employing the best available pre-screening methods, and still, the remains of CRIT's ancestors were crushed in the maw of heavy machines, their life's articles were smashed and tumbled, their jewelry shattered. We will work with DTSC, DOI, PG&E, and their consultants to keep this issue, this preference at the forefront of the design process.	CRIT-4/ Chemehuevi-4/ Cocopah-4, and #1 DOI-1. As mentioned in prior responses, PG&E has and will continue to collaborate with Tribes and Agencies towards a satisfactory resolution of Tribal concerns, for inclusion in the 90% BOD.					
851	Hualapai-147	Cover Letter		**<u>Consideration of Tribal Sensitivities as Design Criteria</u>** - While the Hualapai appreciates the opportunity for continued contribution towards a successful and effective remediation design, it is apparent from the 30% to the 60% designs that the expressed tribal preferences relating to Tribal religious and cultural issues were not substantively factored or considered in engineering designs. The Hualapai requests, at a minimum, equal scientific/engineering rigor should be given to legitimate alternate design constraints. During discussions with PG&E consultants, it is clear that various alternative design options proposed by the Tribes and intended to contribute to the 60% design process were dismissed without an unbiased quantitative comparative analysis. The Hualapai continue to believe however, that some of these discarded options may be substantially preferable to the design shown in the 60% BOD report. Therefore, in future discussions regarding design alternatives the	Regarding consideration of design alternatives, please see PG&E's response to comment #8b Hualapai-3/CRIT-3/Chemehuevi-3/Cocopah-3, #9 FMIT-4/Hualapai-4/CRIT-4/ Chemehuevi-4/ Cocopah-4, and #1 DOI-1. As mentioned in prior responses, PG&E has and will continue to collaborate with Tribes and Agencies towards a satisfactory resolution of Tribal concerns, for inclusion in the 90% BOD.			The Hualapai Tribe appreciates being involved in all stages of the Topock project and look forward to continuing our relationship with all the agencies and stakeholders involved in the project.	This comment and response were discussed at the December 17-18, 2013 TWG meeting.	See RTCs #8b Hualapai-3/CRIT-3/Chemehuevi-3/Cocopah-3, #9 FMIT-4/Hualapai-4/CRIT-4/ Chemehuevi-4/ Cocopah-4, and #1 DOI-1.

				Hualapai and any interested Tribes involved with the Topock Remedial Project, would like to be provided with a detailed quantitative decision matrix that provides transparency into how and why final design options have been selected.						
852	Hualapai-148	Cover Letter		**Consideration of Alternative Design Options** – The Tribes, who have been living on and caring for this land for thousands of years, desire that their cultural values and input be equally weighted in the remedial design to those of PG&E and the remediation contractors who are merely temporary visitors to the Sacred landscape. This is of particular importance to Hualapai, who perceive portions of the remediation effort as an additional desecration to the land. Therefore, there is a strong desire on the part of the Hualapai, that special emphasis be focused on the avoidance and minimization of subsurface impacts at this area. Of particular importance is that sacred ground has existed here for hundreds of years, and should be protected for future generations. Specifically the planned installation of nearly 5 miles of large infrastructure trenches and vaults is a hugely disturbing and invasive construction. Subsurface disturbances permanently change the natural order of the land and require disruptive removal of these utilities once the remedy is complete. Invasive subsurface disturbances need to be avoided to the extent practicable. The Hualapai on numerous occasions have voiced their preference for the short-term visual impacts associated with aboveground pipework over the currently proposed permanent impacts associated with belowground trenching. The attached comments which include alternative designs to some sections of the infrastructure alignments provide a reasonable approach to lessening this impact. These alternative designs should be given full and fair consideration toward the goal of reducing the impacts to this area.	Regarding the placement of facilities aboveground vs. belowground, please see PG&E's responses to comment #8b Hualapai-3/CRIT-3/Chemehuevi-3/Cocopah-3, #9 FMIT-4/Hualapai-4/CRIT-4/ Chemehuevi-4/ Cocopah-4, and #1 DOI-1. As mentioned in prior responses, PG&E has and will continue to collaborate with Tribes and Agencies towards a satisfactory resolution of Tribal concerns, for inclusion in the 90% BOD.			The Hualapai Tribe appreciates being involved in all stages of the Topock project and look forward to continuing our relationship with all the agencies and stakeholders involved in the project.	This comment and response were discussed at the December 17-18, 2013 TWG meeting.	See RTC #8b Hualapai-3/CRIT-3/Chemehuevi-3/Cocopah-3, #9 FMIT-4/Hualapai-4/CRIT-4/ Chemehuevi-4/ Cocopah-4, and #1 DOI-1.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
853	Hualapai-149	Cover Letter		**Consideration for Placement of Staging and Displaced Soils Storage Areas** – The location of displaced soil storage and equipment staging areas is of particular concern, as these locations will inevitably see increased construction vehicle and truck traffic, dust and excessive noise. Therefore, the Hualapai's opinion is that storage and staging areas be located as much as possible away from, and out of sight of all Topock Maze areas. The Hualapai appreciates the ongoing discussions and efforts by all parties to address this issue, and support the continued effort to identify suitable locations for these activities which will address Tribal concerns.	The Tribe's comment is duly noted. PG&E appreciates the Tribe's participation and inputs on identifying and evaluation of suitable locations for soil storage and construction staging areas. PG&E hopes that current open discussions and transparent processes will yield a satisfactory solution that allows the project to move forward expeditiously.			The Hualapai Tribe appreciates being involved in all stages of the Topock project and look forward to continuing our relationship with all the agencies and stakeholders involved in the project.	This comment and response were discussed at the December 17-18, 2013 TWG meeting.	Construction/Remedial Action Work Plan, Figures 4-3 (Locations of Construction Facilities in Moabi Regional Park) and 4-5 (Construction Site Plan and Access Routes).
854	Hualapai-150	Cover Letter		**Consideration for Notification of Chemical Usage** – Chemicals that are foreign to the natural environment and are dissipated into the Sacred landscape are a significant concern to the Hualapai. Therefore, it is requested that full transparency into the specific types of chemicals used within the remediation project be provided prior to the construction and operation of the system. In addition, chemical usage volumes and frequencies should be provided to the stakeholders for review and comment.	See response to comment #13b Hualapai/CRIT/Chemehuevi/Cocopah -8.				Comment resolved.	O&M Manual Main Text, Exhibit L2.2-1 (Communication Framework During O&M).
855	FMIT-198	Cover Letter		**Incorporating Tribal Sensitivities as Design Criteria** - It is apparent that the expressed tribal preferences relating to tribal religious and cultural issues have not been factored or substantively considered in engineering design changes from the 30% to the 60% designs. For example, in its comments on the 30% BOD report, the Tribe expressed a preference for minimizing subsurface pipeline routings. Instead, the intermediate design calls for nearly all the water piping and utilities to be buried without any consideration of the Tribe's reasoning supporting its preference for above-ground alternatives. At a minimum, equal scientific/engineering rigor should be given to these legitimate alternate design constraints in the 90% BOD. Also, PG&E should provide the agencies a choice on how to proceed in balancing different criteria.	Regarding the placement of facilities aboveground vs. belowground and alternative design, please see responses to comment #8a FMIT-3, #9 FMIT-4/Hualapai-4/ CRIT-4/Chemehuevi-4/ Cocopah-4, and #1 DOI-1. As mentioned in prior responses, PG&E has and will continue to collaborate with Tribes and Agencies towards a satisfactory resolution of Tribal concerns, for inclusion in the 90% BOD.			The FMIT appreciates being involved in all stages of the Topock project and look forward to continuing our relationship with all the agencies and stakeholders involved in the project. The FMIT would like to see specifics of how the design achieves the goals of the tribe prior to the 90% design submittal.	This comment and response were discussed at the December 17-18, 2013 TWG meeting.	See RTCs #8a FMIT-3, #9 FMIT-4/Hualapai-4/ CRIT-4/Chemehuevi-4/ Cocopah-4, and #1 DOI-1.

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
856	FMIT-199	Cover Letter		**Avoidance and Minimization of Infrastructure and Project Disturbances** - The Tribe expects that all above- and below-ground disturbances of any duration (short-, mid- and long-term) will be avoided and minimized to the extent feasible. Subsurface infrastructure not only permanently changes the natural order of the land but to respect tribal views, also generally require removal of these utilities once the remedy is complete, which causes additional disruptions. Intrusive subsurface disturbances therefore need to be avoided from the outset to the maximum extent feasible. Installation of remedial infrastructure on the ground surface itself also needs to be minimized in terms of its footprint. As discussed above, the Tribes have previously provided input on their preferences for installation methods that minimize subsurface disturbances throughout the remedies' lifecycles.	Regarding the placement of facilities aboveground vs. belowground, please see responses to comment #8a FMIT-3, #9 FMIT-4/Hualapai-4/CRIT-4/ Chemehuevi-4/ Cocopah-4, and #1 DOI-1. As mentioned in prior responses, PG&E has and will continue to collaborate with Tribes and Agencies towards a satisfactory resolution of Tribal concerns, for inclusion in the 90% BOD.			The FMIT appreciates being involved in all stages of the Topock project and look forward to continuing our relationship with all the agencies and stakeholders involved in the project. The FMIT would like to see specifics of how the design achieves the goals of the tribe prior to the 90% design submittal.	This comment and response were discussed at the December 17-18, 2013 TWG meeting.	See RTCs #8a FMIT-3, #9 FMIT-4/ Hualapai-4/CRIT-4/Chemehuevi-4/ Cocopah-4, and #1 DOI-1.
857	FMIT-200	Cover Letter		**Coordination of Removal of IM-3 with Final Remedy Implementation** - Project documents, including the FEIR, show that concurrent operation of Interim Measure No. 3 (IM-3) and the final groundwater remedy is incompatible. Operation of the IM-3 treatment plant will terminate upon start-up of the final remedy. Pursuant to the December 19, 2012, Settlement Agreement between DTSC and the Tribe ("Tribe/DTSC Agreement") the IM-3 *treatment plant,* will remain in place no longer than a determination that the final remedy is "operating properly and successfully" (OPS). The start-up strategy for the final remedy needs to be efficient, to ensure the earliest possible demonstration that the remedy is "operating properly and successfully" (OPS) so that the IM-3 plant can be decommissioned in a manner consistent with the settlement agreement between the Tribe and PG&E. Immediate restoration of the IM-3 parking/staging area and timely removal and restoration of the IM-3 treatment plant area are of critical importance to the Tribe due to the extreme cultural sensitivity of this	The Tribe correctly states that pursuant to the 2012 Settlement Agreement, the IM-3 treatment facility will be decommissioned when DTSC, with DOI's concurrence, finds that the final remedy is "operating properly and successfully." PG&E intends to abide by the terms of the 2012 Settlement Agreement. The start-up strategy for the final remedy will occur as efficiently as possible, subject to field conditions and the requirements of the agencies that have jurisdiction over this project. PG&E has concluded after consideration that it cannot remove pipelines and wells associated with the IM-3 treatment plant until the final remedy is operating properly and successfully. Wells, pipelines, and other components that are part of the IM-3 system and outside the treatment plant area, if removed, would prevent IM-3 from operating. IM-3's primary purpose is to provide hydraulic gradient control. The four IM-3 wells are used to maintain the gradient. Two extraction wells operate continuously and one injection well is in service with the other in standby mode to allow the extraction wells to continue pumping				This comment and the response were discussed by PG&E and the FMIT.	IM-3 Decommissioning, Removal, and Restoration Work Plan

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				particular area. In addition, apart from removal of the treatment plant, removal of such items as pipelines and wells that are associated with IM-3 should be considered in conjunction with the implementation of the final groundwater remedy to avoid additional disruption of the land surface and to economies during construction.	and maintain the gradient. The piping and electrical conduit connecting the injection and extraction wells are needed to convey water to the treatment system or from the treatment system for re-injection. The extracted groundwater cannot be re-injected without treatment and therefore all of these IM-3 components must be retained. See response to comment FMIT-44, which addresses restoration of the IM-3 treatment plan area, including parking and staging areas.					
858	FMIT-201	Cover Letter		<u>Avoidance or Minimal Use of FMIT Property</u> - The above issues regarding the minimization of infrastructure and project disturbance as well as addressing Tribal sensitivities in design apply in particular to the parcel owned in fee by the FMIT due to the extreme cultural sensitivity of the area. In addition, except to the extent DTSC expressly requires the use of the parcel owned by FMIT for specific purposes, FMIT consent will be required for such uses, consistent with the 2006 settlement agreement with PG&E and the PG&E easement recorded on the property. All planning and design should attempt to avoid and minimize existing and new infrastructure including utility lines, piping, staging or parking areas, storage areas, wells of all types, etc. All future remedy activities should also avoid this property to the maximum extent feasible, consistent with the 2006 settlement agreement between the Tribe and PG&E.	The terms of the 2006 Settlement Agreement and Easement Agreement between PG&E and the FMIT allow for PG&E to "install, access, use, operate, maintain, modify, upgrade and remove any and all additional Remediation-related Facilities required by the DTSC or another agency or governmental body with jurisdiction over the Property or the Remediation, including but not limited to additional treatment equipment, pipelines, extraction wells, injection wells, slurry walls, and in-situ facilities," on the IM-3 Property. Easement Agreement, § 3. The Settlement Agreement also acknowledges that the IM-3 Property may continue to be used for the groundwater remedy - "The Parties recognize that as part of the operation of the IM-3 or the final remedy, construction of additional facilities, such as additional wells, may be required and that this work may require the temporary use of heavy construction equipment, lighting facilities and associated activity." 2006 Settlement Agreement, § VI(B)(2)(a). PG&E agrees that it has an obligation to consult the FMIT on the location of remediation facilities on the IM-3 Property and to honor Tribal concerns to the maximum extent practicable and believes in its design of the groundwater remedy it has fulfilled and is fulfilling the requirements of the 2006 Settlement Agreement. If the FMIT has concerns				This comment and the response were discussed by PG&E and the FMIT.	90% BOD Executive Summary Section ES.3 (see Remedy proposed on FMIT Parcel).

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
					about the location of specific infrastructure PG&E would be happy to discuss those concerns further with the FMIT, as it has done in the past.					
859	FMIT-202	Cover Letter		<u>**Compliance with Mitigation Measures and ARARs -**</u>Proper and full accounting of all mitigation measures and ARARs applicable to Native American, cultural, native flora, and wildlife values must be assured and independently verified by the lead agencies. Periodic reviews and specific reporting of compliance with each mitigation measure should be implemented. The agencies also must provide a transparent process for proposed revisions to existing mitigation measures or proposed application of mitigation measures from one project phase to another.	In compliance with the mitigation measures set forth in the certified EIR, PG&E has and will continue to prepare and submit to DTSC quarterly compliance reports (the first report was published in fourth quarter of 2011). In addition, PG&E has and will continue to submit to DOI documentation of compliance activities with specific ARARs in the design documents and progress reports. PG&E defers to the Agencies on request for process for proposed revisions to existing mitigation measures or proposed application of mitigation measures from one project phase to another.	PG&E is required to provide periodic reporting of the mitigation measures compliance to the agencies. Those compliance reports are considered public document. In response to inquiry on revision to mitigation measures, DTSC cannot substantively change or modify mitigation measures adopted as part of the certified EIR without formal CEQA process, which includes analysis and notifications. Mitigation measures are design to apply to the entire project unless the compliance period is specified.	In accordance with Section 9.4 of the CHPMP, BLM may amend the finalized CHPMP as additional information is developed regarding cultural and historic resources within the APE, in the event that the APE is revised, and for any other reason deemed appropriate by BLM. Revision of the CHPMP shall not require an amendment of the PA. The CHPMP may be revised in phases as the Undertaking progresses as identified in PA Stipulation VII.F.	Okay with DOI's response.	Comment resolved.	90% BOD Section 6, Tables 6.1-1 through 6.2-3.
860	FMIT-203	Cover Letter		<u>**Establishing an Adequate Review Process through the 90% BOD Report -**</u> The recent review experience of the 60% BOD report indicates that the currently scheduled comment period for the 90% design review may not be of sufficient length to allow for complete and meaningful review and comment by the Tribes. The BOD reports are extremely large with many detailed appendices that need review, not only by the Tribe, but its consultants. In addition, at each stage of the design review process, sections have been introduced that have not been previously seen by the reviewers. DTSC and other agencies must allow sufficient time for the Tribes to consult with 1) the Tribes' technical internal consultants; 2) the TRC; 3) Tribal elders and leadership; and 4) other Tribes. The Tribes also need sufficient time to exercise their rights to government-to-government consultations with the agencies in regard to project impacts, an aspect which our Tribe does not want to see curtailed due to arbitrary schedule demands. One resolution might be the provision of interim review between the agencies and Tribes of how Tribal issues and comments will be incorporated into the design prior to submittal of the 90% BOD report.	Please see response to comment #11a FMIT-6.			The FMIT appreciates being involved in all stages of the Topock project and look forward to continuing our relationship with all the agencies and stakeholders involved in the project. The FMIT would like to see specifics of how the design achieves the goals of the tribe prior to the 90% design submittal.	This comment and response were discussed at the December 17-18, 2013 TWG meeting.	CIMP CUL-1a-8d (Protocol for The Review of Project Design Documents)

TABLE I-1

Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
861	FMIT-204	Cover Letter		**Consideration of Alternative Designs -** During various discussions with PG&E and its consultants at the 11/VG, CWG, and other meetings, it is evident that PG&E consultants evaluated internally and then discarded certain options during the 60% design process. These options were disregarded without any proactive discussion or consultation with the Tribes before being set aside. The Tribes are concerned that some of these discarded options may be substantially preferable to the designs presented in the 60% BOD report and provide greater compliance with ARARs. Resolution of the utility of design alternatives might include PG&E consultants/ engineers engaging the Tribes in more detailed discussions with regarding alternative options for such features as transformer configuration, use of potential overhead and/or aboveground utility conveyances, etc., prior to release of the 90 % BOD report. The 90% BOD report should also include a brief summary of design alternatives considered but rejected with an explanation of why they were rejected. Where there are options that might better meet the Tribe's concerns, such options should also be summarized for the agencies in the BOD report.	Regarding alternative designs, Please see responses to comment #8a FMIT-3 and #1 DOI-1. PG&E has and will continue to collaborate with Tribes and Agencies towards a satisfactory resolution of Tribal concerns, for inclusion in the 90% BOD.			The FMIT appreciates being involved in all stages of the Topock project and look forward to continuing our relationship with all the agencies and stakeholders involved in the project. The FMIT would like to see specifics of how the design achieves the goals of the tribe prior to the 90% design submittal.	This comment and response were discussed at the December 17-18, 2013 TWG meeting.	See RTCs #8a FMIT-3 and #1 DOI-1.
862	FMIT-205	Cover Letter		**Avoidance of All Sensitive Areas** - The current "project boundary" limits, as depicted in various project maps, have been shown to be incomplete and/or inconsistent with sensitive areas that should be avoided. This conflict needs to be resolved such that all sensitive areas are excluded from any project activity prior to completion of the 90% BOD report. Recent surveys performed by various Tribal, BLM,PG&E, and DTSC representatives need to be properly accounted for in mapping project boundaries and exclusion areas.	Please see response to comment #12 FMIT-7/Hualapai-7/CRIT-7/ Chemehuevi-7/ Cocopah-7.			The FMIT appreciates being involved in all stages of the Topock project and look forward to continuing our relationship with all the agencies and stakeholders involved in the project. The FMIT would like to see specifics of how the design achieves the goals of the tribe prior to the 90% design submittal.	Ongoing discussion between Tribes and Agencies. This is an open item that will be carried forward.	90% BOD Section 6 Tables 6.1-1 through 6.2-3.
863	FMIT-206	Cover Letter		**Minimization of Chemical Usage** - Chemicals that are foreign to the natural environment are a concern to the Tribe. Additionally, some chemicals may be more offensive for use in a sacred area than others. PG&E should fully disclose the types, volumes, and frequencies of chemical usage associated with the project. The Tribe should be notified of any proposed	See response to comment #13a FMIT-8.			See comment #13a FMIT-8.	Comment resolved.	O&M Manual Main Text Exhibit 2.2-1 (Communications Framework during O&M).

TABLE I-1
Response to Comments on Basis of Design Report/Intermediate (60%) Design
Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution	Where responses are reflected in the 90% design documents?
				changes in the types or significant quantities of chemicals used.						
864	Chemehuevi-147	Cover Letter		In reviewing the 60% BOD document, it was apparent that tribal preferences relating to spiritual and cultural matters were not factored into the proposed design. Alternate routings and design specifics which do address tribal preferences are discussed and presented within the attached comments. At a minimum, equal consideration and fair evaluation should be given to these legitimate and alternative designs. Any design screening evaluation criteria should also specifically consider and include tribal preferences.	Regarding alternative designs, please see responses to comment #8b Hualapai-3/CRIT-3/ Chemehuevi-3/Cocopah-3 and #1 DOI-1.					
865	Chemehuevi-148	Cover Letter		To the extent possible, invasive subsurface disturbances should be avoided, as these are permanent injuries to the natural order of the land. Installation of remedial structures in the subsurface should be minimized both in total volume of earth disturbed, and in the total foot print of the construction.	Regarding the placement of facilities aboveground vs. belowground, please see responses to comment #8b Hualapai-3/CRIT-3/ Chemehuevi-3/ Cocopah-3 and #9 FMIT-4/Hualapai-4/ CRIT-4/Chemehuevi-4/Cocopah-4.					
866	Chemehuevi-149	Cover Letter		The current "project boundary" as indicated in the 60% BOD figures has been shown to not adequately represent the actual culturally sensitive areas. Significant time and effort on the part of the Tribes, DTSC and others has been expended to address this problem and any final documents prepared should reflect that all sensitive areas be excluded from any project activity. This conflict needs to be address and resolved prior to the issuance of the 90%. In addition, the plume boundaries as depicted should reflect the current plume configuration.	Please see response to comment #12 FMIT-7/Hualapai-7/CRIT-7/ Chemehuevi-7/Cocopah-7. An updated Cr(VI) plume boundary will be included in the 90% BOD.				.	
867	Chemehuevi-150	Cover Letter		During construction activities for the remedy installation, due care should be taken, and preparation made for unforeseen encounter with contaminated soils during the significant excavation activities and disturbances. The Tribe is concerned that sufficient contingencies are in place to contain and minimize any additional impacts related to discovery of existing contamination,	The Tribe's comment is duly noted. The Soil Management Plan (Volume 4 of the O&M Manual) addresses the management and handling of potential contaminated soils that may be encountered during remedy construction/O&M activities. Close coordination with the upcoming Soil RFI/RI sampling effort will continue to ensure that the Soil Management Plan reflects the most current

				and any potential release of chemicals or materials utilized during the construction phase.	information on known contaminated soils at the site. In addition, the forthcoming Construction/ Remedial Action Work Plan will include sampling and monitoring as well as contingencies during construction. This Work Plan will be submitted with the 90% design for agencies, Tribes, and stakeholders review and inputs.					
868	Chemehuevi-151	Cover Letter		Chemicals that will be utilized during the operation of the remedy are by definition foreign to the natural environment. The use of chemicals should be minimized, and any chemicals utilized should be fully disclosed with regard to the type, volume, storage and frequency of use.	See response to comment #13b Hualapai/CRIT/Chemehuevi/Cocopah-8.				Comment resolved.	

Attachment A: RTC #1

Pipeline Evaluation Matrix, Visual Simulations, TRC's Response, and Tribes' Letters/Email

TABLE 1

Alternative Pipeline A/H & B Configuration Summary Description

Groundwater Remedy Project

PG&E Topock Compressor Station, Needles, California

Alternative Number	Name	Total Piping Length[a], feet	Underground Piping Length[a], feet	Aboveground Piping Length[a], feet	Bridges (Length, feet)	Power Poles	Radio Towers	Conceptual Layout[c]
0	Pipelines A/H Current Design	4,800	4,600	200	1 (180 feet)	0	0	Figure 1
0a	Pipelines A/H Current Route Above Ground[d]	4,800	830	3,970	3 (180 feet; and 2-30 foot pipe bridges (grade separations))	26	3	Figure 2
1	Pipelines A/H Alternative Route 1[d]	4,300	830	3,470	4 (140-feet; 1-50-foot, and 2-30 foot pipe bridges (grade separations))	26	3	Figure 3
2	Pipelines A/H Alternative Route 2[d]	4,000	650	3,350	5 (280-feet, 330-feet, and 3-30 foot pipe bridge (grade separation))	26	3	Figure 4
B0	Pipeline B - Current Design[b]	2,500	1,900	600	0	0	0	Figure 21
B0a	Pipeline B Alternative 1 (Current Route Aboveground)[b]	2,500	0	2,500	1-30 foot pipe bridge (grade separation))	0	0	Figure 21

Notes:

a. Lengths rounded to nearest 100 feet and represent length of corridor which may consist of 1 or more pipes and conduit.

b. Electrical cable is underground for this alternative and extends for about 1,600 feet.

c. Figures included with visual simulations.

d. Approximately 360 feet of underground conduit is included for this alternative to enable safe access to wells and equipment.

Pipeline A - Segment 1

Evaluation Factors	Evaluation Criteria	Basis for Evaluation[3]	Comments/Notes
Construction Impacts	N, L, I, H[2]	Analysis	**H - Construction impacts are rated high because:** a) This piping alignment is on a steep slope (up to 2:1), which contains loose surface soils. Access is difficult and is less safe than the 60% design alignment. Further, drainage will be required to protect piping/electrical conduits. b) There is an existing, underground 30-inch SoCal gas pipe on the steep slope. Approximately 30-75 ft south of the gas pipe is the BNSF property line, and 25-60 ft north of the gas pipe is a culturally sensitive area as described by Tribes. Taking into account the SoCal Gas ROW (50-ft), the available work space on the south side of the ROW is only 5 ft at the pinch point and up to 50 ft at the widest spread. Construction on a steep slope will require adequate set back/work zone for not only the trench, but also staging of construction equipment staging, benching, etc. Since encroachment into the BNSF RR property is not viable, the south side is eliminated from further consideration. On the north side, the available work space is 0 ft at the pinch point, and up to 35 ft at the widest spread. Cutting into the undisturbed or culturally sensitive area to the north is required for adequate work space. c) New piping/conduits and associated work zone will be conducted outside of the 50-ft SoCal ROW, unless agreed to otherwise by SoCal Gas and allowed otherwise by BLM. d) To allow for future maintainability of the pipes, underground vaults will be required at the bottom and top of slope. Approximate vault dimension is 12-ft long x 6-ft wide. The estimated cost for this segment alone is $300,000.
Ecological Impacts[6]	N, L, I, H[2]	Analysis	**L - Ecological impacts are rated low because:** Segment 1 primarily runs underground with the majority of the route in previously disturbed open creosote bush scrub community, No impacts to desert tortoise are anticipated. Pipeline route is not within potential SWFL and other migratory bird habitat. Several mature plants would likely be removed during construction; such removal of large vascular plants to accomodate the pipeline would pose special problems for transplantation (due to large size and deep roots) or replacement planting (due to the difficulty of establishing native woody plantings in arid environments).
Displaced soil volume (or exacavated soil volume)	cubic yds	Calculation	Cutting into the undisturbed area to the north is required to create adequate work space. The estimated volume of displaced soil is 1,585 cubic yards (cy), excavated soil is 1,745 cy, of which, 300 cy is inside the area outlined as culturally sensitive area by the Tribes.
Worker Safety Impacts (Construction)	N, L, I, H[2]	Analysis	**H - Worker Safety Impacts during construction are rated high because:** a) Limited work space and work on steep slope increase safety risk. b) Construction near high natural gas pipeline increase risk.
Worker Safety Impacts (Operational)	N, L, I, H[2]	Analysis	**I - Worker Safety Impacts during operation are rated Intermediate because:** a) For O&M, there is an increased risk of incidents while working on slope, and while lifting or working in vaults. b) Working in vaults could involve confined space entry.
EIR Impacts	N, L, I, H[2]	(Legal) Opinion	**I - Additional CEQA review will be needed to evaluate the potential impacts of the new route.** The type of additional CEQA review required depends whether the design has new, significant impacts that were not disclosed in the EIR. If there are new, significant impacts, a supplemental EIR would be required; an addendum would not suffice. Further analysis will allow the technical team to determine whether this alternative may have new, significant impacts; one of the primary areas to be evaluated in this respect is the increased earthwork and ongoing maintenance.
Historical/Archaeological Impacts[4, 5]	N, L, I, H[2]	Analysis	**None - Historical/Archaeological impacts are rated none** because: All archaeological and historical sites are avoided.
Likelihood of Failure to Detect or Contain Leaks	N, L, I, H[2]	Analysis	**L - Likelihood of failure to detect or contain leaks is rated low** because of the vault at the bottom of the slope.
O&M Impacts	N, L, I, H[2]	Analysis	**I** - Majority of the maintenance activities will include O&M of erosion control measures (e.g., fix slope to reduce erosion) and cleaning of the vaults. Maintenance of the underground pipes is anticipated to be infrequent. The estimated annuall cost of this maintenance is $10,000.
Public Safety Impacts	N, L, I, H[2]	Analysis	**L** - If required, bollards will be installed to protect the vault at the bottom of the steep slope. The bollards could create safety hazard for motorists travel on NTH.
Ground Disturbance	Lineal Feet	Estimation	Length of pipe on the steep slope is approximately 310 linear feet. Approximately 125 feet traverse an area designated as possibly having cultural significance by the Tribes.

NOTES

[1] Segment description noted below

Segment 1 - Below ground water pipe and electrical conduit in larger casings going west from NTH parallel to SoCal gas pipeline to top of hill. See Figures 22 and 25.

[2] Ratings: N = “None”; L = “Low”; I = “Intermediate”; and H = “High.” These are qualitative ratings based upon the rationale provided and not to be used in a quantitative manner, i.e., the ratings are not additive.

[3] Indicate whether the basis for evaluation is an opinion, calculation, analysis, etc.

[4] Alternatives for Pipeline A & H do not extend into the floodplain for the purposes of this evaluation factor.

[5] PG&E assumes impacts on the Traditional Cultural Property within the APE determined by BLM to be eligible for the National Register of Historic Places will be analyzed under “Cultural Integrity”

[6] Alternatives for Pipeline A & H do not extend into the floodplain for the purposes of this evaluation factor.

Pipeline A - Segment 2

Evaluation Factors	Evaluation Criteria	Basis for Evaluation[3]	Comments/Notes
Construction Impacts	N, L, I, H[2]	Analysis	**I - Construction impacts are rated intermediate because:** a) Constraints along this segment include narrow road sections, cultural resources, mature vegetation, and access roads for BNSF and SoCal Gas. In addition, the City of Needles power poles intersect with this segment as shown in Figure 22. Therefore, the aboveground portions of this alignment would be located off the road. Aboveground pipe rack and guard rail would require 8-ft of clear space for O&M and access. b) New electrical and communication cables would be installed on new poles installed on the abandoned Route 66 to avoid the City of Needles poles. Another reason for this routing is that the poles would run along an existing access new road; placement of power poles elswhere would likely require construction of new access roads (see Figure 22).
Ecological Impacts[6]	N, L, I, H[2]	Analysis	**I - Ecological impacts are rated intermediate because:** Segment 2 runs both above and underground with one bridge structure proposed over Bat Cave Wash. Portions of the route are established in previously disturbed road and open creosote bush scrub community; however, the pipeline alignment goes through approximately 3.45 acres of the blue Palo Verde community. No impacts to desert tortoise are anticipated. Pipeline route is not within potential SWFL and other migratory bird habitat. While this alignment appears to mostly follow along the edge of a previously disturbed roadway, the first above ground segment (southernmost portion approximately 200 feet) appears to pass through a area with large vascular plants (that were not specifically mapped as palo verde or mesquite). Any removal of blue palo verde (a culturally important plant) or any other large vascular plants to accomodate the above-ground pipeline would pose special problems for transplantation (due to large size and deep roots) or replacement planting (due to the difficulty of establishing native woody plantings in arid environments). In addition, the above ground segment runs separately from an above ground power line, which could represent a separate but small additional potential impact for bird strikes.
Displaced soil volume (or exacavated soil volume)	cubic yds	Material take-off	The estimated volume of displaced soil and excavated soil is 210 and 930 cubic yards, respectively.
Worker Safety Impacts (Construction)	N, L, I, H[2]	Analysis	**H - Worker Safety Impacts during construction are rated high because:** a) Limited work space and work on steep slope increase safety risk. b) Construction near high natural gas pipeline increase risk.
Worker Safety Impacts (Operational)	N, L, I, H[2]	Analysis	**L - Worker Safety Impacts during operation are rated low because:** a) For O&M, there is an increased risk of incidents while working on aboveground pipe off the access road and while working in vaults near the pipe bridge. b) Working in vaults could involve confined space entry.
EIR Impacts	N, L, I, H[2]	(Legal) Opinion	**H - Additional CEQA review will be needed because the EIR did not contemplate aspects of this design, including aboveground piping infrastructure, aboveground utility poles, and a potential variance to the Fire Code.** The type of additional CEQA review required depends whether the design has new, significant impacts that were not disclosed in the EIR. Such impacts could include new aesthetic impacts from aboveground utilities and pipelines or new impacts from additional earthwork or possible fire code violations. If there are new, significant impacts, a supplemental EIR would be required; an addendum would not suffice. Further analysis will allow the technical team to determine whether this alternative may have new, significant impacts. For example, if the technical team determines that the location of the poles near Loci B would have new significant aesthetic impacts or new significant impacts on cultural resources, and those impacts cannot be mitigated to a less than significant level, then a supplemental EIR would be required. Following the same pipeline route as the design contemplated in the EIR helps from a CEQA perspective. Tribes and agencies may be concerned, however, about the impact of locating new, above-ground infrastructure so close to Maze Loci B.
Historical/Archaeological Impacts[4, 5]	N, L, I, H[2]	Analysis	**None - Historical/Archaeological impacts are rated none** because: All archaeological and historical sites are avoided.
Likelihood of Failure to Detect or Contain Leaks	N, L, I, H[2]	Analysis	**L - Likelihood of failure to detect or contain leaks is rated low.** All secondary containment piping accessible for visual inspection, but water carrier pipes not accessible. Low point sumps equipped with level switches will be primary means of monitoring for and containing leaks. See also O&M Impacts caused by use of double-contained steel pipe.
O&M Impacts	N, L, I, H[2]	Analysis	**H - O&M Impacts rated high**. O&M impacts are higher than 60% design in large part due to the use of steel pipe through most of the route. Mortar lined steel pipe will resist corrosion, but the lining has a shorter life than underground plastic piping. In addition, the liner will not be suitable for pipe cleaning using strong chemicals or aggressive mechanical methods. In addition, minerals in the groundwater may precipitate on the liner or biological materials may to adhere to the liner reducing pipe capacity. Aboveground pipe supports and steel pipe increase difficulty of maintenance of piping requiring more equipment and personnel. in addition, the aboveground structures will require sand blasting and painting every 10 years. Other maintenance activities will include cleaning of the vaults and maintenance of the underground pipes is anticipated to be infrequent.
Public Safety Impacts	N, L, I, H[2]	Analysis	**I - Public Safety Impacts are rated intermediate.** Aboveground structures increase risk of public safety incidents due to potential vehicle impacts on IM-3 access road and Route 66 west of IM-3. Greater impact given the inherent vulnerability of aboveground piping (members of the public have been known to shoot pipes) and large rocks or other debris that may strike the pipe during a storm event.
Ground Disturbance	Lineal Feet	Material take-off	339

NOTES

[1] Segment description noted below

Segment 2 - Underground across IM-3 access road and run above-ground water pipe on pipe supports along 60% design route to Bat Cave Wash pipe bridge. Electrical power and fiber optic run on new poles from top of hill near SoCal gas pipeline along abandoned Route 66 to Bat Cave Wash. See Figures 22.

[2] Ratings: N = "None"; L = "Low"; I = "Intermediate"; and H = "High." These are qualitative ratings based upon the rationale provided and not to be used in a quantitative manner, i.e., the ratings

[3] Indicate whether the basis for evaluation is an opinion, calculation, analysis, etc.

[4] Alternatives for Pipeline A & H do not extend into the floodplain for the purposes of this evaluation factor.

[5] PG&E assumes impacts on the Traditional Cultural Property within the APE determined by BLM to be eligible for the National Register of Historic Places will be analyzed under "Cultural Integrity"

[6] Alternatives for Pipeline A & H do not extend into the floodplain for the purposes of this evaluation factor.

Evaluation Factors	Description of Baseline (Pre-Construction) Conditions
Cultural Integrity	
Visual Impacts	Baseline views/vistas of the natural landscape include Needles Rock, Topock Maze Loci A, B & C, Chemehuevi Mountains, Colorado River, BLM ACEC and the Havasu National Wildlife Refuge. Baseline views also include manmade features including I-40, BNSF Railroad, the pipeline bridge, Topock Marina, Park Moabi, the Topock Compressor Station and IM-3.
Ecological Impacts	The dominant plant communities at the site consist of creosote bush scrub (generally west of National Trails Highway) and salt cedar (generally between National Trails Highway and the Colorado River and at the mouth of Bat Cave Wash). The habitat in and around the Topock site is suitable for bighorn sheep, bobcats, chuckwallas, red-tailed hawks and other mammals, reptiles, and birds. Observations of mountain lion activity have been reported in this area as well. The Topock area provides foraging and/or nesting habitat for a variety of special-status bird species. Desert tortoise may have historically used the project area, but no evidence of current use has been documented during the protocol-level surveys conducted yearly since 2004.
Noise Impacts	See Final EIR[5] Section 4.9.1.5 for baseline conditions.
Worker Safety Impacts	Under baseline conditions, no work is occurring.
Schedule Impacts	Under baseline conditions, there are no delays to the project.
EIR Impacts	Final EIR for the Topock Compressor Station Groundwater Remediation Project, January 2011 [5].
Historical/Archaeological Impacts	Under baseline conditions, no additional impacts to historical/archeological resources occur for the groundwater project.
Likelihood of Failure to Detect or Contain Leaks	Under baseline conditions, no leaks occur.
Public Safety Impacts	Under baseline conditions, there is no increase impact to public safety due to the project.
Decommissioning Impacts	Under baseline conditions, no system is built therefore there are no decommissioning impacts.
Ground Disturbance	Under baseline conditions, no additional ground disturbance occurs based on the Aerial Map of Disturbed Areas, November 2011 (Appendix A-2 60% Design BOD)
Displaced soil volume	Under baseline conditions, no soil is displaced.
Capital Cost	0
O&M Cost	0
Decommissioning Costs	0
Construction Impacts [14]	Under baseline conditions, no project.
Fire Department Impacts [14]	Under baseline conditions, no project.
O&M Impacts [14]	Under baseline conditions, no project.

	Evaluation Criteria	**Pipelines A/H Current Design**	**Basis for Evaluation[3]**	**Comments/Notes**	**Pipelines A/H Current Route Above Ground**	**Basis for Evaluation[3]**	**Comments/Notes**
Evaluation Factors							
Cultural Integrity	Present/Not Present[6]						
Visual Impacts	N, L, I, H[2]	L	Simulations of views of Alternative 0 based on design drawings as seen from FEIR Key Viewpoints 6 and 9		H	Simulations of views of Alternative 0a based on design drawings as seen from FEIR Key Viewpoints 6 and 9 and two new viewpoints established on elevated areas providing foreground to middleground views of the proposed changes.	Installation of radio tower near compressor station will have little to no impact. From most views, impacts of new wood pole utility lines, above-ground pipelines on low racks, and grade separation structures will have an intermediate level of impact. Bridge crossing structures will have high levels of impacts in both foreground and middleground views. Other project elements will have high levels of impact in foreground views..
Ecological Impacts [11]	N, L, I, H[2]	I	Analysis	The current route primarily runs underground with one bridge structure proposed over Bat Cave Wash. The majority of the route is established in previously disturbed road and open creosote bush scrub community; however, the pipeline alignment goes through approximately 3.45 acres of the blue Palo Verde community and may result in the loss of individual Palo Verde. No impacts to desert tortoise are anticipated. Pipeline route is not within potential SWFL and other migratory bird habitat.	I	Analysis	This alternative route primarily runs aboveground with one bridge structure proposed over Bat Cave Wash. The majority of the route is established in previously disturbed road and open creosote scrub community; however, the pipeline alignment goes through approximately 3.45 acres of the blue Palo Verde community and may result in the loss of individual Palo Verde. No impacts to desert tortoise are anticipated. Pipeline route is not within potential SWFL and other migratory bird habitat.
Noise Impacts (construction)	N, L, I, H[2]	L	65 days (see Note 7 below for equipment list)	Construction noise impacts are created by the number of equipment and duration of construction.	I	85 days (see Notes 7 and 8 below for equipment list)	Construction noise impacts are created by the number of equipment and duration of construction.
Noise Impacts (operational)	N, L, I, H[2]	L	Analysis	Operational noise impacts: The majority of pumps and motors will be located either underground, inside a well, or inside an enclosure (e.g., building). Placing pumps and motors in these locations effectively minimizes the sound emissions. The remaining non-emergency above ground equipment is limited to transformers which are similar in size to the one already operating at IM-3, and communication/control panels.	I	Analysis	Operational noise impacts: The majority of pumps and motors or other equipment will be located either underground, inside a well, or inside an enclosure (e.g., building). Placing equipment in these locations effectively minimizes the sound emissions. The remaining non-emergency above ground equipment is limited to transformers which are similar in size to the one already operating at IM-3, and communication/control panels. Additional noise will be created by wind whistling by and impacting with aboveground structures.

Construction Impacts	N, L, I, H[2]	L	Analysis	Natural gas pipe crossings - 3 crossings will follow normal utility owner procedures to gain approval of crossings (see Worker Safety Impacts).	I	Analysis	Natural gas pipe crossings - 2 crossings will be made using with underground pipes. This would follow normal utility owner procedures to gain approval of crossings (see Worker Safety Impacts). One crossing of Southwest Gas (4") east of Bat Cave Wash on IM-3 access road will be made using aboveground structures. This type of crossing may not be allowed by Southwest Gas (4") resulting in potential design changes and delays. Adding aboveground structures (pipe supports and guard rails) will result several narrow sections of primarily Route 66 west of IM-3 and also at a few points along the IM-3 access road. This can be mitigated by extending the piping into undisturbed areas off the road if there is space available. Using power poles to carry electrical and communications will result in some additional disturbance to enable access to well vaults and other equipment. Safety considerations during design may require greater separation between aboveground structures and poles, resulting in even more disturbance.
Fire Department Impacts	N, L, I, H[2]	L	Analysis	Reducing the available width of Route 66 and IM-3 may result in violations of the San Bernardino County Fire Code for vehicle road access. The Code (Section 503.1 Article III states that roads must be 26 feet in width. Variances may be needed to obtain a permit as long as there are sufficient turnouts located every 600 feet. The existing access roads would likely serve that purpose.	H	Analysis	Reducing the available width of Route 66 and IM-3 may result in violations of the San Bernardino County Fire Code for vehicle road access. The Code (Section 503.1 Article III) states that roads must have 14 feet 6 inches vertical clearance and 26 feet in width. The low pipe racks and other pipe bridges considered for this alternative may need to be changed to taller structures or to an elevated continuous structure to meet the vertical space requirements. Variances for narrow roads are allowed if there are sufficient turnouts (every 600 feet), however these aboveground structures may prevent the minimum width (not specified in the Code, but designated by the Fire Department). The result of seeking this variance may cause additional disturbance to re-locate the pipe supports off the road. Due to the rough terrain and numerous gullies, this may also require additional support structures.
Worker Safety Impacts (Construction)	N, L, I, H[2]	I	Analysis	Underground construction is in general more hazardous than working aboveground. The route follows existing roads enabling relatively easy access and safe working conditions. Increased risk for 180 foot long pipe bridge involving scaffolding and lifting equipment and route to IRL-4 along a steep narrow road. -Natural gas (Southwest (4") and SoCal Gas (34")) pipe crossings south of IRL-3 along pipeline H and Southwest Gas (4") east of Bat Cave Wash on IM-3 access road present safety hazards.	I	Analysis	Aboveground construction is in general less hazardous than working underground. The route follows existing access roads enabling access and safe working conditions except as noted. -Increased risk for 180 foot long pipe bridge and 2-30 foot pipe bridges (grade separation) requiring scaffolding and lifting equipment and route to IRL-4 along a steep narrow road. -Addition of the aboveground pipe on steel support structures, would require the addition of guard rails to protect the pipe from incidental contact. This would reduce the width of the IM-3 access road and Route 66 west of IM-3 in several locations (see also Construction Impacts) resulting in additional safety hazards. -Natural gas (Southwest (4") and SoCal Gas (34")) pipe crossings south of IRL-3 along pipeline H and Southwest Gas (4") east of Bat Cave Wash on IM-3 access road present safety hazards.
Worker Safety Impacts (Operational)	N, L, I, H[2]	L	Analysis	For O&M, underground equipment enables ground-level access to system components, but increases risk of incidents while lifting or working in vaults. Personnel working inside secondary containment vaults (4 for this alternative) would require a confined space entry.	H	Analysis	For O&M, routing electrical overhead puts power lines closer to well vaults, which increases risk of inadvertent contact or static discharge during well maintenance. Guard rails and aboveground piping structures limit access to equipment increasing risk of incidents during maintenance or for O&M personnel vehicle accidents. Personnel working inside secondary containment vaults (9 for this alternative) would require a confined space entry.
Worker Safety Impacts (Decommissioning)	N, L, I, H[2]	L	Analysis	During decommissioning, removal of aboveground structures increase safety hazard (see Decommissioning Impacts below), but as most of the alternative is installed underground, the safety hazard is much lower.	I	Analysis	During decommissioning, removal of aboveground structures increase safety hazard (see Decommissioning Impacts below).
Schedule Impacts [15]	N, L, I, H[2]	65 days	Taken from 60% design schedule	Construction only as the alternative is described here.	85 days	Scaled based on material take-off and compared to 60% design schedule	Construction only as the alternative is described here. Additional EIR review or re-design caused by others would increase overall project schedule. A supplemental EIR review could extend the schedule 1 to 2 years.
EIR Impacts	N, L, I, H[2]	L	Opinion	The current design reflects the assumptions in the EIR. Although project refinement may necessitate further CEQA analysis, the analysis likely will be within the scope of what can be covered in an EIR addendum.	I	Opinion	Additional CEQA review will be needed. The type of additional CEQA review required depends whether the design has new, significant impacts that were not disclosed in the EIR. If there are new, significant impacts, a supplemental EIR would be required and an addendum would not suffice. Further analysis will allow the technical team to determine whether this alternative may have new, significant impacts. Following the same route as the design contemplated in the EIR helps from a CEQA perspective to the extent that the impacts caused by disturbance along this route have been analyzed by the existing EIR. Whether this option causes increased aesthetic impacts will need to be evaluated; if such impacts can be mitigated to a less than significant level, then an addendum could be prepared. If not, a supplemental EIR would be required. A supplemental EIR would result in a delay of approximately 12 to 24 months. The County Fire Code allows for variances from certain requirements. If a variance cannot be obtained, this could result in Fire Code violations and this would be is a new impact that has not been evaluated. If this impact can be mitigated to a less than significant level, an addendum can be prepared. If this impact cannot be mitigated and a variance is required, DTSC could interpret the need for a variance as a new impact triggering the need for a subsequent EIR.

Historical/Archaeological Impacts [12, 13]	N, L, I, H[2]	L	Analysis	Available site location information utilized along with draft Geoarchaeological report. Approx. 30% of route will impact Route 66. All other sites avoided.	L	Analysis	Available site location information utilized along with draft Geoarchaeological report. Approx. 30% of route will impact Route 66. All other sites avoided.
Likelihood of Failure to Detect or Contain Leaks	N, L, I, H[2]	L	Analysis	Almost all piping is underground elminating access to secondarily contained piping. Subject piping[10] is double contained with low point sumps equipped with level switches to detect a release. The majority of piping is plastic which has excellent corrosion resistance resulting in reduced risk of leaks. Underground installation prevents incidental contact further reducing chance of leaks.	I	Analysis	All secondary containment piping accessible for visual inspection, but water carrier pipes not accessible. Low point sumps equipped with level switches will be primary means of monitoring for and containing leaks. See also O&M Impacts caused by use of double-contained steel pipe.
O&M Impacts	N, L, I, H[2]	L	Analysis	O&M impacts are minimal due to use of plastic piping (HDPE) materials for majority of route. Plastic resists corrosion greatly limiting chance of leaks and has excellent record for long-term performance. Underground construction limits access to piping and electrical conduit for most of the line with the exception of the pipe bridge and the concrete trench section (approximately 1,000 feet).	I	Analysis	O&M impacts are higher than the current design in large part due to the use of steel pipe through most of the route. Mortar lined steel pipe will resist corrosion, but the lining has a shorter life than underground plastic piping. In addition, the liner will not be suitable for pipe cleaning using strong chemicals or aggressive mechanical methods. In addition, minerals in the groundwater may precipitate on the liner or biological materials may to adhere to the liner reducing pipe capacity. Aboveground pipe supports and steel pipe increase difficulty of maintenance of piping requiring more equipment and personnel. in addition, the aboveground structures will require sand blasting and painting every 10 years. This alternative is based on the City of Needles supplying power for the remedy facilities. Needles currently supplies the IM No. 3 plant and due to several factors is subject to numerous outages, particularly during the summer monsoon season. In the absence of a backup generator installed in the area, there would be many shutdowns every year. Using radio as a transmission method for control and communications is less reliable than a cable or wired connection. This would affect either control of injection wells or logging of flows into or out of the wells. Results of this include service interruptions for well backwashing and reducing the accuracy of water accounting from the Colorado River basin. Currently multiple companies (PG&E, BNSF, Southwest Gas, SoCal Gas, City of Needles) use the IM No. 3 access road and Route 66 west of IM No. 3. These roads already function as a one-way road (as mentioned by Curt at Jan 23 TWG) when heavy/wide equipment (8 foot wide semi trailers carrying frac tanks requires approximately 21 feet working room for turns).This would primarily affect annual well rehabilitations for the 5 injection wells in the area and any major maintenance activity. Therefore, PG&E cannot reduce the width of the access road.
Public Safety Impacts	N, L, I, H[2]	N	Analysis	Almost no public safety impact due to nearly all piping and electrical installed underground.	H	Analysis	Aboveground structures increase risk of public safety incidents due to potential vehicle impacts on IM-3 access road and Route 66 west of IM-3. Greater impact given the inherent vulnerability of aboveground piping (members of the public have been known to shoot pipes) and large rocks or other debris that may strike the pipe during a storm event.
Decommissioning Impacts	N, L, I, H[2]	L	Analysis	Remove aboveground structures, vaults, equipment, and 1 pipe bridge (180 feet). Abandon in place underground piping and conduit. The removal of belowground infrastructure/piping as an alternative to current proposal to abandon in place would result in soil excavation and disturbance along entire length of Pipelines A and H (approximately 3,800 feet).	I	Analysis	Remove power poles, pipe supports, and other aboveground equipment. (26 power poles and 180 pipe supports. 3630 lf of guard rail @ 6' spacing ~600 supports, 1 pipe bridge (180 feet)) The removal of belowground infrastructure/piping as an alternative to current proposal to abandon in place would result in soil excavation and disturbance along portions of piping and electrical conduit west of Bat Cave Wash to FW-1 and IRL-4. This would occur over a distance of approximately 800 feet.
Ground Disturbance	Lineal Feet	209	Material take-off		209	Material take-off	Not updated for change to underground for approximately 800 feet.
Displaced soil volume	cubic yds	1,869	Material take-off		736	Material take-off	Not updated for change to underground for approximately 800 feet.
Capital Cost	$	$4,900,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs	$7,600,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs
O&M Cost	$ (30 year PV, 7% interest)	$410,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs	$1,700,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs
Decommissioning Costs	$	$350,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs	$1,900,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs

	Evaluation Criteria	Pipelines A/H Alternative Route 1	Basis for Evaluation[3]	Comments/Notes	Pipelines A/H Alternative Route 2	Basis for Evaluation[3]	Comments/Notes
Evaluation Factors							
Cultural Integrity	Present/Not Present[6]						
Visual Impacts	N, L, I, H[2]	H	Simulations of views of Alternative 1 based on design drawings as seen from FEIR Key Viewpoints 6 and 9 and two new viewpoints established on elevated areas providing foreground to middleground views of the proposed changes	Installation of radio tower near compressor station will have little to no impact. From most views, impacts of new wood pole utility lines, above-ground pipelines on low racks, and grade separation structures will have an intermediate level of impact. From views in which project elements are visible in the foreground impacts will be high.	H	Simulations of views of Alternative 2 based on design drawings as seen from FEIR Key Viewpoints 6 and 9 and two new viewpoints established on elevated areas providing foreground to middleground views of the proposed changes	Installation of radio tower near compressor station will have little to no impact. From most views, impacts of new wood pole utility lines, above-ground pipelines on low racks, and grade separation structures will have an intermediate level of impact. Bridge crossing structures will have high levels of impacts in both foreground and middleground views. Other project elements will have high levels of impact in foreground views..
Ecological Impacts[11]	N, L, I, H[2]	I	Analysis	This alternative route primarily runs aboveground with one bridge structure proposed over Bat Cave Wash. The majority of the route is established in previously disturbed road and open creosote scrub community. The pipeline alignment goes through approximately 3.55 acres of the blue Palo Verde community and may result in the loss of individual Palo Verde. A larger disturbance area within creosote bush scrub habitat will be required for this alignment due to the section of pipeline ascending a steep slope near National Trails Highway. No impacts to desert tortoise are anticipated. Pipeline route is not within potential SWFL and other migratory bird habitat.	I	Analysis	This alternative route primarily runs aboveground with two bridge structures proposed over Bat Cave Wash. The majority of the route is established in previously disturbed road and open creosote scrub community. The pipeline alignment goes through approximately 2.55 acres of the blue Palo Verde community and may result in the loss of individual Palo Verde. No impacts to desert tortoise are anticipated. Pipeline route is not within potential SWFL and other migratory bird habitat.
Noise Impacts (construction)	N, L, I, H[2]	I	65 days (see Notes 7 and 8 below for equipment list)	Construction noise impacts are created by the number of equipment and duration of construction.	I	75 days (see Notes 7 and 8 below for equipment list)	Construction noise impacts are created by the number of equipment and duration of construction.
Noise Impacts (operational)	N, L, I, H[2]	I	Analysis	Operational noise impacts: The majority of pumps and motors or other equipment will be located either underground, inside a well, or inside an enclosure (e.g., building). Placing equipment in these locations effectively minimizes the sound emissions. The remaining non-emergency above ground equipment is limited to transformers which are similar in size to the one already operating at IM-3, and communication/control panels. Additional noise will be created by wind whistling by and impacting with aboveground structures.	I	Analysis	Operational noise impacts: The majority of pumps and motors or other equipment will be located either underground, inside a well, or inside an enclosure (e.g., building). Placing equipment in these locations effectively minimizes the sound emissions. The remaining non-emergency above ground equipment is limited to transformers which are similar in size to the one already operating at IM-3, and communication/control panels. Additional noise will be created by wind whistling by and impacting with aboveground structures.
Construction Impacts	N, L, I, H[2]	H	Analysis	This route would run in the Southwest Gas (4") right of way from the IM-3 access road to Bat Cave Wash on Route 66. Installation of aboveground pipe supports would not be typical within a gas pipe right of way. This approach might be rejected resulting in re-design or delays or additional disturbance. Construction of an aboveground pipe on the steep slope located west of the MW-20 Bench will be near the SoCal gas (34") pipeline. To protect the pipe storm drainage improvements are needed (4 drain pipes and earthwork) and would be within the right-of-way. This approach might need to be modified resulting in re-design or delays.	H	Analysis	This route would run in the Southwest Gas (4") right of way from the IM-3 access road to Bat Cave Wash on Route 66. Installation of aboveground pipe supports would not be typical within a gas pipe right of way. This approach might be rejected resulting in re-design or delays or additional disturbance. Construction of an aboveground pipe on the steep slope located west of the MW-20 Bench will be near the SoCal gas(34") pipeline. To protect the pipe storm drainage improvements are needed (4 drain pipes and earthwork) and would be within the right-of-way. This approach might need to be modified resulting in re-design or delays. Construction of two bridges - 330 feet long to cross Bat Cave Wash and 280 feet long to cross a BNSF access road will require consultation with the owners resulting in potential design changes or delays.
Fire Department Impacts	N, L, I, H[2]	H	Analysis	Reducing the available width of Route 66 and IM-3 may result in violations of the San Bernardino County Fire Code for vehicle road access. The Code (Section 503.1 Article III) states that roads must have 14 feet 6 inches vertical clearance and 26 feet in width. The low pipe racks and other pipe bridges considered for this alternative may need to be changed to taller structure or to an elevated continuous structure to meet the vertical space requirements. Variances for narrow roads are allowed if there are sufficient turnouts (every 600 feet), however these aboveground structures may prevent the minimum width (not specified in the Code, but designated by the Fire Department). The result of seeking this variance may cause additional disturbance to re-locate the pipe supports off the road. Due to the rough terrain and numerous gullies, this may also require additional support structures.	H	Analysis	Reducing the available width of Route 66 and IM-3 may result in violations of the San Bernardino County Fire Code for vehicle road access. Variances for narrow roads are allowed if there are sufficient turnouts (every 600 feet), however these aboveground structures may prevent the minimum width (not specified in the Code, but designated by the Fire Department). The result of seeking this variance may cause additional disturbance to re-locate the pipe supports off the road. Due to the rough terrain and numerous gullies, this may also require additional support structures.

Worker Safety Impacts (Construction)	N, L, I, H[2]	H	Analysis	Aboveground construction is in general less hazardous than working underground. The route follows some existing access roads, but has some cross-country routes that increase risk. -Increased risk for 140 foot long pipe bridge and 1-50 foot pipe bridge (grade separation) requiring scaffolding and lifting equipment; segment from MW-20 Bench west up steep slope, and route to IRL-4 along a steep narrow road. -Addition of the aboveground pipe on steel support structures, would require the addition of guard rails to protect the pipe from incidental contact. This would reduce the width of the IM-3 access road and Route 66 west of IM-3 in several locations (see also Construction Impacts) resulting in additional safety hazards. -Natural gas (Southwest (4") and SoCal Gas (34")) pipe crossings south of IRL-3 along pipeline H and SoCal Gas (34") at the top of the slope overlooking National Trails Highway and the MW-20 Bench present safety hazards.	H	Analysis	Aboveground construction is in general less hazardous than working underground. The route follows some existing access roads, but has some cross-country routes that increase risk. -Increased risk for 280-foot and 330-foot pipe bridges and 1-30 foot pipe bridge (grade separation) requiring scaffolding and lifting equipment, segment from MW-20 Bench west up steep slope, and route to IRL-4 along a steep narrow road. -Addition of the aboveground pipe on steel support structures, would require the addition of guard rails to protect the pipe from incidental contact. This would reduce the width of the IM-3 access road and Route 66 west of IM-3 in several locations (see also Construction Impacts) resulting in additional safety hazards. -Natural gas (Southwest (4") and SoCal Gas (34")) pipe crossings south of IRL-3 along pipeline H and SoCal Gas (34") at the top of the slope overlooking National Trails Highway and the MW-20 Bench present safety hazards.
Worker Safety Impacts (Operational)	N, L, I, H[2]	H	Analysis	For O&M, routing electrical overhead puts power lines closer to well vaults, which increases risk of inadvertent contact or static discharge during well maintenance. Guard rails and aboveground piping structures limit access to equipment increasing risk of incidents during maintenance or for O&M personnel vehicle accidents. Working near active gas pipelines creates additional safety hazards. Personnel working inside secondary containment vaults (11 for this alternative) would require a confined space entry.	H	Analysis	For O&M, routing electrical overhead puts power lines closer to well vaults, which increases risk of inadvertent contact or static discharge during well maintenance. Guard rails and aboveground piping structures limit access to equipment increasing risk of incidents during maintenance or for O&M personnel vehicle accidents. Working near active gas pipelines creates additional safety hazards. Personnel working inside secondary containment vaults (11 for this alternative) would require a confined space entry.
Worker Safety Impacts (Decommissioning)	N, L, I, H[2]	H	Analysis	During decommissioning, removal of aboveground structures increase safety hazard (see Decommissioning Impacts below) especially when working near active natural gas pipelines.	H	Analysis	During decommissioning, removal of aboveground structures increase safety hazard (see Decommissioning Impacts below) especially when working near active natural gas pipelines.
Schedule Impacts [15]	N, L, I, H[2]	65 days	Scaled based on material take-off and compared to 60% design schedule	Construction only as the alternative is described here. Additional EIR review or re-design caused by others would increase overall project schedule. A supplemental EIR review could extend the schedule 1 to 2 years.	75 days	Scaled based on material take-off and compared to 60% design schedule	Construction only as the alternative is described here. Additional EIR review or re-design caused by others would increase overall project schedule. A supplemental EIR review could extend the schedule 1 to 2 years.
EIR Impacts	N, L, I, H[2]	H	Opinion	Additional CEQA review will be needed. The type of additional CEQA review required depends whether the design has new, significant impacts that were not disclosed in the EIR. If there are new, significant impacts, a supplemental EIR would be required and an addendum would not suffice. Further analysis will allow the technical team to determine whether this alternative may have new, significant impacts. Whether this option causes increased aesthetic impacts will need to be evaluated; if such impacts can be mitigated to a less than significant level, then an addendum could be prepared. If not, a supplemental EIR would be required. A supplemental EIR would result in a delay of approximately 12 to 24 months. The County Fire Code allows for variances from certain requirements. If a variance cannot be obtained, this could result in Fire Code violations and this would be is a new impact that has not been evaluated. If this impact can be mitigated to a less than significant level, an addendum can be prepared. If this impact cannot be mitigated and a variance is required, DTSC could interpret the need for a variance as a new impact triggering the need for a subsequent EIR.	H	Opinion	Additional CEQA review will be needed. The type of additional CEQA review required depends whether the design has new, significant impacts that were not disclosed in the EIR. If there are new, significant impacts, a supplemental EIR would be required and an addendum would not suffice. If this impact cannot be mitigated and a variance is required, DTSC could interpret the need for a variance as a new impact triggering the need for a subsequent EIR.
Historical/Archaeological Impacts [12, 13]	N, L, I, H[2]	L	Analysis	Available site location information utilized along with draft Geoarchaeological report. Approx. 50% of route will impact Route 66. All other sites avoided.	L	Analysis	Available site location information utilized along with draft Geoarchaeological report. Approx. 25% of route will impact Route 66. All other sites avoided.
Likelihood of Failure to Detect or Contain Leaks	N, L, I, H[2]	I	Analysis	All secondary containment piping accessible for visual inspection, but water carrier pipes not accessible. Low point sumps equipped with level switches will be primary means of monitoring for and containing leaks. See also O&M Impacts caused by use of double-contained steel pipe.	I	Analysis	All secondary containment piping accessible for visual inspection, but water carrier pipes not accessible. Low point sumps equipped with level switches will be primary means of monitoring for and containing leaks. See also O&M Impacts caused by use of double-contained steel pipe.

O&M Impacts	N, L, I, H[2]	I	Analysis	O&M impacts are higher than the current design in large part due to the use of steel pipe through most of the route. Mortar lined steel pipe will resist corrosion, but the lining has a shorter life than underground plastic piping. In addition, the liner will not be suitable for pipe cleaning using strong chemicals or aggressive mechanical methods. In addition, minerals in the groundwater may precipitate on the liner or biological materials may to adhere to the liner reducing pipe capacity. Aboveground pipe supports and steel pipe increase difficulty of maintenance of piping requiring more equipment and personnel. in addition, the aboveground structures will require sand blasting and painting every 10 years. This alternative is based on the City of Needles supplying power for the remedy facilities. Needles currently supplies the IM No. 3 plant and due to several factors is subject to numerous outages, particularly during the summer monsoon season. In the absence of a backup generator installed in the area, there would be many shutdowns every year. Using radio as a transmission method for control and communications is less reliable than a cable or wired connection. This would affect either control of injection wells or logging of flows into or out of the wells. Results of this include service interruptions for well backwashing and reducing the accuracy of water accounting from the Colorado River basin. Currently multiple companies (PG&E, BNSF, Southwest Gas, SoCal Gas, City of Needles) use the IM No. 3 access road and Route 66 west of IM No. 3. These roads already function as a one-way road (as mentioned by Curt at Jan 23 TWG) when heavy/wide equipment (8 foot wide semi trailers carrying frac tanks requires approximately 21 feet working room for turns).This would primarily affect annual well rehabilitations for the 5 injection wells in the area and any major maintenance activity. Therefore, PG&E cannot reduce the width of the access road.	I	Analysis	O&M impacts are higher than the current design in large part due to the use of steel pipe through most of the route. Therefore, PG&E cannot reduce the width of the access road.
Public Safety Impacts	N, L, I, H[2]	H	Analysis	Aboveground structures increase risk of public safety incidents due to potential vehicle impacts on IM-3 access road and Route 66 west of IM-3. Greater impact given the inherent vulnerability of aboveground piping (members of the public have been known to shoot pipes) and large rocks or other debris that may strike the pipe during a storm event.	H	Analysis	Aboveground structures increase risk of public safety incidents due to potential vehicle impacts on IM-3 access road and Route 66 west of IM-3. Greater impact given the inherent vulnerability of aboveground piping (members of the public have been known to shoot pipes) and large rocks or other debris that may strike the pipe during a storm event.
Decommissioning Impacts	N, L, I, H[2]	H	Analysis	Remove power poles, pipe supports, and other aboveground equipment. (26 power poles and 170 pipe supports. 3410 lf of guard rail @ 6' spacing approx. 570 supports, 140 foot long pipe bridge and 1-50 foot pipe bridge (grade separation)) The removal of belowground infrastructure/piping as an alternative to current proposed abandon in place would result in soil excavation and disturbance along portions of piping and electrical conduit west of Bat Cave Wash to FW-1 and IRL-4. This would occur over a distance of approximately 800 feet.	H	Analysis	Remove power poles, pipe supports, and other aboveground equipment. (26 power poles and 120 pipe supports. 2380 lf of guard rail @ 6' spacing approx. 400 supports, 280-foot and 330-foot pipe bridges and 1-30 foot pipe bridge (grade separation)). The removal of belowground infrastructure/piping as an alternative to current proposed abandon in place would result in soil excavation and disturbance along portions of piping and electrical conduit west of Bat Cave Wash to FW-1 and IRL-4. This would occur over a distance of approximately 800 feet.
Ground Disturbance	Lineal Feet	121	Material take-off	Not updated for change to underground for approximately 800 feet.	210	Material take-off	Not updated for change to underground for approximately 800 feet.
Displaced soil volume	cubic yds	562	Material take-off	Not updated for change to underground for approximately 800 feet.	356	Material take-off	Not updated for change to underground for approximately 800 feet.
Capital Cost	$	$6,800,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs	$9,800,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs
O&M Cost	$ (30 year PV, 7% interest)	$1,500,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs	$2,000,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs
Decommissioning Costs	$	$1,700,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs	$2,400,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs

PIPELINE B DESIGN ALTERNATIVE - WITH BASIS FOR EVALUATION [4]

	Evaluation Criteria	Pipeline B - Current Design	Basis for Evaluation[3]	Comments/Notes	Pipeline B Alternative 1	Basis for Evaluation[3]	Comments/Notes
Evaluation Factors							
Cultural Integrity	Present/Not Present[6]						
Visual Impacts	N, L, I, H[2]	L	Analysis	Review of remedy route and disturbance maps, site photos, Google Earth, and design drawings. First 600 feet extending west from arch bridge, would have low pipe rack on northern side of low level of visual contrast with setting and low visibility to potential viewers. The rest of the pipeline would be buried under existing roadway and would have no visual effects.	I	Analysis	Review of remedy route and disturbance maps, site photos and Google earth, and design drawings. Pipeline alternative has potential to be highly visible and cause ground disturbance that may persist in contrast to surrounding landscape. Although there is potential for high level of visual contrast, the impact will be moderate because the changes will not be visible to viewing public.
Ecological Impacts [11]	N, L, I, H[2]	L	Analysis	Pipeline route within disturbed habitat. No impacts to desert tortoise are anticipated. Work restrictions during the nesting season will minimize effects to nesting birds (SWFL and other migratory birds).	I	Analysis	Pipeline route primarily within disturbed habitat and creosote bush scrub. Some impact to hillside Palo Verde community resulting in the potential loss of individuals may occur. No impacts to desert tortoise are anticipated. Work restrictions during the nesting season will minimize effects to nesting birds (SWFL and other migratory birds).
Noise Impacts (construction)	N, L, I, H[2]	L	Similar to Pipeline B Alternative 1 configuration. (see Notes 7 and 8 below for equipment list)	Construction noise impacts are created by the number of equipment and duration of construction.	L	Similar to Pipeline B current design configuration. (see Notes 7 and 8 below for equipment list)	Construction noise impacts are created by the number of equipment and duration of construction.
Noise Impacts (operational)	N, L, I, H[2]	L	Analysis	Operational noise impacts: No pumps or motors are included in this pipeline. Additional noise will be created by wind whistling by and impacting with aboveground structures.	L	Analysis	Operational noise impacts: No pumps or motors are included in this pipeline. Additional noise will be created by wind whistling by and impacting with aboveground structures.

Construction Impacts	N, L, I, H[2]	N	Analysis	Work is within existing roadway.	L	Analysis	Work is on slopes within right of way for PG&E Line 300A. Exiting from bridge aboveground will likely require using Kinder Morgan infrastructure for use as supports. Kinder Morgan and SoCal Gas will need to grant permission to cross under their pipes. Design may need to be changed to obtain approval for installation resulting in re-design or delays or additional disturbance. Construction along slopes will likely involve installing pipe supports on rock.
Fire Department Impacts	N, L, I, H[2]	N	Analysis	No fire access is needed.	N	Analysis	No fire access is needed.
Worker Safety Impacts (Construction)	N, L, I, H[2]	L	Analysis	Similar since construction methods are almost the same.	I	Analysis	Similar since construction methods are almost the same. Greater than current design due to pipe being placed on slope south of existing gas line (Line 300A).
Worker Safety Impacts (Operational)	N, L, I, H[2]	L	Analysis	Operational safety concerns are related to accessing piping (aboveground or underground). Some sections are near active gas pipeline (Line 300A).	I	Analysis	Operational safety concerns are somewhat greater than current design alternative because of route being placed on slope. Alternative route crosses active gas lines.
Worker Safety Impacts (Decommissioning)	N, L, I, H[2]	N	Analysis	No decommissioning safety impacts (see Decommissioning Impacts.	N	Analysis	No decommissioning safety impacts (see Decommissioning Impacts.
Schedule Impacts [15]	N, L, I, H[2]	33 days	Taken from 60% design schedule and scaled based on length of the pipeline under evaluation (see Notes).	Construction only as the alternative is described here. The 60% design schedule lumps the construction schedule together for all of the 9 sections of Pipeline B, while there are 3 sections under which is about 1/3 of the total length.	38 days	Taken from 60% design schedule and scaled based on length of the pipeline under evaluation.	Construction only as the alternative is described here. Additional EIR review or re-design caused by others would increase overall project schedule. A supplemental EIR review could extend the schedule 1 to 2 years.
EIR Impacts	N, L, I, H[2]	L	Opinion	The current design reflects the assumptions in the EIR. Although project refinement may necessitate further CEQA analysis, the analysis likely will be within the scope of what can be covered in an EIR addendum.	I	Opinion	Additional CEQA review will be needed. The type of additional CEQA review required depends whether the design has new, significant impacts that were not disclosed in the EIR. If there are new, significant impacts, a supplemental EIR would be required and an addendum would not suffice. Further analysis will allow the technical team to determine whether this alternative may have new, significant impacts. Following the same route as the design contemplated in the EIR helps from a CEQA perspective.
Historical/Archaeological Impacts [12, 13]	N, L, I, H[2]	L	Analysis	Available site location information utilized along with draft Geoarchaeological report. Approx. 20% of route will impact Route 66. All other sites avoided. Virtually no potential for buried archaeological sites.	L	Analysis	Available site location information utilized along with draft Geoarchaeological report. Approx. 20% of route will impact Route 66. All other sites avoided.
Likelihood of Failure to Detect or Contain Leaks	N, L, I, H[2]	N		Does not apply to freshwater piping [10].	N		Does not apply to freshwater piping [10].
O&M Impacts	N, L, I, H[2]	L	Analysis	Pipeline is accessible. The aboveground structures will require sand blasting and painting every 10 years.	I	Analysis	Additional equipment and personnel required for major pipeline maintenance. In addition, the aboveground structures will require sand blasting and painting every 10 years. The area around the west end of the Arch bridge is congested requiring additional additional equipment and personnel for maintenance .
Public Safety Impacts	N, L, I, H[2]	N	Analysis	Locked gates nearly eliminate public access to this pipeline.	N	Analysis	Locked gates nearly eliminate public access to this pipeline.
Decommissioning Impacts	N, L, I, H[2]	N	Analysis	Facilities left in service after project is completed, so no decommissioning is needed.	N	Analysis	Facilities left in service after project is completed, so no decommissioning is needed.
Ground Disturbance	Lineal Feet	245	Material take-off		280	Material take-off	
Displaced soil volume	cubic yds	126	Material take-off		77	Material take-off	
Capital Cost	$	$360,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs. Electrical not included since common (underground) to both Pipeline B alternatives.	$900,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs. Electrical not included since common (underground) to both Pipeline B alternatives.
O&M Cost	$ (30 year PV, 7% interest)	$70,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs. Electrical not included since common (underground) to both Pipeline B alternatives.	$260,000	Cost estimate	AACE Level 4[9] estimate based on conceptual layouts and material takeoffs. Electrical not included since common (underground) to both Pipeline B alternatives.
Decommissioning Costs	$	$0		Facilities retained after project ends	$0		Facilities retained after project ends

NOTES

[1] Pipelines A/H alternative descriptions noted below

Both Alternatives: above-ground electrical on poles, distributed to FW-1, IRL-1 thru IRL-4 from City of Needles supply on north side of IM-3; fiber optic on same poles, or use wireless telecom/SCADA.

Alternative Route 1: Above-ground water pipe on pipe supports going west from NTH parallel to SoCal gas pipeline to abandoned Rt. 66 alignment, then along said alignment to the north, then northwest, then west to the existing Rt. 66 alignment where it crosses Bat Cave Wash. Then follow, continuing above-ground, following pipe sections A/H routes as laid out in the 60% Basis of Design Report. Presume aerial crossing of Bat Cave Wash, per 60% Basis of Design Report.

Alternative Route 2: Above-ground water pipe on pipe supports going west from NTH parallel to SoCal gas pipeline to intersection with pipe section H route as presented in the 60% Basis of Design Report, then follow, continuing above-ground, pipe sections A & H routes as presented in the Report to wells FW-1, and IRL-1 thru IRL-4.

[2] Ratings: N = “None”; L = “Low”; I = “Intermediate”; and H = “High.” These are qualitative ratings based upon the rationale provided and not to be used in a quantitative manner, i.e., the ratings are not additive.

[3] Indicate whether the basis for evaluation is an opinion, calculation, analysis, etc.

[4] Pipeline Section B Alternative 1 - As presented in 60% design but pipe sections B1, B2 & B3 are above ground on pipe supports and power is either buried, or above-ground on power poles.

[5] Final Environmental Impact Report Volume 2 for the Topock Compressor Station Groundwater Remediation Project, California Department of Toxic Substances Control, January 2011

[6] In the Tribes’ view, this relates to a whole state of being, so there would be no graduation in the rating. Integrity is either present or it is not. Input on this criterion is to be provided by the interested tribes.

[7] Pickup truck (3 ea), Mechanics truck (1 ea), Water Truck (1 ea), Front End Loader (1 ea), Excavator (1 ea), Lift Truck (1 ea), 45 ton crane (1 ea), Welding machine (1 ea), Forklift (1 ea), Boom Truck (1 ea), Backhoe (1 ea), Walk behind compactor (1 ea),

[8] Skid Steer w/auger attachment (could be truck mounted drill rig) (1 ea (only for AG pipe supports)), Two pole trucks with a pickup for electrical OH construction.

[9] AACE = AACE International (cost engineering professional society) Level 4 estimate has +50%/-30% accuracy. This is an estimate for alternative evaluation purposes only.

[10] Piping with secondary containment includes remedy produced water and carbon-amended groundwater.

[11] Alternatives for Pipeline A & H do not extend into the floodplain for the purposes of this evaluation factor. For the Pipeline B alternatives, the eastern end of the pipeline encroaches upon potential SWFL and other migratory bird habitat near the Colorado River.

[12] Alternatives for Pipeline A & H do not extend into the floodplain for the purposes of this evaluation factor.

[13] PG&E assumes impacts on the Traditional Cultural Property within the APE determined by BLM to be eligible for the National Register of Historic Places will be analyzed under "Cultural Integrity"

[14] PG&E proposed this factor for inclusion in the matrix.

[15] Duration estimates are based on the schedule provided with the 60 percent design submittal including the location of staging areas as shown on Figure 7.6-1. Each alternative assumes multiple construction operations may be occurring simultaneously to achieve a reasonably expedited schedule. Operations could include items such as pipe support installation, pipe welding, and electrical installation. Actual duration is a function of overall project requirements, anticipated duration, resource availability, and location and availability of staging areas.

Notes:
1. Conceptual Visualization - This is for illustration purposes only and is not intended as an engineering design.
2. Electrical (12 kV direct-buried cable) is underground from Pipeline J to Compressor Station for both alternatives.
3. For this figure, it is assumed that the water line can be installed beneath the aboveground gas pipeline and also stay 12 feet away from PG&E's Line 300A gas pipeline. If this is not allowed, then possible options include installing a longer pipe bridge (see Figure 8) encompassing the grade separation structure, a 30 foot grade separation structure could be installed here, or the pipe could be re-routed further south to cross over the pipeline when it is underground.

DRAFT Technical Memorandum

From: TRC
To: DTSC and DOI/BLM
Re: Suggested Alternative for Pipeline Segment A/H and B
Date: December 17, 2013

After discussing and evaluating the Department of Interior's Pipeline Evaluation Matrix, PG&E's responses to 60% comments, and the PG&E maps and visual simulations (provided at the November 19-20, 2013 TWG meeting in Henderson, NV), the TRC provides the following recommendations concerning pipeline segments.

All Pipeline Segments

The TRC recommends that ALL below ground infrastructure for all pipeline segments be removed upon completion of the remedy, as part of the decommissioning process.

Pipeline Segment A/H

We recommend Pipeline Alternative A/H Route 2 (Figure 4 of the above-identified visual simulations - attached), with the following recommended modifications and clarifications. The recommendation for Alternative Route 2 is based on our understanding of Tribal preference that the pipeline segment be relocated away from area B to the greatest extent possible.

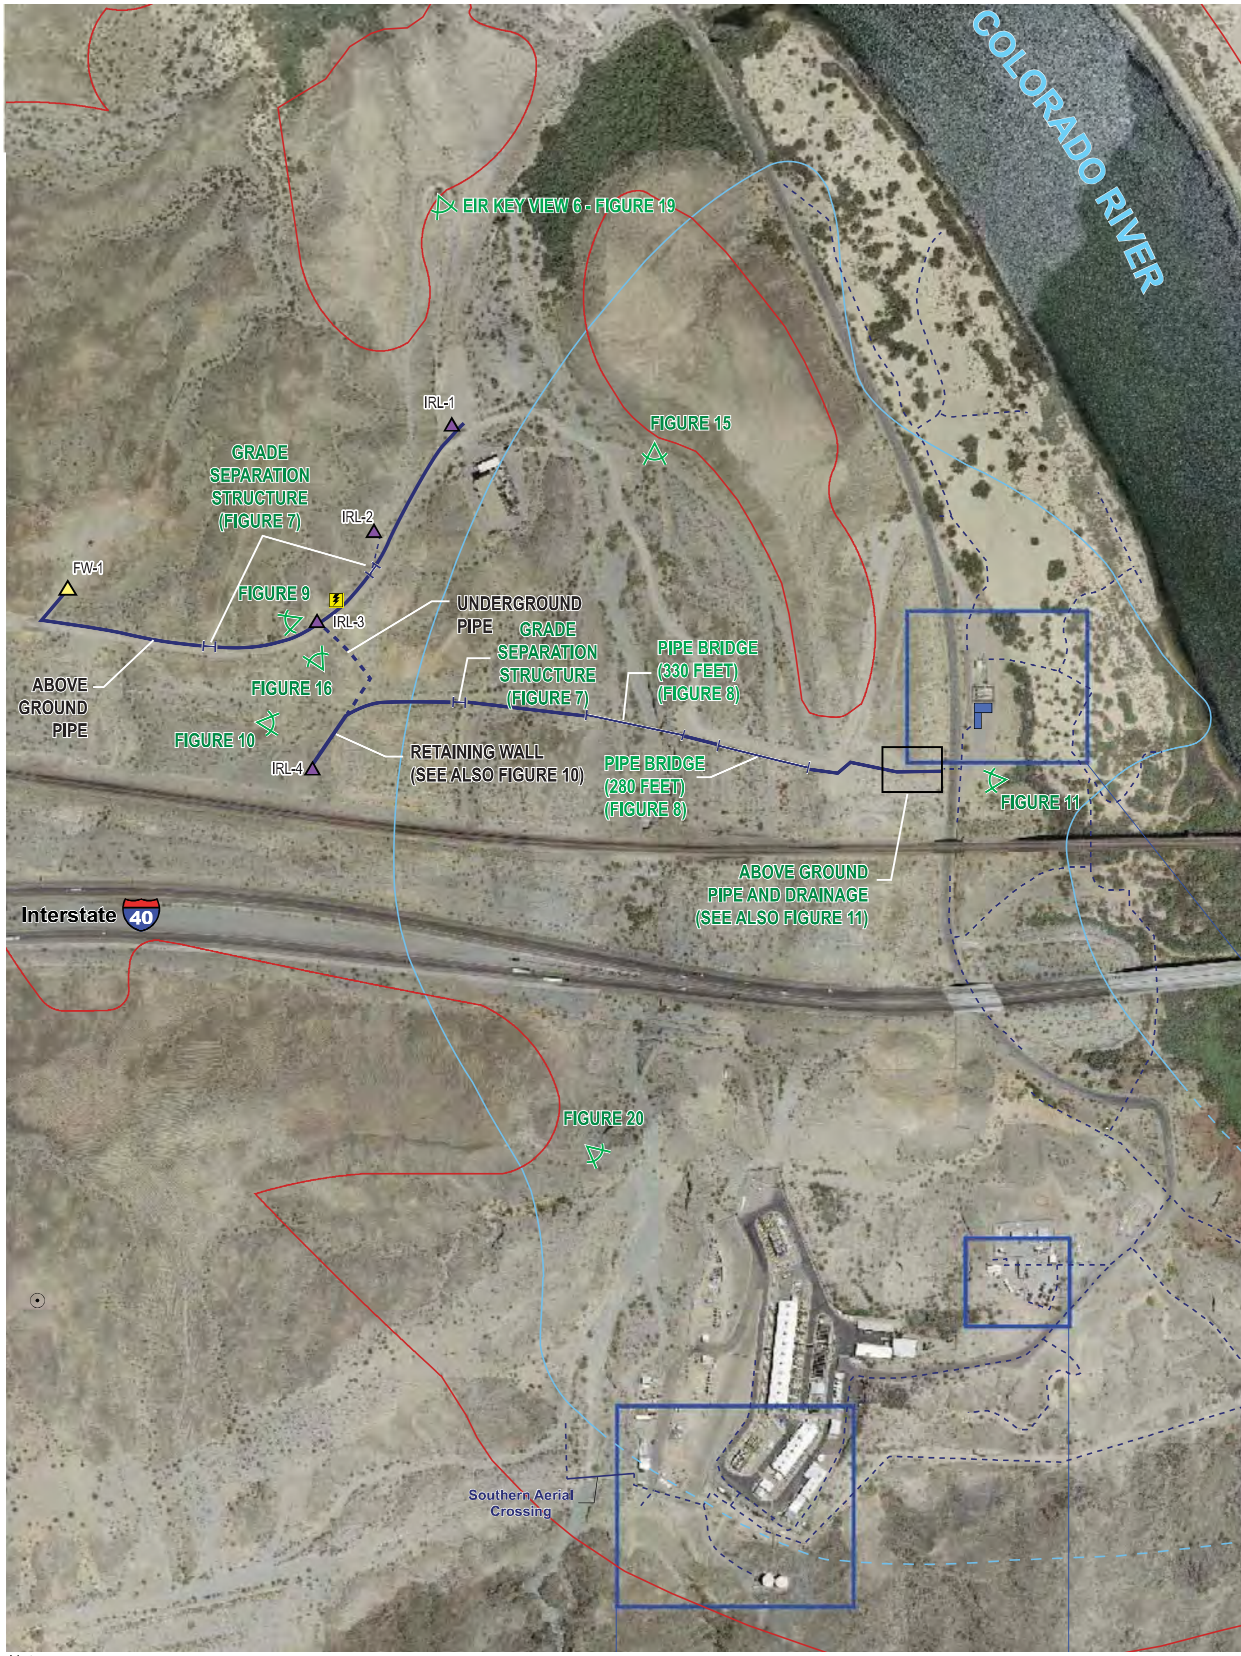
- Evaluate the feasibility of a subsurface bore, suggested by Curt Russell in the November 19-20 TWG meeting, at the eastern end of the alignment, where the Alternative A/H Route 2 pipeline segment meets National Trails Highway. This would eliminate the need for the staircase feature illustrated in Figure 11 of the above-referenced visual simulations.
- Evaluate the feasibility of locating IRL-2 in the center of the roadway, with buried vaults, to avoid intrusion into culturally-sensitive areas or major slope excavation. The roadway would need to be periodically closed for maintenance on the well or related buried infrastructure, but it would still be possible to access other project and IM-3 facilities from the east or west.
- Evaluate the feasibility of using simpler pipe bridges supported in a manner similar to the existing large-diameter Southern California high pressure gas pipeline Bat Cave Wash crossing shown in Figure 13 of the above-referenced visual simulations. Another possibility might be to suspend the pipes from a steel cable, possibly with support/stabilization at points along the ground. The objective would be to minimize the complexity, footprint, cost, maintenance, etc., of the currently-proposed pipe bridge structures. In this scenario, maintenance for the remedy infrastructure would be done in a manner similar to what is presumably presently done for the large-diameter Southern California high pressure gas pipe where it crosses valleys and washes.
- For the portion of the alignment in the area of the shorter of the two proposed pipe bridges, evaluate the feasibility of placing the pipeline above-ground, but without using a pipe bridge.
- Evaluate the feasibility of substituting underground crossings in place of the above-ground grade separation structures, shown in Figure 7 of the above-referenced visual simulations, at all other locations where above-ground grade separation structures are required.
- Evaluate the feasibility of alternative methods of slope support in the area of IRL-4. Alternatives would include shotcrete (sprayed on mixture of sand, cement, fine gravel and water) or sand-cement bags – tinted to match the surroundings. The recent Cost-Effective and Sustainable Road

Slope Stabilization and Erosion Control synthesis by NCHRP (National Co-Operative Highway Research Program) may offer applicable solutions, though bio-engineered methods are probably not applicable in the desert setting of Topock. The simpler the better. The objective would be to minimize the complexity, footprint, visual impact, cost and maintenance of the slope support.

- Evaluate the feasibility of a temporary vehicular closure to the public of what is often referred to as "Route 66" between Park Moabi road and the IM-3/IRL-1 location, for the duration of the project. The road would have locked gates at either end, and be closed to public motorized vehicular traffic, but not closed to public pedestrian access. BLM, PG&E, San Bernardino County Fire Department, the Fort Mojave Indian Tribe and possibly other parties would have gate keys to access the road for their specific needs. If there is no public vehicular access, then the need for guardrail may be eliminated. NOTE: It is very likely, that, from a San Bernardino County point of view, this road is already in a substandard condition: in places, it is only one lane in width, and, in other places, there are drop-offs.
- Evaluate the feasibility of minimizing or eliminating the use of double-contained (dual-wall) water line piping for above-ground portions of the pipelines. If there is a leak, won't it be visible during routine inspections?
- Evaluate the feasibility of using smaller-diameter pipe for above-ground portions of the pipeline in general, and for pipe bridges in particular – to reduce the weight of the pipeline. For the pipe bridges, the friction losses would be higher but the length of pipe is relatively small.
- Evaluate the feasibility of placing above-ground piping closer to the ground to reduced design moments and thus reduce the required support and foundation sizes.
- Evaluate the feasibility of designing the pipeline to have suitable wildlife crossings. For example, above-ground pipeline segment could periodically dive underground for a lateral distance of 5 or 10 feet.
- Evaluate the feasibility of placing all of pipeline segment H above ground.
- Utilize above-ground electrical, fiber-optic and telecommunication utilities per Figure 5 of the above-referenced visual simulations.

Pipeline Segment B

We recommend Pipeline Alternative B0A (Figure 21 of the above-identified visual simulations).



Notes: 1.Conceptual Visualization - This is for illustration purposes only and is not intended as an engineering design.
2. See Figure 5 for Overhead Electical.

-- DRAFT -- FOR DISCUSSION PURPOSES ONLY -- DRAFT --

Simulation of possible above-ground structures

-- DRAFT -- FOR DISCUSSION PURPOSES ONLY -- DRAFT --

Summary of Options for Segment 1- Pipeline A (slope access)

– Bring infrastructure up slope in a trench, adjacent to existing pipeline/easement.
– Bring infrastructure up slope on above ground supports, includes access stairway, pipeline supports, buried drainage pipes and basins; likely additional cut into slope on northern side to accommodate structures within existing pipeline easements.
– Underground “direct piping” bore from NTH to top of slope using tunnel boring machine (TBM). All piping and utilities would be run through permanent 42” casing. Casing is not removable.

Discussion regarding “Segment 4 – Pipeline A”

From top of slope access, across

Bat Cave Wash to IRL-4

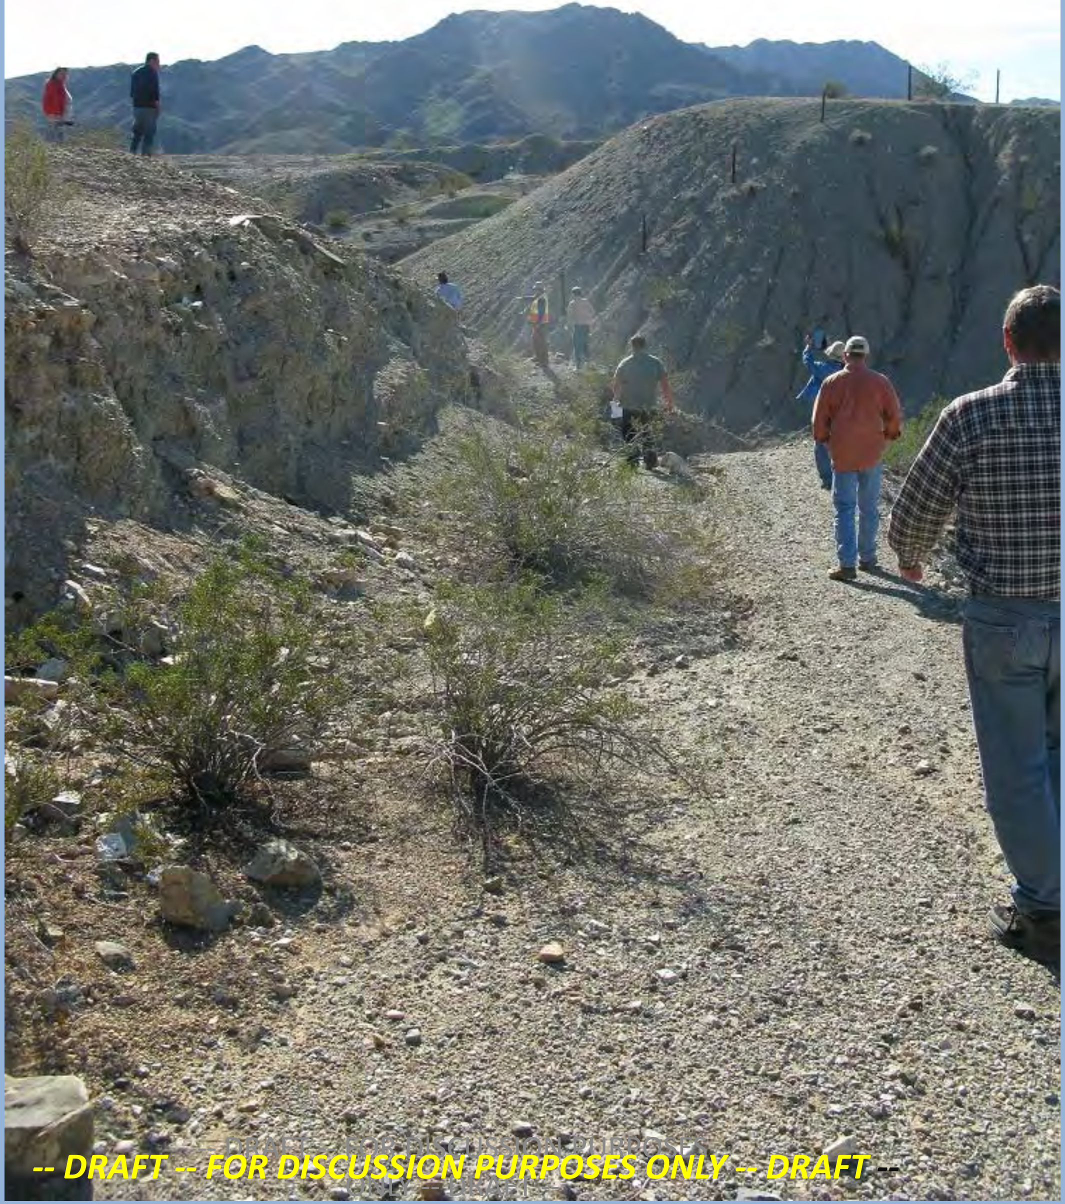
Discussion regarding “Pipeline H”

Access route from Route-66/IRL-3 down into to wash at IRL-4

Pipeline H (to IRL-4)

Pipeline H (to IRL-4)

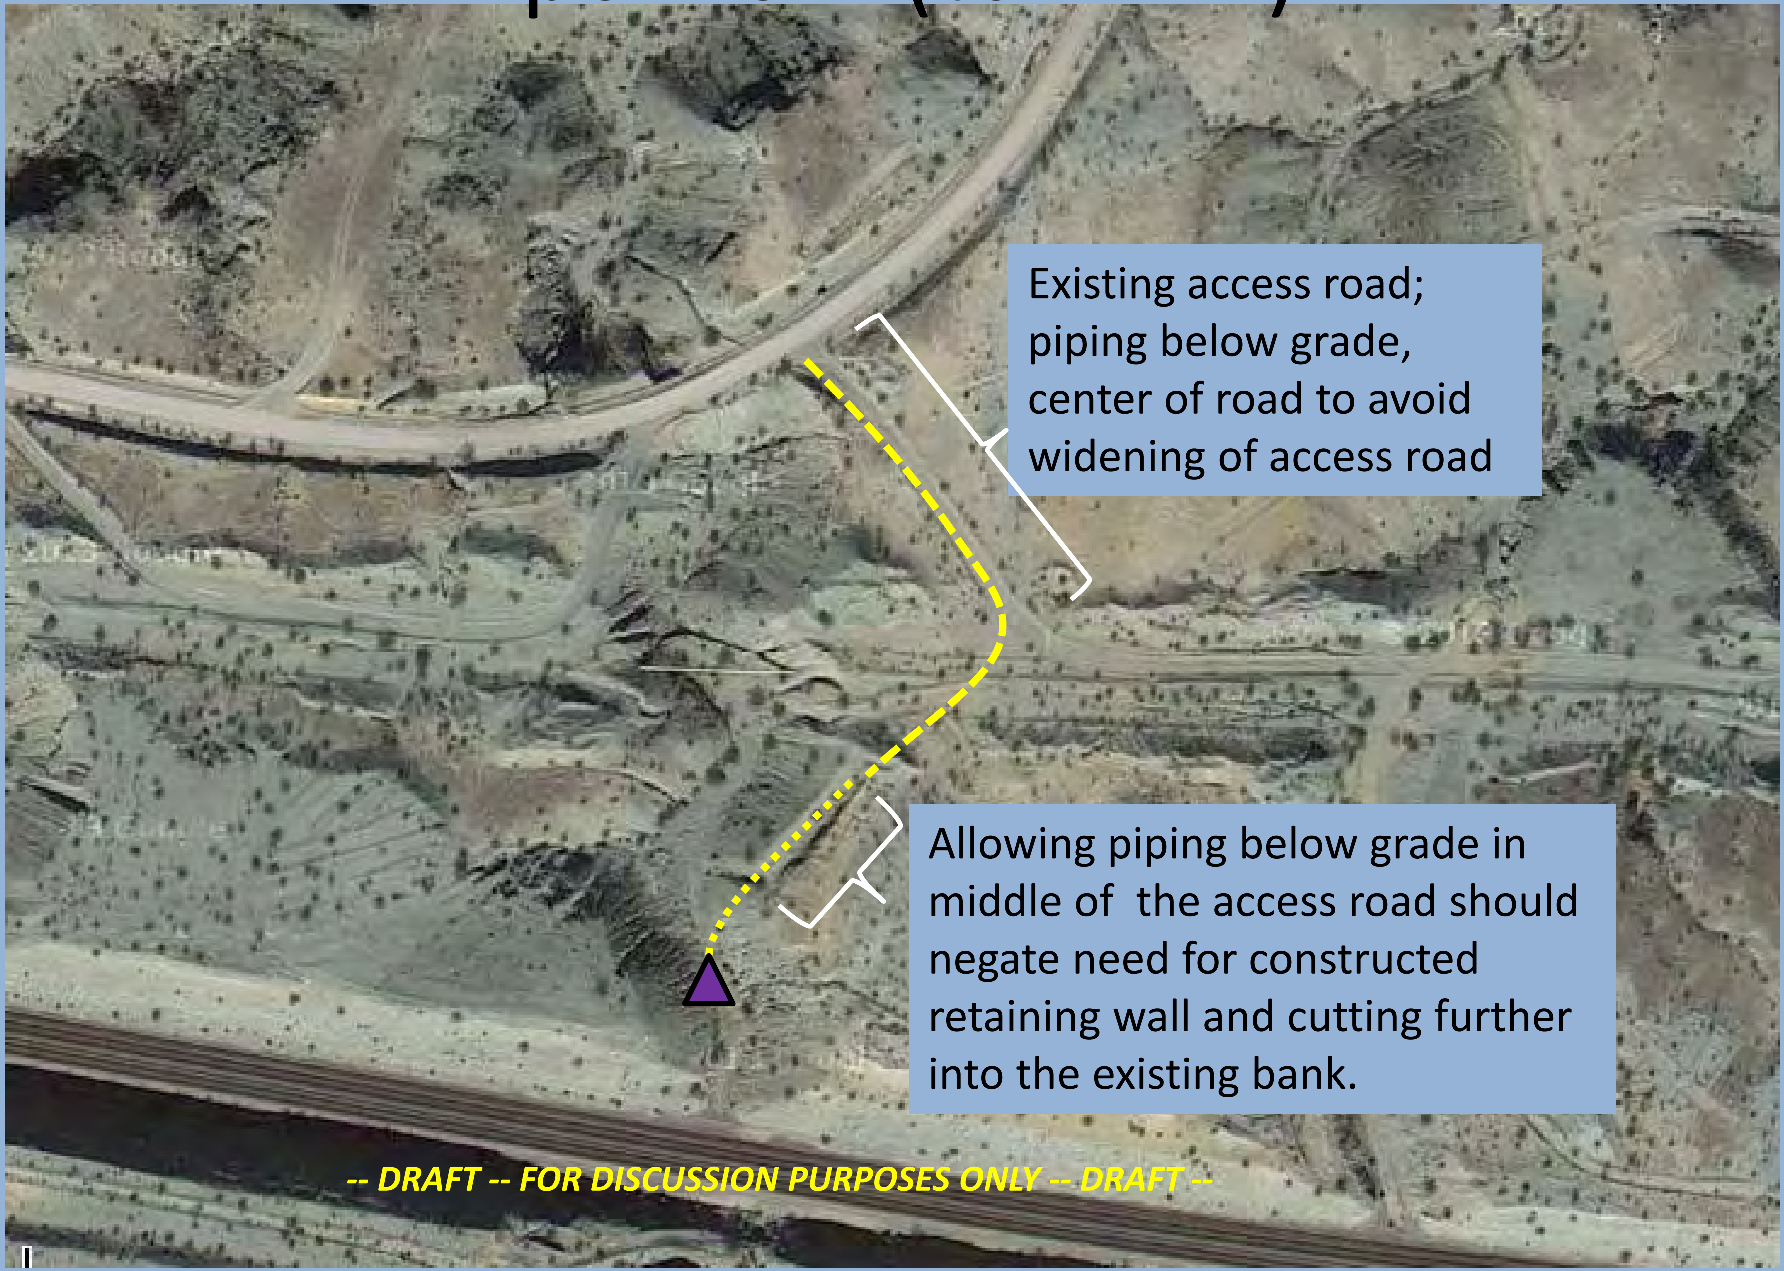
Existing access road portion and bank cut along IRL-4 access route



Simulation of proposed retaining wall along existing bank down to IRL-4

-- DRAFT -- FOR DISCUSSION PURPOSES ONLY -- DRAFT --

Pipeline H (to IRL-4)



Summary of Options for Pipeline H – access to IRL-4

- Existing access road is narrow. Installation of piping to IRL-4 within the center of existing access road should prevent encroachment of the road width into the adjacent landscape.
- Any construction of remaining access road down into wash to IRL-4 should be done along existing pathway using fill only.
- If piping running down to IRL-4 is located within the roadway, this should avoid construction of retaining wall, and minimize width of access and additional encroachment into existing bank.

-- DRAFT -- FOR DISCUSSION PURPOSES ONLY -- DRAFT --

Discussion re Route 66 width/access

In order to limit the potential for bank widening as a result of installing above ground piping along Route 66 between IM-3 and FW-1, options are to:

1) CLOSE the section between IM3 and Park Moabi road. Locked gate at each end, utility crews would need keys for access to existing pipeline(s) installed along south side of roadway.

2) Make the section between IM-3 and Park Moabi road ONE-WAY only. This would negate requirement to widen road to maintain 2-way access along the above ground piping.

COMMENT RESOLUTION PIPELINE SECTIONS A/H: ALTERNATIVE ROUTINGS & COMPONENT DESIGNS
BASIS OF DESIGN REPORT - INTERMEDIATE (60%) DESIGN
PG&E Topock Compressor Station, Needles, California

TECHNICAL COMMENTS OF THE TRIBAL TECHNICAL REVIEW TEAM

PURPOSE

This evaluation has been prepared for tribal consideration and discussion. If there is a consensus among the Tribal representatives that alternatives developed as part of this approach are preferred over corresponding components of the 60% design submittal by PG&E, then the Tribes may want to propose any or all of the recommended alternatives to the TWG.

CONTEXT

This evaluation is based primarily on technical and engineering reviews of the 60% BOD. Additionally there have been several site walks and discussions during the 60% design review and comment period during which the Tribes' technical review team has had the opportunity to view features in the field and to discuss issues with Tribal representatives and form overall impressions. Still, the Tribes' technical reviewers cannot speak to or fully understand the spiritual and cultural impacts of the proposed project. Nevertheless, the reviewers have endeavored to summarize the physical impacts that would be associated with construction of various design options. In particular, the team has noted that the Tribes seem to prefer designs that, to the extent practicable, a) preserve existing natural materials in-place, and b) avoid specific culturally significant areas. In a broader sense, the team understands that the Topock site is, in its entirety, a sacred landscape within the Mojave Valley. This evaluation attempts to emphasize both of these two considerations.

SCOPE

This evaluation provides a design process and design criteria that PG&E should use while developing the 90% design for pipeline sections A & H. Additionally, this evaluation provides analysis of alternative pipeline and electrical infrastructure routings for pipeline Sections identified in the 60% BOD report and design drawings. Alternative routings are presented for Pipeline Sections A and H. Analysis is presented for four segments of Pipeline A, and for Pipeline H:

- Segment 1 Pipeline A (See Figure): MW-20 Bench to Access Road routed parallel to Southwest Gas Pipeline easement north side (600 feet long)
- Segment 2 Pipeline A (See Figure): Access Road to IM-3 Plant along 60% BOD Report alignment
- Segment 3 Pipeline A (See Figure): 60% BOD Report alignment from IM-3 Plant to FW-1
- Segment 4 Pipeline A (See Figure): Alternative II TRC Routing Memo Access Road to IRL-4 Branch Pipeline H
- Pipeline H (See Figure): 60% BOD Report alignment from Pipeline A to IRL-4

DRAFT ONLY – FOR REVIEW AND DISCUSSION ONLY

DESIGN PROCESS AND CRITERIA FOR PIPELINE SECTIONS A & H

Continuing through the present time, stakeholder and particularly Tribal input to the project design has been reactive, rather than collaborative. That is, one party does something and the other reacts. Then, the other party then counter-reacts. This continues until an agreement or impasse is reached. Thus, the process largely becomes piece-meal. Consider that, while the status of the project is being reported as 60% (intermediate design), the potential for having to reroute pipelines with all the attendant considerations of above- vs. below-ground, clearing rights of way, etc. essentially reverts the design to a significantly lesser completion status. To improve this process, it would be better if PG&E would engage in an ongoing collaborative dialogue during preparation of the 90% design. Specifically, we recommend an alternative collaborative approach for pipeline sections A & H, as well as for related infrastructure served by those pipeline sections, e.g., IRL-1 thru IRL-4 and monitoring wells in the vicinity. Basically, this would be a separate process from the current Response to Comment (RTC) process which by design is simply reactive. Not having upfront Tribal involvement in the actual ongoing design decisions is inefficient and unlikely to achieve reasonable resolution of the issues. During collaboration, the respective parties would sit down together in a facilitated setting and discuss the options and jointly craft the parameters of the design. This collaboration should include the agencies throughout the process .

With the above in mind, we recommend the following design criteria for pipeline sections A & H. These criteria should be applied to each and every system and subsystem for pipeline sections A & H.

- Minimize excavation, disturbances, and visual impacts, with areas of greatest sensitivity identified as cultural and spiritual areas identified by Tribes.

Examples of minimization might include but are not limited to:

- Where above-ground power is used, select line routing to minimize access roads, e.g., by installing poles at the margins of existing roadways, so that the poles can be installed and maintained with no need for access roads to minimize further encroachment into the landscape.
- If wells and related infrastructure can be installed in the middle of an existing roadway, that is preferable to constructing new access roads (e.g., IRL-2).
- If small changes in well locations lead to reduced excavation or area of disturbance, make those changes.
- Minimizing infrastructure on the upper mesa areas avoids proximity to culturally sensitive areas as well as visibility from these places of significance.

Segment 1 Pipeline A

DRAFT ONLY – FOR REVIEW AND DISCUSSION ONLY

Options for bringing piping up the slope alongside the existing large-diameter high-pressure Southern California gas pipeline are discussed below. This routing avoids the culturally sensitive area on the south end of Locus B.

Options for Segment 1 Pipeline A

A) Install water piping and electrical on slope, in a buried trench along north side of existing gas line trench	B) Install water piping and electrical on slope, above ground	C) Install piping within 36-42" pipe installed using "direct piping" methods
Structural components include: A1) Concrete boxes at base of embankment, top of embankment for valves, electrical pull boxes. A2) Pipeline and electrical trenches approximately 8.5 wide depth 4 to 6 feet A3) Electrical trench will include red concrete encasement around the high voltage line (approximately 1/2-foot by 1-foot). A4) drainage structures and erosion control may be required over and around vaults and structures. The burial depth would depend on detailed engineering of the slope to provide stable slope and minimize potential for pipe exposure.	Structural components include: B1) <u>structural pipe supports</u> (concrete footings ~10' deep into slope were suggested by CH_2MHill during the 12/27 site walk). With a slope length of approximately 200 lineal feet, supports will be required every 20 feet. B2) <u>access stairway</u> alongside aboveground pipes to allow maintenance and access to piping. Platforms every 40 feet. B3) <u>Drainage structures including:</u> basin/structure at the top of the slope to collect runoff, divert to buried pipes alongside structure, beneath NTH, and to culvert/erosion basin on flood plain B4) Vaults would be needed at either end. B5) discussion on 12/27 site walk indicated that this overall approach would likely require <u>additional cutting into slope on north side of gas line easement</u> in order to fit pipe supports, drainage structures, and access stairway <u>outside of</u> existing gas line easement. B5) Installation of ~40-foot power poles on 100 feet centers going up slope B6) Installation of pipe 2 boxes for Southwest Gas Pipeline Crossing.	Note this is a relatively new method for installing trenchless conduits. This method has been used in only a few projects so far in the US, it has been utilized mainly in Europe. it has not been confirmed with the contractors who do this type of work would be willing to bid on this particular job. (Note: traditional directional drilling does not appear possible due to cobbles & boulders, and the unconsolidated nature of geologic materials in this area.)

Range of estimated soil removed for trenching: Given the assumption of 600 lineal feet and 8.5 feet wide and an average excavation depth of 4 to 6 feet assumptions, <u>potential range of disturbed earth may range between 750 to 1130 cubic yards.</u>	Range of estimated soil removed for approximately 600 lineal feet (200 ft. of slope and an additional 400 ft. to the west of the top of the slope). Footings for structural pipe supports: <u>40 cubic yards</u> Footings for stairway support: Assuming for 4 concrete piers per platform and 2 supports between platform: <u>50 cubic yards</u> Trenching/installation of drainage basin/pipes: <u>80 cubic yards</u> Additional Trenching/installation of drainage beneath NTH, to storm water basin on flood plain: <u>~100 cu yds.</u> Potential excavation into side of existing notch, into in-place bank soils to provide additional room for structures assuming 5 feet width and 3 foot of depth for 200 lineal feet: 110 cubic yards. Total estimated soil excavation: <u>280 cubic yards</u>	Assuming beginning in the flood plain and boring beneath NTH and the existing slope/gas lines and daylighting beyond the top of the slope, approximately 400 west of the top of slope; <u>assuming 42" piping conduit installed: 220 cubic yards</u> The work areas required for mobilization and construction of the 42" conduit would be quite large and damaging, as use of a tunnel boring machine (TBM) requires extensive work area to lay out the equipment and drill string. These drilling cuttings would be mixed with some sort of drilling fluid, so would not be able to be reused on site, at least not without further dewatering, and possible other processing.
Removal/Demo issues: Trench could be dug out to remove piping – either for repair or replacement during the project life, or for decommissioning.	Removal/Demo issues: <u>Above grade structures</u> such as stairway, pipe supports and piping could be removed. <u>Deep concrete footings</u> for these structures could be excavated and removed, but it would be difficult achieve structurally stable soil compacting in the excavations to prevent erosion. <u>Buried drainage pipes</u> could be excavated and removed.	Removal/Demo issues: Once installed, the outer 36-42"casing installed using this method could NOT be removed. Piping running inside the casing could be pulled out for repair, replacement or decommissioning.

SUMMARY EVALUATION for SEGMENT 1, PIPELINE A : These options to the PG&E 60% BOD Report approach offer positive modifications which help avoid specific areas, reduce the length of the infrastructure and overall excavation volume, and avoid much of the upper mesa that would have been traversed for implementation of the original 60% BOD Report approach. One issue that needs to be resolved is that of the right of way associated with the existing gas pipeline. This would determine whether the new pipelines could be placed within the area of the existing disturbance or whether they need to be moved further north into areas where soils have not been previously disturbed.

Option C (direct piping) is not considered viable because it introduces a large, permanent disturbance to the subsurface at the site. In addition, mobilization and work areas required for the construction of the 42" conduit could be quite large and damaging. Also, there is considerable uncertainty associated with viability of this option.

Analysis of the volumes of potentially excavated soils suggests that, although the stairway, pipe rack and drainage (Option B) would create a lot of disturbance, it would still result in a lesser volume of disturbed soil than required to construct the large trench needed piping and electrical. This seems to stay true even if up to 5-feet of the existing bank needs to be cut into to widen existing gas pipeline easement notch. Even if the side bank excavation needed to be wider, the massive dimensions of the anticipated trench (est. 7 to 8.5 feet wide, 4 to 6 feet in depth) still makes the above-grade scenario the lesser of the two with respect to volume of natural soils that would need to be removed. The Tribes may wish to also take into consideration issues related to the potential nuisance associated with public access to the mesa area adjacent to Locus B. The Tribes may wish to recommend omitting the proposed maintenance staircase in favor of alternative ways for personnel to inspect and maintain the pipes. This is supported by the fact that the purpose of the stairway access would primarily be for visual inspection. Significant or frequent "hands on" maintenance would presumably (and hopefully) not be required.

Note that for the segments where there is electrical, this may be conveyed in a trench with the rest of the piping if in a trench, or aboveground using telephone poles. One suggested alternative requires power to the segment between IRL-1 and IRL4 be provided by the City of Needles. The expressed desire of PG&E is that all power for the remedy be provided by the compressor station itself.

Options for Segment 2 Pipeline A (60% BOD Report Routing)		
A) Install Pipeline per 60-% BOD Report design approach Structural components include: A1) Pipeline and electrical trenches approximately 7 to 8.5 wide depth 3 to 4 feet per the basis of design report A2) Northern aerial crossing of Bat Cave Wash A3) Buried electrical lines [[A1=maximum excavation]] [[A2=B2=C2 (aerial crossing same for all]] Range of Excavation for trenching: [[10'*8.5'*4'= 12.6 cu yds 10'*7'*3'= 7.8 cu yds]]	**B) Install water piping below grade and electrical above-grade** Structural components include: B1) Pipeline trenches approximately 6 to 7 wide depth 3 to 4 feet per the basis of design report B2) Northern aerial crossing of Bat Cave Wash B3) Above grade electrical lines and control on poles ~40-foot power poles on average of 100 feet centers B4) Potential for access roads to power poles depending upon location. . The final specific spacing and location of power poles is highly relevant as it directly impacts disturbance related to installation and maintenance of the electric lines. [[B1=A1 LESS electrical trench volume, but adds unknown potential access roads and pole installation auger holes]] Range of Excavation for trenching for comparison: [[10'*7'*4'= 10.4 cu yds (~82% of A1 version) 10'*6'*3'=6.7 cu yds (~85% of A1 version)]]	**C) Install water piping and electrical above-grade. Install guard rail and grade separation structures** Structural components include: C1) structural pipe supports (concrete footings ~2' diameter 6' deep into based by CH2M conceptualizations) spaced 20 feet on center C2) Northern aerial crossing of Bat Cave Wash. C3) Above grade electrical lines and control on poles ~40-foot power poles on average of 100 feet centers C4) Potential for access roads to power poles depending upon location. C5) Installation of W-style guard rail; assumes post imbedded 4 feet every 6 feet.
Range of estimated soil removed for trenching: Given the assumption of 100 lineal feet and	Range of estimated soil removed for trenching and poles: Given the assumption of 100 lineal feet and 6	Range of estimated soil removed for guard rails, supports and poles: Given the assumption of 100 lineal feet:

8.5 feet wide and an average excavation depth of 3 to 4 feet assumption, potential disturbed earth would be 100 cubic yards per 100 feet of pipeline and electrical.	feet wide and an average excavation depth of 3.5 feet assumption, potential disturbed earth would be 70 cubic yards per 100 feet of pipeline and electrical. Disturbance associated with power poles would be less than a 0.2 cubic yards per pole, but does not include access roads for power poles. Aboveground electric lines also eliminates the need for red concrete trench liner mandated for buried electrical lines	Disturbance associated with power poles would be less than 0.2 cubic yards per pole, but this does not include access roads for power poles. Disturbance associated with pipe supports are 3.5 cubic yards per 100 feet. Disturbance associated with guard rail is 1 cubic yard per 100 lineal feet. Greater area may be need to be disturbed if road needs to be widened. [[Should note that a) this caveat may be significant, and b) likely that any road widening would cut into in-place roadside materials, c) closing the Route 66 segment to public traffic should reduce but may not eliminate the need for road widening]]

SUMMARY EVALUATION for SEGMENT 2, PIPELINE A : Above-ground electrical infrastructure would require a lower volume trench excavation, eliminate the need for red-concrete, as compared with the original 60% BOD. Nevertheless, the overall the trench excavation is massive for both Options A & B. If considering the amount of material excavated alone, the above-ground installation (Option C) is much less impactful than either trenching scenario. Other factors regarding the impacts of the above-ground scenario that should be considered by the Tribes include that the placement of power poles, above-ground pipe supports, guard rails, and multiple access roads (to power poles). Collectively, these could result in more encroachment onto the undisturbed landscape. The largest unknown factor will be the degree and location where the road may need to be widened to accommodate both vehicle traffic and the aboveground alignment of pipe supports, guard rail, and power poles.

Options for Segment 3 Pipeline A

A) Install Pipeline per 60% BOD Report	B) Install water piping below grade and electrical above-grade	C) Install water piping and electrical above-grade. Install guard rail and grade breaks.
Structural components include: A1) Pipeline and electrical trenches approximately 7 to 8.5 wide depth 3 to 4 feet per the 60% BOD Report A2) Buried electrical lines Range of Excavation for trenching: [[10'*8.5'*4'= 12.6 cu yds 10'*7'*3'= 7.8 cu yds]]	Structural components include: B1) Pipeline trenches approximately 6 to 7 wide depth 3 to 4 feet per the basis of design report B2) Above grade electrical lines and control on poles ~40-foot power poles on average of 100 feet centers. The final, specific spacing and location of power poles is highly relevant as it directly impacts disturbance related to installation and maintenance of the electric lines. B3) Potential for access roads to power poles depending upon location Range of Excavation for trenching for comparison: [[10'*7'*4'= 10.4 cu yds (~82% of A1 version) 10'*6'*3'=6.7 cu yds (~85% of A1 version)]]	Structural components include: C1) <u>structural pipe supports</u> (concrete footings ~2' diameter 6' deep into based by CH2M conceptualizations) spaced 20 feet on center C2) Above grade electrical lines and control on poles ~40-foot power poles on average of 100 feet centers C3) Potential for access roads to power poles depending upon location. C4) Two grade separation structures for access across pipeline (could be above or below grade. Above grade would require pipe bridge for vehicle access across. Below grade would include two pipe vaults and underground trench between vaults) C5) Installation of W style guard rail; assumes post imbedded 4 feet every 6 feet. Road widening could result from detailed engineering of guard rail system and additional area of disturbance.
Range of estimated soil removed for trenching: Given the assumption of 100 lineal feet and 8.5 feet wide and an average excavation depth of 3 to 4 feet assumption, potential disturbed earth would be 100 cubic yards per 100 feet of pipeline and electrical.	Range of estimated soil removed for trenching and poles Given the assumption of 100 lineal feet and 6 feet wide and an average excavation depth of 3.5 feet assumption, potential disturbed earth would be 70 cubic yards per 100 feet of pipeline and electrical. Disturbance associated with power poles would be less than a 0.2 cubic yards per pole, but does not	Range of estimated soil removed for trenching and poles Range of estimated soil removed for guard rails, supports and poles Given the assumption of 100 lineal feet. Disturbance associated with power poles would be less than a 0.2 cubic yards per pole, but does not include access roads for power poles. Disturbance associated with pipe

DRAFT ONLY – FOR REVIEW AND DISCUSSION ONLY

	include access roads for power poles.	supports are 3.5 cubic yards per 100 feet. Disturbance associated with guard rail is 1 cubic yard per 100 lineal feet. Greater area may be need to be disturbed if road needs to be widened.
Removal/Demo issues: Above grade structures panels could be removed. Buried pipes and electrical conduit could be excavated and removed. Area would need to be backfilled with appropriate material. Dyed concrete would require removal.	Removal/Demo issues: Above grade structures panels, power poles could be removed. Buried pipes and pole footings could be excavated and removed. Area would need to be backfilled with appropriate material	Removal/Demo issues: Above grade structures panels, pipe, pipe supports, power poles, and guard rails could be removed. Pipe support and pole footings could be excavated and removed. Area would need to be backfilled with appropriate material

SUMMARY EVALUATION for SEGMENT 3, PIPELINE A: Although above-ground electrical infrastructure would result in a lower volume trench excavation, eliminate the need for red-concrete, overall, the trench excavation is massive for both Options A & B. If considering the amount of material excavated for trenching alone, the above-ground installation (Option C) appears much less impactful than either trenching scenario.

However, this section of Route 66 is generally narrow, and in many places bordered by a drop off, or a several-foot high cut slope/embankment. These features were likely created when the original Route 66 roadway was cut into the landscape. Therefore, along this segment, the width of the roadway is constrained on both sides by topographic changes, and also by the buried relatively small-diameter Southwest Gas pipeline which runs along the south side of the road. The present width of the roadway is probably narrower than the original roadways as a result of the emplacement of the thick layer of aggregate that PG&E has placed on top of the road to protect the road bed.

To allow for the installation of above-ground pipes and protective guard rails, PG&E has stated that, along some portions of this segment, the road must be widened to allow for the above-ground infrastructure in conjunction with 2-way public traffic. It has been indicated that this would be required by the County of San Bernardino since this is a "public road." Unfortunately, the degree to which additional slope cuts would be necessitated to accommodate above ground piping has not been evaluated since this alternative was not part of the 60% design. Any expansion of the original roadway cuts could result in large volumes of native materials being excavated, and also significant changes in the topography along the roadway. This represents the largest unknown factor since there is no specific design to indicate the degree and location where the road may need to be widened to accommodate both vehicle traffic and the aboveground alignment of pipe supports, guard rail, and power poles.

Other factors that the tribes may wish to consider regarding the impacts of the above-ground scenario include that the placement of power poles, above-ground pipe supports, guard rails, and multiple access roads (to power poles) could collectively result in more encroachment onto the undisturbed landscape.

It may be difficult for the Tribes to be able to weigh the various options when there remains so much uncertainty as far as how a given option will be implemented at this point in time. However, it may be possible to provide a set of construction and/or design constraints which could be used to move the design forward along this segment, while limiting potential damage:

- Since additional slope cuts would be required, mainly due to road width requirements, anything that would reduce the required width could also limit further potential road cuts. There have been two suggestions, 1) to close this road from just west/south of IM-3 out to Park Moabi road. This would mean locked gates at each end. PG&E voiced significant concerns regarding access to this route as there are various maintenance crews which inspect/work on the gas lines and require access. This may be addressed by an automated gate such that any service crews would need to get out of the vehicle to lock or unlock the gate. 2) a simpler suggestion may be to simply make this road 1-way from IM-3 out to Park Moabi road. This should result in a narrower road width requirement, which could hopefully mean little or no additional road cuts in the existing slopes.
- The Tribes could request that, when designing the short access roads, such as up to IRL-2, only fill material be used, and no additional excavation or road cuts be made to the extent possible.

Tribal Option for Segment 4 Pipeline A

A) Install water pipeline above-grade and electrical above-grade from top of slope at east end to pipeline section H; control via radio. (The route in the existing 60% BOD Report follows existing Route 66 alignment all the way out to NTH, bisecting the southern portion of Loci B, and the approach is to put everything underground.) Structural components include: A1) Concrete valve boxes (vaults) at underground crossings of gas lines or access roads. A2) Pipeline supports spaced on 20 foot centers A3) Two pipeline bridges, one 330 feet across Bat Cave Wash, one 280 feet east of Bat Cave Wash A4) One grade separation structure west of Bat Cave Wash		
Range of estimated soil removed for Bat Cave Wash bridge: The western bridge landing based on conversations on 12/27/13 in the field would require removal of part of a slope on the southern side of the Southern California Gas Company pipeline easement to provide separation from the pipeline. Soil removal amounts would be in the hundreds of cubic yards but detailed engineering would be necessary to evaluate.		

Removal/Demo issues: Above grade structures such as bridges, pipe supports and piping could be removed. Deep concrete footings for bridge structures may be left in place or removed by breaking and removing concrete and digging out footings. Grade would be restored by installation of backfill in the footings.		

SUMMARY EVALUATION for SEGMENT 4, PIPELINE A: While this is listed as single-option segment, there is another option that could be followed, with above-ground infrastructure, the proposed 60% BOD Report pipeline section A alignment from the western end of Segment 1, discussed above, to the eastern end of Segment 2, also discussed above. We provide this option, because it will likely be less-intrusive, visually. If City of Needles' power is used for IRL-1 thru IRL-4 and FW-1, there would be no power poles along this segment. If PG&E provides its own power, power poles would be required. One pipeline bridge would be eliminated, and the Bat Cave Wash pipeline bridge would be moved to a lower elevation and farther to the north. We anticipate that considerably less excavation and ground disturbance would be required. PG&E would likely need to close the road or convert it to one-way traffic in order to fit the above-ground infrastructure onto the edge of the existing roadway.

Options for connection of groundwater pipelines from IRL-3 to IRL-4. The 60 % BOD Report alignment is along a narrow access road that has culturally sensitive land on each side, so it is imperative to prevent additional disturbance which would be caused by widening the access road. A buried pipeline and conduits through this section would minimize the footprint in this area.

Options for Pipeline H		
A) Install Pipeline and electrical based on 60-% BOD Report design but aligned in the center of the existing access road and the newly extended road to IRL-4 Structural components include: A1) Buried electrical and control conduits and water pipelines from IRL-3 to IRL-4 A2) Pipeline and electrical trenches approximately 7 feet wide depth 3 to 4 feet A3) Electrical trench will include red concrete encasement around the high voltage line (approximately 1/2-foot by 1-foot). A4) Grading of access road from mesa to IRL-4 location, using existing cut slope. This alternative would be attractive if the retaining wall going to IRL-4 could be eliminated and the trench could be installed in the new access road that would be constructed down to IRL-4.	**B) Install Pipeline and electrical based on 60-percent BOD design but aligned in the existing access road and transition to above-grade along the newly extended road to IRL-4. Install retaining wall along access road.** Structural components include: B1) Buried electrical and control conduits and groundwater pipelines from IRL-3 to new access road to IRL-4 B2) Above ground-electrical and control conduits and groundwater pipelines along new access road to IRL-4. B3) structural pipe supports (concrete footings ~2' diameter 6' deep into based by CH2M conceptualizations) spaced 20 feet on center B4) Above-ground electrical lines and control on poles ~40-foot power poles on average of 100 feet centers B5) Installation of W style guard rail; assumes post imbedded 4 feet every 6 feet. Road widening would probably result from detailed engineering of guard rail system and additional area of disturbance. B6) Install approximately 90 feet of retaining wall, cut back undisturbed slope approximately 6-8 feet.	

DRAFT ONLY – FOR REVIEW AND DISCUSSION ONLY

Range of estimated soil removed for trenching: Given the assumption of 100 lineal feet and 7 feet wide and an average excavation depth of 3.5 feet assumption, potential disturbed earth would be 90 cubic yards per 100 feet of pipeline and electrical.	Range of estimated soil removed for trenching: For the below grade section given the assumption of 100 lineal feet and 7 feet wide and an average excavation depth of 3.5 feet assumption, potential disturbed earth would be 90 cubic yards per 100 feet of pipeline and electrical. The retaining wall would take a minimum 200 cubic yards of disturbance, approximately double the volume of disturbance resulting from the buried pipeline.	
Removal/Demo issues: Trench could be dug out to remove piping and dyed concrete.	Removal/Demo issues: <u>Above grade structures</u> panels, pipe, pipe supports, power poles, and guard rails could be removed. Retaining wall would not likely be removed since it would protect the access road to IRL-4. If road removed then the wall could be re-contoured and re-vegetated. <u>Pipe support and pole footings</u> could be excavated and removed. Area would need to be backfilled with appropriate material	

SUMMARY EVALUATION for SEGMENT H: The narrow width of the existing one-lane access road, and existing embankment where road would be built to provide access down to IRL-4 does not appear to allow for both vehicle access and above grade piping and supports. The additional width would also require a retaining wall on the existing cut slope, and more slope cutback to provide safe wide enough access for field vehicles. It appears clear that the Tribes may wish the foot print of activity in this area to remain strictly constrained to the existing dirt road, therefore, in this instance placing the water pipes in the center of the access road for segment H may be preferable in order to prevent additional encroachment in this area.

Re: Fort Mojave Indian Tribe Comments on Alternative Pipeline Routings and Proposed Soil Storage/Staging Areas for the Topock Compressor Station 60% Groundwater Remedy Design

Dear Mr. Yue and Ms. Innis:

Hargis + Associates, Inc. ("H+A"), on behalf of and at the request of its client, the Fort Mojave Indian Tribe ("the Tribe" or "FMIT"), is hereby providing this letter regarding the Tribe's review of alternative pipeline routings for the Topock Compressor Station 60% groundwater remedy design (Enclosure A).

As you are aware, these alternative routings have been the subject of discussion at recent meetings of the Technical Working Group ("TWG") and, most recently, the FMIT along with representatives of the Hualapai, Colorado River Indian Tribes, and Cocopah, performed a site walk on February 21, 2014, during which tribal representatives and their technical consultants conferred on the acceptability of these various alternatives. The FMIT was represented by nine Tribal members including a member of Tribal Council. Afterwards, the FMIT members conferred and completed the enclosed matrix providing the Tribe's position on each of the various segments along the pipeline route (Enclosure A). This information is being provided as the Tribe's final comments on the 60% design, with the understanding that you will be directing the Pacific Gas & Electric Company ("PG&E") to take this information into consideration during the preparation of the 90% Basis of Design. The matrix also assumes that any construction or deconstruction would be done in the least impactful manner and in consultation with the Tribe.

Additionally, the Tribe is also presenting herein its position on the various staging and soils storage areas proposed by PG&E (Enclosures B & C). Please find an attached matrix addressing those preferences. Please note that on the matrix, there are several sites for which the Tribe has outstanding questions. Therefore, before the Tribe can determine the final acceptability of these sites, answers to these questions need to be provided to the Tribes.

Finally, the Tribe wishes to add that the comments and preferences as expressed herein do not in any way constitute an endorsement or acceptance of the design as originally presented or as potentially modified by these alternatives. For as you have repeatedly been made aware, many of the adverse impacts associated with this project are permanent and irreversible.

Thank you in advance for consideration of these comments. Please contact me if you have further questions.

Sincerely,

HARGIS + ASSOCIATES, INC.

FMIT PIPELINE SEGMENT ANALYSIS

PIPELINE SEGMENT ANALYSIS

PIPELINE POINTS (Segment Description)	**ABOVE/BELOW GROUND**	**CONDITIONS OF USE COMMENTS**
A TO B (NTH near MW20 Bench, access upslope to top of slope, adjacent to the SoCal pipeline easement)	NEITHER	After much review and consideration, there does not seem to be either an above- or below-ground alternative for this segment that appears acceptable. Assuming it will not be possible to intrude into the easement, instead, use the "C to B" segment for piping alignment
C TO B (Entrance along NTH, along road south of Locus B; to top of slope, across from MW20 bench)	Below	Although above-ground is generally preferred, the narrowness of the roadway along this segment makes it unlikely the piping could be placed above ground with sufficient road access without making significant cuts and disturbance into the in-place geologic materials alongside this road segment. Note this segment of road runs through a large cultural area on either side, therefore no additional disturbance, outside of the present-day existing roadway, should be made. 1) No additional cuts would be made into the banks on either side of the roadway. 2) Existing slopes would not be disturbed. 3) No activity, storage or personnel activity should extend beyond the current roadway. This includes the slopes adjacent to the existing road. All below ground piping will be removed after remedy completion.
B TO D (Section of dirt access road from top of slope west to Bat Cave Wash)	Above	Given the wide road access along this segment, above-ground piping could be installed. 1) Construction activity, storage and personnel activity should be limited to the roadway to the extent possible to minimize encroachment into the areas adjacent to the existing road.
D TO E (Continuing along access road, along the east side of Bat Cave Wash to where road crosses wash near IM-3)	Above	1) Construction activity, storage and personnel activity should be limited to the roadway to the extent possible to minimize encroachment into the areas adjacent to the existing road.
E TO F (From Bat Cave Wash crossing, along Route 66 westward past IM-3 to IRL-3)	Above	Above-ground installation is preferred. 1) No additional cuts would be made into the banks on either side of the roadway. 2) Existing slopes would not be disturbed.

PIPELINE SEGMENT ANALYSIS

PIPELINE POINTS (Segment Description)	**ABOVE/BELOW GROUND**	**CONDITIONS OF USE COMMENTS**
F TO G (From IRL-3 along single land dirt access road, down into wash and location of IRL-4.)	Below	This short section from IRL-3 to IRL-4 in the wash is along a narrow, one-lane access road. The narrow width of the existing one-lane access road, and existing embankment where road would be built to provide access down to IRL-4 does not appear to allow for both vehicle access and above-ground piping and supports. While above-ground installation is preferred where possible, placing the injection well piping below-ground along this segment should constrain disturbance to the foot print of the existing roadway 1) Activity and construction in this area to remain strictly constrained to the existing dirt road. 2) Construction of the roadway down into the wash for IRL-4 should consist of fill placement, rather than any additional cut, to the extent possible. 3) All below ground piping will be removed after remedy completion.
F TO H TO I (From IRL-3, west along Route 66 to FW-1)	Above	Above ground installation is preferred. 1) No additional cuts would be made into the banks on either side of the roadway. 2) Existing slopes would not be disturbed.

Re: 60% Pipeline Alternatives and Soils / Staging Matrices

Dear Mr. Yue:
On behalf of the Hualapai Tribe, we appreciate being able to discuss pipeline alternatives as presented in various meetings and consultative group walks regarding the 60% Basis of Design for the Topock Remediation Project. As you are aware, the Hualapai along with other Tribal representatives met at Topock on February 21st, 2014 to visit and discuss alternative pipeline routings for the 60% groundwater remedy. Hualapai tribal representatives and two Hualapai Tribal Council members were present during this meeting. After the meeting it was agreed that a pipeline matrix and soils staging area table would be sent to interested tribes that included tribal comments wile in the field.

In this letter we formally present Hualapai's comments regarding pipeline alternatives and soils / staging areas considered by Pacific Gas & Electric for the 90% Basis of Design. Even though we are aware that the groundwater remedy infrastructure is creating permanent and irreversible cumulative negative impacts, both spiritually and to the cultural landscape at Topock, we are confident that PG&E will do everything in their power to remove all infrastructure components (whether or not pipelines are placed above or below ground) five years after all remediation activity ceases.

Figure 1 below, shows pipeline alternatives with Table 1 documenting comments from Hualapai. Regarding Table 2, below, this table has tribal responses that were solicited on January 14, 2014. It also has comments and questions regarding several areas visited on February 21st. Perhaps we can discuss these at the March 14th CHPMP meeting with BLM. There is one outstanding soils location (#20) that still requires visitation. Perhaps we can do this on March 14th, 2014 (CHPMP meeting with BLM, in the morning followed by visit to Topock), when we will be out at Topock.

We appreciate our on-going consultations and collaborations with the Topock Remediation Project and look forward to meaningful dialogue through-out the up-coming years. If you have any concerns please feel free to contact myself, or Dawn Hubbs, Program Manager and we will be happy to assist you.

Sincerely,

Loretta Jackson-Kelly

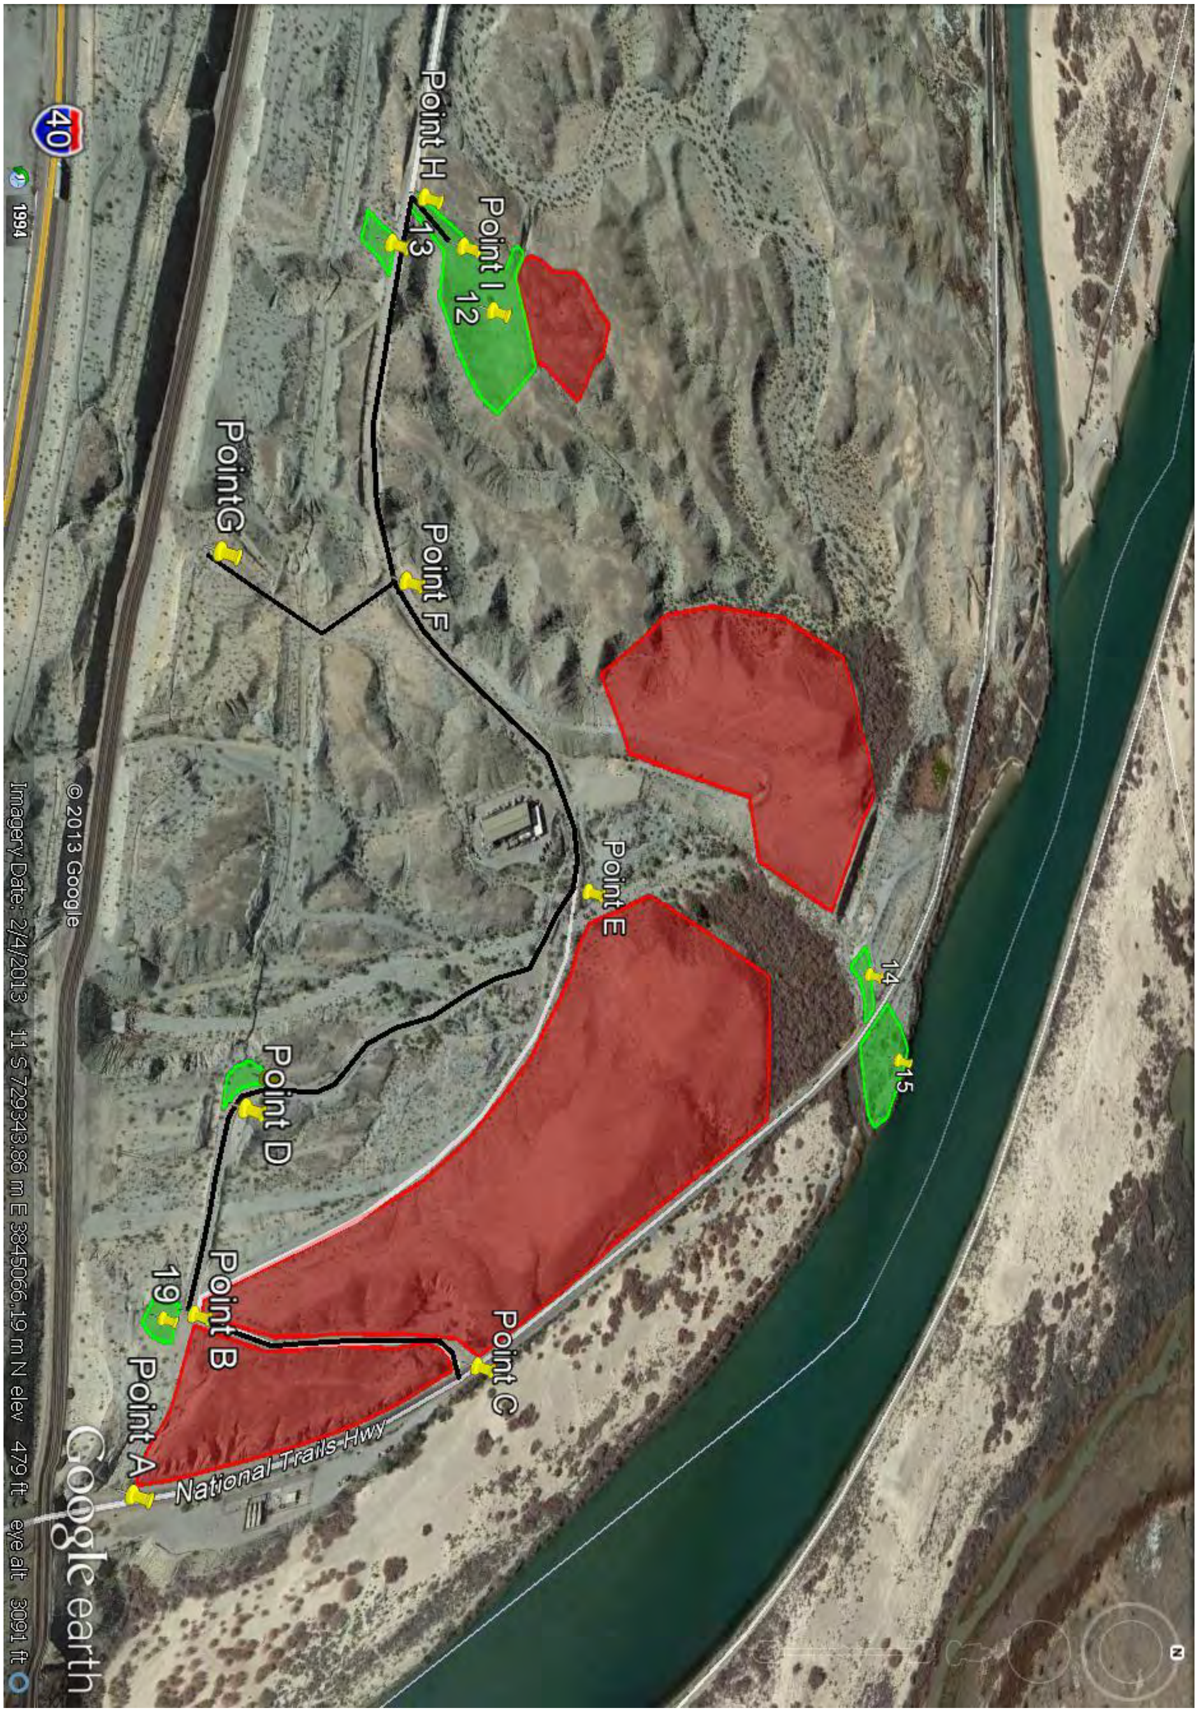

Figure 1: Red Areas = Cultural Sites - Green Areas = Soils Staging Areas - Black Line = Pipeline

Table 1: Hualapai Department of Cultural Resources Pipeline Points and Comments

PIPELINE POINTS	ABOVE/BELOW GROUND	CONDITIONS OF USE COMMENTS
A TO B	**Neither.** Hualapai do not want to see this alternative used at all.	Hualapai do not want this segment of the pipeline to be used. There is significant damage to this area (which is not being refurbished or maintained for erosion and run-off) and this segment would cause more damage. It would also impact a multi-component archaeological site. Avoidance is recommended.
B TO C	**Below Ground**	The segment is in an existing road. Please go in the center of the road, no additional widening or slope cutting due to cultural materials on the upper slopes. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.
B TO D	**Above Ground or Below Ground**	The segment is in an existing road. Please go in the center of the road, no additional widening or slope cutting. Soils location 19 is near this segment. We would prefer that this segment not utilize location 19 as there is a point west and down the road that would be preferable for staging. See Table 2. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.
D TO E	**Above Ground or Below Ground**	The segment is in an existing road. Please go in the center of the road, no additional widening or slope cutting. Cultural materials are in this vicinity. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance

		levels of Chrome VI.
E TO F	**Above Ground or Below Ground**	The segment is in an existing road. Please go in the center of the road, no additional widening or slope cutting. Prefer minimal bridge construction considerations. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.
F TO G	**Below Ground**	This is a very small area without a lot of room. There is an archaeological site (CA-SBR-11939) in this area and there is a plan to put IRL3 in this vicinity also. There is going to be a great deal of activity in this small area, so we request cultural clearances with tribal monitors in attendance, prior and during this segment's construction phase. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.
F TO H TO I	**Above Ground**	This area is very close to cultural materials. Prefer that there be no additional widening of the existing road. We request cultural clearances with tribal monitors in attendance, prior and during this segment's construction phase. There is a plan to put FW1 near this location also. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.

Re: 60% Pipeline Alternatives and Soils / Staging Areas

Dear Mr. Yue/Ms. Innis:

The Cocopah Indian Tribe appreciates the opportunity to provide comments and discuss the 60% Pipeline Alternatives and Soils / Staging Areas.

The Cocopah Indian Tribe along with council members and representatives from other interested tribes, visited the Topock area on February 21, to view and walk the Soil Staging areas proposed by PG&E and the alternative pipeline route for the Topock Compressor Station 60% groundwater remedy design. During this meeting and site walk, it was agreed that a table and map illustrating the staging and pipeline route would be produced and used to provide comments regarding the staging areas and pipeline route.

Attached you will find Cocopah's comments regarding the Pipeline route and Staging areas. The attachments are as follows:

- Figure 1 is a map illustrating the Staging areas and Pipeline
- Table 1: Cocopah Comments regarding Pipeline Points
- Table 2: Cocopah Comments regarding Soils Staging / Construction Areas

If you have any questions feel free to contact me at: Cell: 928-287-5042 or Office: 928-627-4849, or by email at CocopahTPM@Gmail.com

Thank you

Edgar Castillo
Cocopah Indian Tribe
Topock Project Manager

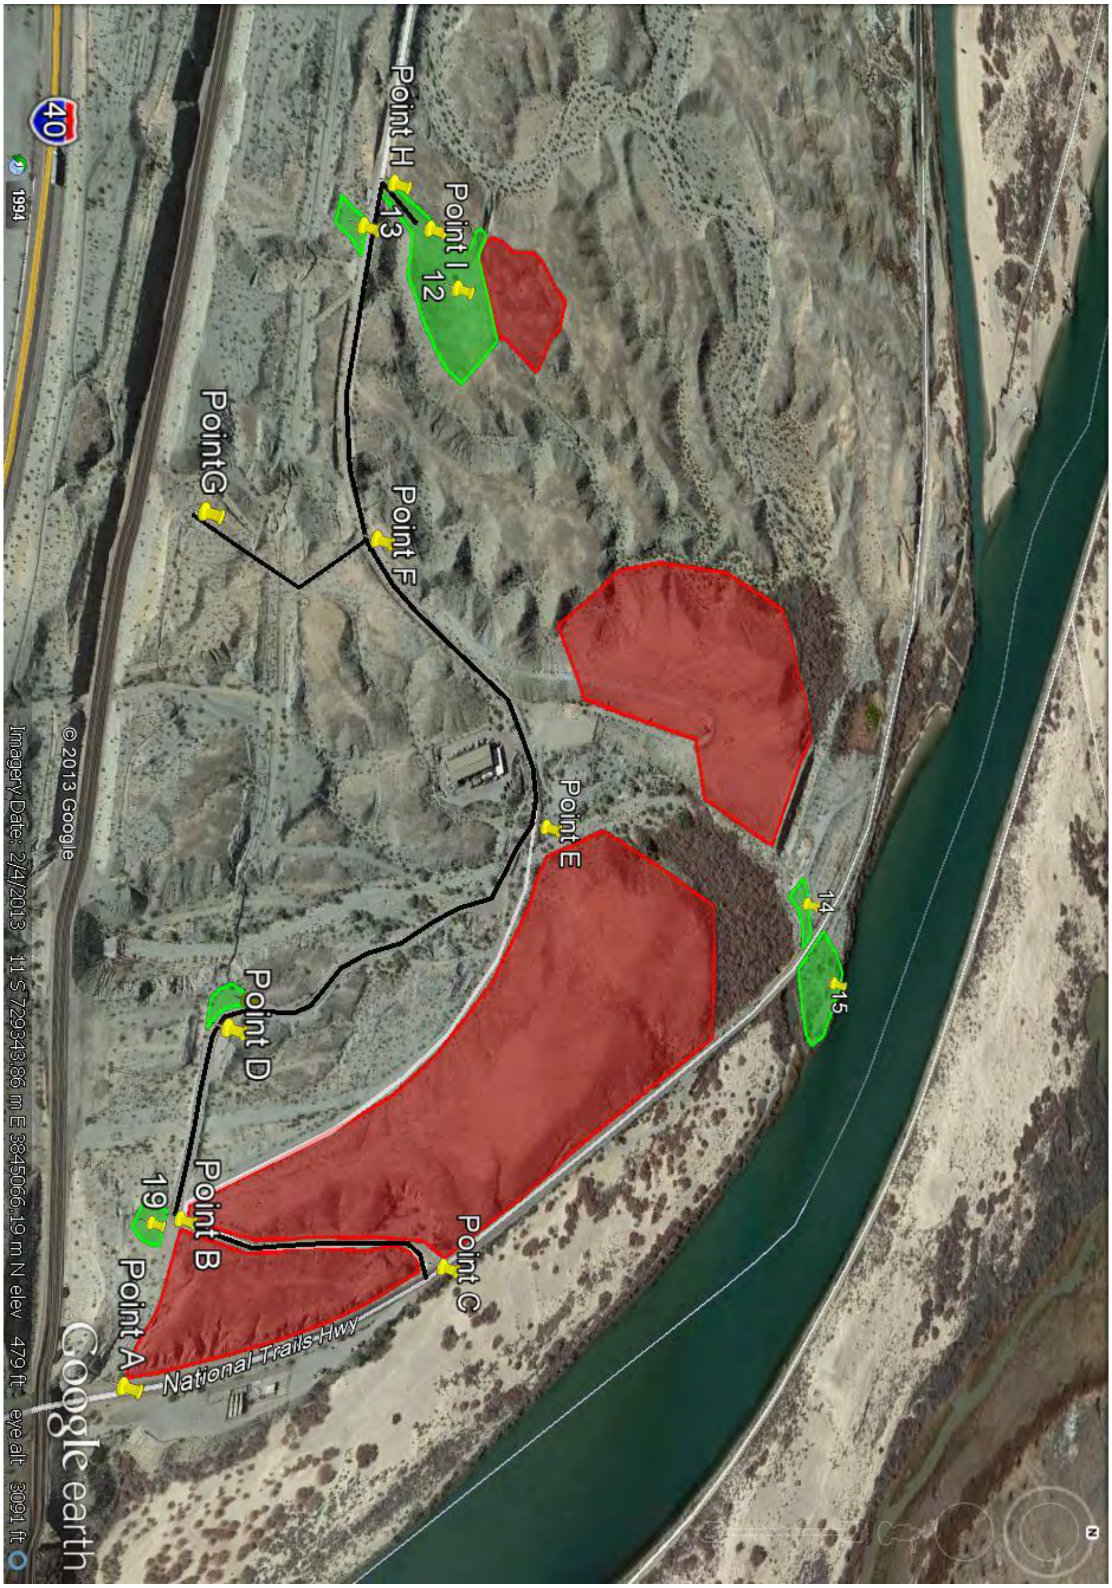

Figure 1: Red Areas = Cultural Sites
Green Areas = Soils Staging Areas
Black Line = Pipeline

Table 1: Cocopah Comments on the Pipeline Points

PIPELINE POINTS	ABOVE/BELOW GROUND	CONDITIONS OF USE COMMENTS
A TO B	Neither	Tribe's conclusion is that this is not an acceptable route for the pipeline. It is noted that there is significant damage to this area and this pipeline segment would cause more damage. The tribe recommends that this area be avoided.
C TO B	Above/Below	This segment intersects a large Cultural Resources Area. Any additional widening or cutting into the sides of the road is to be avoided as to not cause any damage to the cultural materials present on the slopes. All activity including staging, storage or personnel would be strictly limited to the roadway. Piping should go in the center of the existing roadway. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
B TO D	Above/Below	This segment is in an existing roadway. All activity including staging, storage or personnel would be strictly limited to the roadway. Piping should go in the center of the existing roadway. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
D TO E	Above/Below	This segment is in an existing roadway. All activity including staging, storage or personnel would be strictly limited to the roadway. Piping should go in the center of the existing roadway. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
E TO F	Above/Below	This segment is in an existing roadway. All activity including staging, storage or personnel would be strictly limited to the roadway. Piping should go in the center of the existing roadway. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
F TO G	Above/Below	This is a small area that contains archaeological site CA-SBR-11939. Cultural clearances with tribal monitors are requested, prior to and during construction. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
F TO H TO I	Above/Below	This area is very close to cultural materials. Cultural clearances with tribal monitors are requested, prior to and during construction as with the previous point. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.

Table 2: Cocopah Comments on the Soils Staging / Construction Areas

Subject: Comments on Noise/ Vibration and Pipeline Routing

Mr. Yue, the Colorado River Indian Tribes will not be submitting further comment for the 60% Design phase on the Noise and Vibration issues nor on the Pipeline Routing issues at this time. We have participated in the discussions of those issues, and are satisfied the DTSC, DOI and PG&E have heard our concerns directly, and through the other Tribal comments. We will consider adding further input as the design process moves forward.
Thank you for your efforts in this regard. db

Attachment B: RTC# 2

Info for the Refuge's Appropriate Use Analysis/Compatibility Determination

Information for the Refuge's Appropriate Use Analysis and Compatibility Determination (AUA/CD)	
Items listed in DOI's October 23, 2008 letter *"PG&E Topock Compressor Station Remediation Site – Evaluation of Attainment of Fish and Wildlife Service Location-Specific ARARs for the Proposed Remedial Alternatives"*	**Action (60% Design Report Compliance Status)**
What the proposed actions/ facilities are – including specifics (such as how many wells, the spacing of wells, detailed sizes/lengths of facilities, etc.)	The 60% design was submitted to DOI on April 5, 2013. Section ES. 3 and Table ES-1 (Summary of Engineering Design Parameters and Key features) of the 60% BOD report provide an executive summary and high level description of the remedy features (wells, pipelines, supporting systems and utilities, structures/buildings, access roads, etc.) including references to specific report figures that show the locations of these features. Detailed descriptions of the remedy features are provided throughout the BOD report, specifically: • Section 3.2 describes the in-situ remediation system and its configuration including the IRZ wells, the Riverbank extraction wells, the Inner Recirculation Loop wells, the TCS Recirculation Loop wells, the Freshwater injection wells, and the associated pipeline alignment. • Section 3.3 describes the source of freshwater, the pre-injection treatment system, and freshwater piping conveyance including storage. • Section 3.4 describes the remedy-produced water management system. • Section 3.5 describes the utilities and other supporting facilities including power supply, SCADA, and structures/ buildings to support the remedy. • Section 3.6 describes the monitoring network/wells. • Section 5 describes the ICs which are also required components of the remedy.
Where the use would be conducted – including specific areas of use, habitat types and acres, key wildlife species that occur there, proportion of refuge or habitat type involved, and other areas affected incidental to use – provide in site maps	Section 2.4 (Other Site Conditions Affecting Design) of the 60% BOD report describes the baseline site conditions that affect remedy design. Among the documented conditions related to ecological resources at the site are surface water and wetlands, vegetation communities, special status plants, and special status wildlife, avian, and aquatic species. A series of maps were provided in Section 2.4 that overlays the remedy features on surveyed ecological resources – notably Figure 2.4-5 (Jurisdictional Waters and Wetlands), Figure 2.4-9 (Vegetation Communities), Figure 2.4-10 (Habitat of Desert Tortoise Species), and Figure 2.4-11 (Indigenous Plants of Traditional Cultural Significance). Updates to these site maps will be included in the 90% design. In addition, an additional map will be prepared to reflect the survey results for arrowweed and lycium conducted in response to 60% design comment #311 DOI-140.

When the use would be conducted—including time of day and year; duration of use; and a timeline of implementing, performing/ maintaining, and closing out the actions/facilities	An estimated project schedule is included in Exhibit 7.5-1 of the 60% BOD report. Exhibit 7.5-1 provides an estimated timeline for implementing the remedial action through remedy start-up and start of full remedy operations (anticipate end of 2017). Consistent with the CMS/FS and Agencies Decision Documents (ROD, Statement of Basis), it is anticipated that this remedy could require 30 years of operations on refuge lands. Per the November 20, 2013 State Water Resources Control Board letter, monitoring on refuge land will be required in order to demonstrate that the water quality objective for arsenic in the receiving groundwater is met "within the earlier of (i) 20 years after achieving the remedial action objective for chromium or (ii) 20 years after ceasing injection of the water containing naturally occurring arsenic at concentrations above the water quality objective." After the remedial action is complete, the remedy facilities will be decommissioned. An updated project schedule will be included in the 90% design and the future Remedial Action Work Plan.
How the use would be conducted—including techniques and equipment used, the number of people involved, routine operation and maintenance procedures	O&M procedures are described in Volume 1 of the Draft O&M Manual (Appendix L of the 60% BOD). Additional details will be provided for O&M of the freshwater supply in the 90% design, after a freshwater water well site is selected for the remedy. Additional details related to construction of the remedy will be included in the future Remedial Action Work Plan.
What would be the anticipated impacts—identifying and describing the impacts; citing available sources of information (plans, environmental assessments, narratives, research, state plans, field experience, consultation with others); distinguishing between long-term and short-term impacts; documenting direct, indirect, and cumulative impacts on refuge resources	Section 2.4 (Other Site Conditions Affecting Design) of the 60% BOD report describes the baseline site conditions that affect remedy design. Among the documented conditions related to ecological resources at the site are surface water and wetlands, vegetation communities, special status plants, and special status wildlife, avian, and aquatic species. A series of maps were provided in Section 2.4 that overlays the remedy features on surveyed ecological resources – notably Figure 2.4-5 (Jurisdictional Waters and Wetlands), Figure 2.4-9 (Vegetation Communities), Figure 2.4-10 (Habitat of Desert Tortoise Species), and Figure 2.4-11 (Indigenous Plants of Traditional Cultural Significance). PG&E, USFWS, and DOI are coordinating on the Programmatic Biological Assessment (PBA) for the final groundwater remedy. The ESA Section 7 consultation will be completed prior to the approval of the Construction/Remedial Action Work Plan. Measures outlined in the forthcoming PBA and associated USFWS determination will be implemented before and during construction activities. Biological completion reports will be submitted to USFWS documenting areas of impacts and monitoring of construction activities.

	Impact analysis for proposed construction and operation activities are also described in the EIR Section 4.3.3.3 and include: BIO-1 – Potential Fill of Wetlands and Other Waters of the US or removal of Riparian Habitat; BIO-2 – Direct Disturbance of and Loss of Habitat for Special-Status Birds and Desert Tortoise; and BIO-3 Fish Mortality, Interference with Spawning Habitat, and Other Adverse Effects. Of these, only BIO-1 and BIO-2 are related to the proposed activities. The certified EIR summarizes results from site-specific surveys that were conducted for Southwestern willow flycatcher, Mojave desert tortoise, Yuma clapper rail, and other avian species which were also identified during these surveys. Implementation of the EIR mitigation measures would reduce all of these impacts to a less-than-significant level. Subsequent studies have been conducted to document the type and extent of jurisdictional wetlands and waters of the US (Wetland Delineation Report, Aug 2013); as well as the type and location of rare and protected plants (Floristic Survey Report, Aug 2013) and culturally significant plants (Ethnobotany Survey Report, Aug 2013). Additional survey for lycium and arrowweed was conducted in response to comment #311 DOI0140. Potential impacts to sensitive resources during remedy implementation will be documented as required by the EIR. Additionally, applicable cultural resource mitigation measures included in the Programmatic Agreement (PA) (BLM 2010), Cultural and Historic Properties Management Plan (CHPMP) and the EIR Section 4.4 are being and will continue to be implemented to avoid, minimize, or mitigate adverse effects to cultural and historic properties on refuge land.
What mitigation is planned for loss of functional value of refuge while use is in operation	The future Remedial Action Work Plan will include a Habitat Restoration Plan in compliance with the CD, Appendix C (Scope of Work), Article 3. PG&E is committed to working with DOI and the HNWR beginning in 2014, on mitigation planning for potential loss of functional value of the refuge while use is in operation.
How and when the actions/facilities would be closed out—including restoration plans	In compliance with the CD, Appendix C (Scope of Work), Article 9, the Remedy Decommissioning Plan will include procedures for the removal and decommissioning of the groundwater remedy. The Plan will also incorporate planning/approaches for post-remedy restoration (including, but not limited, to a series of photo points). This future Plan will be submitted to DOI within 120 days of DOI's certification of completion of the remedial action and a determination by DOI that removal of such facilities is protective of human health and the environment. In addition, the future Remedial Action Work Plan will include a Habitat Restoration Plan in compliance with the CD, Appendix C (Scope of Work), Article 3.

What contingency plans will be in place—identifying actions that will be taken should an accident, unintended discharge, etc. occur.	Contingency Plans are described in Volume 3 of the Draft O&M Manual of the 60% BOD report. Additional details on Contingency Plans for the Remedy Construction will also be included in the future Remedial Action Work Plan.

Freshwater Pre-injection Treatment System Design Basis

Addendum to Freshwater Pre-injection Treatment System Design Basis, PG&E Topock Compressor Station, Needles, California

PREPARED FOR: Pacific Gas and Electric Company

PREPARED BY: CH2M HILL

DATE: December 5, 2013

1.0 Introduction

Since the submittal of the 60% design (CH2M HILL 2013), the State Water Resources Control Board (State Board) has issued a decision letter on November 20, 2013, and DTSC has provided direction in its comment on the 60% design (#145 DTSC-50) that the design criteria for the potential future pre-treatment of freshwater at Topock will be limited to arsenic removal only and will be included in the 90% design only as a contingency. In compliance with this recent DTSC's directive, this technical memorandum presents the design basis for a potential future pre-treatment option for freshwater.

This pre-treatment option assumes that the primary source is groundwater from a well in Arizona and the secondary source is water from the current PG&E Topock Compressor Station (TCS) source wells (Topock-2/3). This assumption will be revisited after completion of the alternative freshwater source evaluation—the field work is currently under way. The potential future treatment system, referred to herein as the freshwater pre-injection treatment system (FWPTS), will be located in the vicinity of the planned remedy-produced water-conditioning plant. All components of the FWPTS are located on previously disturbed areas within the PG&E-owned parcel.

The treatment goals of the FWPTS are arsenic removal to concentrations less than the federal and California maximum contaminant level (MCL) of 10 micrograms per liter (µg/L) (California Department of Public Health, 2013). This technical memorandum discusses the evaluation of available treatment technologies for arsenic; the selection of technologies for bench-scale testing; the results from bench-scale testing at CH2M HILL's Applied Science Laboratory (ASL) in Corvallis, Oregon; and the design basis/design criteria for the FWPTS. This document also includes a process flow diagram, a preliminary equipment layout, and a preliminary list of key equipment.

The design information presented herein has been developed based on Topock-specific information (that is, bench-scale testing results of HNWR-1 water) and experience in designing and operating arsenic groundwater treatment systems on non-Topock projects. Because of its location, the potential future FWPTS will be designed to achieve a safe, harmonious, and sustainable operation within TCS. Engineering efforts are being conducted and design details of the FWPTS will be included in the 90% design.

2.0 Freshwater Water Quality, Treatment Goals, and Design Flow Rates

For the purpose of this conceptual design, it is assumed that the water quality from the future supply well in Arizona is similar to that of the HNWR-1 well. PG&E has collected and analyzed six samples from HNWR-1 starting in November 2010. Analytical results from November 2010 through January 2013 indicate that the naturally-occurring arsenic concentrations in HNWR-1 water were 15-16 µg/L, greater than the federal and California MCL of 10 µg/L arsenic. The average concentration of arsenic in Topock-2 was 12.3 µg/L (CH2M HILL 2009) and in Topock-3 was 14 µg/L (CH2M HILL 2013). Table 1 summarizes available arsenic results for HNWR-1 and Topock-2/3 wells. As previously mentioned, the treatment goals for the FWPTS are to remove arsenic to concentrations less than 10 µg/L.

The total freshwater supply flow rates are based on the sum of the modeled freshwater flows into the Freshwater and Inner Recirculation Loop injection wells. The FWPTS will be designed to treat freshwater for remedy injection only. Exhibit 1 shows the FWPTS design flow rates.

Element	Unit	Minimum Flow	Nominal Flow	Maximum Flow
Freshwater Pre-Injection Treatment System (FWPTS)	gpm	150	450	900

3.0 Evaluation and Selection of Treatment Technologies

For this conceptual design basis, PG&E has identified and evaluated proven treatment technologies for arsenic that are United States Environmental Protection Agency (USEPA) Best Available Technologies and have been successfully used by municipalities and industry. Unproven technologies or technologies that have not been used in full-scale applications were not considered.

The initial list included nine technologies: anion exchange, activated alumina (AA) adsorbents, reverse osmosis (RO), electrodialysis reversal (EDR), lime softening, distillation, iron-based adsorbents, titanium-based adsorbents, and coagulation/filtration (see Exhibit 2). These technologies were evaluated and screened in a two-step process: (1) the initial screening was based the experience of the engineering team with the individual technology, and (2) the second-level screening was based on a set of criteria - namely treatment effectiveness, reliability and flexibility, operational complexity, waste generation, footprint, and cost effectiveness. After completion of the technology screening and evaluation process, the AA technology with disposable and regenerable (AA) adsorptive media, coagulation filtration, and iron-based adsorbent granular ferric hydroxide (GFH) were selected for bench-scale testing. For more details of this screening and a description of the evaluation processes, see Appendix A.

EXHIBIT 2
Technologies Considered for Arsenic Removal
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum,
PG&E Topock Compressor Station, Needles, California

Technology	Evaluation Status
Anion exchange	Screened out, significant waste generation.
AA	Selected for bench-testing
Titanium-based adsorbents	Screened out, similar as other adsorbents considered, with less experience.
Reverse osmosis (RO)	Screened out, significant waste generation.
Electrodialysis reversal (EDR)	Screened out, significant waste generation.
Lime softening	Screened out, significant waste generation.
Distillation	Screened out, significant energy use and capital cost.
Coagulation filtration	Selected for bench-testing
Iron-based adsorbents	Selected for bench-testing

4.0 Summary of Bench-scale Testing Results

The objectives of bench-scale testing were to: (1) verify the effectiveness of each adsorptive media in removing arsenic from HNWR-1 water to the treatment goals, (2) understand the time to break through (critical for equipment sizing and waste management) for AA and GFH, (3) understand effectiveness of coagulation with a jar test, and (4) understand waste generation amounts. This section summarizes the testing and results to date as it relates to arsenic treatment.

To accomplish the first two objectives, CH2M HILL's ASL employs a testing procedure for evaluating adsorptive media effectiveness in removing arsenic in a small-diameter laboratory column analogous to the rapid small-scale column test method developed for assessing granular-activated carbon in a continuous flow system. This method significantly reduces the amount of time and water required for testing compared to pilot-scale and full-scale systems (USEPA 1996). A jar test was performed to evaluate the effectiveness of ferric chloride as coagulant.

A groundwater sample was continuously pumped, sampled, and collected in three 55-gallon drums from HNWR-1 well in early January 2013 and was shipped to ASL for bench-scale testing. The groundwater sample was processed continuously through the column, and the treated water was sampled and analyzed for arsenic until breakthrough (defined as at least 70 percent of the average influent concentration). After the first breakthrough, the media was regenerated, and the test was repeated. Two treatment cycles (termed Service Cycle 1 and Service Cycle 2) were conducted for regenerable AA. Because of time constraints, not all media samples were able to be tested until breakthrough. In total, 133 liters of HNWR-1 well water were processed using disposable AA and 204 liters using GFH. These samples were tested for as long as time permitted in the laboratory. The rapid small-scale column test results provide information on adsorption capacity (extent of adsorption) and the rate of adsorption (adsorption kinetics), which are the two dominant factors affecting breakthrough in the media columns.

The rapid small-scale column test for arsenic removal was performed using the following media

- Regenerable AA (BASF AA-400G)
- Disposable AA (BASF AA-FS50)
- Alum-impregnated AA (AIAA)
- GFH

Prior to passing the water over the media, the groundwater was pretreated as follows: the pH was adjusted to 6.5 with hydrochloric acid and the water was injected with chlorine to maintain a residual concentration of 1 mg/L for 60 seconds (this is to oxidize any arsenite present in the water to arsenate), and was followed by inline filtration.

Column Testing Treatment Effectiveness and Time to Breakthrough

Figure 1 (located at the end of this memo) shows concentrations of arsenic in treated water versus the number of bed-volumes of groundwater passed through (one bed-volume is equivalent to the amount of adsorptive media in the column). During the first service cycle, the regenerable AA performs well, but in the second service cycle the effluent concentration begins to increase more rapidly indicating after the initial service cycle the media loses capacity to adsorb arsenic. Due to this fact and the difficulty in regenerating AA media which requires using strong chemicals like caustic and sulfuric acid, this method is eliminated from further analysis. The AIAA performed somewhat better than the regenerable AA, but not as well as the disposable AA media. The poorer performance and the additional effort to impregnate the alum onto the AA, eliminates this media from further evaluation. The disposable media performed well to more than 44,000 bed volumes, although the arsenic effluent concentration appears to have increased more than the effluent from the GFH media column.

To ascertain the relative performance of the two media, another figure was prepared (Figure 2), which shows the effluent concentration as a function of the amount of arsenic adsorbed on the treatment media. The effluent concentration in the disposable AA, begins to rise rapidly when the adsorption reaches 0.4 µg/mg media where as in the GFH varies between 0.15 and 0.35 µg/mg media until the test was stopped. These results more clearly indicate GFH will perform better.

Jar Testing Results

Jar testing was performed to test arsenic removal by coagulation with ferric chloride. Water samples were pre-oxidized with free chlorine dosed to provide approximately 1 mg/L free chlorine residual for 60 seconds prior to ferric chloride addition and mixing. Ferric chloride was added to reach doses 5, 10, 15, and 20 mg/L. The mixers were run at 70 revolutions per minute (rpm) for 30 seconds followed by 25 rpm for 20 minutes. The samples were then filtered through a 0.45 micron filter and the filtered water tested for arsenic and pH.

Figure 3 shows the arsenic concentration versus ferric chloride dose applied during testing. Jar testing demonstrated that arsenic could effectively be removed to <10 µg/L with ferric chloride dosed to 5 mg/L.

Process Selection

As shown above, the GFH was effective at removing arsenic to below the treatment goals (the federal and California MCL of 10 µg/L). The effluent remained less than 1 µg/L of arsenic for over 70,000 bed-volumes. The GFH media performed better than the disposable AA offering longer running periods between media change-outs. Coagulation and filtration although effective creates a solid waste stream that must be transported and disposed of off-site and is more difficult to operate. Based on these reasons, GFH was selected for the FWPTS design.

Section 5 discusses the treatment and backwash process in more details and provides a summary of the sustainability factors.

5.0 Freshwater Treatment Process and System Description

As previously mentioned, GFH was selected as the treatment technology to be carried forward into the design of the FWPTS. GFH is a granular, ferric-based, non-regenerative media that adsorbs arsenic and other heavy metal ion from solution. The USEPA has identified GFH as an effective media to remove arsenic (USEPA 2003). This section describes the design philosophy, the treatment process, and the system configuration envisioned at this stage. This section also discusses the uncertainties with the ongoing design and the work that is currently underway or being planned to address these uncertainties.

5.1 Treatment System Description

Groundwater will be pumped and conveyed from the future water supply well in Arizona to the remedy freshwater storage tank. Water will be pumped from this tank and will be injected with hypochlorite for arsenic oxidation and with acid to reduce pH to 6.5; both hypochlorite and lower pH improve arsenic removal in the media vessels. After chemical injection, water will be passed through bag or cartridge filters to remove solids that would otherwise clog the media, reducing performance and runtime. With the solids removed, the water will be divided into two or three streams (nominal or maximum flow) and each will be processed through a single treatment media vessel (configured in parallel) in a downward flow direction. Automatic valves will divert the flow to the proper vessels and will control the flow rate into each in service vessel. During nominal flow, the third and fourth treatment media vessel will be in standby mode. During maximum flow, three treatment media vessels will be operating. Prior to backwashing a vessel, a standby vessel will be brought on line and the first vessel requiring backwash will be put into standby. The remaining in service vessels will be backwashed in turn.

PG&E is evaluating dechlorination alternatives to remove residual chlorine from the treated freshwater. Dechlorination is often accomplished by addition of chemicals such as ascorbic acid, calcium thiosulfate, and hydrogen peroxide. The equipment would involve chemical storage drums or totes, metering pumps, and an inline static mixer. The proposed FWPTS location has sufficient space for this equipment. Additional details will be provided as part of the 90% design submittal.

5.2 Media Backwash & Replacement Process

The amount of wastewater generated is primarily a function of backwash frequency. Backwashing prevents over compaction of the media bed enabling good flow conditions. The media bed should be backwashed once a month for proper media maintenance. Backwashing occurs in an upflow mode, the reverse of normal forward down-flow operation. Once the backwash process is complete, normal forward down-flow operation may resume. Each media vessel backwash process is expected take ten minutes.

At some point during treatment operations, the media will lose its adsorptive capacity and will need to be replaced. Based on bench scale testing, this point is anticipated to be after more than 70,000 bed-volumes or about 8 months at maximum flow rates. The actual replacement frequency will be determined during full-scale operation. For the purpose of the conceptual design, it is assumed that the media will be replaced once a year. Spent media will be removed from each vessel and sent to a landfill. Prior experience operating GFH treatment process shows the spent media is not hazardous (Ela 2006). Waste characterization testing will be performed in accordance with state and federal requirements and facility waste acceptance procedures. Virgin media will be placed in the media vessel and normal forward down-flow operation may resume.

Wastewater & Solid Waste Generation

The volume of wastewater needing to be managed is estimated based on the following assumptions:

- Backwash rate is 15 gpm/sq. ft. and vessel cross section area is 50 sq. ft.
- Backwashing time is 10 minutes resulting in 7,550 gallons per backwash
- Four vessels backwashed monthly at 900 gpm and two vessels backwashed monthly at 450 gpm
- 95 percent of the backwash water is recycled to the beginning of the process

At 450 gpm – 7,550 gallons/backwash x 2 vessels per month x 12 months per year x 5% = 9,000 gallons per year

For 900 gpm – 7,550 gallons/backwash x 4 vessels per month x 12 months per year x 5% = 18,000 gallons per year

The remaining (5 percent of the) backwash water can be discharged to the cooling tower makeup, the TCS evaporation ponds, or disposed offsite at permitted facilities. There is no need to treat or neutralize the pH of the discharged backwash water as it will be within acceptable ranges. Treated water is used for backwashing and no arsenic desorbs from the media during the backwashing process. Discharged backwash water will have more solids compared to the treated water but it will be able to be used for cooling tower makeup, TCS evaporation ponds, or disposed offsite without treatment.

Periodic disposal of the spent GFH media would be required also as a solid waste stream. Based on the bench testing, this would be no more frequently than every 8 months, but is expected to be less frequent. For the purposes of this conceptual design, it is assumed that the media will require annual replacement. The mass of solid waste to be managed

- The media has a specific gravity of 1.1 with water density of 62.4 pounds per cubic foot

- Each vessel has 200 cubic feet of media
- Four vessels need replacement at a rate 900 gpm and 2 vessels at a rate of 450 gpm

At 450 gpm – 200 cubic feet/vessel x 2 vessels per year x 1.1 x 62.4 pounds per cubic foot / 2,000 tons/pound = 13.7 tons per year

At 900 gpm – 200 cubic feet/vessel x 4 vessels per year x 1.1 x 62.4 pounds per cubic foot / 2,000 tons/pound = 27.5 tons per year

5.3 Chemical and Media Use

Chemicals will be used in the treatment system. Chlorine in the form of calcium hypochlorite tablets is used to oxidize arsenite to arsenate. Arsenate is more readily removed by the treatment process. Acid is used in pretreatment to improve adsorption by lowering the pH to about 6.5. Dechlorination of the treated water is under consideration and will be developed further for the 90% design submittal. The estimated chemical use is shown in Exhibit 3.

EXHIBIT 3
Annual Chemical Usage Rates
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Flow Case	Flowrate, gpm	Hypochlorite, pounds/year	93% Sulfuric Acid, gallons/year	Dechlorination Chemical[a]
Nominal	450	3,500	5,150	TBD
Maximum	900	7,000	10,300	TBD

a. Typical dechlorination agents include ascorbic acid, calcium thiosulfate, and hydrogen peroxide.

5.4 Sustainability Summary

For each of the treatment plant operating scenarios (450 and 900 gpm), sustainability parameters such as waste generation, chemical usage, energy use, and greenhouse gas emissions were estimated for the FWPTS as shown on Exhibit 4.

EXHIBIT 4
Sustainability Summary [a]
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum,
PG&E Topock Compressor Station, Needles, California

				Operations					Construction	
Treatment Case	Chemical Truck Trips	Solid Waste Truck Trips	Electricity, kw-hr/yr	Wastewater Generation, MG/yr	Solid Waste Generated, tons/ year	Chemical Use, gal/yr	Total Miles/ year	Emissions, CO2 eq, Tons/year [b]	CO2 eq, Tons [c]	Footprint, sf [d]
450 gpm	14	2	280,000	Minimal	18	20,000	5,000	180	210	2,400
900 gpm	27	~3	320,000	Minimal	35	40,000	10,000	200	250	3,900

Notes: Units: kw-hr/year = kilowatt-hours per year; MG/yr = million gallons per year; gal = gallons; sf = square feet; gpm=gal per minute; CO2 eq – carbon dioxide equivalent

a: Previously submitted on March 29, 2013. Additional effects for using a dechlorination agent if required will be added to this table in the 90% design submittal.

b: Operational emissions include vehicle emission and electricity generation

c: Construction includes site work, material delivery, and workers travel

d: Footprint based on foundations for building, process tanks, and chemical storage

5.5 Controls Philosophy

The system will be automated to reduce the need for continuous operator oversight. Electronic notifications will be sent automatically to on-site operators that notify them of system alarms, shutdown, or other issues. System automation will be controlled using a programmable logic controller that will communicate with the groundwater remedy supervisory control and data acquisition system. Pneumatic valves will be automated to control flow. Online pH, turbidity, and conductivity sensors will be incorporated to enable remote process monitoring and control. Arsenic cannot be monitored using an online analyzer. Grab samples will be collected periodically and analyzed using a bench top colorimetric instrument in the sample room (located in the Remedy Produced Water Conditioning Building or the Central Maintenance Facility) to monitor arsenic levels.

5.6 Other Related Systems and Infrastructure

Electricity will be provided from the compressor station in a new building located next to the Remedy Produced Water Conditioning Building. The new FWPTS location will have a heating, ventilation, and air conditioning (HVAC) system for only critical equipment such as electrical and controls equipment.

5.7 Design Philosophy/Uncertainties in Design

As previously mentioned, the FWPTS will be designed to achieve a safe, efficient, and sustainable operation within the compressor station over the anticipated decades-long life of the remedy. Most of the uncertainty in the design is related to the bed life and adsorptive capacity of the media. Based on bench testing, it is anticipated that the media will not need to be replaced before 70,000 bed volumes are processed– or every 8 months. The actual adsorptive capacity will need to be determined during full-scale operation and the result will greatly influence the amount of wastewater and solid waste generated by the process.

6.0 Design Information

Process calculations used to develop the design criteria were prepared using the conservative assumption that the treatment vessels each needed to be backwashed once a month and media replaced annually. Conceptual design information is presented in Tables 2, 3, and 4 and on Figures 4, 5, and 6 at the end of this technical memorandum. More detailed design information will be included in the 90% design.

TABLE 2
Design Criteria for Arsenic Treatment System
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum,
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
	OPERATIONAL CRITERIA	
Maximum Groundwater Injection Flow Capacity	900 gpm	
Minimum Groundwater Injection Flow Capacity	150 gpm	
Average Groundwater Injection Flow Capacity	450 gpm	
	SITE CIVIL	
Location	Designated freshwater treatment at PG&E Topock Compressor Station near Needles, California.	
Building Finish Floor Elevation	Finished first floor, Elevation 626 feet (NGVD88).	
Grading	Longitudinal Slopes: Minimum 1% away from structures (2% desirable).	
Vehicle Access	WB 50 (turning radius for semi-truck and trailer with 50-foot wheel base). HS 20 (wheel loading on access roadways and parking areas). 50-foot minimum turning radius. Designated site accommodates truck circulation. Roads will be constructed at new facility for maintenance activities.	Required for delivery of chemicals, pumps, motors, and fire vehicles.
Site Constraints	Proposed facility located within the boundary of the compressor station. Access to all critical compressor station facilities must be maintained.	No modifications to the perimeter site fence or entrance gate will be made.
Parking	No parking will be required for new facility.	
Pedestrian Traffic	Limited to paved roadways, sidewalks are not located between existing facilities.	
	PROCESS EQUIPMENT, MOTORS, VALVES, AND ANCILLARIES	
Remedy Freshwater Storage Tank		
Material	Steel	Welded steel in accordance with American Water Works Association Standard D-100. Internal coatings will be applied for corrosion resistance.
Number	One	
Capacity	10,000-gallons	Based on remedy design flow of 900 gpm and four freshwater supply well pump starts per hours plus provision for dead storage. Assumes fire water will be supplied by the existing freshwater storage tanks.

TABLE 2
Design Criteria for Arsenic Treatment System
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum,
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Treatment Process	Pre-oxidation, influent pH adjustment, followed by ligand exchange with granular ferric hydroxide for arsenic removal. Periodic backwash of media with treated water and annual media replacement. Treated water may be dechlorinated to enhance remedy performance (see Dechlorination System below).	Design criteria listed below is what is expected from planned pre-purchase bid, but not a guarantee of what equipment will be selected. The information in this section will be verified during the detailed design.
Granular Ferric Hydroxide (GFH) Treatment		
Treatment Objective	Arsenic removal	
Number of Vessels	Four when operating a maximum flow: Four: three online, one on standby. Two online when operating at nominal flow;	
Residence Time	5 minutes empty bed contact time	USEPA guidance.
Vessel Height	10.5 feet overall	
Vessel Diameter	8 feet	4 to 8 gpm/ft^2 hydraulic loading.
Materials of Construction	Low-carbon steel with epoxy lining that is NSF 61 listed.	
Media	Granular ferric hydroxide	Siemens, Severn Trent, or equal
Performance Limits		
Effluent Arsenic Concentration	< 10 µg/L	
Wastewater Volume	9,000 – 18,000 gal/year	
Chlorine Feed System		
Chemical Feed System	One calcium hypochlorite tablet feeder system—HDXLPE (with oxidation resistant liner) mix tank, feed pump, tablet hopper, controller and panel with disconnect. Sized for 0.2 to 2 lbs/hour of chlorine. Three days' minimum tablet capacity.	Feed system located in a containment area.
Safety Equipment	One eyewash and shower unit	
Coatings/Finishes	Chemical resistant coatings in chemical areas	
Controls	Chemical flow meter flow rate and totalizer	
	Chemical feed pump speed control	
Sulfuric Acid Feed System		
Chemical Feed System	One 1,000-gallon carbon steel with baked phenolic lining. Desiccant drier installed on vent. Sulfuric acid tank with tank pad.	Tank will be located in a containment area. Weekly fill frequency is the design basis,
	One chemical feed skid with two controllable chemical feed pumps	Solution concentration will be 93%.
Safety Equipment	One eyewash and shower unit	
Coatings/Finishes	Chemical resistant coatings in chemical areas	
Controls	Chemical flow meter flow rate and totalizer	
	Chemical feed pump speed control	
Backwash Tank and Treated Water Tank		

TABLE 2
Design Criteria for Arsenic Treatment System
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum, PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Material	Fiberglass Reinforced Plastic (FRP)	
Number	Two	
Capacity	10,000-gallons tanks	Backwash is anticipated to be just over 7,000 gallons per vessel – 10 minutes of backwashing at 15 gpm/ft^2. Backwash tank will have floating decanter or cone bottom to aid in solids recovery and improve backwash recycle rate. Selection to be made in 90 per cent design.
Dechlorination System		Agent and strength to be determined – likely substances include ascorbic acid, calcium thiosulfate, hydrogen peroxide.
Chemical Feed System	Drums or chemical tote compatible with dechlorination agent. One chemical feed skid with two controllable chemical feed pumps	Container will be located in a containment area. Monthly fill frequency is the design basis, It is assumed there is sufficient space for this equipment.
Safety Equipment	One eyewash and shower unit	
Coatings/Finishes	Chemical resistant coatings in chemical areas	
Controls	Chemical flow meter flow rate and totalizer Chemical feed pump speed control Inline static mixer	
Flow Meters		
Type	Magnetic	
Number	Nine	
Flow Control Strategy	FWPTS will receive raw water from the primary source wells into a new freshwater storage tank (10,000 gallons). The secondary source Topock-2/-3 wells will flow by gravity from the existing TCS storage tanks only when required.) A booster pump with variable frequency drive will vary the flow through the treatment plant to maintain set point water levels in the treated water tank and prevent pump operating when the remedy freshwater storage tank water levels are below the setpoint. Media vessel inlet control valves equalize flows through each vessel.	
Pressure Transmitters	Furnished before/after media vessels.	
Static Mixer		
Number	One (at the inlet)	
Diameter	One 10-inch	
Type	Wafer style with integral injection ports	
Piping Materials		

TABLE 2
Design Criteria for Arsenic Treatment System

Subject	Criteria	Comments/Reason
	PLUMBING	
Lavatory/Toilet Room	No facilities provided.	
Potable Water	Emergency shower/eye wash stations.	Per 2010 California Plumbing Code, and ANSI Z358.1.
Non-potable Water	The non-potable water supply will have a reduced pressure backflow preventer. Non-potable water will be supplied for wash down water. Wash down hose valves, hoses and hose racks will be furnished in the area as required.	Per 2010 California Plumbing Code.
	ELECTRICAL	
Electrical Load	The electrical load will consist of process pumps, motor operated valves, filter system, control panel and instrumentation, building HVAC, convenience receptacles and interior and exterior lighting. Power distribution will be sized in accordance with NFPA 70 (National Electric Code) to operate process and facility loads. Short-circuit current interrupting capacity of power distribution equipment will be coordinated with existing power distribution system.	.
Service Voltage	480V, 3-phase, 3-wire power will be supplied from XFMR 099	
Utilization Voltage	Appendix C, Basis of Design Report (CH2M HILL 2013)	
Redundancy Requirements	Power distribution system redundancy will be limited to equipment supporting the operation of back-up process and facility equipment (i.e. motor control combination starters, and breakers,). Power distribution system for FWPTS will incorporate spare breakers and fuses. Supporting quick replacement of failed components. Backup power by diesel generator located at Transwestern Bench.	.
Manufacturers of Electrical Equipment, Grounding, Lightning Protection, Illumination, Emergency Lights, Stand-by/Backup Power, Raceways, and Duct Banks	Appendix C, Basis of Design Report (CH2M HILL 2013)	
	SECURITY	
Security	None	All security covered through TCS main facility

TABLE 2
Design Criteria for Arsenic Treatment System
*Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum,
PG&E Topock Compressor Station, Needles, California*

Subject	Criteria	Comments/Reason
	CONTROL AND TELEMETRY	
Control and Telemetry Design Criteria	The treatment vessels will be a packaged system with the equipment manufacturer providing a fully configured programmable logic controller based system control panel with panel-mounted operator interface terminal. The control panel will be specified with an uninterruptible power supply to provide true online conditioned power sized to operate the connected load for 30 minutes.	
Communications, Other Networks, Supervisory Control and Data Acquisition, Instrumentation	Appendix C, Basis of Design Report (CH2M HILL 2013)	
Environmental Requirements	Equipment and instrumentation will be suitable for the following conditions: Air-conditioned Spaces: 10°C to 35°C and a relative humidity of 10 to 80 percent. Non-air-conditioned Spaces: 0°C to 50°C and a relative humidity of 10 to 95 percent. Outdoors: 0°C to 60°C and a relative humidity of 5 to 100 percent.	Environmental controls, such as heaters, fans, and air conditioning will be provided to maintain equipment within the operating conditions recommended by the manufacturer.
Standards/References	Appendix C, Basis of Design Report (CH2M HILL 2013)	

TABLE 3
Major Equipment List
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum,
PG&E Topock Compressor Station, Needles, California

Quantity	Name	Description
4	Treatment Media Vessels	8-feet-diameter low-carbon steel with epoxy lining (9 - 18 gpm/ft^2 hydraulic loading rate)
1	Hypochlorite Feeder	Calcium hypochlorite tablet feeder: HDXLPE (with oxidation-resistant liner) mix tank, feed pump, tablet hopper, controller, and panel with disconnect
1	Sulfuric Acid Tank	1,000-gallon, (93% sulfuric acid), desiccant drier installed on vent. Baked phenolic lining on steel.
1	Acid Feed System	Pre-engineered skid with two chemical metering pumps for 93% sulfuric acid (0.5 to 2 gph)
1	Dechlorination System	To be determined – Pre-engineered chemical feed skid, storage tote or drum, and static mixer.
1	Pre-treatment Wafer-Style Static Mixer	With integral injection ports
2	Booster Pumps	Centrifugal pump with variable frequency drive
3	Filters skids with replaceable elements	Package unit with differential pressure indication and alarm. Bag or cartridge type
2	Backwash Recycle Pumps	Centrifugal pump with VFD
2	Backwash Pumps	Centrifugal pump 755 gpm (15 gpm/ft^2 hydraulic loading rate) with VFD
2	Treated Water Pumps	Centrifugal pump with VFD

Appendix A
Arsenic and Fluoride Treatment Technology Screening

APPENDIX A

Arsenic and Fluoride Treatment Technology Screening

As part of the pre-conceptual design work, several treatment technologies were identified and screened to help select an effective and efficient treatment process. After technology identification, the list was screened qualitatively with a more detailed screening was completed on a short list of five technologies. Bench-scale testing was then performed to select the technology to carry forward into design.

A.1 Initial Screening

The United States Environmental Protection Agency, water and wastewater utilities, industrial concerns, research universities and centers, and industry groups have published numerous case studies and reports on testing and performance of these technologies in treating arsenic and fluoride in water (American Water Works Association, 1999; Odell, 2010). The initial list of technologies evaluated for the Topock freshwater pre-injection treatment system was developed from those technologies that have been successfully used by municipalities and industry. Unproven technologies or technologies that have not been used in full-scale applications were not considered in the screening. The initial list included anion exchange, activated alumina (AA), reverse osmosis (RO), electrodialysis reversal (EDR), lime softening, distillation, iron-based adsorbents, titanium-based adsorbents, and coagulation/filtration. The status of selection is summarized in Table A-1.

TABLE A-1
Technologies Considered for Arsenic and Fluoride Removal
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum,
PG&E Topock Compressor Station, Needles, California

Technology	Status
Anion exchange	Screened out, significant waste generation.
AA	**Selected for bench-testing. Primary treatment option is regenerable AA if arsenic and fluoride treatment required.**
Titanium-based adsorbents	Screened out, similar as other adsorbents considered, with less experience.
RO	Screened out, significant waste generation.
EDR	Screened out, significant waste generation.
Lime Softening	Screened out, significant waste generation.
Distillation	Screened out, significant energy use and capital cost.
Coagulation Filtration	Screened out, this process does not treat fluoride. If arsenic-only treatment is required, this technology would be screened out due to more residuals are generated, additional chemicals are used, and the process is more complex than iron-based adsorbents.
Iron-based Adsorbents	Screened out, this process does not treat fluoride. **If arsenic-only treatment required, this process may be used.**

A brief process description is provided below.

Anion Exchange. Anions such as fluoride, nitrate, arsenate, selenate, and chromate can be removed from water by using ion exchange with resin. This physical-chemical process involves an easily displaceable ion on the solid phase, exchanging with an unwanted ion in the water that adsorbs to the solid phase. To accomplish the exchange reaction, a packed bed of ion-exchange resin beads is used. Source water is continually passed through the bed in a downflow or upflow mode until the adsorbent is exhausted, as evidenced by the appearance (breakthrough) of the unwanted contaminant at an unacceptable concentration in the effluent.

The most useful ion-exchange reactions are reversible. In the simplest cases, the exhausted bed is regenerated using an excess of the displaceable ion in the form of salt brine. Ideally, no permanent media structural change occurs during the exhaustion/regeneration cycle. This is a proven technology, is widely used, and is easy to automate, but it generates considerable wastewater.

Activated Alumina*.* AA is a semi-crystalline porous inorganic adsorbent, is a proven technology for fluoride removal, and effectively removes arsenic. The removal mechanism, which is one of exchange of contaminant anions for surface hydroxides on the alumina, is generally called adsorption, although ligand exchange is a more appropriate term for the highly specific surface reactions involved. Packed beds of AA are used in water treatment plants in a similar manner to anion exchange. Regeneration is accomplished using a basic solution like sodium hydroxide (caustic). The adsorbent media can be purchased in a disposable form as well. In this case, the spent media is disposed in an offsite facility. This is a proven technology, is widely used, is easy to automate, but it generates considerable wastewater.

Titanium-based adsorbents*.* These are porous adsorbents made with titanium that work similarly to AA in that surface hydroxides exchange with fluoride in the water stream. Similarly, caustic is used to regenerate the adsorbent in the packed beds. This is a newer process with fewer systems in service.

Reverse Osmosis. RO is a membrane water treatment system in which water is pressurized to more than 100 pounds per square inch and is directed through small pores in a synthetic membrane. Treated water is produced through the other side of the small pores while larger particulates are retained on the inlet side of the membrane. RO is effective in removing uranium, radium, arsenic, fluoride, nitrates, microbial contaminants, and many chemicals. Because of the high pressure required for the process, RO systems typically are energy-intensive and have high initial costs. Furthermore, these systems can require more operator attention and can require membrane integrity testing. RO systems also risk fouling and scaling from hard water, colloids, and bacteria. The fouling and scaling increase the pressure drop and result in a shorter lifetime for the membrane or frequent chemical cleaning. In addition, this process generates considerable volumes of wastewater.

Electrodialysis Reversal. EDR is a membrane water treatment process that relies on polarizing electrodes to remove contaminants. The ions in the water are attracted to the membrane by a cathode or anode. Once attracted to the membrane, the ion is transported electrically through the membrane. EDR systems reverse the polarity of the electrodes every 15 to 20 minutes. This process releases accumulated ions and has the following advantages:

- Breaks up scale and reduces the potential for scaling.
- Reduces microbiological growth on the membrane.
- Reduces membrane cleaning frequency.

EDR systems operate at higher pressures than most water treatment systems but not as high as RO systems. They are maintenance intensive and generate considerable volumes of wastewater.

Lime Softening. Hardness in water is characterized by elevated levels of magnesium and calcium. Lime softening removes the hardness by mixing lime (slaked or hydrated) during the treatment process. The lime addition increases the pH of the water and causes the magnesium and calcium to precipitate out. Flocculation and sedimentation units are employed to provide a sufficient time and space to accumulate solids. Magnesium requires a higher pH than calcium to cause precipitation and results in water with a pH as high as 11. Carbon dioxide is used commonly to reduce the pH back to desired levels. This process, although used often, requires careful chemical dosing and process monitoring, requires large amounts of chemicals, and generates large amounts of waste sludge.

Distillation. To distill water, water is heated until boiling and vaporized. The resulting steam is collected and condensed in a clean storage tank. Distillation is effective in removing metals, hardness, and particulates because they do not vaporize with the water. The boiling process also kills bacteria and some viruses. Distillation is ineffective in removing contaminants with a lower boiling point than water, such as benzene. These contaminants must be removed before condensation or recontamination will occur. This process is straightforward to operate but uses high amounts of energy and requires costly metal alloys for construction.

Coagulation Filtration. Coagulation is a process in which smaller particles in suspension attach to one another through electrostatic forces. As the particles attach to one another, larger particles start to form. Aluminum and ferric salts are the most commonly used compounds to enhance coagulation because aluminum or iron hydroxide is formed. Once finished with the coagulation process, the water is filtered through a media filter or microfilter to remove the aggregated particles. Coagulation filtration has been found very effective in removing arsenic from water. While often some form of pretreatment is needed (usually chlorine oxidation), coagulation filtration systems can achieve over a 90 percent reduction in arsenic. However, this process does not treat fluoride. The process is relatively easy to operate.

Iron-based Adsorbents. Contaminated water is passed through a pressure vessel that contains iron based adsorbents that remove arsenic. Granular ferric hydroxide is a common example that is in an amorphous crystalline form. Iron-based adsorbents have been shown effective in removing arsenic (not fluoride) at pH levels normally found in drinking water; however, best performance happens at lower pH levels. Lower pH levels may result in the need for more operator attention and the possibility of handling hazardous chemicals. Once the media has been lost its adsorbent capacity, the spent media is replaced.

A.1.1 Initial Screening Results

As a result of the screening, five technologies were retained for further evaluation:

- Anion exchange
- AA adsorption – disposal media and regenerable media
- Iron-based adsorbents
- Coagulation/filtration

The following technologies were rejected based on the reasons listed below.

- **EDR and RO:** processes generate large residual wastewater streams that must be disposed of.
- **Lime softening:** generates large volume of waste sludge that is difficult and costly to dispose of.
- **Titanium-based adsorbents:** effective at very low pH or with expensive rare earth metals and has the fewest number of operating systems.
- **Distillation:** high cost for energy use.

A.2 Second-level Screening

The two remaining technologies were screened at a second level with AA divided into regenerable and disposable forms. The screening criteria were as follows:

1. Treatment Effectiveness
   - Ability to achieve treatment goals
2. Reliability and Flexibility
   - Ability to allow variation in influent water
   - Expandability

3. Operational Complexity
   - Ease of operation
   - Safety
4. Waste Generation
   - Quantity and quality
5. Footprint
6. Cost Effectiveness

As a result of the screening, anion exchange was not carried forward and was dropped from further consideration because of its lower effectiveness, greater operational complexity, the wastewater volumes generated, and its higher operating cost. The four processes— regenerable AA and disposable AA, iron-based adsorbents, and coagulation/filtration —were advanced to bench-scale testing.

A.3 Bench-scale Testing

As described in the body of the Design Basis Technical Memorandum, bench-scale testing was performed after the technology screening. Testing showed that regenerable AA and iron-based adsorbent were the technologies that best met design needs if both arsenic and fluoride removal, or arsenic removal alone is required Disposable AA was eliminated from further evaluation.

Re: Fort Mojave Indian Tribe Comments on Alternative Pipeline Routings and Proposed Soil Storage/Staging Areas for the Topock Compressor Station 60% Groundwater Remedy Design

Dear Mr. Yue and Ms. Innis:

Hargis + Associates, Inc. ("H+A"), on behalf of and at the request of its client, the Fort Mojave Indian Tribe ("the Tribe" or "FMIT"), is hereby providing this letter regarding the Tribe's review of alternative pipeline routings for the Topock Compressor Station 60% groundwater remedy design (Enclosure A).

As you are aware, these alternative routings have been the subject of discussion at recent meetings of the Technical Working Group ("TWG") and, most recently, the FMIT along with representatives of the Hualapai, Colorado River Indian Tribes, and Cocopah, performed a site walk on February 21, 2014, during which tribal representatives and their technical consultants conferred on the acceptability of these various alternatives. The FMIT was represented by nine Tribal members including a member of Tribal Council. Afterwards, the FMIT members conferred and completed the enclosed matrix providing the Tribe's position on each of the various segments along the pipeline route (Enclosure A). This information is being provided as the Tribe's final comments on the 60% design, with the understanding that you will be directing the Pacific Gas & Electric Company ("PG&E") to take this information into consideration during the preparation of the 90% Basis of Design. The matrix also assumes that any construction or deconstruction would be done in the least impactful manner and in consultation with the Tribe.

Additionally, the Tribe is also presenting herein its position on the various staging and soils storage areas proposed by PG&E (Enclosures B & C). Please find an attached matrix addressing those preferences. Please note that on the matrix, there are several sites for which the Tribe has outstanding questions. Therefore, before the Tribe can determine the final acceptability of these sites, answers to these questions need to be provided to the Tribes.

Finally, the Tribe wishes to add that the comments and preferences as expressed herein do not in any way constitute an endorsement or acceptance of the design as originally presented or as potentially modified by these alternatives. For as you have repeatedly been made aware, many of the adverse impacts associated with this project are permanent and irreversible.

Thank you in advance for consideration of these comments. Please contact me if you have further questions.

Sincerely,

HARGIS + ASSOCIATES, INC.

ENCLOSURE A

FMIT PIPELINE SEGMENT ANALYSIS

PIPELINE SEGMENT ANALYSIS

PIPELINE POINTS (Segment Description)	**ABOVE/BELOW GROUND**	**CONDITIONS OF USE COMMENTS**
A TO B (NTH near MW20 Bench, access upslope to top of slope, adjacent to the SoCal pipeline easement)	NEITHER	After much review and consideration, there does not seem to be either an above- or below-ground alternative for this segment that appears acceptable. Assuming it will not be possible to intrude into the easement, instead, use the "C to B" segment for piping alignment
C TO B (Entrance along NTH, along road south of Locus B; to top of slope, across from MW20 bench)	Below	Although above-ground is generally preferred, the narrowness of the roadway along this segment makes it unlikely the piping could be placed above ground with sufficient road access without making significant cuts and disturbance into the in-place geologic materials alongside this road segment. Note this segment of road runs through a large cultural area on either side, therefore no additional disturbance, outside of the present-day existing roadway, should be made. 1) No additional cuts would be made into the banks on either side of the roadway. 2) Existing slopes would not be disturbed. 3) No activity, storage or personnel activity should extend beyond the current roadway. This includes the slopes adjacent to the existing road. All below ground piping will be removed after remedy completion.
B TO D (Section of dirt access road from top of slope west to Bat Cave Wash)	Above	Given the wide road access along this segment, above-ground piping could be installed. 1) Construction activity, storage and personnel activity should be limited to the roadway to the extent possible to minimize encroachment into the areas adjacent to the existing road.
D TO E (Continuing along access road, along the east side of Bat Cave Wash to where road crosses wash near IM-3)	Above	1) Construction activity, storage and personnel activity should be limited to the roadway to the extent possible to minimize encroachment into the areas adjacent to the existing road.
E TO F (From Bat Cave Wash crossing, along Route 66 westward past IM-3 to IRL-3)	Above	Above-ground installation is preferred. 1) No additional cuts would be made into the banks on either side of the roadway. 2) Existing slopes would not be disturbed.

PIPELINE SEGMENT ANALYSIS

PIPELINE POINTS (Segment Description)	ABOVE/BELOW GROUND	CONDITIONS OF USE COMMENTS
F TO G (From IRL-3 along single land dirt access road, down into wash and location of IRL-4.)	Below	This short section from IRL-3 to IRL-4 in the wash is along a narrow, one-lane access road. The narrow width of the existing one-lane access road, and existing embankment where road would be built to provide access down to IRL-4 does not appear to allow for both vehicle access and above-ground piping and supports. While above-ground installation is preferred where possible, placing the injection well piping below-ground along this segment should constrain disturbance to the foot print of the existing roadway 1) Activity and construction in this area to remain strictly constrained to the existing dirt road. 2) Construction of the roadway down into the wash for IRL-4 should consist of fill placement, rather than any additional cut, to the extent possible. 3) All below ground piping will be removed after remedy completion.
F TO H TO I (From IRL-3, west along Route 66 to FW-1)	Above	Above ground installation is preferred. 1) No additional cuts would be made into the banks on either side of the roadway. 2) Existing slopes would not be disturbed.

Re: 60% Pipeline Alternatives and Soils / Staging Matrices

Dear Mr. Yue:
On behalf of the Hualapai Tribe, we appreciate being able to discuss pipeline alternatives as presented in various meetings and consultative group walks regarding the 60% Basis of Design for the Topock Remediation Project. As you are aware, the Hualapai along with other Tribal representatives met at Topock on February 21st, 2014 to visit and discuss alternative pipeline routings for the 60% groundwater remedy. Hualapai tribal representatives and two Hualapai Tribal Council members were present during this meeting. After the meeting it was agreed that a pipeline matrix and soils staging area table would be sent to interested tribes that included tribal comments wile in the field.

In this letter we formally present Hualapai's comments regarding pipeline alternatives and soils / staging areas considered by Pacific Gas & Electric for the 90% Basis of Design. Even though we are aware that the groundwater remedy infrastructure is creating permanent and irreversible cumulative negative impacts, both spiritually and to the cultural landscape at Topock, we are confident that PG&E will do everything in their power to remove all infrastructure components (whether or not pipelines are placed above or below ground) five years after all remediation activity ceases.

Figure 1 below, shows pipeline alternatives with Table 1 documenting comments from Hualapai. Regarding Table 2, below, this table has tribal responses that were solicited on January 14, 2014. It also has comments and questions regarding several areas visited on February 21st. Perhaps we can discuss these at the March 14th CHPMP meeting with BLM. There is one outstanding soils location (#20) that still requires visitation. Perhaps we can do this on March 14th, 2014 (CHPMP meeting with BLM, in the morning followed by visit to Topock), when we will be out at Topock.

We appreciate our on-going consultations and collaborations with the Topock Remediation Project and look forward to meaningful dialogue through-out the up-coming years. If you have any concerns please feel free to contact myself, or Dawn Hubbs, Program Manager and we will be happy to assist you.

Sincerely,

Loretta Jackson-Kelly

Loretta Jackson-Kelly, Director and Tribal Historic Preservation Officer
Hualapai Department of Cultural Resources

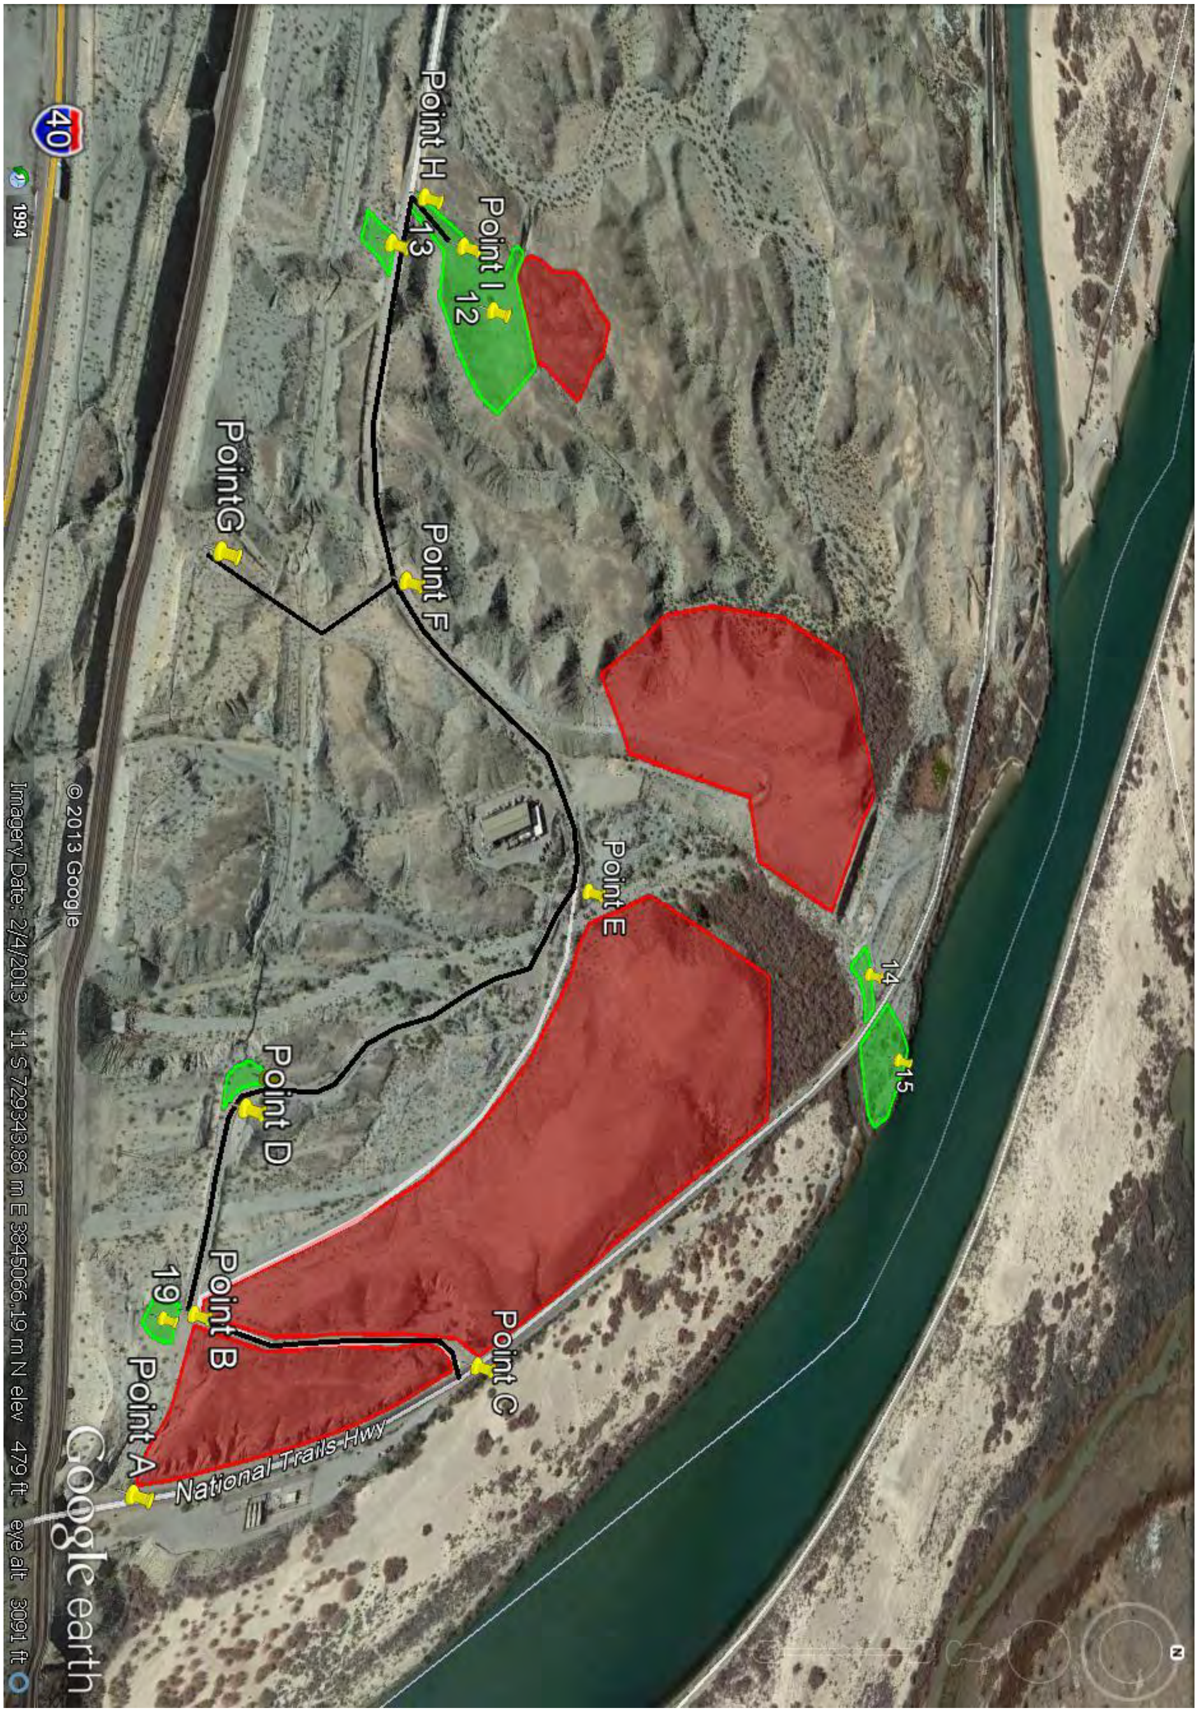

Figure 1: Red Areas = Cultural Sites - Green Areas = Soils Staging Areas - Black Line = Pipeline

Table 1: Hualapai Department of Cultural Resources Pipeline Points and Comments

PIPELINE POINTS	ABOVE/BELOW GROUND	CONDITIONS OF USE COMMENTS
A TO B	**Neither.** Hualapai do not want to see this alternative used at all.	Hualapai do not want this segment of the pipeline to be used. There is significant damage to this area (which is not being refurbished or maintained for erosion and run-off) and this segment would cause more damage. It would also impact a multi-component archaeological site. Avoidance is recommended.
B TO C	**Below Ground**	The segment is in an existing road. Please go in the center of the road, no additional widening or slope cutting due to cultural materials on the upper slopes. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.
B TO D	**Above Ground or Below Ground**	The segment is in an existing road. Please go in the center of the road, no additional widening or slope cutting. Soils location 19 is near this segment. We would prefer that this segment not utilize location 19 as there is a point west and down the road that would be preferable for staging. See Table 2. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.
D TO E	**Above Ground or Below Ground**	The segment is in an existing road. Please go in the center of the road, no additional widening or slope cutting. Cultural materials are in this vicinity. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance

		levels of Chrome VI.
E TO F	**Above Ground or Below Ground**	The segment is in an existing road. Please go in the center of the road, no additional widening or slope cutting. Prefer minimal bridge construction considerations. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.
F TO G	**Below Ground**	This is a very small area without a lot of room. There is an archaeological site (CA-SBR-11939) in this area and there is a plan to put IRL3 in this vicinity also. There is going to be a great deal of activity in this small area, so we request cultural clearances with tribal monitors in attendance, prior and during this segment's construction phase. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.
F TO H TO I	**Above Ground**	This area is very close to cultural materials. Prefer that there be no additional widening of the existing road. We request cultural clearances with tribal monitors in attendance, prior and during this segment's construction phase. There is a plan to put FW1 near this location also. All infrastructure materials to be removed five years after achieving acceptable ground water tolerance levels of Chrome VI.

Table 2: Soils Staging / Construction Areas Hualapai Comment Table

Re: 60% Pipeline Alternatives and Soils / Staging Areas

Dear Mr. Yue/Ms. Innis:

The Cocopah Indian Tribe appreciates the opportunity to provide comments and discuss the 60% Pipeline Alternatives and Soils / Staging Areas.

The Cocopah Indian Tribe along with council members and representatives from other interested tribes, visited the Topock area on February 21, to view and walk the Soil Staging areas proposed by PG&E and the alternative pipeline route for the Topock Compressor Station 60% groundwater remedy design. During this meeting and site walk, it was agreed that a table and map illustrating the staging and pipeline route would be produced and used to provide comments regarding the staging areas and pipeline route.

Attached you will find Cocopah's comments regarding the Pipeline route and Staging areas. The attachments are as follows:

- Figure 1 is a map illustrating the Staging areas and Pipeline
- Table 1: Cocopah Comments regarding Pipeline Points
- Table 2: Cocopah Comments regarding Soils Staging / Construction Areas

If you have any questions feel free to contact me at: Cell: 928-287-5042 or Office: 928-627-4849, or by email at CocopahTPM@Gmail.com

Thank vou

Edgar Castillo

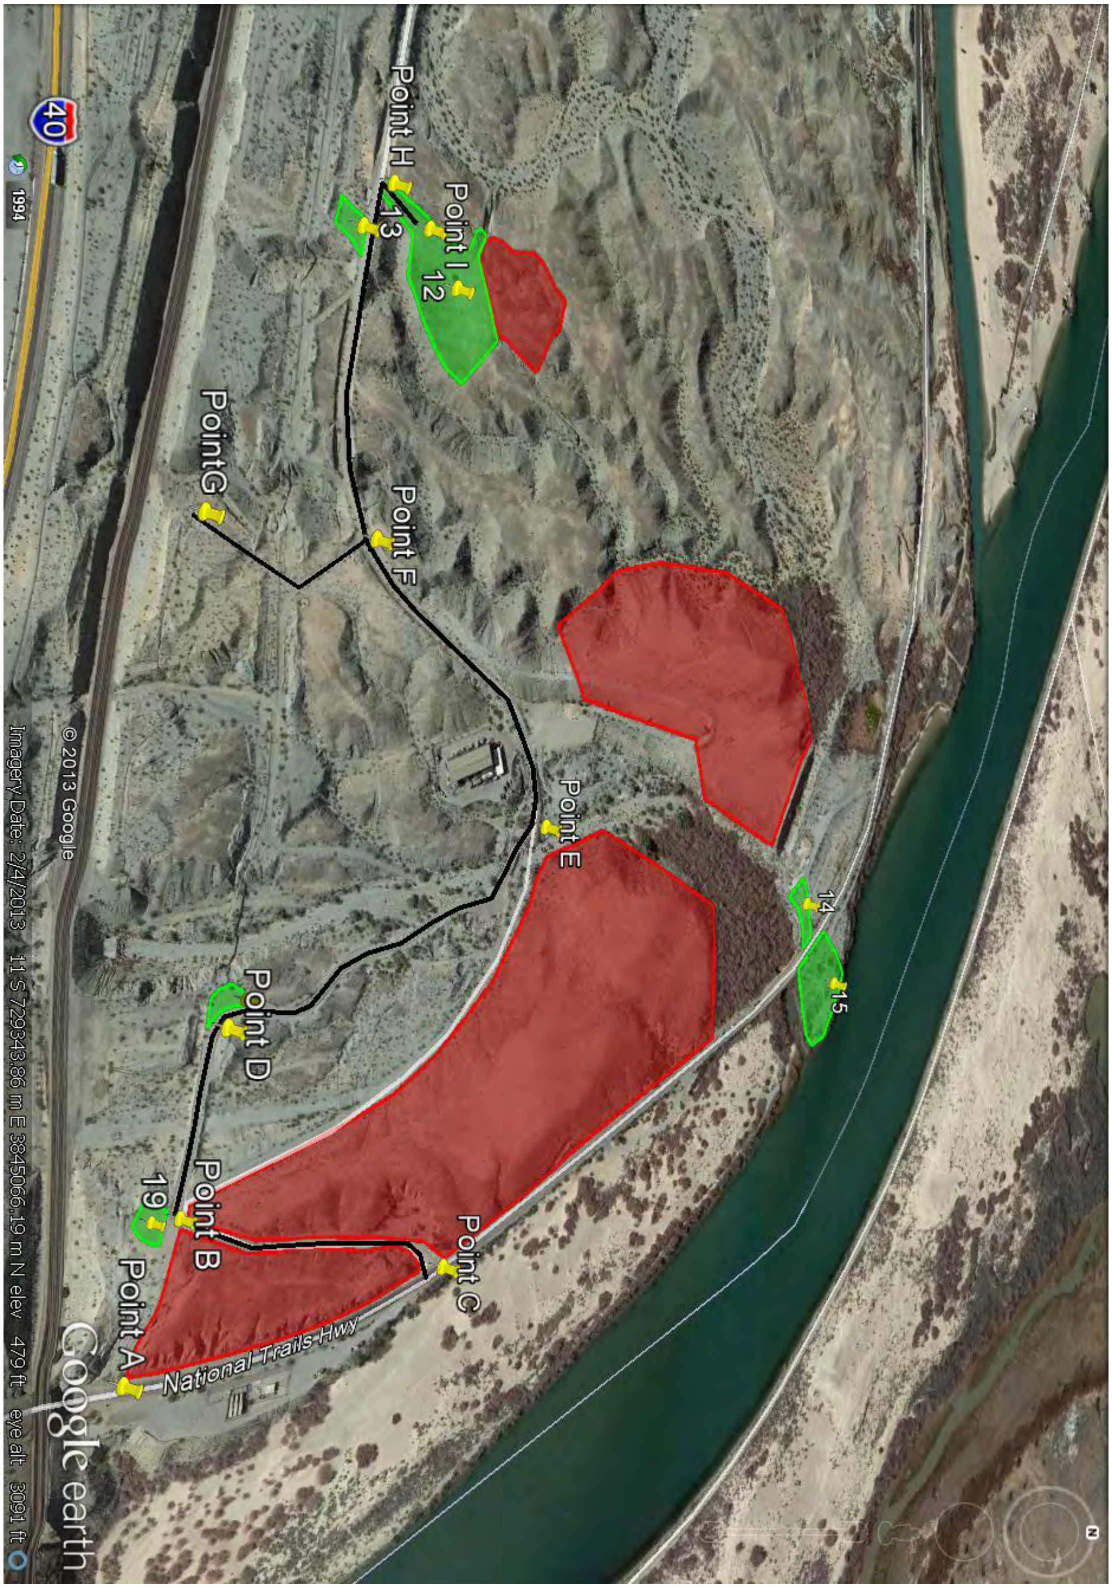

Figure 1: Red Areas = Cultural Sites
Green Areas = Soils Staging Areas
Black Line = Pipeline

Table 1: Cocopah Comments on the Pipeline Points

PIPELINE POINTS	ABOVE/BELOW GROUND	CONDITIONS OF USE COMMENTS
A TO B	Neither	Tribe's conclusion is that this is not an acceptable route for the pipeline. It is noted that there is significant damage to this area and this pipeline segment would cause more damage. The tribe recommends that this area be avoided.
C TO B	Above/Below	This segment intersects a large Cultural Resources Area. Any additional widening or cutting into the sides of the road is to be avoided as to not cause any damage to the cultural materials present on the slopes. All activity including staging, storage or personnel would be strictly limited to the roadway. Piping should go in the center of the existing roadway. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
B TO D	Above/Below	This segment is in an existing roadway. All activity including staging, storage or personnel would be strictly limited to the roadway. Piping should go in the center of the existing roadway. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
D TO E	Above/Below	This segment is in an existing roadway. All activity including staging, storage or personnel would be strictly limited to the roadway. Piping should go in the center of the existing roadway. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
E TO F	Above/Below	This segment is in an existing roadway. All activity including staging, storage or personnel would be strictly limited to the roadway. Piping should go in the center of the existing roadway. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
F TO G	Above/Below	This is a small area that contains archaeological site CA-SBR-11939. Cultural clearances with tribal monitors are requested, prior to and during construction. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.
F TO H TO I	Above/Below	This area is very close to cultural materials. Cultural clearances with tribal monitors are requested, prior to and during construction as with the previous point. All infrastructure materials to be removed five years after achieving acceptable Chrome VI levels.

Table 2: Cocopah Comments on the Soils Staging / Construction Areas

Subject: Comments on Noise/ Vibration and Pipeline Routing

Mr. Yue, the Colorado River Indian Tribes will not be submitting further comment for the 60% Design phase on the Noise and Vibration issues nor on the Pipeline Routing issues at this time. We have participated in the discussions of those issues, and are satisfied the DTSC, DOI and PG&E have heard our concerns directly, and through the other Tribal comments. We will consider adding further input as the design process moves forward.
Thank you for your efforts in this regard. db

PG&E's Responses to Tribes' Questions about Staging Areas #14, #15, #17, and #19

Construction Staging Area #14

1. Is it temporary?

Response: Yes, all construction staging areas are temporary by nature, and are specifically set up to provide support for specific construction activities in specific areas.

2. Fencing? With what?

Response: Yes, some construction staging areas are anticipated to include temporary fencing for security and safety reasons. Fencing will likely be chain link fences with posts or panels.

3. SHPO Clearance?

Response: In accordance with the Programmatic Agreement, it is PG&E's understanding that the groundwater remedy will require BLM review and concurrence prior to start of construction. SHPO consultation is also likely to be necessary, consistent with the Programmatic Agreement's Consultation Protocol.

4. What Activities?

Response: Staging areas (also called support zones) are located adjacent to or near a primary work zone where actual construction activities will take place. Staging areas will be used for location of temporary facilities such as portable toilets and breaks areas. Staging areas are also used for lay-down of construction equipment (including heavy equipment), materials, supplies, and tools needed for construction activities in the primary work zones. In addition, most temporary stockpiling (less than 90 days) of displaced soils/materials will take place in the staging areas. Management of displaced soils and materials will be in accordance with the Displaced Soils Management Protocol.

In addition, PG&E plans to conduct daily planning and health and safety meetings at the main construction yard and, as needed, in the support zones prior to commencing work. Staging areas will also serve as the communication and coordination center for emergency situations.

5. Lighting?

Response: Since staging areas, in general, are not intended to be staffed 24/7, PG&E does not consider night-time lighting at these staging areas to be necessary, except for limited circumstances such as when PG&E personnel or contractors need to enter the staging areas during nighttime hours because they must continue to work during the night on work that cannot be disrupted or suspended. If needed, temporary lighting may be powered by portable generators. PG&E will comply with the EIR mitigation measures to reduce impacts from construction lighting.

6. Extent of Staging Areas? From where to where?

Response: For practical reasons, a useful staging area would occupy an accessible, flat, well graded, and previously disturbed area while avoiding sensitive resources. The extent of staging areas will be field verified and demarcated prior to set up, with participation from qualified archaeological monitor(s) and biologist(s). Tribal monitors will be invited to participate in/or observe the demarcation of all staging areas.

7. What has BLM determined regarding eligibility and potential impacts to this area?

Response: A report titled National Register of Historic Places Eligibility Evaluation of CA-SBR-11862H, San Bernardino County, California (September 2013) was prepared by AE. The report concluded that significant historical associations of the site, and its representativeness as a historically significant type, were lost with the removal of the buildings and other features. This loss of integrity means that the site cannot be considered eligible for the NRHP under Criteria A or C; however, the archaeological remains at CA-SBR-11862H do meet standards of both significance and integrity with respect to NRHP Criterion D and the site is eligible for the NRHP under this criterion. PG&E understands that BLM has concurred with this recommendation.

Based upon current information, the construction staging area which may be sited within CA-SBR-11862H boundaries as part of the Project avoids the historical debris deposits that contribute to the property's significance. Therefore, BLM has concluded that this historic property would not be affected adversely. The BLM is seeking the concurrence the CA SHPO regarding the determination of eligibility to the NRHP and the determination of no adverse effect.

Construction Staging Area #15

1. Vegetation Removal? Tribes do not want vegetation removed.

Response: Consistent with the EIR mitigation measures to reduce visual impacts, PG&E will work to avoid and protect woody or perennial plants in this area. PG&E assumes that occasional removal of weeds, if needed for the purpose of staging is acceptable. Again, as mentioned above, the extent of staging areas will be verified and demarcated prior to construction set up, with participation from qualified biologist(s). Tribal monitors will be invited to participate in/or observe the demarcation of all staging areas.

2. Wider access/modifications? Tribes do not want that.

Response: PG&E does not intend to modify or widen access to this area for use as construction staging. For access to this area, PG&E plans to open up the existing entrance by moving the large rocks that currently block the entrance. The precise locations of the rocks will be determined in the field concurrent with the pre-construction field verification and demarcation of the staging area.

3. Watchmen? Guards? Restroom?

Response: As mentioned above, PG&E does not intend to staff construction staging areas, therefore, there will not be watchmen and guards stationed at the staging areas. It is likely that there will be portable toilets at some staging areas, although, which staging areas will have these facilities and their precise locations within the staging areas have yet to be determined.

4. What activities?

Response: See response to #4 above.

5. Lighting?

Response: See response to #5 above.

6. When was this area last surveyed for cultural materials?

Response: This area was last formally surveyed in 2004 and reported in AE's 2007 report. Since that time, the area has been revisited during the course of considering this area as a staging area. Per PG&E's standard process, the area will be reexamined prior to any ground disturbing activities.

7. Extent of Staging Areas? From where to where?

Response: See response to #6 above.

Construction Staging Areas #17 and #19

1. Modifications?

Response: PG&E does not intend to improve or modify these areas.

2. Fencing? With what?

Response: Unlike other staging areas, these two areas are currently used as turnaround and parking areas for vehicle traffic along the access road. Therefore, to preserve this functionality, PG&E does not intend to install temporary fences in these two areas.

3. Structures?

Response: PG&E does not intend to install any structures in these two areas.

4. Blading, leveling, gravel import?

Response: PG&E does not intend to make surface improvements to these areas. Gravel import is neither planned nor anticipated to level or blade these areas.

5. Lighting? Generators?

Response: See response to #5 above.

6. Berm cuts along road?

Response: PG&E does not intend to do any berm cuts along road.

For Area #19, the Tribes also had the following question: "There is a better place to the west (down the slope) where there already exists a large level place with a well (MW25). Why not go there instead? Proposed IRL-7 nearby. Also N (?).

Response: The level place to the west of Area #19 serves as an access road used by BNSF, Southwest Gas Company, and PG&E gas transmission department. The access to their facilities cannot be impeded by PG&E's remediation work. Although a small portion of this area may be periodically useful and available for PG&E remediation work, these other utility constraints and limited access using a steep driveway and tight turning radius led PG&E to conclude that this potential staging area has little value to the project.

PUNCH LIST #5 FROM SEPTEMBER 17 – 18 TWG MEETING

60% Design, Appendix L – Volume 4: Soil Management Plan

Comment FMIT-194, Hualapai/Chemehuevi/Cocopah/CRIT-144 - Potential Soil Storage Location Decision Matrix

The current groundwater EIR does not specifically address long-term storage of soil within the APE. Please indicate how impacts to cultural and visual resources associated with long-term soil storage will be evaluated. While stakeholder input has been requested in regards to potential locations for soil storage it is not clear how the final decision will be made. This process needs to be transparent. <u>Therefore please provide a matrix which includes all parameters used in the decision/rationale behind final storage locations that will be discussed with the Tribe</u>. Parameters that should be transparently discussed in regards to the final soil storage location would include proximity to cultural resources, whether access routes are adjacent to cultural resources, distance of storage to point of origin and will potential locations have any visual impacts that are not currently addressed in the GW EIR

Potential Soil Storage Location Decision Matrix

Potential Soil Storage and Staging Locations	Total Area (acres)*	Approximate distance to storage location from remedy construction area	Acceptable to Tribes?	Impacts to Cultural Value	Potential visual impacts of storage location	Access to storage location (existing or improvements needed)	Potential ecological impacts of storage location
Soil Storage Areas (shown in yellow on map)							
1 - Park Moabi RV Storage Area	2.11	2 miles	TBD	TBD	TBD	Good No improvements needed	Low Located in relatively unvegetated/disturbed area; not within sensitive plant or wildlife habitat
2 - Park Moabi RV Storage Area	1.94	2 miles	TBD	TBD	TBD	Good No improvements needed	Low Located in relatively unvegetated/disturbed area; not within sensitive plant or wildlife habitat
3 - Park Moabi RV Storage Area	5.09	2 miles	TBD	TBD	TBD	Good No improvements needed	Low Located in relatively unvegetated/disturbed area; not within sensitive plant or wildlife habitat
4 -Paintball Area	0.91	2 miles	TBD	TBD	TBD	Good Minor improvements needed	Low Located in relatively unvegetated/disturbed area; not within sensitive plant or wildlife habitat
5 - BOR OHV Staging Area	1.45	2 miles	TBD	TBD	TBD	Good No improvements needed	Low Located in relatively unvegetated/disturbed area; not within sensitive plant or wildlife habitat

Potential Soil Storage and Staging Locations	Total Area (acres)*	Approximate distance to storage location from remedy construction area	Acceptable to Tribes?	Impacts to Cultural Value	Potential visual impacts of storage location	Access to storage location (existing or improvements needed)	Potential ecological impacts of storage location
6 - Area near IM-3 treatment plant	0.67	0-1 mile	TBD	TBD	TBD	Good No improvements needed	Low Located in relatively unvegetated/disturbed area; not within sensitive plant or wildlife habitat
7 -Area near IM-3 treatment plant	0.28	0-1 mile	TBD	TBD	TBD	Good No improvements needed	Low Although appears to be located within vegetation polygon, actual location is in unvegetated area adjacent to access road
8- Area near IM-3 treatment plant	0.17	0-1 mile	TBD	TBD	TBD	Good No improvements needed	Low Although appears to be located within vegetation polygon, actual location is in unvegetated area adjacent to access road

* - Estimated total acreage for the subject area (actual area available for remedy use will be less and will need to be verified).

Proposed Remedy Construction Staging Areas Matrix

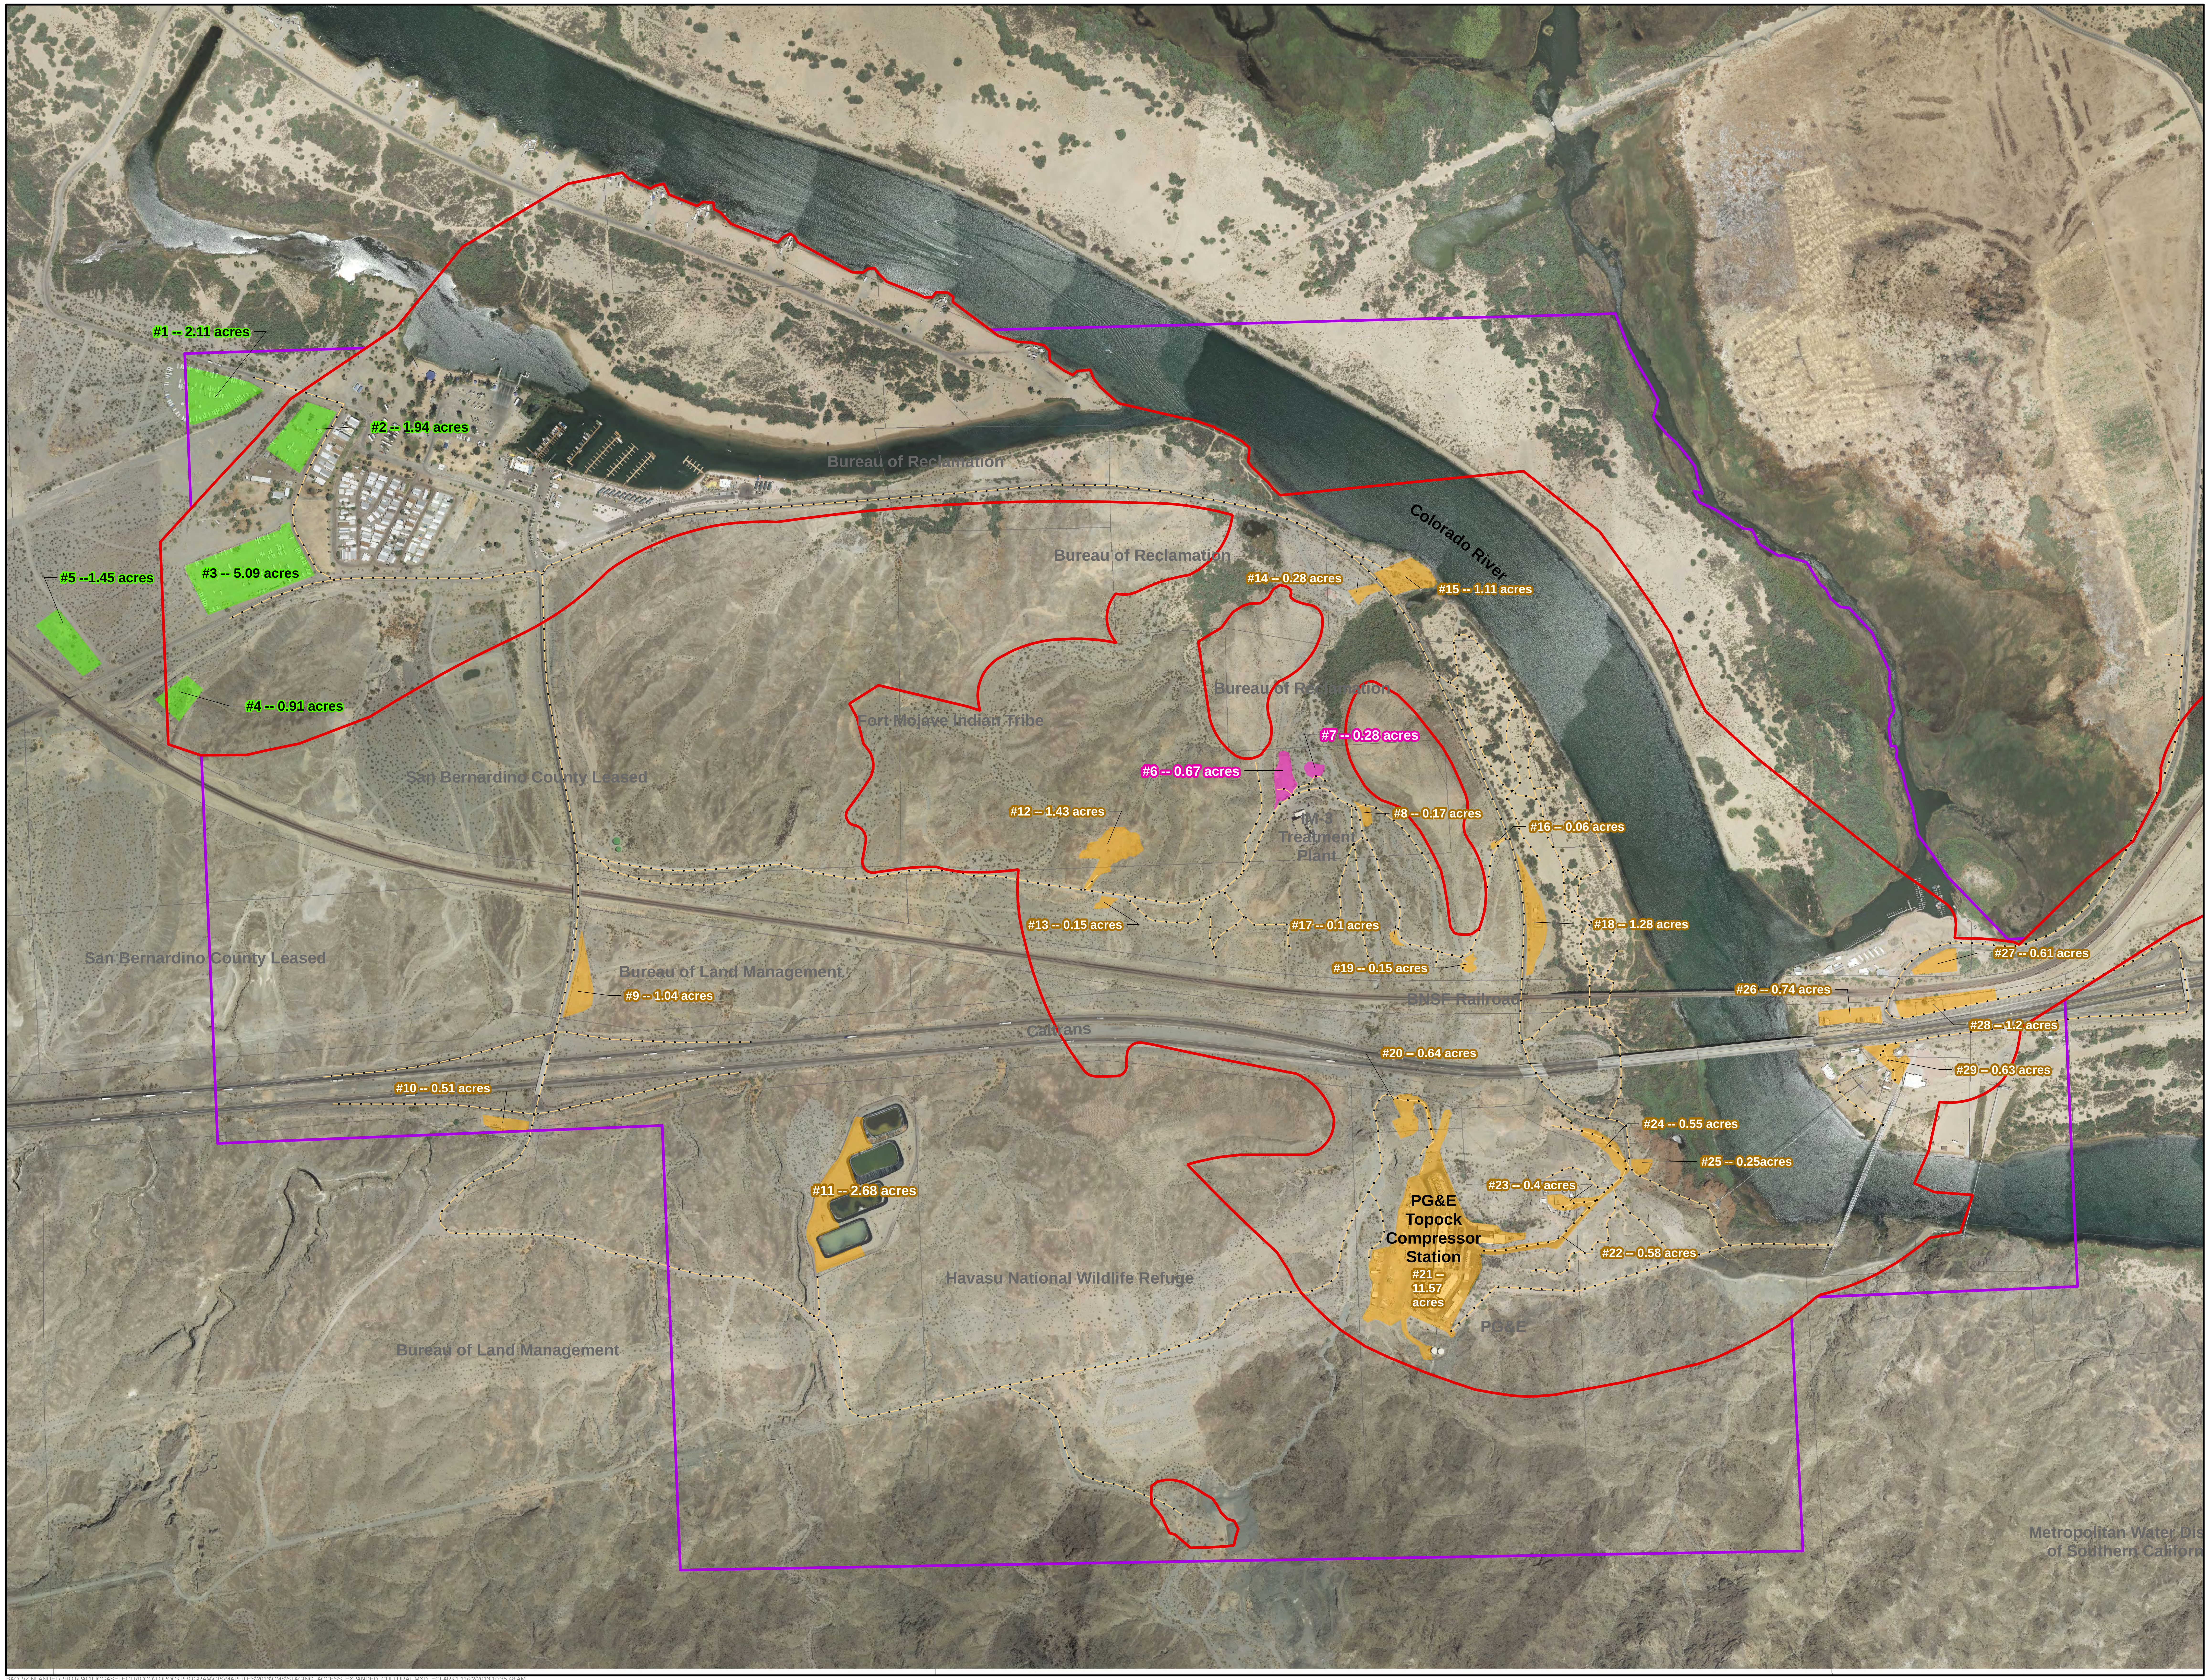
Staging Locations	Total Area (acres)*	Acceptable to Tribes?	Impacts to Cultural Value	Potential visual impacts of staging location	Potential ecological impacts of storage location
9	1.04				Low Located in disturbed area; not within sensitive plant or wildlife habitat
10	0.51				Low Located in disturbed area; not within sensitive plant or wildlife habitat
11	5.69				Low Located in disturbed area; not within sensitive plant or wildlife habitat
12	1.43				Low Located in disturbed area; not within sensitive plant or wildlife habitat
13	0.15				Low Located in disturbed area; not within sensitive plant or wildlife habitat
14	0.28				Low Located in disturbed area; not within sensitive plant or wildlife habitat

Staging Locations	Total Area (acres)*	Acceptable to Tribes?	Impacts to Cultural Value	Potential visual impacts of staging location	Potential ecological impacts of storage location
15	1.11				Low Located in disturbed area; not within sensitive plant or wildlife habitat
16	0.06				Low Located in disturbed area; not within sensitive plant or wildlife habitat
17	0.1				Low Located in disturbed area; not within sensitive plant or wildlife habitat
18	1.28				Low Located in disturbed area; not within sensitive plant or wildlife habitat
19	0.15				Low Located in disturbed area; not within sensitive plant or wildlife habitat
20	0.64				Low Located in disturbed area; not within sensitive plant or wildlife habitat

Staging Locations	Total Area (acres)*	Acceptable to Tribes?	Impacts to Cultural Value	Potential visual impacts of staging location	Potential ecological impacts of storage location
21 - Compressor Station	11.57				Low Located in disturbed area; not within sensitive plant or wildlife habitat
22	0.58				Low Located in disturbed area; not within sensitive plant or wildlife habitat
23	0.4				Low Located in disturbed area; not within sensitive plant or wildlife habitat
24	0.55				Low Located in disturbed area; not within sensitive plant or wildlife habitat
25	0.25				Low Located in disturbed area; not within sensitive plant or wildlife habitat
26	0.74				Low Located in disturbed area; not within sensitive plant or wildlife habitat

Staging Locations	Total Area (acres)*	Acceptable to Tribes?	Impacts to Cultural Value	Potential visual impacts of staging location	Potential ecological impacts of storage location
27	0.61				Low Located in disturbed area; not within sensitive plant or wildlife habitat
28	1.2				Low Located in disturbed area; not within sensitive plant or wildlife habitat
29	0.63				Low Located in disturbed area; not within sensitive plant or wildlife habitat

* - Estimated total acreage for the subject area (actual area available for remedy use will be less and will need to be verified).



LEGEND

- EIR Project Area
- Area of Potential Effects (APE)
- Proposed Access Routes
- Potential Soil Storage Area/ Proposed Staging Area for Remediation Project
- Proposed Staging Areas for Remediation Project
- Areas #6 and #7 are proposed by DOI for consideration as soil storage areas only from the IM-3 decommissioning and sampling activities (see comment #775 DOI-320). PG&E proposes these two areas as staging areas during construction of the remedy and decommissioning of IM-3 facilities. Area #6 is also proposed as a waste management area for non-hazardous waste only during decommissioning of IM-3 (see Draft IM3 Decommissioning Work Plan). Note that the FMIT has opposed the use of these two areas for any remediation related purposes. See FMIT comment on 60% design, #291 FMIT-44

Notes:

1. PG&E may use all or a subset of these potential temporary staging areas during remedy construction.
2. Note that in compliance with EIR mitigation measure CUL-1a-9 as well as PA and CHPMP mitigation measures, the proposed access route west of National Trails Highway is located in an existing, previously disturbed, access road. The location of the access road was field verified and does not create any direct physical impact or effect on the Topock Maze, as it is manifested archaeologically, in compliance with EIR mitigation measure CUL-1a-10 and PA and CHPMP mitigation measures

PG&E's Response to TRC Technical Memorandum on Appendix A8 and Tribe's Letter to close-out unresolved noise and vibration comments

Responses to Charlie Schlinger's Memo (12/10/13)

Comment Item 317 addressed Appendix A8 and requested a narrative "that explains how these baseline data will be used in any decision-making process(es), and as a part of Mitigation Measures NOISE-1, NOISE-2 or NOISE-3". The PG&E response to this comment provides some background as to why the supplemental data were collected, and how these data are part of documenting site conditions prior to remedy implementation. This background information helps with the broader understanding of the work done so far, and should be included in the upcoming 90% BoD report. However, the RTC response does not explain how these data will be used. As I considered this comment, the response, and reviewed the Appendix A8 data, I identified several additional pertinent questions:

A) I understand that there was considerable discussion about the meaning of the term "baseline". Will the meaning of "baseline" as used in Appendix A8 be clarified and agreed upon as part of resolution of this or other sound/noise-related comments?

RESPONSE: *As discussed at the November 19-20, 2013 TWG meeting, baseline site conditions means conditions of the site prior to remedy implementation.*

B) It seems clear that some parties decided (and I concur) that the sound level data gathered as part of EIR development were insufficient, and therefore the additional data were acquired. Is there a record of that discussion and decision?

RESPONSE: *There was no determination that sound level data gathered as part of EIR development was insufficient.*

C) The response to the comment indicates that these noise data are available for use, if needed and as appropriate. The response needs to indicate how the data will be or should be used.

RESPONSE: *Until there is an actual construction or operational noise concern, PG&E cannot opine on how or if this data will be useful. Rather, this was a pro-active step taken by PGE to be as prepared as possible for a meaningful discussion should the need arise.*

D) Why were no frequency (spectral) characteristics of the measured noise determined? Also, why were no sound recordings made, e.g., of events that exceed a certain threshold? My understanding is that the 831 sound level meter can readily collect this information, which is most informative, for example, when trying to understand if the noise has a characteristic frequency range, or, to identify the source(s) of loud noise(s) that influence the record at a site.

RESPONSE: *The EIR identified the applicable criteria as A-weighted, therefore the measurement results were summarized on the A-weighted scale. Should the need arise to evaluate an actual concern, additional data collection and analysis can be conducted.*

Comment Item 318 requested a tabular inventory and map of noise source locations. I very much appreciate PG&E's willingness to provide this – as indicated in the PG&E Response to 60% Design Comments column.

A challenge of this project is to quantify, in advance, the environmental noise impact(s) of the remedy. Clearly, the FEIR made an effort to do this, but that attempt was done well in advance of actual knowledge of the remedy design. Now that design is well underway, it would make sense to re-valuate the likely noise impacts based on the actual design. I expect that noise impacts during routine operation and maintenance will be minor – assuming that permanent stationary noise sources are selected for low noise emission or are buried, enclosed, etc. I expect that noise impacts during the main construction period and during decommissioning will be significant. Similar activities may also intermittently occur during the life span of the remedy due to repairs or equipment updates or replacements. Until mobile and stationary noise source locations are identified, and source noise levels are quantified, cumulative environmental noise impacts on noise-sensitive Tribal (or other) receptors cannot be properly anticipated, forecast or assessed. It is probably worthwhile to note on the map or inventory that not all noise sources will be generating noise at the same time.

> **RESPONSE:** *PG&E agrees that the quantitative sound levels from the project operations will likely be low. Construction including decommissioning are considered short term, isolated noise events. The EIR analyzed the potential noise impacts from the construction and operation of the project and established mitigation measures. PG&E is committed to complying with the thresholds established in the EIR and implementing the mitigation measures.*

Comment Item 319 concerns how the selection and specification of equipment will utilize noise restrictive criteria. This focuses on the selection of all equipment with specific consideration for its capacity to generate noise. The PG&E response addresses this partially, but the response language seems to focus on equipment selection for the permanent (life-of-project) infrastructure, whereas the response needs to address equipment selection for each of the construction, operation & maintenance, and, decommissioning periods. The PG&E comment response references Section C.11 in Appendix C – Design Criteria (page C-32) of the 60% BoD Report, and I have several questions concerning that section, which is reproduced below.

1) A design margin of 3 to 5 A-weighted decibels (dB[A]) will be considered in all noise design criteria.
2) In conformance with the EIR mitigation measures NOISE-3 and CUL-1a-10, the operational noise design criteria for the project will be per San Bernardino County Development Code 83.01.080 for acceptable exterior noise standards for place of worship, which is 55 dB(A) Leq daytime (7 a.m.-10 p.m.) and 45 dB(A) Leq nighttime (10 p.m.-7 a.m.) (Leq is the equivalent average hourly noise level) (see page 4.9-24 of the EIR [DTSC 2011]). The noise measurement locations will be at the edge of the Maze closest to the subject facilities and at the short-term ambient noise measurement locations (ST-1, ST-2, and ST-3) in Exhibit 4.9-2 of the certified EIR (DTSC 2011).
3) For remedy facilities in Arizona, the operational noise design criteria will be 60 dB daytime and 50 dB nighttime average at closest residences (per current Mohave General Plan, Exhibit V-5, Maximum Noise Levels for Various Land Use).
4) For remedy facilities on the Refuge, the operational noise design criteria will be 60 dB.
5) For remedy facilities located on the Compressor Station and within PG&E property, the operational noise design criteria will be consistent with the noise environment at the Station, per San Bernardino County Development Code 83.01.080 for industrial land use, 70 dB(A).
6) The construction noise criteria will conform to San Bernardino Development Code and Mojave County standards, as well as the EIR mitigation measures NOISE-1, -2, and -3.
Per San Bernardino County Code Division 3 Chapter 83.01.080, temporary construction, maintenance, repair, or demolition activities between 7:00 a.m. and 7:00 p.m., except Sundays and federal holidays, are exempt from noise limits.

> A) Regarding the first bulleted item, please explain what is meant by this statement. How will this design margin be applied, and what facilities are being designed using the margin?

RESPONSE: *Anticipated overall operational sound levels for the groundwater remediation project will be compared to the criteria stated in Items 2 through 5 above. The design goal will be that the operational sound levels are 3-5 dBA less that the stated criteria. That is, as the project proceeds through detailed design, it will not be designed right up to the stated criteria. This is considered good engineering practice. The facilities are those related to the remedy, are stationary and of non-emergency nature.*

B) Concerning the second bulleted item, operational noise criteria are identified, and noise measurement locations that will supplement existing locations ST-1, ST-2 & ST-3 are called out. Will the Tribes be consulted in the selection of these supplemental locations? Will these supplemental locations and the existing ST locations be utilized for construction-period noise monitoring? Will background noise levels be established at these supplemental locations in advance of the construction period – similar to what is being done for Short-Term locations ST-1, ST-2 & ST-3? To what does the term “subject facilities” refer?

RESPONSE:
Once the groundwater remedy is in operation, should the Tribes have concerns about operational noise that is generated by the remedy, PG&E will work with the Tribes to select measurement locations at the edge of or within the Maze, if the Tribes desire, and conduct monitoring at these selected locations. Subject facilities noted under Item 2 refer to remedy facilities that are stationary and of non-emergency nature.

Item 6 above pertains to noise generated during construction. With regard to noise monitoring during construction, PG&E will comply with the EIR mitigation measure NOISE-2c which states that “When construction activities are conducted within the distances outlined above (i.e., 1,850 feet and 5,830 feet from California receptors and 330 feet and 735 feet from Arizona receptors for daytime and nighttime noise, respectively) relative to noise-sensitive uses in the project area, noise measurements shall be conducted by a qualified acoustical consultant at the nearest noise-sensitive land use relative to the construction activities with a sound level meter that meets the standards of the American National Standards Institute (ANSI Section S14 1979, Type 1 of Type 2) to ensure that construction noise associated with the project component complies with applicable daytime and nighttime noise standards.” Coordination and communication with Tribes on all project noise-generating activities will be in accordance with the Draft CIMP protocol for CUL-1a-8h, which is intended to reduce auditory impacts during remedy implementation.

C) In the fourth bulleted item, will noise data, if and when measured, be collected at the property line of the Refuge or at other locations, possibly within the Refuge? Where, specifically?

RESPONSE: *PG&E does not anticipate operation of this project will result in an exceedance of the design criteria. Should a specific and actual concern arise during operations, PG&E will conduct appropriate measurements to address that concern. It would be purely speculative to identify specific locations at this time as there is no reason to anticipate a specific concern.*

D) Is the 70 dB(A) noise criterion, identified in bulleted item 5, an Leq value, and if so is it a daytime, nighttime or 24-hr value?

RESPONSE: *San Bernardino County Development Code 83.01.080, specifically Table 83-2, establishes an Leq metric during both the day and night. It is reproduced below:*

Table 83-2 Noise Standards for Stationary Noise Sources		
Affected Land Uses (Receiving Noise)	7 am-10 pm Leq	10 pm-7 am Leq
Residential	55 dB(A)	45 dB(A)
Professional Services	55 dB(A)	55 dB(A)
Other Commercial	60 dB(A)	60 dB(A)
Industrial	70 dB(A)	70 dB(A)
Leq = (Equivalent Energy Level). The sound level corresponding to a steady-state sound level containing the same total energy as a time-varying signal over a given sample period, typically 1, 8 or 24 hours.		
dB(A) = (A-weighted Sound Pressure Level). The sound pressure level, in decibels, as measured on a sound level meter using the A-weighting filter network. The A-weighting filter de-emphasizes the very low and very high frequency components of the sound, placing greater emphasis on those frequencies within the sensitivity range of the human ear.		
Ldn = (Day-Night Noise Level). The average equivalent A-weighted sound level during a 24-hour day obtained by adding 10 decibels to the hourly noise levels measured during the night (from 10 pm to 7 am). In this way Ldn takes into account the lower tolerance of people for noise during nighttime periods.		

E) The sixth bulleted item, states (correctly) that the San Bernardino County Code exempts temporary construction, maintenance and repair activities from noise limits provided that the activity occurs between the hours of 7 AM and 7 PM, Sundays and Federal holidays excluded. (They have a similar exemption for vibration.) The inclusion of this statement in the design documents is troubling, because it is at odds with Section 4.9.3.2 of the FEIR (Thresholds of Significance), in which this basically unlimited noise threshold was rejected. Why then, is it used as a noise criterion in the Basis of Design report?

RESPONSE: *This was not intended to be confusing. Construction noise was appropriately identified as potentially significant and mitigation measures were established in "Mitigation Measure NOISE-2: Project Generated Construction-Related Noise Levels."*

Comment Item 320 concerns the importance of meteorological effects on noise propagation. The comment response appears to address stationary/permanent noise sources during the operational period, but it should be expanded to address mobile and transient sources, such as those used during well construction and rehabilitation, because those latter sources will generate higher noise levels, and quite possibly at lower frequency.

RESPONSE: *Construction equipment noise levels and ranges, as well as potential influence of meteorology on sound propagation are well documented. Construction noise for the project was appropriately identified as potentially significant and mitigation measures were established in "Mitigation Measure NOISE-2: Project Generated Construction-Related Noise Levels."*

Comment Item 321 as initially worded, concerned what was felt to be a nearly complete absence of data interpretation and discussion in Appendix A8. Additional clarification to the comment was provided subsequent to the comment period. The PG&E and DTSC responses provide sought-after background on the various metrics used in the Appendix A8 report, and on the ST site selection, and that is much-appreciated. While one could have made their own assumptions, quite possibly erroneous, it is most helpful to have an explanation of what was measured, averaged, statistically-developed, and recorded. This information and discussion should be included in Appendix A8 of the 90% BoD Report. The comment response mentions the November 8, 2012, PG&E Topock Groundwater Remediation Project Sound Level Measurements Protocol, which, I recollect, perhaps incorrectly, was issued (based on its date) after supplemental sound level measurements had already commenced. Please clarify if the protocol was developed before the August 2012 measurement period and if so, was it distributed to all interested parties?

> **RESPONSE:** *The protocol was developed prior to the August 2012, and was distributed to interested parties in November 2012. The Tribes were notified of the field work associated with the August 2012 and subsequent noise monitoring events.*

Re: Invitation to Review and Comment on Unresolved Noise- and Vibration-Related Comments

Dear Mr. Yue:
On behalf of the Hualapai Tribe, we appreciate being able to respond to unresolved noise and vibration related comments. With the assistance of the Technical Review Committee, Hualapai supports the following language usage for the below stated comments in regards to the close out for the 60% Design.

<u>Comments 260 & 263</u>

Use the following language for closure of each of these comments:

> The DTSC response indicates that Noise and Vibration-Sensitive Land Uses in section 4.9.1.5 did identify the Topock Cultural Area as a sensitive land use. We note that, apparently, no impacts to this use were analyzed. The development of the 90% Basis of Design Report should include a consultation with the Tribes to consider and identify vibration- and noise-sensitive Tribal uses and users.
>
> Comment closed. The Tribes would request that as the sound monitoring details are resolved, the usage of the Topock area as a location of deep spiritual meaning and associated usage would be taken into account to the fullest extent possible.

Comments 320 & 321

Use the following additional language for closure of each of these comments:

1. Revise the noise measurement protocol in consultation with the Tribes. Specifically, the protocol needs to include the collection and archiving of noise measurements that include spectral content (noise level as a function of frequency, which consist of unfiltered and un-weighted, or un-averaged, raw data, aka band spectra), and noise recordings accompanied by a spoken or written narrative addressing what noise and sounds are being heard.
2. Following the above revised protocol, collect additional noise data during the summer and early winter of 2014.
3. Adopt the protocol for use on the project, going forward.

Comment closed.

Comment 322

Comment 322 should be considered as closed.

We appreciate our on-going consultations and collaborations with the Topock Remediation Project and look forward to meaningful dialogue through-out the up-coming years. If you have any concerns please feel free to contact myself, or Dawn Hubbs, Program Manager and we will be happy to assist you.

Sincerely,

Loretta Jackson-Kelly

Loretta Jackson-Kelly, Director and Tribal Historic Preservation Officer

Item	Comment Number	Section/ Page	Reference Text	60% Design Comment	PG&E Response to 60% Design Comments	DTSC Response to 60% Design Comments	DOI Response to 60% Design Comments	Tribe Response to 60% Design Comments	Final Comment Resolution
General Comments									
260	FMIT-36 Hualapai-25 Chemehuevi-25 Cocopah-25 CRIT-25	Table 6.1-1 p. 6-37	Noise-1a	Vibration-sensitive land uses are assumed to consist only of residential and mobile home parks. Based on this assumption Tribal land uses are neglected. Tribal land use must be considered.	The stated assumption is consistent with the certified EIR (see page 4.9-20), and was expressly mentioned in both the 30% and 60% designs. No comments were received on this topic in the 30% design.	Noise and Vibration-Sensitive Land Uses in section 4.9.1.5 which did identify the Topock Cultural Area as a sensitive land use. NOTE TO KEEPER OF THE MATRIX: THIS DTSC RESPONSE, AS PRESENTLY WORDED, APPEARS TO BE INCOMPLETE (COMPARE TO THE DTSC RESPONSE FOR ITEM 263, BELOW.)			This comment and the responses were discussed at the December 12, 2013 TWG telecon.
263	FMIT-39 Hualapai-28 Chemehuevi-28 Cocopah-28 CRIT-28	Table 6.1-1 p. 6-38	Noise-2c	While vibration-sensitive receptors are discussed and identified as part of Noise-1, there is no similar discussion and identification of noise- sensitive receptors.	The certified EIR defined noise sensitive receptors in Chapter 4.9.1.5 (Existing Noise Environment, page 4.9-5).	Noise and vibration- sensitive receptors are discussed in the Noise and Vibration-Sensitive Land Uses section 4.9.1.5 which did identify the Topock Cultural Area as a sensitive land use.			This comment and the responses were discussed at the December 12, 2013 TWG telecon.
320	FMIT-53 Hualapai-39 Chemehuevi-39 Cocopah-39 CRIT-39	Append A8		The important effect(s) of meteorological conditions on the long-range propagation of sound should be addressed.	Meteorological effects are most pronounced for elevated sources or very loud sources, particularly those with strong low frequency content (such as a train). The operational sources of noise associated with this project are primarily located within buildings or underground, therefore their sound emissions are minimized and are not elevated. This project does not utilize equipment which is known to emit high levels of low frequency noise (such as train engines or unsilenced simple-cycle combustion exhaust stacks). See also response to TRC's (Charlie Schlinger) memorandum dated December 10, 2013, included in **Attachment H**, at the end of this table.				Written comments on the responses to this comment were received from the TRC (Charlie Schlinger) on November 15, 2013. PG&E provided a response to the written comment on December 10, 2013 (see memo included in **Attachment H**, at the end of this table).
321	FMIT-54 Hualapai-40 Chemehuevi-40 Cocopah-40 CRIT-40	Append A8 p. 1 and Figure 1	*The sound measurement locations were selected near the short term measurement locations in the Final Environmental Impact Report (FEIR) (DTSC,2011).*(shown in Exhibit 4.9-2 as ST-1, ST-2, and ST-3) (see Figure 1)	The three sites, ST-1, ST-2 & ST-3, have quite different levels of background sound levels and time—distributions, but this is not discussed. The report as it stands provides practically no quantitative evidence about the nearby noise sources and their (expected/measured) spatial contribution to the background noise. Such information is crucial to properly analyze and understand the highly variable background noise which was measured across the three sites. Further, it is unclear as to why these sites were chosen. *"PGE asked for clarification of this comment prior to response. The following clarification of comment was obtained from TRC on October 17, 2013. Response addresses the clarified comment.* *It is unclear what the data entries included in*	American National Standards Institute (ANSI) S1.4 Type 1 (precision) sound level meters were used to monitor ambient sound levels. The sound level meters were programmed to report the average (L_{eq}) and statistical sound level	A specific rationale for the selection of individual sites for noise measurements was not provided in the Groundwater Final EIR. Based on the locations of the monitoring locations, the following can be inferred: ST 1 was chosen for its proximity to Maze Loci A; ST 2 was chosen for its proximity to Maze Loci C; ST 3 was chosen for its proximity to residences and traffic intersection at Park Moabi; LT A was chosen to provide ambient noise data from I-40; and LT B was chosen to provide ambient noise data from the BNSF rail line. It can also be inferred from the text in the Final		The Tribe was not involved in the selection of the sites in the FEIR and the 2012-2013 study. The Tribes also note that there is no noise monitoring plan.	Written comments on the responses to this comment were received from the TRC (Charlie Schlinger) on November 15, 2013. PG&E provided a response to the written comment on December 10, 2013 (see memo included in **Attachment H**, at the end of this table).

				Appendix A8 Tables (1 & 2) represent? It is assumed that these data represent averages of other numbers presumably numbers in the Appendices (C-H) of Appendix A8. Please confirm if this assumption is correct. In addition it is not clear what the numbers in Appendices C-H represent? Presumably, they too are "averages" of other numbers - these latter numbers probably being what was actually measured. Please provide additional detail that allows the reader to understand what was actually measured and for what duration(s). That is, what are the basic measurements for this baseline sound characterization, and what "averaging" methods were used to develop the tabular summary information?	metrics (Leq, L50, and L90) at hourly intervals. The sound level meters continuously monitor the sound levels during each hourly interval and automatically calculate and report the average and statistical levels at the conclusion of the hourly interval. This process repeats continuously until the meters are manually turned off or the batteries are depleted and the meter automatically turns off. Appendices C through H present the data reported by the sound level meters in tabular and graphical format. The data in Table 1 is a summary of the data presented in Appendices C through H. Table 1 presents the maximum and minimum hourly Leq sound pressure level and corresponding wind speed for each monitoring location during both the daytime (7 a.m. to 10 p.m.) and nighttime (10 p.m. to 7 a.m.) periods for both the summer and winter monitoring events. For example, the data presented in Appendix C (ST-1, August 2012) was reviewed to identify the maximum and minimum L_{eq} during the daytime and nighttime periods. These maximum and minimum levels were summarized for in Table 1 along with the wind speed that occurred during those maximum and minimum periods for ST-1 during August 2012. Table 2 presents the same sound pressure level data that is in Table 1 alongside the data collected from the 2008 EIR (the wind speed which was reported in Table 1 was omitted from Table 2 to enhance readability of Table 2). Table 2 shows that the short-term data collected for the 2008 EIR is within the range of the longer-term data collected over both a summer and winter period. Had the 2008 EIR sound level data fallen substantially outside the range of that recorded during this longer term monitoring event, its reproducibility could have been questioned. This did not occur. That is, there was nothing anomalous or spurious occurring during the time the sound level data reported in the 2008 EIR was collected.	EIR that the five locations were identified in recognition of the existing noise environment associated with the site (i.e., the diversity of background sound levels that exist on the site) and the existing noise-sensitive land uses. Further, because intervening topography exists between the compressor station and other portions of the project areas in the form of mesas that generally shield noise-sensitive receptors from full exposure of current on-site operations, multiple representative sites for ambient noise measurements were necessary. To accurately describe potential noise related impacts, the Final EIR used the ambient noise survey data from the individual locations to determine impacts to nearest sensitive receptors from the proposed project (i.e., the data collected for the three sites was not averaged). The normalization of the data described above, was conducted for individual sites only.			
				Site selection is a critical matter when it comes to developing a baseline. In the case of noise on this project, 3 sites were selected, with very little basis/justification provided in the FEIR. (The initial response to comments for this comment goes a long way in providing some explanation, but it is not complete, as ST-1 and ST-2 are indeed located on "mesa" tops (upland areas) and one, ST-3, is located down off of the "mesa",	These sites were chosen by the EIR preparer for noise measurements because mesas that generally shield noise sensitive receptors from full exposure of operations that were occurring when the EIR was prepared, exist between the compressor station and other portions of the project areas (see FEIR, page 4.9-5). Additional data				

				at a street intersection.) Please provide additional detail regarding what is it about these sites that is representative and meaningful when it comes to baseline noise measurements? Why are these locations appropriate for developing the baseline sound characterization? *The reporting in Appendix A8 is too clinical and terse; there are no more than a half-dozen sentences given to the discussion of results, mainly with an eye toward wind effects on noise measurements. While there are essential footnotes related to measured wind speed, which is highly relevant to noise measurements, there is no interpretation and discussion of the numerical values in Tables 1-2, or in the Tables in Appendices C-H in terms of individual site location and proximity to known noise sources, time of day, actual noise from these sources, season, atmospheric conditions, topographic conditions, or any other factor known to influence the measurements.* *There needs to be clear communication, in the design documents, of how these most recent noise data, together with the FEIR noise data collected in 2008, will be used as part of the project design.*	was collected in proximity to these sites in 2012 – 2013. Agencies, Tribes, and Stakeholders were informed of this selection as documented in the *Sound Level Measurements Protocol Technical Memorandum* (Appendix B to the 60% BOD Appendix A8). See also response to comment #322 FMIT-55/Hualapai-41. The *Sound Level Measurements Technical Memorandum* in Appendix A8 is intended to report the supplemental data collected during the 2012-2013 event. Since the existing site conditions (e.g., noise environment, topographic condition) are well documented in the FEIR, that body of information is intentionally not repeated in this technical memorandum. If helpful, additional references to the FEIR can be added to this technical memorandum. See responses to comment #317 FMIT-50/Hualapai-36 and #319 FMIT-52/ Hualapai-38, as well as TRC's (Charlie Schlinger) memorandum dated December 10, 2013, included in **Attachment H**, at the end of this table.				
322	FMIT-55 Hualapai-41 Chemehuevi-41 Cocopah-41 CRIT-41	Append A8 p.1 and Photo 1 & 2		The 60% BOD Report Appendix A-8 noise measurement locations are reported to be "near" and "in proximity to" the certified EIR noise measurement locations. The meanings of these terms are ambiguous and need clarification. Why were the certified EIR noise measurement locations not used?	Precise GPS locations were not available for the locations used in the certified EIR. The 2012 – 2013 noise measurement locations were selected based on their suitability for a longer term noise measurement. All of these locations are within approximately 100 feet of the EIR noise measurement locations and are well within the same acoustical environment.			The Tribes were not involved in the selection of the sites in the FEIR and the 2012-2013 study. The Tribes also note that there is no noise monitoring plan.	This comment and response were discussed at the October 16-17, 2013 TWG meeting.

Appendix 2

This issue has its origins with DTSC's EIR requirement for very minimal 15-minute-duration acoustic measurements at 3 locations, ST-1, ST-2 & ST-3, which were not selected in consultation with the Tribes. Further, the protocol for EIR acoustic measurement was developed without Tribal consultation. To its credit, the EIR well-addressed and quantified known noise sources – the railway and interstate highway, and the data from those noise source measurements, provided in the EIR, forms a part of our understanding of the "noise-scape" at Topock.

As part of its design process, PG&E, apparently voluntarily and unilaterally, collected additional acoustic measurements, of much greater duration than those obtained as part of the EIR development. The protocol for these measurements was circulated to the stakeholders after the first half (August 2012) of the acoustic measurements had been completed. The sites consisted of the same 3 locations identified above.

This additional information goes part of the way toward remedying the situation, but that other vital information was not recorded. This comes down to a matter of measurement protocol.

In order to have a complete record of the baseline, it is essential to not only record 15-minute or hourly averages of noise levels, but to also record information on the frequency content of the noise being measured, to actually record typical identifiable noise, and to provide a written narrative that explains the origins (railroad, interstate, compressor station, motorized watercraft, wind, etc.) of signals that have been recorded, and links this knowledge to the corresponding measured averaged noise levels. This would allow the contributions of specific and well-known noise sources to be quantified for the locations of interest, and understood by all parties, not just acoustic engineers. The instrumentation that has been used is certainly capable of recording this data, though the observer must keenly observe, take good field notes, and prepare the narrative. However, due to a narrowly-focused protocol, this was not done. Instead, the information provided represents averages of noise levels observed over extended time periods (typically an hour).

Subject: Comments on Noise/ Vibration and Pipeline Routing

Mr. Yue, the Colorado River Indian Tribes will not be submitting further comment for the 60% Design phase on the Noise and Vibration issues nor on the Pipeline Routing issues at this time. We have participated in the discussions of those issues, and are satisfied the DTSC, DOI and PG&E have heard our concerns directly, and through the other Tribal comments. We will consider adding further input as the design process moves forward.
Thank you for your efforts in this regard. db

PG&E's Response to TRC Technical Memorandum on Chemistry

Response to Memo from Win Wright titled "RTC728_Memorandum_Nov18_2013_with comments_rev" (12/9/2013)

Comment 1 - For the Topock project, many of the groundwater samples will contain concentrations of ethanol or reaction products from the IRZ operations, and these samples will be inherently unstable.

Response – *As discussed below, PG&E believes that once preserved, stability is assured and approved method holding times apply.*

Comment 2 - Two graphs plotted by the commenter showing data from the Upland In-Situ Pilot Test (ISPT) report. During the ISPT ethanol-injection experiment, samples from monitoring wells were collected for analysis in the field (which were analyzed within 24 hours at the IM-3 facility laboratory), and samples were collected for analysis in the laboratory, where the holding time for Cr(VI) analysis was 28 days (per PG&E Holding Time Tech Memo, January 4, 2008, also attached).

Response - *PG&E believes that the basic construction of these plots is based on a questionable premise. The inherent assumption in these plots is that screening level field data quality are equal and comparable to laboratory data quality. Screening field data cannot reasonably be compared to fixed laboratory data quality and therefore, the conclusions of the table are somewhat suspect.*

Based on PG&E's experience with sampling chromium at Topock and Hinkley, any Cr(VI) present in the samples at the time of collection would be detected in the Cr(T) results, even if there were reaction in the sample bottle during transport or storage. In addition, in virtually all cases the Cr in the Cr(T) and Cr(VI) sample containers are approximately equal [Cr(T) ≅ Cr(VI)] (please note that there are specific conditions where this may not be true, see bottom of response to comment 3 below). Data at both the Topock and Hinkley project sites particularly demonstrate this connection at chromium concentrations that exceed 10 µg/l.

A graphic comparison of the laboratory Cr(T) results to laboratory Cr(VI) results yields better agreement in the range of 10-1000 µg/l (Figure 1, attached), than the graphs presented by the commenter using field Cr(VI) data to compare against laboratory Cr(VI) data. Below 10 µg/l, there is more scatter in the Cr(T) versus Cr(VI) results.

Comment 3 - Exhibit RTC-728a: Water from monitoring wells that showed TOC (ethanol) breakthrough, results plotting to the right of the 1:1 Line indicate that many of the field-analyzed Cr(VI) results were greater than the laboratory Cr(VI) results. Some samples showed positive results in the field, but showed below-detection results in the laboratory. An ideal scenario would be for all of the samples to fall on the 1:1 line.

Response - *A review of the Topock and Hinkley in situ data set yields the following observations with respect to the possibility of continued reduction of Cr(VI) to Cr(III) in the sample bottle after sample collection:*

- *For the Topock Upland ISPT, 443 samples were collected and analyzed for both Cr(T) and Cr(VI); 41 (9.3%) have results where the Cr(T) and the Cr(VI) are different by more than 10 µg/l and have a RPD that is greater than 20%. Of the 41 samples, six (1.4% of the 433 samples) have Cr(VI) results that are greater than Cr(T) results (i.e., reduction not possible) and 35 (7.9% of the 433 samples)* *have Cr(VI) results that are lower than the Cr(T) results. Therefore, assuming the difference between Cr(T) and Cr(VI) will vary equally for both analytes (based on the expected precision and accuracy levels of these methods), approximately 6.5% of the sample results could indicate a possibility of continued reduction in the sample bottle.*

In addition, there was no correlation between samples with an RPD greater than 20% and a difference of 10 µg/l or greater and the presence of TOC. Only 15 samples (3.3% of the 433 samples) were associated with TOC that exceeded 50 mg/L and met the conditions necessary for continued reduction to have occurred [i.e., Cr(VI) results that are lower than the Cr(T) results, RPD greater than 20%, and a difference greater than 10 µg/l] (further explanation of these conditions is provided below). For the 24 samples with TOC concentrations that exceeded 1000 mg/l, the results showed no indication the samples continued to be reduced after sample collection and preservation.

- *For the Hinkley IRZ project, of the 8684 samples that have both Cr(T) and Cr(VI) results, 433 (5%) have results where the Cr(T) and the Cr(VI) are different by more than 10 µg/l and have a RPD that is greater than 20% . Of the 433 samples, 154 (1.8% of the 8684 samples) have Cr(VI) results that are greater than the Cr(T) results (i.e., reduction not possible), and 279 (3.2% of the 8684 samples) have Cr(VI) results that are lower than the Cr(T) results. Assuming the difference between Cr and Cr(VI) will vary equally for both analytes (based on the expected precision and accuracy levels of these methods), approximately 1.4% of the samples have results that could indicate possible continued reduction in the sample bottle.*

- *In summary, with over 9,000 sample results between the Topock and Hinkley in-situ projects, less than 2% show a possibility that continued reduction could occur in the sample container after sample collection and preservation.*

The following are considered the only conditions where Cr(VI) can possibly be reduced in a sample bottle after collection and preservation:

- ***Cr(VI)<Cr(T)*** *– If Cr(VI) is greater than Cr(T), reduction is not possible in the sample bottle during transport or storage.*

- ***RPD>20% -*** *Because the Cr(T) and Cr(VI) analyses are performed by different methods and use different instruments, a relative percent difference (RPD) of 20% or more is possible based on the expected precision and accuracy levels of these methods.*

- ***Difference between Cr(VI) and Cr(T)>10 µg/l -*** *Sample results that differ by less than 10 µg/l (for low concentration samples) could be caused by naturally occurring "dissolved" chromium, whether colloidal or trivalent. Such difference could also be caused if the rate of Cr(III) precipitation is lower than the rate of Cr(VI) reduction in the aquifer.*

Comment 4 - Exhibit RTC-728b: Even at low TOC breakthrough concentrations (146 mg/L), the field Cr(VI) results are 20-30% greater than the laboratory Cr(VI) results. These discrepancies could be inherent in the different methods, or could be caused by turbid field samples or high iron concentrations which interfere with the field colorimetric method. However, these discrepancies also could be caused by conversion of Cr(VI) to Cr(III) within the sample bottle during the 28-day holding time; hence, the laboratory Cr(VI) results were lower than the field Cr(VI) results.

Response - *See response to comment 2 for comparison of laboratory and field screening data. PG&E agrees with the possible causes of discrepancies identified in the comment, i.e., inherent in the* *different methods, or could be caused by turbid field samples or high iron concentrations which interfere with the field colorimetric method. PG&E believes that these are also reasons why the data cannot be compared to one another.*

PG&E does not agree with the statement regarding the conversion of Cr(VI) to Cr(III) in a preserved sample regardless of holding time. Both chemical and biological reactions are severely slowed or stopped due to the decrease in temperature (samples are around 27 °C when they come out of the wells and are cooled to 4°C as soon as possible). In addition, after the buffer solution is added to the samples, pH (pH 9.3 - 9.7) also severely slows or stops all chemical and biological reactions.

Furthermore, the data collected at PT-9S (the location with a TOC breakthrough of 146 mg/L, as noted in the comment) do not indicate a relationship between the arrival of TOC with discrepancies between field and laboratory concentrations of Cr(VI). Results for laboratory and field measured Cr(IV), Cr(T), and TOC over time are plotted in Figure 2. A discrepancy was measured in the first, baseline sample collected, prior to introduction of TOC into the aquifer, and discrepancies also occurred in other samples collected before the TOC arrived on November 12, 2008. Following TOC arrival, the discrepancies do not correlate with the presence of TOC. Cr(T) and laboratory Cr(VI) concentrations were in better agreement than laboratory and field Cr(VI) throughout the dataset, reinforcing that the laboratory Cr(VI) concentrations are indicative of aquifer conditions.

It should also be noted that samples should always be analyzed as soon as possible after collection. The holding time listed by the method is a maximum time that samples may be held before the start of analysis and still be considered valid without being qualified. Although a maximum holding time of 28 days was established for Cr(VI), the average holding time over the last 4 years has been 8 days for the groundwater monitoring samples and under four days for the IM3 facility samples; analyzed by the off-site laboratory.

Comment 5 - Attached is a press release from the California Dept. of Public Health, where the holding time of 5 days is recommended for Cr(VI) analyses by EPA 218.6 (ion chromatography with post-column derivatization).

Response - T*he press release refers to recommendations regarding drinking water. Topock groundwater samples are collected for environmental data analysis, not drinking water analysis. The PG&E holding time study was performed over two sampling events covering 60 samples collected from randomly selected Topock wells with Cr(VI) concentrations ranging from 0.2 µg/L to 14,800 µg/L. The study results strongly support longer holding times (and follows the EPA Final Methods Update Rule published May 18, 2012).*

With regard to the use of the borate buffer solution referenced in the press release, the buffer was intended to be used as a way to make sure the desired pH range of the sample was obtained. The current buffer PG&E uses is approved by EPA and DTSC, and is mandated by the Water Board on the Hinkley project. There has been no issue with obtaining the desired pH. PG&E believes that changing buffer is not needed at Topock and is not required by the EPA method.

Recommendations:

1) Holding time of 5 days for analysis of Cr(VI) by EPA method 218.6 (or alternatively EPA 218.7). Field filtration and preservation with borate-carbonate buffer.
2) Holding time of 24 hours for SM-3500 Cr-B. Field filtration, and preservation with a basic solution (sodium hydroxide, or alternatively ammonium sulfate/ammonium hydroxide buffer). Since chlorine may be used as post-treatment for water from HNWR-1, the ammonium sulfate will help remove chlorine.

3) Holding time of 24 hours for the Hach hexavalent chromium method. Field filtration, no preservation.
4) Revisit and update the PG&E Holding Time Study, where different preservatives, holding times, TOC spike samples, and Cr(VI) spike samples can be compared.
5) Sample splits--continue to analyze for field Cr(VI) and laboratory Cr(VI). Splits should comprise 10% of all monitoring well samples collected as part of the groundwater remedy, until confidence can be proven that preservation methods and holding times are providing the best data regarding Cr(VI) results.

Response to Recommendations:

1) *Disagree. The five day holding time and the borate-carbonate buffer are recommendations from the State for drinking water analysis and were not intended for environmental analysis. It is more appropriate to use the May 2012 EPA Update Ruling which specifies the buffer and holding time criteria for CrVI) in environmental analysis. No changes are proposed to the 28 days holding time.*
2) *Disagree. The May 2012 EPA Update Ruling specifies the buffer and holding time criteria for Cr(VI) in environmental analysis and does not apply for just the EPA 218.6 method. Note method SM-3500 Cr-B is only used for samples when concentrations are expected to be greater than 100 µg/L. The standard ammonium sulfate/ammonium hydroxide buffer was showed to work for this method as well. No changes are proposed to the 28 days holding time.*
3) *Agree. The field laboratory protocols follow the 24 hour holding time, the field filtration, and the use of no preservative.*
4) *Disagree. PG&E does not believe that the additional holding time studies are needed or warranted because the current holding time follows the EPA Final Methods Update Rule published May 18, 2012. Furthermore, producing a carbon spike that would mimic the field conditions would be very difficult or impossible.*
5) *Disagree. See response to comment 2. Note that field screening data are intended as screening level data of process control purposes only and are not intended to replace laboratory data.*

Hinkley IRZ Well Fouling

PG&E Topock Compressor Station, Needles, CA
Summary of IRZ Well Fouling at Hinkley as it Relates to Re-Injection of Remedy Produced Water into IRZ Injection Wells at Topock
1/27/2014

One option for reuse of remedy produced water at the PG&E Topock Compressor Station site is to condition and re-inject into National Trails Highway (NTH) In Situ Reactive Zone (IRZ) injection wells. This summary presents information on the factors affecting IRZ injection well fouling based on experience at the PG&E Hinkley Compressor Station site; and an evaluation of the potential for re-injection of conditioned remedy produced water to affect IRZ injection well performance at Topock. Experience with IRZ well fouling at Hinkley has been incorporated into the remedy design for Topock. Operational information collected to date at Hinkley continues to support the design criteria for the remedy produced water conditioning system proposed in the 60% design.

Summary of IRZ Well Fouling at Hinkley
IRZ injection well fouling occurs as the result of the generation of biomass and/or formation of mineral precipitates caused by organic carbon injections. Two primary types of fouling have been observed in the Hinkley IRZ injection wells:

- Microbial biomass and associated extracellular polysaccharides.
- Mineral precipitates. These are comprised primarily of reduced iron sulfide minerals formed through the generation of ferrous iron from iron reduction and sulfide from sulfate reduction. In addition to these types of precipitates, carbonate minerals may also form within IRZ injection wells as carbonate is generated by microbial respiration.

IRZ well fouling is currently managed at Hinkley by chemical rehabilitation, typically with phosphoric acid (NuWell 120) and a biodispersant (NuWell 310). Water extracted from injection wells during rehabilitation is filtered for solids removal and blended with recirculated groundwater for re-injection.

Evaluation of Potential for Remedy Produced Water to Foul IRZ Injection Wells Conducted as Part of the Remedy Design
As indicated in Table F-1 in Appendix F of the 60% Basis of Design, the majority of remedy produced water is anticipated to be similar in water quality to the water from the Arizona aquifer or to the water from the aquifer at the NTH IRZ and Riverbank remedial wells, and may potentially contain sediment, IRZ byproducts, and rehabilitation chemicals. As discussed in the 60% Basis of Design, two parameters were considered important for the re-injection of remedy produced water into IRZ injection wells in order to minimize potential fouling based on this profile, and were included in the design specifications for the conditioning plant (Exhibit 3.4-5 on the 60% Basis of Design):

- **pH** - As stated in the design, the pH of the conditioned water will only be adjusted if it falls outside a neutral range (specifically a range of 6.5 to 8.5). The range was selected to match closely with the natural pH of the groundwater in the NTH IRZ and is prescribed to minimize adverse geochemical reactions that might increase the precipitation of minerals.

- **Sediment**- Solids will be removed from the remedy produced water to minimize IRZ injection well clogging, with a design specification of total suspended solids (TSS) less than 5 microns.

Other potential constituents in the remedy produced water were evaluated as part of the remedy design but not considered likely to have a significant effect on well fouling. Therefore, design criteria were not specified for constituents/parameters other than pH and sediment measured as TSS. Other constituents reviewed included the following:

- **IRZ Byproducts:** Elevated concentrations of IRZ byproducts, such as dissolved iron and dissolved manganese, are expected to remain soluble in the reducing environment of the IRZ and are not expected to have a significant effect on fouling.

- **Rehabilitation Chemicals:** The chemical rehabilitation process at Topock will employ similar techniques as have been used at Hinkley, including the use of commercially available well rehabilitation products that are designed for drinking water well rehabilitation and remediation well rehabilitation. Based on experience at Hinkley, management of water generated during well rehabilitation through solids removal, blending with re-circulated groundwater and re-injection does not exacerbate fouling.

- **Total Dissolved Solids:** Total dissolved solids is comprised of cations, anions, alkalinity, and dissolved metals. Several of these ions (e.g. calcium, magnesium, bicarbonate/carbonate, and sulfate) could potentially precipitate as carbonate or gypsum minerals causing fouling. Others (e.g., sodium, potassium, chloride) are highly soluble and not anticipated to cause precipitation or fouling, even if added as sodium hydroxide or hydrochloric acid for conditioning. The potential for fouling of carbonate or gypsum was considered minimal, particularly in comparison with fouling due to iron sulfide minerals and biomass generated by the IRZ, based on the following:

    - Concentrations of calcium, magnesium, and carbonate in the remedy produced water are anticipated to be lower or comparable to the aquifer in the vicinity of the NTH IRZ injection wells, limiting the potential for precipitation of carbonates and gypsum from mixing.

    - Gypsum, if formed from the addition of sulfuric acid for pH adjustment during conditioning, would be removed by filtration in the conditioning process prior to injection.

Re: FMIT comments on modeling issues related to the 60% BOD Report for the PG&E Topock Compressor Station

Dear Mr. Yue and Ms. Innis:

Hargis + Associates, Inc., at the request of its client, the Fort Mojave Indian Tribe ("FMIT" or "the Tribe") is herewith forwarding the enclosed comments and recommendations received from the Topock Technical Review Committee ("TRC") regarding concerns related to modeling performed in support of the 60% Basis of Design ("BOD") Report for the Pacific Gas & Electric, Company ("PG&E") Topock Compressor Station groundwater remedy.

As you may be aware, the Tribe relied heavily on the TRC's technical expertise in numerical modeling in preparing its comments on the 60% BOD Report. The enclosed comments from the TRC represent a summary of subsequent discussions arising from the Technical Working Group ("TWG") meetings, remaining concerns, and proposed recommendations for resolution at the forthcoming 90% BOD stage. The Tribe supports this analysis by the TRC and is forwarding the technical memorandum for inclusion in the 60% BOD Report Response to Comments (RTC).

However, the Tribe would like to add a few edits to the comments for the purposes of clarification. These are as follow:

- p. 1, 2nd to last paragraph – The Tribe wants to make clear that "… all remaining 60% BOD comments …," refers to only the resolution of outstanding *modeling* comments, not *all* comments and issues that the Tribe has raised in regard to the entire 60% BOD.

Other Offices:
Mesa, AZ
San Diego, CA

- p. 4, at the 3rd bullet – There are a few typos including an extra "the" after PG&E in the first line, and there should be a "c)" before "chemical reactions."
- p. 7 – The Tribe wants to make it clear that the bolded text refers to the attainment of RAO *as presently stated*. In other words, the Tribe leaves open the option for "improving" the RAOs.

Please contact me or Ms. Nora McDowell if you have questions concerning this submittal.

Sincerely,

HARGIS + ASSOCIATES, INC.

839.07 Modeling RTC

Integrated Hydro Systems, LLC

Thursday, April 3, 2014

To: Topock Tribal Representatives, TRC Members

From: Bob Prucha, TRC

Subject: Overview of Key Concerns Related to Modeling in the 60% BOD and Recommendations for Comment Resolution

Overview

I reviewed the PG&E April 2013 60% BOD Report, focusing primarily on the modeling section (Appendix B) but also Section 3 and the Executive Summary. I focused my comments primarily on the numerical modeling as it relates to the proposed system design and operation. My comments generally fell into the following categories:

- Modeling Objectives
- Model Sensitivity Analysis/Calibration
- Model Prediction Uncertainty
- Model Optimization
- Possible Effects of High TDS/Density on Remedial Performance

Though the majority of comments were resolved through the RTC process, many remain unresolved. Based on things learned going through the RTC process (i.e., original 60% BOD review/comments and subsequent discussions in TWG meetings, in phone calls, emails, and iterations on RTC tables), I identified two main issues, related to uncertain model predictions about the length of time needed to clean up the plume so the remediation system can be removed. I believe these issues could be resolved if PG&E follows these two recommendations:

a) The 90% BOD Report should include a plan detailing specific data that will be collected **<u>during remedy installation and commissioning</u>** (such as hydraulic testing), specific details on how these data will be used to update and re-calibrate the model, and what scenarios would be re-run. This important data set would be critical to assessing the preliminary design/operation assumptions and allow for adjustments to operational parameters.

b) The 90% BOD Report should also present a detailed plan on how the models (i.e., flow, fate/transport, geochemical) will be updated, re-calibrated, and which scenarios are re-run **<u>during operation</u>**, including adjustments to the operations over time. More details are needed on the proposed basis for triggering when models are updated, and that any operational adjustments improve system performance towards meeting both short- and long-term RAOs.

If such plans and details are developed by PG&E, for example in the 90% BOD Report, all remaining unresolved 60% BOD comments could simply point to these plans in the RTC tables. To date, it has not been possible to adequately address these larger concerns and recommendations in a single RTC comment. I believe detailed plans to update and utilize the numerical models in an ongoing fashion, for example when adjustments to the operation are made, would greatly help reduce potential negative surprises in the currently proposed (60% BOD) remediation system and operation, much of which was designed and developed using these important modeling tools. This should benefit all stakeholders.

I first provide general concerns and recommendations related to each of the modeling areas above, and then summarize the two main issues and recommendations in the last section of this Memo.

Proposed Comment Resolution – by Category

Modeling Objectives

Associated Comments:

25, 367a, 388a, 388b, 391, 402, 404,

For standard modeling projects, modeling objectives must be stated as clearly and unambiguously as possible, because this strongly influences exactly how models are set up, what simulations are needed, and how accurate results must be.

General Concerns:

In my review, I found that modeling objectives as stated in Appendix B appear inconsistent with the broader objectives of the Remedial Action Objectives (RAOs) as outlined in the body of the report. For example:

RAOs (stated in Executive Summary) include:

1) ***Prevent ingestion of groundwater*** as a potable water source having Cr(VI) in excess of the regional background concentration of 32 µg/L.
2) ***Prevent or minimize migration*** of total chromium (Cr[T]) and Cr(VI) in groundwater to ensure concentrations in surface water do not exceed water quality standards that support the designated beneficial uses of the Colorado River (11 µg/L Cr[VI]).
3) ***Reduce the mass of Cr(T) and Cr(VI) in groundwater*** at the site to achieve compliance with the applicable or relevant and appropriate requirements (ARARs) in groundwater. This RAO will be achieved through the cleanup goal of the regional background concentration of 32 µg/L of Cr(VI).
4) Ensure that the geographic location of the ***target remediation area does not permanently expand*** following completion of the remedial action.

Modeling Objectives (Stated in Appendix B of the 60% BOD Report):

The objectives of this modeling study were to develop a groundwater flow and solute transport model for use as follows:

1) **evaluate** subsurface flow conditions
2) **evaluate** the fate and transport of Cr(VI)
3) **evaluate** fate and transport of manganese and arsenic
4) **evaluate** potential remedial system configurations

It appears as though the objectives of the 60% BOD Report modeling were to only 'evaluate' flow, fate/transport and remedial system configurations. However, for a 60% Design and Operation Plan – I was expecting the modeling objectives to clearly state how the model would be used to:

a) Determine 'optimum' well layout (locations, spacing, total depths, screened zones) to meet RAO objectives;
b) Define operations necessary (injection/extraction flow rates, organic carbon injection locations and rates etc.) to meet RAO objectives;
c) Identify procedures to optimize the long-term operation of the system;
d) Determine where additional remediation wells could go;
e) Optimize the IM-3 decommissioning and startup of the new remediation system to minimize negative impacts to the system (to meet RAO objectives);
f) Determine a range of impacts due to manganese and arsenic by product generation.

PG&E's 60% BOD Report (Page 3, App B.) indicates that the modeling tool(s) represent the most important guide for the design and operation of the proposed remediation system: "*For the Site, the conceptual model forms the single most important guide for the design and operation of the proposed remediation system, as it is the basis for the numeric modeling, comprised of groundwater flow and contaminant fate and transport that simulate the operation of the remediation system.*"

In my experience, a primary reason for 'failure' of models (i.e., poor predictions) is poor definition of modeling objectives. The objectives stated in the 60% BOD Report seem to point to a fundamental problem with the overall strategy for using the modeling tool(s):

a) Objectives were vague and unclear. For example, which objective is the most important, or which provides the greatest constraints on model optimizations?

b) A standard methodology in developing/applying/testing/validating the models or considering uncertainty was not presented. Some standard methodologies are mentioned (i.e., American Standards Testing Methods – ASTM), but a clearly-organized modeling method, based on clearly-defined objectives, is not provided.

c) A clear plan was not presented for how this primary design tool will be updated or used during and following system installation, during which a substantial amount of new data in key areas will be collected in a short period of time. Discussions with Arcadis and CH2MHill modelers seemed to confirm that limited consideration has been given to the following:

   a. How will modeling tool(s) be re-calibrated with new data obtained during initial installation, and shaped by additional data obtained over the long-term?

   b. How will the newly re-calibrated model be used to assess the final (100% BOD Report predictions?

   c. How will the newly re-calibrated model be used to modify things like well locations, depths, pumping rates etc. prior to completing the initial installation?

   d. How will the newly re-calibrated model be used to assess the location and design of potential provisional wells, or modify groundwater pumping and/or TOC injection rates?

Recommendations

1) Though not much can be done in the 60% BOD Report, all modeling objectives that have been attained should be clearly defined.

2) Objectives and scope of work should be clearly defined in the 90% BOD Report for all modeling to be conducted during installation, startup and long-term operation (this is described more in the last section of this memo).

Model Prediction Uncertainty

Associated Comments:

359, 370, 371, 382, 385, 388a, 388b, 392, 394, 401, 402, 404, 405, 406

General Problem:

- Uncertainty related to model predictions was not adequately addressed in the 60% BOD Report. A standard, comprehensive uncertainty analysis was not conducted, and an uncertainty analysis was confused with a sensitivity analysis. Though, this would have been challenging to perform, given the complexity of their models, it should have been considered at some level, and discussed in a standard fashion, given the scale and complexity of the design and operation, and overall investment by all stakeholders. I've worked on other projects, where the modeling is quite complicated, but modeling teams have used standard approaches/methodologies to both evaluate and convey uncertainty in design/operation. During discussions, the PG&E consultants indicated that they believe enough 'flexibility' has been built into the system design and operation to account for the effects of any uncertainties.

- The model is the primary tool used to design the remediation system; well locations, depths, screened zones, pumping rates, injected organic carbon, etc., are each and all based on the model. As a result, the design of these components and their operation are uncertain. The consultants (Arcadis/CH2MHill) acknowledge the lack of an uncertainty analysis and the uncertainty in the design, but simply assumed, based on 'professional judgment', a certain amount of 'flexibility' to account for this uncertainty (i.e., additional, contingent wells, and a range of possible flow rates at each well, among others). Changes in the original design and operation at Hinkley represent an example of what happens when incorrect assumptions, or guesses are made. If they don't have enough flexibility built into the system design/operation, they will need more wells, or the system may operate for 50 years or even longer to meet RAO objectives.

- The modeling conducted by PG&E the consultants simulates three things: a) water flow; b) transport/reaction of chemical species; and, geochemical reactions. It is standard engineering (and modeling) practice to provide an estimate of uncertainty with any modeling predictions, and this seems especially warranted in this instance given the overall costs and complexity of this system design and operation.

- The modelers were uncertain how long it would take to remediate the Cr(VI) concentrations to meet RAO objectives. The range seemed to be from 30 years, to even 200+ years in discussions. This is probably one of the most important issues identified during my review.

Recommendations

a) Although the 60% BOD is complete, the 90% BOD should include further evaluation and discussion on the uncertainty in model predictions associated with:

a. The length of time the system will need to operate to meet objectives of the remediation system.
b. The placement of wells, well screens, total depths. How confident is PG&E that the placement of proposed wells, including contingent wells, is adequate to meet objectives?
c. The number of wells required. How confident is PG&E that the proposed maximum number of wells is adequate to meet objectives? How confident are they that they haven't proposed too many wells?
d. Operational factors (flow rates, water quality, TOC inputs etc.). What is the confidence in the combination of proposed well #/locations and operational ranges (i.e., pumping rates) will be sufficient to meet remedial objectives?

b) Determine implications of predictive uncertainty on the proposed design and operation. Some sort of assessment could be provided in the 90% BOD Report.

c) The 90% BOD should consider the benefits of a phased installation and testing plan. Data obtained from early well drilling and testing could be fed back into the model and adjustments to the final BOD could be made before the entire system is installed and begins operating.

Model Sensitivity Analysis/Calibration

Associated Comments:

360, 361, 362

General Problems:

- Two types of sensitivity analyses are typically conducted; calibration and prediction. A calibration sensitivity analysis attempts to identify and rank the most important factors to which groundwater flow is most sensitive. Prediction sensitivity analyses assess sensitivity of model predictions to variations of important model parameters. No distinction was made in the 60% BOD Report about which type of analysis was performed, and the sensitivity analysis was confused with a standard uncertainty analysis.

- The consultants did not test the sensitivity of groundwater flow/heads to all factors, or combinations of factors. Instead, they showed the sensitivity of predicted groundwater conditions to adjustments of only a select set of parameters. In addition, they failed to demonstrate that groundwater flow or water quality predictions were most sensitive to the selected parameter set. The parameter adjustments evaluated did not seem to cover a realistic range based on reported field observations. So, sensitivity predictions don't really convey a realistic range of what might occur upon actually startup and commissioning of the remediation system.

- The model has many factors (r 'knobs' that can be adjusted to change the operation of the system). Once operating, any changes to the system will certainly have the potential to change long-term performance of the system regarding achieving RAOs. Without conducting a comprehensive evaluation of key flow and fate/transport parameters (or boundary conditions), PG&E will likely experience the following during operation because of the limited sensitivity analysis they conducted:

    - Problems in determining which of the many factors (model inputs) that affect the performance of the remediation system should be adjusted (in priority) to meet long-term RAOs (optimally);

    - Not knowing how much to adjust these factors to meet long-term RAOs.

Recommendations:

A list of all model parameters and input should be prepared. These model parameters should be ranked based on the sensitivity of groundwater flows and water quality transport sensitivity to them. This will help operators better understand which 'knob' to adjust, by how much, and what the system response might be. Such a list should be refined as new data is obtained during installation and operation. Failure to maintain such a list and the model, could result in reduced performance of the system towards achieving RAOs.

Model Optimization

Associated Comments:

358, 364a, 364b, 365, 366, 367a, 367b, 368, 369, 386, 388a, 388b, 393, 398, 403a, 403b

General Concerns:

- The modelers mention optimization many times, but this was not described well, nor did it constitute a formal engineering optimization to support the proposed design of this type of complex, large, long-term remediation system. A clear optimization strategy was never presented in the 60% BOD, describing appropriate performance targets and metrics. I attribute much of this to the very poorly/vaguely defined modeling objectives.

- Though the consultants claim the proposed remediation design/operation were ‘optimized’, this was never adequately demonstrated in the document (i.e., describing/showing multiple simulations aimed at ‘optimizing’ key targets.)

- No performance metrics were really defined to optimize the system. They show current proposed well locations, screened intervals, pumping rates, TOC injection rates etc., but also show that complete reduction of Cr(VI) can take 50+ years. **The design and operation, even if uncertain, should be based on a performance target of achieving RAOs within 30 years, or less.** The modeling conducted here appears more like an evaluation of a conceptual design (and operation), than an actual basis for an engineering design and operation document at 60%.

Recommendations

A clear methodology should be presented on how the modeling tool(s) will be used in conjunction with installation and subsequent hydraulic testing to optimize or refine fixed design features (i.e., well placement, screened zones etc.) that can’t be changed once installed.

A clear methodology should be presented on how the primary design tool will be used to optimize/refine operational factors (i.e., pumping rates, TOC injection rates etc.) Show explicitly how and when modeling tools (flow, transport and geochemical) will be updated, with what data, and how and where new model predictions will be used in these operational schematics (see Figures 2.2-2 through 2.2-9 in Appendix L).

Possible Effects of High TDS/Density on Remedial Performance

Associated Comments:

357a, 357b, 384a, 384b

General Problems

- Contrasts in water density (fresh water and denser, 'saltier' water) can affect system performance. When fresh, lighter water is injected into denser water, depending on a number of factors, the difference in densities can cause lighter water to float on top of the denser water due to buoyancy. As a result, this can limit the ability of freshwater injection wells to fully flush water through denser water zones (lower in aquifer, because dense water sinks).

- Two issues with simply assuming this won't be a problem are:

  - A detailed plan describing exactly how they will actually confirm whether water densities are causing a problem was not provided.

  - Without knowing if density contrasts are a problem at a given location, incorrect 'knobs' could be adjusted the wrong amount, or the wrong way, thereby reducing the performance of the remediation system in achieving RAOs.

Recommendations

In the 90% BOD:

1) The possibility of density contrasts affecting performance should be acknowledged, even though this may not be highly likely in most wells.

2) Discuss what can be monitored to confirm this will or won't be a problem.

3) Finally, if it is determined to be a problem (i.e., poor flushing at depth due to buoyant 'bypass') – A plan should be developed, describing what will be done to 'adjust' the problem within current proposed design and operational constraints.

Key Issues and Recommendations

Installation, Startup, Long-term Operation and Use of Modeling

General Concerns

Through various discussions with PG&E consultants (Arcadis and CH2MHill), mostly during TWG meetings and phone meetings to discuss modeling comments, I've identified two additional concerns:

1) When PG&E installs the system, a large amount of new data will be collected in key areas.

Problems:

a) Aracadis and CH2MHill did not appear to concur with each other on the type, or level of hydraulic testing to be conducted as a part of well installation and commissioning.

b) I saw no detailed plan on what hydraulic testing would be done as the system is installed. These details are not covered in Appendix L (Operations and Maintenance), which focus on groundwater monitoring, but not testing. Nor is anything presented in Appendix L on future modeling details with the exception of very vague text related to their Adaptive Operations Approach – Section 1.2.2) which Arcadis has referenced in response to my comments. Given the limitations on number and location of proposed remedial wells, it makes sense to conduct hydraulic tests on all wells <u>as they are installed</u>, or even better on groups of wells in localized areas to identify problem wells and develop mitigation plans. Having done this, there is a greater likelihood that the original model predictions (which are uncertain – see discussion on the lack of uncertainty analysis) will still be valid and still allow the system to perform, within the somewhat arbitrary 'flexible' ranges assumed by modelers, without having to add more wells. Testing could also suggest that fewer wells are needed than originally planned in the Final BoD Report. Either way, as new test results are used to update the model, the model can then be used to improve initial startup and operational factors to minimize potential negative impacts upon startup. Incorrect adjustments may not only increase cleanup times, but can potentially exacerbate the existing problem.

c) In discussions, consultants appeared to lack concurrence on how, or even whether the model would be used during installation, or afterward the remedy commences operation. The model's proposed use during installation and operation does not appear to have been well thought out. This is surprising because the model is clearly the primary tool used to design the remediation well layout (i.e., pumping/injection well locations, depths, screened intervals, pumping rates, TOC injection locations, timing and rates/cycles etc.). Given the lack of any formal analysis of uncertainty in model predictions, or an adequate sense of which factors to adjust and by how much (i.e., limited sensitivity analysis) to meet long-term performance metrics (RAOs), all new data should be used to update the model during construction, re-calibrate it to be consistent with hydraulic test results obtained during well installation, and to re-run long-term simulations of proposed operations to assess whether the 100% design needs any modifications. The installation period, when drilling rigs are mobilized and on-site is the best time to adjust the 100% design (i.e., well locations, well numbers, well depths, etc).

2) Once the system is running, Arcadis indicated that they will rely mostly on observation data as a basis for making any adjustments to the remediation system and its operation.

Problems:

a) Where and when model updates are discussed, the basis and specific approach for the updating is vague. For example, in response to comment #360, Arcadis states "*The groundwater flow and solute transport model will be updated and recalibrated if significant differences from the conceptual site model are encountered with respect to hydrogeologic characterization or remedy performance. This will allow the model to be used as a tool to evaluate the performance and guide the operation of the remedial design after including the adjusted data.*"

I don't believe the consultants have defined the conceptual flow and transport model well enough to know when 'significant' differences would be encountered. The entire system design and operation has been designed based on model simulations, which they also admit are uncertain, and the model was only tested in a limited fashion (i.e., limited sensitivity analyses), and wasn't really optimized in a standard engineering way. I am convinced that the model remains the only tool available to assess how any changes to model inputs will affect long-term system performance. I also believe that without updating these modeling tools constantly, and especially early in the installation and operational phases, it will be difficult for them to convince the Tribes (and other stakeholders, as well as the owner) that the current, complicated operational cycling/injection/extraction system will reduce Cr(VI) concentrations, plume size, and by-product development within the 30 year time frame.

b) It is clear that many 'knobs' can be adjusted in the proposed remediation system operation, for either the new wells or to replacement and contingency wells that may be added over time. Information learned at the Hinkley Site indicates significant problems resulted when the plume bypassed a portion of the initial proposed well network, moving between wells, and on the sides and below the well network. The limited sensitivity analysis Arcadis conducted for Topock gives little confidence they will adjust the right 'knobs', and by how much (in the right direction, magnitude and priority) to 'optimize' system performance to meet long-term (decades) RAO remediation objectives. Arcadis has argued that observation data will be the primary information used to guide any changes to the remediation system and its operation. Although observation data will certainly be useful in assessing **current** system performance, for guiding appropriate adjustment of the right 'knobs' to meet long-term objectives, the model must be updated and improved (calibrated) systematically, using the observation data. This is especially true given the proposed long cycles of on/off TOC injections.

c) The consultants have provided no detailed plan on how and when they will update the model, what simulations they'd run, or generally how they'd use the modeling along with observation data to help optimize system performance (i.e., achieve overall objectives most efficiently, such as minimizing overall remediation time, byproducts etc.).

Recommendations

During Installation:

1) Develop a plan that includes the following:

    a. Conduct hydraulic tests during installation for all wells, to confirm that well locations, depths, screened zones, productivity and drawdowns are within the proposed operational range. Through discussions with Arcadis and CH2MHill, this operational range was apparently determined 'through professional' judgment and not via a formal uncertainty analyses. This is fine, but this should be thoroughly tested **<u>during the initial phases of well installation</u>,** so that adjustments could be made before finalizing the entire installation and finding out that the system doesn't perform as expected (or predicted by the model(s)).

    b. A plan should be developed to update, re-calibrate and re-run short- and long-term model scenarios to confirm that the proposed design and operation are within the largely assumed ranges of performance and will still meet RAOs. Given the expected duration for installation, the model(s) could be continuously updated and used to confirm performance in specific areas.

    c. Results should be provided on all model updates and simulations to the Tribes and all stakeholders.

During Operation:

1) A plan should be developed showing a more realistic basis for when the model(s) will be updated. I believe model(s) should be updated every TOC on/off injections cycle, at least for the first few years, when the most significant changes to the existing system will occur. When changes in operation are made, for example, to TOC injection rates, locations, depths, timing, or injection/extraction well flow rates, the model(s) should be updated.

2) In the plan, discuss how the model(s) will be updated, and also re-calibrated against newly acquired 'operational' flow and water quality data , and how long-term simulations will be re-run to evaluate and confirm that long-term projections don't deviate from what is proposed in the 60%BOD Report (which is actually unclear) towards achieving RAOs.

3) Every time the model(s) are updated, re-calibrated and long-term simulations re-run, results should be documented and submitted to stakeholders.

Re: Comments on Modeling Issues related to the 60% BOD Report for the PG&E Topock Compressor Station

Dear Mr. Yue and Ms. Innis:

Attached to this letter you will find comments prepared by the TRC regarding key concerns related to modeling in the 60% BOD. If you have any questions feel free to contact me at: Cell: 928-287-5042 or by email at CocopahTPM@gmail.com

Thank you

Edgar Castillo

Subject: Overview of Key Concerns Related to Modeling in the 60% BOD and Recommendations for Comment Resolution

Overview

I reviewed the PG&E April 2013 60% BOD Report, focusing primarily on the modeling section (Appendix B) but also Section 3 and the Executive Summary. I focused my comments primarily on the numerical modeling as it relates to the proposed system design and operation. My comments generally fell into the following categories:

- Modeling Objectives
- Model Sensitivity Analysis/Calibration
- Model Prediction Uncertainty
- Model Optimization
- Possible Effects of High TDS/Density on Remedial Performance

Though the majority of comments were resolved through the RTC process, many remain unresolved. Based on things learned going through the RTC process (i.e., original 60% BOD review/comments and subsequent discussions in TWG meetings, in phone calls, emails, and iterations on RTC tables), I identified two main issues, related to uncertain model predictions about the length of time needed to clean up the plume so the remediation system can be removed. I believe these issues could be resolved if PG&E follows these two recommendations:

a) The 90% BOD Report should include a plan detailing specific data that will be collected **during remedy installation and commissioning** (such as hydraulic testing), specific details on how these data will be used to update and re-calibrate the model, and what scenarios would be re-run. This important data set would be critical to assessing the preliminary design/operation assumptions and allow for adjustments to operational parameters.

b) The 90% BOD Report should also present a detailed plan on how the models (i.e., flow, fate/transport, geochemical) will be updated, re-calibrated, and which scenarios are re-run **during operation**, including adjustments to the operations over time. More details are needed on the proposed basis for triggering when models are updated, and that any operational adjustments improve system performance towards meeting both short- and long-term RAOs.

If such plans and details are developed by PG&E, for example in the 90% BOD Report, all remaining unresolved 60% BOD comments could simply point to these plans in the RTC tables. To date, it has not been possible to adequately address these larger concerns and recommendations in a single RTC comment. I believe detailed plans to update and utilize the numerical models in an ongoing fashion, for example when adjustments to the operation are made, would greatly help reduce potential negative surprises in the currently proposed (60% BOD) remediation system and operation, much of which was designed and developed using these important modeling tools. This should benefit all stakeholders.

I first provide general concerns and recommendations related to each of the modeling areas above, and then summarize the two main issues and recommendations in the last section of this Memo.

Proposed Comment Resolution – by Category

Modeling Objectives

Associated Comments:

25, 367a, 388a, 388b, 391, 402, 404,

For standard modeling projects, modeling objectives must be stated as clearly and unambiguously as possible, because this strongly influences exactly how models are set up, what simulations are needed, and how accurate results must be.

General Concerns:

In my review, I found that modeling objectives as stated in Appendix B appear inconsistent with the broader objectives of the Remedial Action Objectives (RAOs) as outlined in the body of the report. For example:

RAOs (stated in Executive Summary) include:

1) ***Prevent ingestion of groundwater*** as a potable water source having Cr(VI) in excess of the regional background concentration of 32 µg/L.
2) ***Prevent or minimize migration*** of total chromium (Cr[T]) and Cr(VI) in groundwater to ensure concentrations in surface water do not exceed water quality standards that support the designated beneficial uses of the Colorado River (11 µg/L Cr[VI]).
3) ***Reduce the mass of Cr(T) and Cr(VI) in groundwater*** at the site to achieve compliance with the applicable or relevant and appropriate requirements (ARARs) in groundwater. This RAO will be achieved through the cleanup goal of the regional background concentration of 32 µg/L of Cr(VI).
4) Ensure that the geographic location of the ***target remediation area does not permanently expand*** following completion of the remedial action.

Modeling Objectives (Stated in Appendix B of the 60% BOD Report):

The objectives of this modeling study were to develop a groundwater flow and solute transport model for use as follows:

1) **evaluate** subsurface flow conditions
2) **evaluate** the fate and transport of Cr(VI)
3) **evaluate** fate and transport of manganese and arsenic
4) **evaluate** potential remedial system configurations

It appears as though the objectives of the 60% BOD Report modeling were to only 'evaluate' flow, fate/transport and remedial system configurations. However, for a 60% Design and Operation Plan – I was expecting the modeling objectives to clearly state how the model would be used to:

a) Determine 'optimum' well layout (locations, spacing, total depths, screened zones) to meet RAO objectives;
b) Define operations necessary (injection/extraction flow rates, organic carbon injection locations and rates etc.) to meet RAO objectives;
c) Identify procedures to optimize the long-term operation of the system;
d) Determine where additional remediation wells could go;
e) Optimize the IM-3 decommissioning and startup of the new remediation system to minimize negative impacts to the system (to meet RAO objectives);
f) Determine a range of impacts due to manganese and arsenic by product generation.

PG&E's 60% BOD Report (Page 3, App B.) indicates that the modeling tool(s) represent the most important guide for the design and operation of the proposed remediation system: "*For the Site, the conceptual model forms the single most important guide for the design and operation of the proposed remediation system, as it is the basis for the numeric modeling, comprised of groundwater flow and contaminant fate and transport that simulate the operation of the remediation system*."

In my experience, a primary reason for 'failure' of models (i.e., poor predictions) is poor definition of modeling objectives. The objectives stated in the 60% BOD Report seem to point to a fundamental problem with the overall strategy for using the modeling tool(s):

a) Objectives were vague and unclear. For example, which objective is the most important, or which provides the greatest constraints on model optimizations?

b) A standard methodology in developing/applying/testing/validating the models or considering uncertainty was not presented. Some standard methodologies are mentioned (i.e., American Standards Testing Methods – ASTM), but a clearly-organized modeling method, based on clearly-defined objectives, is not provided.

c) A clear plan was not presented for how this primary design tool will be updated or used during and following system installation, during which a substantial amount of new data in key areas will be collected in a short period of time. Discussions with Arcadis and CH2MHill modelers seemed to confirm that limited consideration has been given to the following:

    a. How will modeling tool(s) be re-calibrated with new data obtained during initial installation, and shaped by additional data obtained over the long-term?
    b. How will the newly re-calibrated model be used to assess the final (100% BOD Report predictions?
    c. How will the newly re-calibrated model be used to modify things like well locations, depths, pumping rates etc. prior to completing the initial installation?
    d. How will the newly re-calibrated model be used to assess the location and design of potential provisional wells, or modify groundwater pumping and/or TOC injection rates?

Recommendations

1) Though not much can be done in the 60% BOD Report, all modeling objectives that have been attained should be clearly defined.

2) Objectives and scope of work should be clearly defined in the 90% BOD Report for all modeling to be conducted during installation, startup and long-term operation (this is described more in the last section of this memo).

Model Prediction Uncertainty

Associated Comments:

359, 370, 371, 382, 385, 388a, 388b, 392, 394, 401, 402, 404, 405, 406

General Problem:

- Uncertainty related to model predictions was not adequately addressed in the 60% BOD Report. A standard, comprehensive uncertainty analysis was not conducted, and an uncertainty analysis was confused with a sensitivity analysis. Though, this would have been challenging to perform, given the complexity of their models, it should have been considered at some level, and discussed in a standard fashion, given the scale and complexity of the design and operation, and overall investment by all stakeholders. I've worked on other projects, where the modeling is quite complicated, but modeling teams have used standard approaches/methodologies to both evaluate and convey uncertainty in design/operation. During discussions, the PG&E consultants indicated that they believe enough 'flexibility' has been built into the system design and operation to account for the effects of any uncertainties.

- The model is the primary tool used to design the remediation system; well locations, depths, screened zones, pumping rates, injected organic carbon, etc., are each and all based on the model. As a result, the design of these components and their operation are uncertain. The consultants (Arcadis/CH2MHill) acknowledge the lack of an uncertainty analysis and the uncertainty in the design, but simply assumed, based on 'professional judgment', a certain amount of 'flexibility' to account for this uncertainty (i.e., additional, contingent wells, and a range of possible flow rates at each well, among others). Changes in the original design and operation at Hinkley represent an example of what happens when incorrect assumptions, or guesses are made. If they don't have enough flexibility built into the system design/operation, they will need more wells, or the system may operate for 50 years or even longer to meet RAO objectives.

- The modeling conducted by PG&E the consultants simulates three things: a) water flow; b) transport/reaction of chemical species; and, geochemical reactions. It is standard engineering (and modeling) practice to provide an estimate of uncertainty with any modeling predictions, and this seems especially warranted in this instance given the overall costs and complexity of this system design and operation.

- The modelers were uncertain how long it would take to remediate the Cr(VI) concentrations to meet RAO objectives. The range seemed to be from 30 years, to even 200+ years in discussions. This is probably one of the most important issues identified during my review.

Recommendations

a) Although the 60% BOD is complete, the 90% BOD should include further evaluation and discussion on the uncertainty in model predictions associated with:

a. The length of time the system will need to operate to meet objectives of the remediation system.
b. The placement of wells, well screens, total depths. How confident is PG&E that the placement of proposed wells, including contingent wells, is adequate to meet objectives?
c. The number of wells required. How confident is PG&E that the proposed maximum number of wells is adequate to meet objectives? How confident are they that they haven't proposed too many wells?
d. Operational factors (flow rates, water quality, TOC inputs etc.). What is the confidence in the combination of proposed well #/locations and operational ranges (i.e., pumping rates) will be sufficient to meet remedial objectives?

b) Determine implications of predictive uncertainty on the proposed design and operation. Some sort of assessment could be provided in the 90% BOD Report.

c) The 90% BOD should consider the benefits of a phased installation and testing plan. Data obtained from early well drilling and testing could be fed back into the model and adjustments to the final BOD could be made before the entire system is installed and begins operating.

Model Sensitivity Analysis/Calibration

Associated Comments:

360, 361, 362

General Problems:

- Two types of sensitivity analyses are typically conducted; calibration and prediction. A calibration sensitivity analysis attempts to identify and rank the most important factors to which groundwater flow is most sensitive. Prediction sensitivity analyses assess sensitivity of model predictions to variations of important model parameters. No distinction was made in the 60% BOD Report about which type of analysis was performed, and the sensitivity analysis was confused with a standard uncertainty analysis.

- The consultants did not test the sensitivity of groundwater flow/heads to all factors, or combinations of factors. Instead, they showed the sensitivity of predicted groundwater conditions to adjustments of only a select set of parameters. In addition, they failed to demonstrate that groundwater flow or water quality predictions were most sensitive to the selected parameter set. The parameter adjustments evaluated did not seem to cover a realistic range based on reported field observations. So, sensitivity predictions don't really convey a realistic range of what might occur upon actually startup and commissioning of the remediation system.

- The model has many factors (r 'knobs' that can be adjusted to change the operation of the system). Once operating, any changes to the system will certainly have the potential to change long-term performance of the system regarding achieving RAOs. Without conducting a comprehensive evaluation of key flow and fate/transport parameters (or boundary conditions), PG&E will likely experience the following during operation because of the limited sensitivity analysis they conducted:

    - Problems in determining which of the many factors (model inputs) that affect the performance of the remediation system should be adjusted (in priority) to meet long-term RAOs (optimally);

    - Not knowing how much to adjust these factors to meet long-term RAOs.

Recommendations:

A list of all model parameters and input should be prepared. These model parameters should be ranked based on the sensitivity of groundwater flows and water quality transport sensitivity to them. This will help operators better understand which 'knob' to adjust, by how much, and what the system response might be. Such a list should be refined as new data is obtained during installation and operation. Failure to maintain such a list and the model, could result in reduced performance of the system towards achieving RAOs.

Model Optimization

Associated Comments:

358, 364a, 364b, 365, 366, 367a, 367b, 368, 369, 386, 388a, 388b, 393, 398, 403a, 403b

General Concerns:

- The modelers mention optimization many times, but this was not described well, nor did it constitute a formal engineering optimization to support the proposed design of this type of complex, large, long-term remediation system. A clear optimization strategy was never presented in the 60% BOD, describing appropriate performance targets and metrics. I attribute much of this to the very poorly/vaguely defined modeling objectives.

- Though the consultants claim the proposed remediation design/operation were 'optimized', this was never adequately demonstrated in the document (i.e., describing/showing multiple simulations aimed at 'optimizing' key targets.)

- No performance metrics were really defined to optimize the system. They show current proposed well locations, screened intervals, pumping rates, TOC injection rates etc., but also show that complete reduction of Cr(VI) can take 50+ years. **The design and operation, even if uncertain, should be based on a performance target of achieving RAOs within 30 years, or less.** The modeling conducted here appears more like an evaluation of a conceptual design (and operation), than an actual basis for an engineering design and operation document at 60%.

Recommendations

A clear methodology should be presented on how the modeling tool(s) will be used in conjunction with installation and subsequent hydraulic testing to optimize or refine fixed design features (i.e., well placement, screened zones etc.) that can't be changed once installed.

A clear methodology should be presented on how the primary design tool will be used to optimize/refine operational factors (i.e., pumping rates, TOC injection rates etc.) Show explicitly how and when modeling tools (flow, transport and geochemical) will be updated, with what data, and how and where new model predictions will be used in these operational schematics (see Figures 2.2-2 through 2.2-9 in Appendix L).

Possible Effects of High TDS/Density on Remedial Performance

Associated Comments:

357a, 357b, 384a, 384b

General Problems

- Contrasts in water density (fresh water and denser, 'saltier' water) can affect system performance. When fresh, lighter water is injected into denser water, depending on a number of factors, the difference in densities can cause lighter water to float on top of the denser water due to buoyancy. As a result, this can limit the ability of freshwater injection wells to fully flush water through denser water zones (lower in aquifer, because dense water sinks).

- Two issues with simply assuming this won't be a problem are:

    - A detailed plan describing exactly how they will actually confirm whether water densities are causing a problem was not provided.

    - Without knowing if density contrasts are a problem at a given location, incorrect 'knobs' could be adjusted the wrong amount, or the wrong way, thereby reducing the performance of the remediation system in achieving RAOs.

Recommendations

In the 90% BOD:

1) The possibility of density contrasts affecting performance should be acknowledged, even though this may not be highly likely in most wells.

2) Discuss what can be monitored to confirm this will or won't be a problem.

3) Finally, if it is determined to be a problem (i.e., poor flushing at depth due to buoyant 'bypass') – A plan should be developed, describing what will be done to 'adjust' the problem within current proposed design and operational constraints.

Key Issues and Recommendations

Installation, Startup, Long-term Operation and Use of Modeling

General Concerns

Through various discussions with PG&E consultants (Arcadis and CH2MHill), mostly during TWG meetings and phone meetings to discuss modeling comments, I've identified two additional concerns:

1) When PG&E installs the system, a large amount of new data will be collected in key areas.

Problems:

a) Aracadis and CH2MHill did not appear to concur with each other on the type, or level of hydraulic testing to be conducted as a part of well installation and commissioning.

b) I saw no detailed plan on what hydraulic testing would be done as the system is installed. These details are not covered in Appendix L (Operations and Maintenance), which focus on groundwater monitoring, but not testing. Nor is anything presented in Appendix L on future modeling details with the exception of very vague text related to their Adaptive Operations Approach – Section 1.2.2) which Arcadis has referenced in response to my comments. Given the limitations on number and location of proposed remedial wells, it makes sense to conduct hydraulic tests on all wells as they are installed, or even better on groups of wells in localized areas to identify problem wells and develop mitigation plans. Having done this, there is a greater likelihood that the original model predictions (which are uncertain – see discussion on the lack of uncertainty analysis) will still be valid and still allow the system to perform, within the somewhat arbitrary 'flexible' ranges assumed by modelers, without having to add more wells. Testing could also suggest that fewer wells are needed than originally planned in the Final BoD Report. Either way, as new test results are used to update the model, the model can then be used to improve initial startup and operational factors to minimize potential negative impacts upon startup. Incorrect adjustments may not only increase cleanup times, but can potentially exacerbate the existing problem.

c) In discussions, consultants appeared to lack concurrence on how, or even whether the model would be used during installation, or afterward the remedy commences operation. The model's proposed use during installation and operation does not appear to have been well thought out. This is surprising because the model is clearly the primary tool used to design the remediation well layout (i.e., pumping/injection well locations, depths, screened intervals, pumping rates, TOC injection locations, timing and rates/cycles etc.). Given the lack of any formal analysis of uncertainty in model predictions, or an adequate sense of which factors to adjust and by how much (i.e., limited sensitivity analysis) to meet long-term performance metrics (RAOs), all new data should be used to update the model during construction, re-calibrate it to be consistent with hydraulic test results obtained during well installation, and to re-run long-term simulations of proposed operations to assess whether the 100% design needs any modifications. The installation period, when drilling rigs are mobilized and on-site is the best time to adjust the 100% design (i.e., well locations, well numbers, well depths, etc).

2) Once the system is running, Arcadis indicated that they will rely mostly on observation data as a basis for making any adjustments to the remediation system and its operation.

Problems:

a) Where and when model updates are discussed, the basis and specific approach for the updating is vague. For example, in response to comment #360, Arcadis states "*The groundwater flow and solute transport model will be updated and recalibrated if significant differences from the conceptual site model are encountered with respect to hydrogeologic characterization or remedy performance. This will allow the model to be used as a tool to evaluate the performance and guide the operation of the remedial design after including the adjusted data."*

I don't believe the consultants have defined the conceptual flow and transport model well enough to know when 'significant' differences would be encountered. The entire system design and operation has been designed based on model simulations, which they also admit are uncertain, and the model was only tested in a limited fashion (i.e., limited sensitivity analyses), and wasn't really optimized in a standard engineering way. I am convinced that the model remains the only tool available to assess how any changes to model inputs will affect long-term system performance. I also believe that without updating these modeling tools constantly, and especially early in the installation and operational phases, it will be difficult for them to convince the Tribes (and other stakeholders, as well as the owner) that the current, complicated operational cycling/injection/extraction system will reduce Cr(VI) concentrations, plume size, and by-product development within the 30 year time frame.

b) It is clear that many 'knobs' can be adjusted in the proposed remediation system operation, for either the new wells or to replacement and contingency wells that may be added over time. Information learned at the Hinkley Site indicates significant problems resulted when the plume bypassed a portion of the initial proposed well network, moving between wells, and on the sides and below the well network. The limited sensitivity analysis Arcadis conducted for Topock gives little confidence they will adjust the right 'knobs', and by how much (in the right direction, magnitude and priority) to 'optimize' system performance to meet long-term (decades) RAO remediation objectives. Arcadis has argued that observation data will be the primary information used to guide any changes to the remediation system and its operation. Although observation data will certainly be useful in assessing **current** system performance, for guiding appropriate adjustment of the right 'knobs' to meet long-term objectives, the model must be updated and improved (calibrated) systematically, using the observation data. This is especially true given the proposed long cycles of on/off TOC injections.

c) The consultants have provided no detailed plan on how and when they will update the model, what simulations they'd run, or generally how they'd use the modeling along with observation data to help optimize system performance (i.e., achieve overall objectives most efficiently, such as minimizing overall remediation time, byproducts etc.).

Recommendations

During Installation:

1) Develop a plan that includes the following:

   a. Conduct hydraulic tests during installation for all wells, to confirm that well locations, depths, screened zones, productivity and drawdowns are within the proposed operational range. Through discussions with Arcadis and CH2MHill, this operational range was apparently determined 'through professional' judgment and not via a formal uncertainty analyses. This is fine, but this should be thoroughly tested **during the initial phases of well installation,** so that adjustments could be made before finalizing the entire installation and finding out that the system doesn't perform as expected (or predicted by the model(s)).

   b. A plan should be developed to update, re-calibrate and re-run short- and long-term model scenarios to confirm that the proposed design and operation are within the largely assumed ranges of performance and will still meet RAOs. Given the expected duration for installation, the model(s) could be continuously updated and used to confirm performance in specific areas.

   c. Results should be provided on all model updates and simulations to the Tribes and all stakeholders.

During Operation:

1) A plan should be developed showing a more realistic basis for when the model(s) will be updated. I believe model(s) should be updated every TOC on/off injections cycle, at least for the first few years, when the most significant changes to the existing system will occur. When changes in operation are made, for example, to TOC injection rates, locations, depths, timing, or injection/extraction well flow rates, the model(s) should be updated.

2) In the plan, discuss how the model(s) will be updated, and also re-calibrated against newly acquired 'operational' flow and water quality data , and how long-term simulations will be re-run to evaluate and confirm that long-term projections don't deviate from what is proposed in the 60%BOD Report (which is actually unclear) towards achieving RAOs.

3) Every time the model(s) are updated, re-calibrated and long-term simulations re-run, results should be documented and submitted to stakeholders.

Attachment T: RTC #6, Narrative on Key Decommissioning Steps

Attachment T

Response to Comment #6 FMIT-1/Hualapai-1/Chemehuevi-1/CRIT-1/Cocopah-1

Comment #6: *A conceptual narrative for the anticipated steps in the decommissioning of this proposed remedy should be included to assist in both evaluating the design elements and how they would impact removal of the remedy infrastructure, and in evaluating the total, cumulative impacts of this project.*

Response to Comment:

Conceptually, the key steps in the decommissioning of remedy facilities may include, but not limited to the following:

- **Site preparation and demarcation** – typical activities include mobilization of resources (personnel, equipment, materials), delineate access/haul routes, demarcate work and support zones including staging areas, and set up temporary facilities. Temporary facilities may include trailers, restroom facilities, safety and security lighting, equipment storage area, and parking area.
- **Utility survey and isolation** – typical activities include locating and marking underground utilities prior to intrusive work, and isolation of identified utilities. Utilities may include water, sewer, gas, phone, and power lines. Underground Service Alert or "Dig Alert" will be contacted to identify public utilities that operate within the work areas. Identified utilities will be isolated and disconnected by the utility provider prior to decommissioning and removing portions of a utility.
- **System components decommissioning** – decommissioning renders the components permanently out of service. Typical activities include decontamination and removal or abandonment in place. Decontamination will involve cleaning and removing waste materials, and render the components appropriate for reuse, recycle, or disposal. After decontamination, the components will be removed or abandoned in place.
- **Waste characterization and management –** waste generated from decommissioning may include liquid wastes, solid wastes, and sludge. Waste will be characterized and managed appropriately.

- **Soil confirmation sampling, as needed** – subsequent to decommissioning and removal, soil confirmation sampling may be conducted to assess soil conditions as needed.
- **Post-decommissioning restoration** – after decommissioning and confirmation sampling are complete, site restoration will commence. Restoration activities will start with returning the land to a safe condition, backfilling of excavated infrastructure, and compacting uneven areas. Light grading and contouring may be required to provide proper drainage and to control erosion. Revegetation will occur after final grading and contouring.

The above conceptual steps apply to pipelines and vertical infrastructure. Decommissioning of wells will be in accordance with the approach outlined in the project Well Decommissioning SOP (Well-SOP-01).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
General Comments									
1	DOI-1	General Comment		The 30% design package meets the substantive requirements of the 2009 Model Consent Decree as shown in Table 8-1. It represents a considerable level of effort.	Comment noted.				
2	DOI-2	General Comment		The Basis of Design (BOD) references the CERCLA Model Remedial Design/Remedial Action (RD/RA) Consent Decree throughout. PG&E and DOI have negotiated a Consent Decree and the document is going through the final approval process. It is DOI's expectation that future design documents reference the final Consent Decree rather than the model.	Comment noted. The final Consent Decree will be referenced when it is available.			Comment resolved.	The Consent Decree executed in 2012 and lodged with the court in January 2013 was referenced throughout this BOD Report.
3	DOI-3	General Comment		The text should identify specific wells by number in the discussions of well extraction and injection. It appears there are inconsistencies in understanding which wells are used for each particular purpose. For example, discussions in the modeling appendix indicate that wells UPGRAD-INJ-3 and -4 will be used for fresh water injection and wells UPGRAD-1 and -2 will be used for injection of carbon-amended water from the riverbank wells. This is not consistent with DOI's understanding, which is that all UPGRAD-INJ wells will be used for carbon-amended water injection. However, it was not possible to verify which wells were being used for what purpose because the discussion in the design basis sections (Section 3 of the main report) does not identify the wells by number, nor do the design drawings resolve this question.	The design and model presented in the 30% design uses UPGRAD-INJ-3 and -4 for fresh water injection and UPGRAD-INJ-1 and -2 for un-amended Riverbank well water. However, Riverbank well water will be amended with carbon if Cr(VI) exceeds 32ug/L, prior to injection into UPGRAD-INJ-1 and -2. In the 60% design the well references will be clarified and be more specific than in the 30% to minimize confusion. It should be noted that alternative injection scenarios involving these injection wells will be considered as part of the 60% design and flexibility has already been designed into the system to accommodate alternative flow scenarios. Additional detail will be included in the 60% design.		Okay pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Section 3.2 and Appendix B of the BOD Report.
4	DOI-4	General Comment		There appear to be some inconsistencies in pipeline cross references between related P&ID drawings. It is recommended that all cross references be verified for the 60% design submittal.	Comment noted. All cross references will be verified for the 60% design submittal.		Okay pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix D of this BOD Report.
5	DOI-5	General Comment		The BOD does not address green and sustainable remediation practices. It is the expectation of DOI that PG&E evaluate the current design and employ strategies for the Topock Remediation Project that uses natural resources and energy efficiently, including the use of renewable energy sources where practical, reduces negative impacts on the environment, minimizes or eliminates pollution at its source, protects and benefits the community at large, and reduces waste to the greatest extent possible. The BOD should include a specific section that references these practices.	The 30% BOD addressed green and sustainable remediation practices in many ways. As requested, the 60% design document will include a separate section to enumerate and discuss application of green and sustainable remediation practices. Examples where the 30% BOD addressed these issues include: **Energy Use** – a) design criteria included energy efficient architectural elements (see Appendix C.7), energy efficient equipment and lighting (see Appendix C.5.2), b) EPANET water supply program was used to design the piping network and minimize energy consumption. **Materials/Recycling/Reuse** – the concepts of reuse, shared use, and recycling of existing facilities and infrastructure were incorporated into the design (e.g., shared		Okay pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Section 4 – Application of Green Remediation Practices of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					use of existing storage tanks, repurposing of existing buildings); the concept of using native materials sourced from the site was included in Section 3.5.4 (this will be further detailed in the 60% design as the strategy for handling of displaced materials is further developed by agencies, Tribes, and PG&E); the design criteria included the International Green Building Code (see Appendix C.7). **Protection of Sensitive Resources** – Surveys and mapping are underway to document baseline conditions (e.g., mature plants, vegetation conditions, wetlands delineation, protocol surveys for sensitive bird species); and results have been and will continue to be used to guide the design to protect, avoid, and minimize potential impact to resources. Furthermore, plans such as the bird avoidance and minimization plan are being prepared that will include best management practices for remedy activities. **Waste Minimization** – operational experience with well backwash/ rehabilitation at Topock and the ongoing pilot test of backwash frequency at Hinkley have been and will continue to be incorporated into the design of the remedy produced water management system to minimize waste (see Appendix F). **Water Management** – most water needs for the remedy will be taken from and returned to the target IRZ barrier thereby maintaining the aquifer's net water balance; optimizing recirculation flowrates and careful carbon dosing will minimize generation and migration of by-products, while maintaining the required carbon distribution. **Airborne NOx and SOx, Greenhouse gas emissions, and Airborne particulates** - Careful dosing of carbon will reduce carbon substrate needs and thereby reduce air emissions associated with transportation of materials to the site. In addition, the timeframe for site remediation is reduced through the use of freshwater flushing, which induces a hydraulic gradient that is essential to creating more efficient and effective treatment. Any reduction in treatment time results in reductions to water use, materials use, waste generation, energy use, air emissions generated, health and safety hazards, and adverse effects on biological resources, stakeholders, and local economy.				

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					Furthermore, Table 8-3 lists a host of forthcoming plans and documents including the Access Plan and the Security Plan, as well as signage and information kiosk that are designed to protect public health and safety and to reduce potential damage to environmental resources.				
6	DTSC-GC4	General Comment: Green / Sustainable Remediation		Green Sustainability Factors need to be identified in the beginning stages of the design and factored in to the goals and objectives for minimizing impacts to the environment.	Comment noted. As discussed in response to comment #5 DOI-5, the 60% design submittal will include a separate section on application of green and sustainable remediation practices. PG&E's approach to green and sustainable remediation is aligned with the DTSC Interim Advisory for Green Remediation, and include the following steps: 1. Identify the green sustainability factors (e.g., energy use, materials, greenhouse gas emissions, etc.); 2. Identify sustainability best management practices (BMPs) to address each factor (e.g., reducing the number of site mobilizations, utilizing low-emitting technologies, etc.); 3. Evaluate the sustainability impacts and to assess the benefits of the implemented BMPs.	Okay pending review of 60% submittal		Comment resolved.	See Section 4 – Application of Green Remediation Practices of this BOD Report.
7	DOI-6	General Comment		Treatment and disposal of remedy-produced water is seemingly very complex and labor intensive to implement. This is a result of multiple types of remedy produced water (various sources of backwash water, rehab water [first and second flush], and other sources); options for both trucking and pipeline conveyance of wastewater; each type of wastewater requiring different degrees of treatment; and each potentially having a different final disposition. Although the O&M Plan is expected to flesh out the operational procedures in great detail, the 30% design package should offer further discussion on how wastewater conveyance, treatment, and disposal will be accomplished in practice.	The management plan and proposed facilities for remedy-produced water have been designed with flexibility to support, and not constrain the remedy over the anticipated multiple decades of operation. Figures 1 and 2 are simplified schematics to illustrate the management of the various streams of produced water as proposed in the preliminary (30%) design. Additional details will be included in the draft O&M plan.		Okay pending review of future documents.	Comment resolved.	See Section 3.4 and Appendix F of this BOD Report. Also see the draft O&M Manual (Volume 1 – O&M Plan and Volume 3 – Contingency Plan).
8	DOI-7	General Comment		Selection of the initial carbon source (ethanol or lactate) is still not finalized. As the upland and floodplain ISPTs have been completed, and Hinkley treatment system has been in operation for many years, it is not clear what data or analysis is pending to permit selection of the carbon source.	Based on the past success and level of experience with ethanol, it is currently planned for use in the final remedy, as will be stated in the 60% design. Substrate selection may change over the lifetime of the project as substrate costing varies. In addition, other substrates, such as longer lasting substrates, could be useful for certain situations that arise over the life of the project, and as such documents written to date have preserved the option of using additional substrates.		Okay pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Section 3.2.1.2 (Design Basis) under the heading Organic Carbon Substrate Selection.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
9	DOI-8	General Comment		Suggest adding a figure that includes the approximate chromium (VI) plume boundary, groundwater flow direction, and the remedy design components for reference.	PG&E proposes to add the approx. Cr(VI) plume boundary and groundwater flow direction to Figure 3-1 in the forthcoming BOD Report for intermediate (60%) design submittal.		Okay pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Figure 2.1-1 of this BOD Report.
10	DOI-9	General Comment		The recent findings of high flow rates and elevated contamination levels at Site H must be considered in the discussions of East Ravine bedrock flow and contamination conditions, as well as the remedy design. Although early investigation results for the East Ravine resulted in a preliminary conceptual model by PG&E that fracture flow in the bedrock was of limited rate and radius of influence, and provided the basis for the 30% design, recent findings at Site H raise questions about whether higher flow conditions and fracture interconnectivity may exist within the bedrock. Investigations of the hydrogeologic conditions in the East Ravine bedrock are ongoing, and substantial revision of the conceptual flow and contamination model of the East Ravine may prove to be warranted. The 30% design document must acknowledge the uncertainties in the conceptual model at this time and the possibility for substantial revision of the East Ravine bedrock remedy design at the 60% stage. PG&E should refrain from statements in the 30% design document regarding the bedrock generally having limited fracture interconnectivity, flow rates at wells, and radius of influence.	The 60% design submittal will include an update of the conceptual site model for the East Ravine that addresses conditions observed at Site H.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	Results of the East Ravine groundwater investigation were summarized in a technical memorandum entitled *Addendum to the Summary of Findings Associated with the East Ravine Groundwater Investigation, Pacific Gas and Electronic Company, Topock Compressor Station, Needles, California*. The Addendum was submitted to agencies on November 12, 2012 and results were discussed at the January 17, 2013 TWG meeting in Henderson, NV. Comments were received from DTSC and DOI on February 15, 2013. The Addendum is currently being revised to incorporate comments.
11	DOI-10	General Comment		Given the holidays and time allotment for review of the 30% design package, a detailed evaluation of many of the design elements could not be done to the desired level. DOI has identified some errors and included those in our comments, however we believe there may be others. Due to the aforementioned, we anticipate that an extended review period may be needed at the 60% design to flesh out design details such as piping networks, valving and controls, hydraulic profiles, water mass balance calculations as well as others.	Comment noted. PG&E defers decision on extension of review period to DTSC and DOI.	DTSC agrees that additional review time would be necessary for the review of the 60% design document.			See Exhibit 1.0-1 of this BOD Report, which reflects an extended 60-day review period of CWG/TWG and Tribes and a 75-day review period for DTSC and DOI.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
12	DTSC-GC1	General: Report organization and structure		Current organization of the document is fragmented and makes it difficult to follow a cohesive discussion of design elements. ***Example*** *IRZ Component*: Section 3.2.1 discusses the component of the IRZ, but one must flip to Fig 1-2 to see the proposed layout, then Section 4.4.1 of Appendix B to review the discussion on modeling and resulting well spacing, but the reported differences between the two scenarios were not discussed in that section and was not mentioned until the Section 6 under sensitivity analysis which then points to the corresponding figures in B-39 and B-40. Add to that, the model Figures 27 – 30 did not provide a legend or any notable area of focus, leaving the reviewer to interpret the modeling results. DTSC suggests that the report be reorganized so that each component of the remedy is evaluated from beginning to end with corresponding tables and figures before moving into another component. The report can be tied together with an executive summary, introduction and conclusion.	Comment noted. Each section will be reviewed to ensure report text, figures, tables, conclusions, and supporting materials are tied together well. Figures and tables will be included at the end of each section (instead of at the end of text)	Okay pending review of 60% review		Comment resolved.	See new Executive Summary, as well as locations of figures and tables after each section of this BOD Report.
13	DTSC-GC2	General: Report organization and structure		Design basis/criteria can also be presented in a table format for ease of reference to the rationale to assist review. *For example*: The IRZ injection well backwash pump for IRZ-11 is designed for 40 gpm (shown on design drawings) which is based on 2 times (discussed in Section 3, with no rationale) the maximum injection flow rate of 20 gpm (shown in Table 3-1). This maximum flow rate is found within Appendix B modeling discussion. An example table is already in the document (Page 3-31, Exhibit 3-9 Remedy-Produced Water Conditioning System Design Criteria). It would much easier to review if a similar table is provided for each remedial component.	Comment noted. Design basis/ criteria will be presented in table format (similar to Exhibit 3-9) for ease of reference.	Okay pending review of table		Comment resolved.	See BOD Section 3.2.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
14	DTSC-GC3	General Comment Design Dependencies		Design dependencies are not clear. Do not begin sections by referring readers to other sections. Make a summary, synopsis or substantive argument for the category. Move references at the end of the section as they relate to supporting arguments or summaries. PG&E should develop a risk probability and impact assessment. A probability and impact matrix will provide an understanding of the probability of risks and costs or rewards in taking certain risks. Focus on opportunities and risks and identifies those risks and places values to the risks and response planning, monitoring and control to those risks. PG&E has the opportunity to discuss strategies for negative risks – avoid, transfer or mitigate certain risks, and to discuss strategies for positive risks in order to enhance, expand and ultimately share with stakeholders those inherent risks to get a shared understanding of priorities and responses for contingencies. Such a matrix will allow stakeholders to understand operational constraints and weigh them with other values, costs or risks that may not be associated with PG&E.	See response to comment #12 DTSC-GC1 (Report Organization/ Structure). PG&E intends to use a recognized and established tool (used in industry and government) called Failure Modes and Effects Analysis (FMEA), for preparation of the contingency plans. The FMEA tool provides an analytical and systematic approach to reviewing potential failure modes and their associated causes, and therefore, will help to assess which risks have the greatest concern and to prioritize risk management in order to prevent problems before they arise. Failure modes are any errors or defects in a process, design, or item and can be potential or actual. Effects analysis refers to studying the consequences of those failures.	Okay pending review of 60% design submittal.		Comment resolved.	See draft O&M Manual, Volume 3 – Contingency Plan.
15	DTSC-GC5	General Comment: Communication s Management Plan		Identify methods and criteria to use to inform, resolve issues, approve change requests and corrective actions to unexpected occurrences. It should cover the regular periodic communication that needs to occur as well as when the project experiences unexpected changes. Define what the unexpected changes/risks that may occur and present a risk analysis describe the weekly or monthly status reports and list the chain of communication when a change occurs. Define who should be notified in the case of a significant change – determine factors for what is a significant change (Cr6, byproducts concentrations? other parameters?)	Comment noted. Communications framework, procedures, and protocols will be included in the Draft O&M Plan and the Draft Construction/Remedial Action Work Plan.	Okay pending review of future documents, DTSC, however, recommends that an outline of those reporting frameworks and procedures be provided as early as possible so that stakeholders can begin the evaluation process and develop consensus on framework where applicable.		Comment resolved.	See draft O&M Manual Main text, Section L.2 for communications framework, and O&M Volume 2 (Sampling and Monitoring Plan) for decision rules/ operational framework.
16	DTSC-GC6	General Comment: Scheduling		Identify general process steps, an activity list that includes sequencing of activities and estimated durations for construction and then for operations. Sequencing will describe how activities are interdependent or related. Critical path scheduling will demonstrate what drivers or dependencies are anticipated and assist in the development of contingencies for drivers that we cannot afford to fail. Discussing dependencies and whether they are mandatory or discretionary allows us to agree on importance of issues that may be incidental or critical to all stakeholders whether they are technical, cultural, budgetary or other elements.	Comment noted. An updated project schedule will be provided in the 60% design submittal.	Okay pending review of 60% submittal		Comment resolved.	See BOD Section 7 – Project Delivery Strategy/ Updated Schedule.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
17	DTSC-GC7	General Comment: Contingency Planning		For the 60% design, PG&E should develop in the contingency plan some criteria that may require contingencies to be executed. PG&E should also define measurable short term remedial goals with criteria for the contingencies. This may include contamination (define unacceptable levels Chrome VI or byproducts) increasing or not decreasing as anticipated for a certain period of time, or if the water resources are no longer available (river water vs. HNRW-1 water), etc.	Comment noted.	Okay		Comment resolved.	See draft O&M Manual, Volume 3 – Contingency Plan.
18	DTSC-GC8	General Comment: Progress Reports		PG&E should discuss a method or progress reporting and the parameters to determine progress. Cost, contaminant removal, GSR factors, time, and schedule using methods such as Schedule or Cost performance indices or forecasting techniques.	Comment noted. A discussion on progress reporting will be included in the Draft O&M Manual.	Okay pending review of O&M plan		Comment resolved.	See draft O&M Manual (Main text, Section L.2).
19	HA-GC1	General Comment		As you are aware, the draft 30% BOD is a voluminous compilation of information on the Topock groundwater remedy design basis, design criteria, drawings, and specifications. Additionally, the document reflects the limited information available for presentation at a preliminary (30%) level of design, with the understanding that additional detail, representing a 60% and 90% level of design, will be provided for Tribal review and comment over the next several months. Moreover, as discussed in the *Revised Corrective Measure Implementation/ Remedial Design (CMI/RD) Work Plan for Solid Waste Management Unit (SWMU) 1/ Area of Concern (AOC) 1 and AOC 10* (the "CMI/RD WP"), there are several more items needed to support the design and implementation of the groundwater remedy. Accordingly, the comments issued by the Tribe at this time in review of this 30% BOD necessarily are not to be considered as comprehensive or complete. Essential parts of the plan are missing, for example the monitoring plan and a contingency plan. Thus this review process requires that comments provided at each stage be reconsidered in the context of the newer information so every commenter is afforded an opportunity to reconsider the continuing applicability of earlier comments and/or the need to refine and/or add to those prior comments.	Comment noted. PG&E is committed to deliver the design documents and plans as presented in the CMI/RD Work Plan.	Comment noted.	Comment noted.	Noted.	See draft O&M Manual Volume 2 (Sampling and Monitoring Plan) and Volume 3 (Contingency Plan).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
20	HA-GC2	General Comment		As has been emphasized many times in the past by the Tribe, this remedial project as well as the existing compressor facility and other man-made constructions are present on hallowed grounds and are of deep cultural value to the Tribe. Desecration of the purity and sanctity of these sacred grounds is significant and ongoing as a result of the continuing presence and operation of the compressor station in addition to the impacts associated with the remedial actions. In particular regard to the 30% BOD, the Tribe has concerns over the process leading to the transition from the Interim Measure No. 3 ("IM3") to the final remedy. Specifically, the IM3 water treatment plant (WTP), which is located within and operating within the footprint of the Topock Maze, and is a continuing adverse effect, must be decommissioned as expeditiously as practicable to minimize that adverse effect. The presence of this facility on the sacred Tribal grounds is spiritually harmful and distressing to members of FMIT and other tribes having cultural affinity to this area. Certainly, this situation is not unknown to PG&E, the California Department of Toxic Substances Control ("DTSC"), or the U.S. Department of the Interior ("DOI") ("the Agencies"), to whom this offense has been made known since the start of the IM3 operations. According to DTSC decision documents, the purpose of IM3 is to protect human health and the environment by preventing seepage of groundwater contaminated with hexavalent chromium ("Cr(VI)") into the Colorado River. However, as set forth in the 30% BOD and accompanying materials, upon implementation of the final groundwater remedy, the IM3 will necessarily be shut off and thus will be providing no further protection unless (1) some event were to occur that would result in shutting down the final remedy extraction wells, and (2) the IM3 WTP could handle the volume and chemistry of water then needed to be extracted. There is no discussion in the 30% BOD as to any foreseeable scenario under which the final remedy extraction wells would be shut down (to allow IM3 extraction wells to come back on line) or whether under such a scenario the water extracted by IM3 could even be treated by the IM3 WTP. Given that the hydraulic regime associated with IM3 operation are concededly inconsistent (and to a large extent directly opposite) the hydraulic regime associated with the final remedy design, there does not appear to be any reasonably foreseeable scenario under which IM3 would be reactivated. If IM3 is not to be immediately decommissioned upon the completion of startup of the final remedy, which would remove its	PG&E acknowledges the Tribe's statement of its position regarding the decommissioning of IM-3. These topics are currently being addressed in confidential settlement discussions between the Tribe, DTSC and PG&E, and PG&E defers any response on these issues to those settlement discussions.	Comment noted. DTSC agrees that the IM3 Treatment Plant will be decommissioned when the remedy is operating properly and successfully based the remedy decision documentation. IM3 decommissioning is currently a subject of litigation filed by the FMIT. Therefore, additional discussion is deferred.	Defer response.		See BOD Section 7.4 (Criteria for Approval of IM-3 Decommissioning)

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				continuing adverse effect, the agencies must explain what conditions are reasonably foreseeable that support continuing this adverse effect. Additionally, even if there were a scenario under which restarting IM3 would be indicated, the IM3 WTP technology would be incapable of managing the type of chemical treatment and volume that the final remedy would have established in situ. There is presently no technical basis to support continuing the presence of the IM3 WTP following the completion of final remedy startup. While the draft 30% BOD discusses an IM3 transition process broadly in Section 8.3, it is not clear that the criteria listed for this evaluation are those that would necessarily be acceptable to the agencies or to FMIT, nor that the transition process described by PG&E will meet the criteria anticipated by the Agencies. That transition process (including the timing and criteria for directing decommissioning) must be more clearly defined and supported by a reasonable factual foundation.					
21	Hualapai-GC	General Comment		With the assistance of the TRC Committee Hualapai's review focused on the groundwater flow and solute transport modeling described in Appendix B and the estimated 30-year time frame for completion of the remediation. As the Topock modeling incorporated parameters generated from the two In-Situ Pilot Tests (ISPTs) conducted in the upland and flood plain areas, attention was also given to 1) the data generated from these pilot tests, 2) how those data were incorporated into the groundwater model, and 3) the potential impact on estimates of the actual clean-up time frame. We appreciate that the work has been done in a professional and through manner and that the regional model seems to have been developed with appropriate, standard practice and care. Our comments herein are prepared to provide additional, constructive input which we hope will provide positive contributions to the continued design of the remedial system, and to continue to incorporate the concerns and interests of the Tribes. The TRC Committee has been invaluable throughout this review and they welcome the opportunity to discuss any of these points with any technical consultants for the project, and appreciate the opportunity to contribute to a successful and effective remediation.	PG&E appreciates the Tribe's comment and welcomes the TRC's review and inputs.	Comment noted.	Comment noted.		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
Section 1 Comments – Introduction									
22	DOI-12	Section 1.0, Paragraph 2, Sentence 3		Please change the text to "The DOI is the lead federal agency overseeing response actions for land under its jurisdiction, custody, or control …", removing "on or emanating from" for consistency with previous documents.	The text will be changed as suggested.		Okay pending review of text in 60% design submittal.	Resolved pending review of 60% design submittal.	See Section 1.0 of this BOD Report.
23	HA-1a	p. 1-1, para. 3		This paragraph establishes that the scope of this document pertains to the "final groundwater remedy" and distinguishes its purpose "... from other future actions that may be selected for the *soil media* at the Compressor Station." [Emphasis added]. In the past, the Tribe has commented about its concern regarding the project's separation of the groundwater and soils components of this project. Fundamentally, the remedial program makes this distinction, but in reality the potential interrelationship between soil and groundwater contamination is quite evident from various actions and decisions, such as parts of the soils remedial investigation that are designed to test the potential for downward migration of soil contaminants to act as continuing sources of groundwater contamination. See comment #2 below.	The intent of this paragraph is to provide additional information about the decision documents for the groundwater remedy and clarification on terminology to be used in the design document. If helpful, the following text in the last sentence of the third paragraph can be deleted in the 60% design submittal: "…~~to distinguish it from other future actions that may be selected for the soil media at the Compressor Station~~".	Proposed changes are okay.	Proposed changes are okay.		See Section 1.0 of this BOD Report.
24	HA-1b	p. 1-1, para. 4		This paragraph acknowledges that further refinement to the groundwater remedy will result from input provided by "stakeholders, Agencies, and Tribes" throughout the review process that will continue through November of 2012. The obligation of the Agencies to timely and meaningfully consult with the Tribes should be expressly acknowledged. Considering the complex and voluminous nature of these documents, sufficient time for Tribal review should be allocated, which may be greater than 30 to 45 days. The obligation of the agencies to consult with the Tribes should be added to the project's "Rainbow Schedule."	Comment noted. The project's "Rainbow Schedule" includes step and duration for Tribal Consultation, as set forth in the Programmatic Agreement, for each design document (30/60/90%). See Consultation Protocol of the PA (Appendix B).	Comment and response noted. DTSC has requested that additional time be allocated for the review of the 60% design document.	DOI acknowledges the complexity of design documents and have suggested an extension to the review period as well (See DOI Comment 10). We suggest a 60-day review period for the Tribes and stakeholders with an additional 15 calendar days for the agencies to review those comments prior to our comment submittal.		See Exhibit 1.0-1 of this BOD Report, which reflects an extended 60-day review period of CWG/TWG and Tribes and a 75-day review period for DTSC and DOI.

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
25	HA-2	Ex.1-1, p. 1-2		This schedule indicates that the East Ravine/Topock Compressor Station Groundwater Investigation is ongoing through January 2012. Again, this is an example of where the schedules for the groundwater and soils investigations overlap but are not in sync. This is an example of where the ultimate impacts of this project may have not been fully and properly assessed. The East Ravine may be an area where groundwater risks have not been fully accounted for thereby adding to uncertainty related to the design and may therefore result in further disturbances in attempting to resolve the uncertainty. The details of the groundwater remedy design for this area will need to be addressed in the forthcoming design reports as indicated on the schedule.	Legal counsel for the Tribe has confirmed in discussions with PG&E counsel that this comment was intended to refer to the status of the East Ravine investigation and not the adequacy of the analysis in the EIR. To date, the East Ravine-Compressor Station Groundwater Investigation has focused on collecting the most important data for the design first and those data (groundwater quality and subsurface lithology) have been and will continue to be incorporated into the design as efficiently as possible, following validation and QA. Information and data from the investigation have been and will continue to be shared and discussed with agencies, stakeholders, and Tribes on screen calls to ensure opportunities for inputs. As mentioned at the January 18, 2012 CWG meeting, the East Ravine-Compressor Station groundwater investigation report will be included as an appendix to the 60% design submittal.	Comment and response noted.	Comment and response noted.		Results of the East Ravine groundwater investigation were summarized in a technical memorandum entitled *Addendum to the Summary of Findings Associated with the East Ravine Groundwater Investigation, Pacific Gas and Electronic Company, Topock Compressor Station, Needles, California*. The Addendum was submitted to agencies on November 12, 2012 and results were discussed at the January 17, 2013 TWG meeting in Henderson, NV. Comments were received from DTSC and DOI on February 15, 2013. The Addendum is currently being revised to incorporate comments.
26	HA-3a	p. 1-3, para. 2		In the first sentence delete the word "considered." The area is indeed sacred to the FMIT. Also, after the words "adjacent lands" add "... are the aboriginal homelands and such lands ..." Delete the next sentence that begins with "The Tribes believe ..." This area is a holy place to the Fort Mojave People. It is hallowed ground based on the religious beliefs of the FMIT and other Native American Tribes.	PG&E acknowledges the FMIT's statement of its beliefs regarding the sacred nature of the area. The text appropriately refers to these statements as statements of belief; this terminology was used in the EIR including the Tribe's comments on the EIR. PG&E also believes that the last sentence of the paragraph should be clarified to more accurately state BLM's findings in the Programmatic Agreement. Accordingly, the last sentence should be revised to state that "….and the BLM has also determined that a traditional cultural property or property of traditional religious and cultural significance that is eligible for listing on the National Register of Historic Places exists in the area of the Topock project <u>within the APE."</u>	Comment and response noted pending review of text in 60% design submittal	Comment and response noted pending review of text in 60% design submittal		See Section 1.1 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
27	DOI-13	Section 1.1, Paragraphs 2 & 3		This section is entitled “Background” however the information primarily pertains to the cultural significance of the area. This is misleading. One would expect a background section to provide project history. It is recommended that this section be revised to discuss project history and a new section or subsection be added to address the cultural significance, cultural and historic resources and ecological resources, including the ACEC and HNWR. It is the agencies intent to minimize, to the extent practicable, impacts to the cultural significance of the area and to protect cultural, historic and ecological resources.	The following changes will be made to Section 1.1 (Background) (inserted verbiage shown in underline typeface, deleted text shown in ~~strikethrough~~ typeface): **1.1 Background** The Compressor Station is located adjacent to the Colorado River in eastern San Bernardino County, California, approximately 12 miles southeast of Needles, California, south of Interstate 40 (I-40), in the north end of the Chemehuevi Mountains (see Figure 1-1~~; all figures are located at the end of this document~~). The selected groundwater remedy addresses existing chromium contamination from past discharges of wastewater into the Former Percolation Bed (SWMU1) and the area around the Former Percolation Bed (AOC1) within Bat Cave Wash near the Compressor Station. The groundwater remedy also addresses groundwater within the East Ravine (AOC10) and under the Compressor Station. The following presents a description and history of SWMU1/AOC1 and AOC10 (CH2M HILL 2009d), and description of the cultural, historical, and ecological resources in the project area. **Description and History of SWMU1/AOC1 and AOC10** SWMU1 was formerly the site of wastewater percolation within Bat Cave Wash. AOC1 is defined as areas affected by flow of wastewater from the percolation bed, including the floor of Bat Cave Wash in the area surrounding the location of the discharge area (SWMU1) and the floor of Bat Cave Wash downstream from the discharge area towards the Colorado River. From 1951 to 1970, facility wastewater was discharged to this area and was allowed to percolate into the ground and/or evaporate. In addition, there have been several incidentals releases of facility wastewater, a few of which have resulted in wastewater released to Bat Cave Wash. Wastewater discharged to Bat Cave Wash consisted primarily of cooling tower blowdown (about 95 percent) and a minor volume of effluent from an oil/water separator (OWS) and other facility maintenance operation (about 5 percent). From 1951 to 1964, cooling tower blowdown was not treated prior to being released to the wash. During that period, the cooling tower blowdown contained Cr(VI). From 1964 to 1969, the cooling		Response/additional text are okay pending review of text in 60% design submittal		See Section 1.1 of this BOD Report. Please note that the sentences in italicized typeface under the PG&E Response to 30% Design Comment column of this comment have been added for completeness and accuracy.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					tower blowdown was treated with a one-step system to reduce Cr(VI) in the wastewater to Cr(III) prior to discharge to the wash. Beginning in late 1969, cooling tower blowdown was treated with a two-step system to reduce Cr(VI) to Cr(III) and then to remove Cr(III) from the wastewater prior to discharge to Bat Cave Wash. The continuous discharge of wastewater to Bat Cave Wash ceased in May 1970 when injection well PGE-08 was brought online. From May 1970 to September 1971, however, some treated wastewater may have been temporarily discharged to the percolation bed in Bat Cave Wash when injected well PGE-08 was offline for repairs or maintenance. All wastewater discharges to the percolation bed in Bat Cave Wash stopped when the first of four single-lined evaporation ponds was installed in September 1971. Since 1989, industrial wastewater from the Compressor Station has been disposed at Class II (double-lined) evaporation ponds. AOC10 (East Ravine) is located southeast of the Compressor Station, and includes four subareas, designated as AOC10a, 10b, 10c, and 10d. Subarea 10a is the location of the termination of a storm drain leading from the southeastern portion of the Compressor Station. The remaining subareas are locations within the East Ravine where water and sediment have collected within low areas or behind one of three earthen embankments. Two historical aerial photographs of this portion of the site show a low area within the AOC10c subarea that apparently contained liquids behind the largest embankment. While the composition of such liquids is not known, it is noted that this is the location of some of the highest chromium concentrations detected in soil sampling. Thin layers of white powdery materials have also been identified in the East Ravine area. Drainage to this ravine includes minor runoff from the access road to the facility, runoff from the mountains to the south, and some runoff from the compressor station. **Cultural and Historical Resources** The Topock site and adjacent lands are contained within a larger geographic area that is considered sacred by the Fort Mojave Indian Tribe and by other Native American Tribes. The Tribes believe that the environmental, cultural, and spiritual resources may not be physically				

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					perceptible. DTSC has concluded within the January 2011 certified EIR that the project site “appears to qualify as a historic resource under CEQA [California Environmental Quality Act] as an area that is significant in the social and cultural annals of California,” and the BLM also has determined that a traditional cultural property or property of traditional religious and cultural significance that is eligible for listing on the National Register of Historic Places exists in the area of the Topock project within the APE (AECOM 2011). *The Topock site is also located in a Riparian and Cultural Area of Critical Environmental Concern (ACEC), designated under the BLM Resources Management Plan (BLM 2007).* Thousands of years of human history are evident in the area surrounding the Compressor Station. Among the larger and better known cultural resources on the site is an expansive desert geoglyph or intaglio known as the Topock Maze. Although the Maze is viewed as one contiguous element of a larger area having unique value to some Tribes, archaeological documents refer to three geographically-distinct parts, two of which overlie the groundwater plume. Prominent historic-era features in the landscape, several of which intrude upon the Maze and also overlie the groundwater plume, include segments of historic United Stated Route 66, the National Old Trails Highway, and the right-of0way of the Atlantic and Pacific/Atchison, Topeka, and Santa Fe Railroad. A broad spectrum of archaeological resources is also present within the project area and on adjacent lands. Properties on and near the Topock site that are eligible for or listed on the National Register of Historic Places include Native American cultural resources and elements of the historic “built environment”. **Ecological Resources** A large portion of the site and surrounding area is the Havasu National Wildlife Refuge (HNWR). The Lower Colorado River National Wildlife Refuges Comprehensive Management Plan 1994-2014 (USFWS and BOR 1994), adopted in 1994, currently guides land management at the HNWR. The Comprehensive Management Plan emphasizes that the HNWR should be used in a manner that will facilitate protection of (1) the endangered and threatened species found in the Refuge, (2) marsh and wetland

PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					habitat for both endangered and threatened species, and (3) habitat for migratory, wintering, and nongame avian species and their habitat. *Portions of the Topock site are also located in an Riparian and Cultural ACEC and the Topock-Needles Special Cultural Resource Management Area (SCRMA),* designated under the BLM Resources Management Plan (BLM 2007). In recognition of this, all remedial activities are planned in such a way as to minimize impact to this area. Specifically, impacts to cultural resources will be minimized by implementing the mitigation measures required by the EIR and the Programmatic Agreement. The work will be conducted in a manner that recognizes and respects these resources and the spiritual values of the area. ~~Practices that will be implemented with this objective in mind include: minimizing additional disturbance to the area by installing facilities in previously disturbed areas where possible; minimizing the size of drilling pads and staging areas; use of all-terrain drilling and sampling equipment in areas not served by existing roadways; constructing wells with multiple well screens at different depths in a single boring where possible rather than drilling individual borings for each well depth; minimizing the amount of equipment and duration that equipment is present on site; and providing training to all site employees to ensure that they are aware of and respectful of the spiritual value of this area that is considered sacred by certain Tribes.~~				
28	DOI-14	Section 1.1, Paragraph 3, Sentence 2		The text states that “impacts to cultural resources will be minimized by implementing the mitigation measures required by the EIR.” Although it is further discussed in Section 1.2.2, this paragraph should acknowledge that mitigation measures will be developed in accordance with the BLM PA and the CHPMP and in consultation with the Tribes throughout the design process.	The following text will be added to this paragraph in the 60% design submittal: “In addition, mitigation measures will be implemented in accordance with the PA and the CHPMP and in consultation with the Tribes throughout the design process”.		OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Section 1.1 of this BOD Report.
29	HA-3b	p. 1-3, para. 3		The Final Environmental Impact Report[1] (“FEIR” or “EIR”) concluded that “... even with the implementation of mitigation ... significant impacts to the Topock Cultural Area ... within the project area are expected to be significant and unavoidable.” This paragraph should reiterate this conclusion. [1] DTSC, 2011. *Final Environmental Impact Report for the Topock Compressor Station Groundwater Remediation Project.* SCH #2008051003. p. 6-33.	PG&E acknowledges the comment and the conclusion in the EIR. It is not necessary, however, for the basis of design report to reiterate conclusions set forth in the EIR.	The draft EIR is a record in itself. The resulting potential project impacts are used for the project decision. Restating a conclusion in the EIR in the design is not necessary.	Defer response.		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
30	HA-3c	p.1-3, para. 3		Consultation with the Tribe is ongoing, so this list of mitigating measures is incomplete. Each step of the remedial project will require consideration of further mitigation to address potentially different and additional impacts of the particular action. Among the mitigating measures required by the EIR, the list should also include a commitment to continue working with the tribes to establish work implementation policies that are acceptable to the tribes, such as the ongoing effort to establish a disturbed soils policy and a well decommissioning policy or procedure. There should also be a mechanism established so that the effectiveness of the adopted mitigation measures is regularly assessed and mechanisms to improve mitigation performance established.	Counsel for the Tribe, in discussions with PG&E counsel, has confirmed that the reference to further mitigation in this comment refers to consideration of further mitigation measures already specified in the EIR. The summary of measures on page 1-3 is a short list of the measures in Table 7-1, which provides a summary of how the 30% design complies with the EIR. If helpful, the following text can be deleted in response to this portion of comment: " ~~Practices that will be implemented with this objective in mind include: minimizing additional disturbance to the area by installing facilities in previously disturbed areas where possible; minimizing the size of drilling pads and staging areas; use of all-terrain drilling and sampling equipment in areas not served by existing roadways; constructing wells with multiple well screens at different depths in a single boring where possible rather than drilling individual borings for each well depth; minimizing the amount of equipment and duration that equipment is present on site; and providing training to all site employees to ensure that they are aware of and respectful of the spiritual value of this area that is considered sacred by certain Tribes~~." Regarding the request to include a commitment to continue working with the tribes, PG&E re-iterates here our commitment to work with Tribes through our ongoing processes, our MOUs, and implementation of numerous EIR mitigation measures (e.g. CUL-1a provides for tribal input to the final design. (Final EIR at 4.4-62).) Specifically, PG&E has convened a Technical Review Committee that includes technical representatives of the Interested Tribes to review project-related documents, participate in project-related meetings, and advise interested tribal members on technical matters relating to the final design and remedy. (Final EIR at 4.4-64.) Tribal representatives on the Technical Review Committee have input into work implementation policies, including the disturbed soils policy and the well decommissioning procedure. Further, the mitigation monitoring and reporting program (MMRP) as implemented by a Qualified Cultural Resource Consultant ensures that the effectiveness of adopted mitigation measures is regularly assessed and that if necessary, mechanisms to improve	The evaluation of mitigation measures is a subject of litigation. DTSC is committed to continue dialogue with all interested tribes during the design, construction and implementation of the remedy.	Defer response.		See Section 1.1 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					mitigation performance will be established. (Final EIR at 4.4-63.) Finally, the Cultural Impact Mitigation Program (CIMP) is being developed in coordination with Interested Tribes and shows PG&E's commitment to working with the Tribes. (Final EIR at 4.4-65-4.4-66.) Through the development of the CIMP, the Tribes will have the opportunity to participate in the creation of many design specific protocols and methods, including, among others, protocols to for continued communication between PG&E and the interested Tribes, protocols for the appropriate treatment of archaeological materials that may be disturbed, protocols for the review of cultural resource-related documents, protocols for the review of project design documents, protocols for the appropriate methods to be used to restore the environment on decommissioning individual groundwater remedy facilities, a plan for decommissioning and removing the IM-3 facility, protocols for the repatriation of clean soil cuttings generated during Project activities, and provisions affording sufficient tribal monitors to observe ground-disturbing activities and/or other scientific surveying that may occur in preparation for construction activities. (Id.) Tribal consultation is also ongoing pursuant to the Programmatic Agreement's Consultation Protocol. Additionally, the mitigation measures under the Programmatic Agreement and the Cultural and Historic Properties Management Plan are also being followed in order to minimize impacts to cultural resources.				

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
31	HA-4a	p. 1-4, Section 1.2.1 (Remedial Action Objectives)		The Tribe has previously commented on the fact that these RAOs do not include goals for minimizing cultural impacts in the course of implementing this list of technical objectives. The impacts to the cultural setting have and continue to affect the health and well being of the Mojave people mentally, emotionally, and spiritually. It should be noted that the American Society for Testing and Materials (ASTM) has recognized the need for non-risk RAOs in addition to risk-based corrective action measures.[2] Non-risk criteria are typically non-numeric narratives. Among the non-risk criteria listed in the ASTM standard are property use requirements and community concern, both of which may relate to concerns of the Tribe. [2] ASTM, 2012. ASTM E2616 - 09 *Standard Guide for Remedy Selection Integrating Risk-Based Corrective Action and Non-Risk Considerations.* Accessed at: http://www.astm.org/Standards/E2616.htm	Comment noted. As the RAOs for the groundwater remedy are established in the decision documents, PG&E defers to DTSC and DOI.	The RAOs were identified and established during the CMS/FS documentation. The RAOs were developed by following the USEPA guidance to define RAOs by media, and specific for each receptor group. The RAOs are consistent with the National Contingency Plan for measurable objectives. In reviewing the scope established by the ASTM standards, the non-risk remedial action objectives are stated as objectives which “may include resource protection standards and the prevention of aesthetic or nuisance impacts in addition to protection of human health and the environment” The scope of the ASTM E2616 further states that “other non-risk criteria are typically non-numeric and may include: remediation timeframe, implementability, cost effectiveness, regulatory compliance, property use requirements, liability control, and community concern.” Although the Tribe may object to the conclusions, DTSC believes that through our remedy selection process, including the certified EIR, these goals have been considered,	The RAOs provided in the CMS/FS are based on CERCLA guidance. The National Contingency Plan specifies that “In developing and, as appropriate, screening the alternatives, the lead agency shall: Establish remedial action objectives specifying contaminants and media of concern, potential exposure pathways, and remediation goals. Initially, preliminary remediation goals are developed based on readily available information, such as chemical-specific ARARs or other reliable information.” The RAOs for the Topock Groundwater remedy were established during the development of the CMS/FS and finalized in the DOI ROD and the DTSC FEIR and Decision Package. DOI will consider the ASTM guidance in the development of the soil CMS/FS and future decision documents.

32	HA-4b	p. 1-4, Section 1.2.2 (Incorporation of ARARs ...)		This section states that the Bureau of Land Management's (BLM) Programmatic Agreement (PA) has helped "... to guide the BLM's planning and decision-making as it affects cultural and historic properties specific to the groundwater remedy." Please provide an example as to how this process has served to properly protect the Topock Cultural Area. Furthermore, only one tribe, the Hualapai, signed the PA. Other affected tribes did not based on the fact that the PA failed to address a number of their concerns. The Tribes are requiring that formal consultation be carried out on a government-to-government basis with non-signatory tribes pursuant to Section 106 of the National Historic Preservation Act. The language in this section does not portray this situation accurately. The language should reflect the process being used to engage Tribal perspectives on this project	PG&E defers to BLM/DOI.		Comment noted. The BLM, the CA and AZ SHPO's, and the Advisory Council for Historic Preservation executed the Programmatic Agreement (PA) on October 26, 2010. The execution of the PA streamlines the consultation process, and allows the implementation of the Selected Remedy in a timely manner. All further consultations with the nine federally-recognized American Indian tribes affiliated with the PG&E Topock Remediation Project are to be conducted in furtherance of BLM's compliance under Section 106 and pursuant to the PA Consultation Protocol (Appendix B). The BLM made a reasonable and good faith effort to gain and incorporate the views of the FMIT and other consulted tribes into the PA for this Undertaking. The provisions of the PA will be followed as the Topock Remediation Project proceeds. The Cultural and Historic Properties Management Plan (CHPMP) is the treatment plan for how effects to historic properties and cultural values will be taken into account given approval and implementation of the Selected Remedy. The PA also stipulates how consultation under the National Historic Preservation Act (NHPA) will occur as the selected Remedy is implemented. Initially, none of the consulted Tribes signed the PA as Invited Signatories and two tribes (FMIT and the Hualapai Tribe) expressly declined to do so. Later, the Hualapai Tribe changed their position and signed the PA on July 20, 2011. Tribal views regarding the significance of the cultural resources and values adversely

							affected and the importance of mitigating adverse effects on those resources and values will continue to be solicited through government to government and face to face consultations under the Consultation Protocol of the PA (Appendix B) and incorporated into the decision-making process.		
33	HA-4c	p. 1-4, same section, last para. – (refer to earlier comment # 3)		Again, this paragraph understates the fact that mitigating measures "... capable of reducing these impacts to less-than-significant levels" could not be enacted for several cultural impacts important to the Tribe. The Tribes have throughout this process stated that anything that transpires on the hallowed ground is an impact of irreversible and damaging effect and further desecrates the area. No mitigation can resolve such impacts to the spiritual cleaning area we know as present-day Topock.	As this statement is from the EIR, PG&E defers to DTSC.	Comment noted.	Comment noted.		
34	DOI-15	Section 1.3, Paragraph 1		Please ensure that the text is updated, as appropriate, and refers to the Consent Decree between DOI and PG&E when it becomes available.	Comment noted. The final Consent Decree will be referenced when it is available.		Response noted.	Comment resolved.	The Consent Decree executed in 2012 and lodged with the court in January 2013 was referenced throughout this BOD Report.
35	DOI-11	Section 1		A Section 1.4 should be added that summarizes the specific elements of the design that will be included in the 60% design package and are either not included in the 30% design package or will be extensively refined. This refers to design details only, not plans and other submittals as shown in Table 8-1.	PG&E proposes to add a table, instead of a separate section, into the 60% design submittal that meets the substantive requirements of DOI's request.		Okay pending review of 60% design submittal	Resolved pending review of 60% design submittal.	See Exhibit 1.3-1 of this BOD Report.
Section 2 Comments — Baseline Site Conditions and Pre-Design Work									
36	HA-5	p. 2-1, Section 2.1.1 (Hydrogeologic Setting), para. 3		This paragraph attributes the fluctuations in the Colorado River primarily due to regulation at Davis Dam. Does Parker Dam also play a significant role in affecting River stage?	Parker Dam does play a role in the river fluctuation pattern, mainly during heavy rain/higher river flow conditions. Our river level predictions are tied to the Davis Dam release rates and Lake Havasu level. Most of the time, the Davis Dam releases are the dominant factor in determining river levels at Topock. This text will be added to the 60% design submittal.	Noted pending review of text in 60% design submittal	Noted pending review of text in 60% design submittal		See Section 2.1 of this BOD Report.
37	HA-6	p. 2-1, Section 2.1.1 (Hydrogeologic Properties)		Please provide an approximate value or range of values for the magnitude of the landward hydraulic gradient imposed by the IM.	The hydraulic gradient imposed by IM-3 pumping is measured in three pairs of monitoring wells. Over the period from August 2007 through December, 2011, the average landward gradient in these three wells pairs has been approximately 0.005 ft/ft. This information will be added to the first bullet under Section 2.1.2 (Hydrogeologic Properties).	OK	Okay.		See Section 2.1 of this BOD Report.

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
38	Hualapai-31			<u>Further considerations for the 60% Design Evaluation</u> The CMS-FS reported, and DTSC confirmed, that there will be "recalcitrant" areas that may be difficult to remediate. 5.3.6 Alternative E – In-situ Treatment with Fresh Water Flushing (starting p. 5-30). Note that, on page 5-31: *The estimated time for five pore volumes to be flushed with this alternative is approximately 29 years. The actual cleanup time will be dependent on the rate at which organic carbon can be distributed to all areas of contaminated groundwater in the flood-plain and/or contaminated groundwater in recalcitrant zones in the upland areas can be flushed to the IRZ treatment line where it will be treated by injected organic carbon. These factors are subject to considerable uncertainty. It is estimated that the range of cleanup time is from 10 (based on two pore volumes) to 110 years (based on 20 pore volumes). The estimated time for this alternative is derived based on the assumed configuration described above. The estimated time for this alternative could be adjusted by modifying the number and location of wells and/or by modifying the flow rates. Under this alternative, an institutional control would be maintained during the remediation period to restrict use of groundwater in the plume area until the cleanup goals are attained, thereby eliminating the pathway for human health risk from direct exposure to groundwater. The area subject to the institutional control would include a buffer area surrounding the plume to prevent the consumption of water that potentially could migrate from the plume in other directions as a result of pumping from hypothetical future local water supply wells.* Note that the concept of "recalcitrant" zones is mentioned in several of the remedies that were discussed in this document. So it is a concept that was included in the evaluation of each of these remedies prior to the selection of the current remedy. There are data gaps in the understanding of these recalcitrant areas. If these could be mapped by examination of core logs, for example, then these areas could be stimulated either with higher TOC concentrations or introduction of Cr-reducing microbes.	The range of cleanup times of alternatives presented in the CMS/FS was based on a pore-volume flushing approach which was based on observed data from in situ pilot study tracer data and floodplain stable isotope data. In those cases, the approximate range of pore volume flushing required to replace initial groundwater concentration with final concentration was 2-20 pore volumes. This was considered a reasonable screening tool for comparison of alternatives. The current model uses reactive solute transport parameters to estimate concentration changes over time. Recalcitrant zones in groundwater cleanup projects may be caused by several factors. The most common is probably high concentrations of contaminants in low permeability silt or clay zones. Other causes can be stagnation points in the groundwater flow field, or in the case of in-situ remediation, geochemical heterogeneities that adversely affect the chemistry of the in-situ process. Examination of core logs would not be expected to yield useful data on the location of recalcitrant zones. In the complex alluvial fan depositional environment of the Topock site, there is often very little correlation in lithology even between adjacent wells, so the core logs do not provide a clear picture of where sizable silt or clay inclusions may exist. Even if it were possible to identify sizable clay inclusions from the core logs, there is no data from which to determine the concentration of Cr(VI) in the clays. A clay inclusion that is not contaminated does not represent a recalcitrant zone, so there would be no need to apply additional remedial effort to it. Recalcitrant zones typically become apparent after a few years of remediation. At that time, optimization measures can be implemented as necessary to speed the cleanup in recalcitrant zones.	Response noted.	Comment and response noted.		
39	DOI-16	Section 2.1.2/2-2/1st Paragraph/last sentence		It should be mentioned that a borehole in the East Ravine encountered a flowing bedrock fracture.	A full discussion of the ramifications of the conditions encountered at Site H will be provided in the 60% design submittal.	OK pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Section 2.1 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
40	DOI-17	Section 2.2/2-2/ 1st Paragraph/last sentence		There should be some discussion of the mechanism by which bedrock groundwater is contaminated if there are upward gradients from the bedrock to the alluvium.	Below are some potential mechanisms: 1) There is photographic evidence of surface water ponding in East Ravine. During the time the ponds were present, there could have been sufficient head in alluvial aquifer at the ponds to overwhelm the slight upward gradients we see today between bedrock and alluvium. 2) The discharge of cooling water in Bat Cave Wash may have elevated groundwater levels in the alluvium relative to the bedrock, producing downward gradients under the compressor station and along alluvial bedrock contact at the north edge of East Ravine. There are insufficient data to identify to what extent these or other potential mechanisms may be responsible for Cr(VI) in East Ravine bedrock.		Okay.	Resolved	
41	DOI-18	Section 2.2, Last Paragraph, Sentence 5		The statement that “bedrock in East Ravine has relatively few conductive fractures” is broad and not well supported as evidenced by the extent of the plume and conductivity of some of the wells. For example, a borehole in the East Ravine (Site H) encountered a flowing bedrock fracture. This information should be added to support the discussion of conductive fractures.	As noted in response to comment #10 DOI-9, the 60% design submittal will include an update of the conceptual site model for the East Ravine that addresses conditions observed at Site H.		Okay pending review of 60% design submittal.	Comment resolved.	See Section 2.2 of this BOD Report. Results of the East Ravine groundwater investigation were summarized in a technical memorandum entitled *Addendum to the Summary of Findings Associated with the East Ravine Groundwater Investigation, Pacific Gas and Electronic Company, Topock Compressor Station, Needles, California*. The Addendum was submitted to agencies on November 12, 2012 and results were discussed at the January 17, 2013 TWG meeting in Henderson, NV. Comments were received from DTSC and DOI on February 15, 2013. The Addendum is currently being revised to incorporate comments.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
42	DTSC-1	Page 2-3, 3rd Paragraph	Though the interpretation of the southern extent of the chromium plume has expanded slightly due to new wells being installed since the CMS/FS (CH2M HILL 2009d), other parts of the plume have shrunk since that time, resulting in a slightly smaller extent overall.	What basis is PG&E using to state that the resulting plume is slightly smaller overall when the Eastern extent of East Ravine is still unknown?	The shallow plume was drawn around all East Ravine wells, similar to what was done for the CMS/FS. It is acknowledged that the ER has not been fully characterized, and the southern boundary of the plume remains an approximation. The 60% submittal will provide updated plume dimensions. For clarification, the sentence will be deleted in the 60% design report,	Okay		Comment resolved.	See Section 2.2 of this BOD Report.
43	DTSC-2	Section 2.3, Baseline Distribution of Other Compounds		Generally this section needs to include a design discussion on how the baseline distribution of each constituent discussed has a capacity or probability [or not] of impacting the proposed design. While the discussion on the distribution brings out salient qualities of the COPC, a direct statement on the design impact or lack thereof is missing.	Text will be added to clarify that the COPCs (selenium, molybdenum, and nitrate) and other general geochemical indicators parameters (TDS and sulfate) are not expected to impact remedy performance and therefore do not impact the design. With regards to TDS and sulfate, pilot test data indicates that Cr(VI) treatment is not affected by the presence of TDS and sulfate, as presented at the January 6 and January 19, 2012 TWG meetings. These findings will be discussed in the text. With regards to in-situ byproducts, the remedy is already designed to control the generation and migration of these compounds.	Okay		Comment resolved.	See Section 2.3 of this BOD Report.
44	DTSC-3	Page 2-3, 2.3 Baseline Distributions of Other Compounds		The document will need to expand the list of baseline constituents to the full title 22 metals list as well as a full suite of general minerals, etc., as DTSC will require these analyses during early startup of certain remedial facilities. For injection wells, the program will be very similar to that previously used at IM-3 injection wells.	Comment noted. A statistical summary table (similar to Table 2-1) will be included in the Draft O&M Manual for the full Title 22 metals list and available general minerals information, This will serve as a point of comparison for remedy monitoring data in the future.	Okay		Comment resolved.	See Table 2.2-2 of this BOD Report that includes a statistical summary of the full Title 22 metals and available general minerals information.
45	DTSC-4	Section 2.3.1, Page 2-3, Constituents of Potential Concern		Each section should include a discussion of the level of concern of the COPC existing presently and evolving during the remediation, and qualitatively discuss whether the COPC is a design driver or significant/insignificant risk factor to consider in the remedy and why. Then summarize how contingencies can be developed or alternatives to address those factors.	Text will be added to clarify that the COPCs (selenium, molybdenum, and nitrate) are not expected to impact remedy performance and therefore do not impact the design. The 2009 Groundwater Risk Assessment (ARCADIS 2009) concluded that selenium, molybdenum, and nitrate do not represent a significant health risk too future hypothetical users of the groundwater.	Okay		Comment resolved.	See Section 2.3 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
46	DTSC-5	Page 2-3/2-4, Section 2.3.1.1 Selenium		The section should be revised to indicate that elevated selenium almost exclusively occurs within or immediately adjacent to the boundary of the chromium plume. Well MW-17 is the only exception out of the eleven elevated wells as evidenced in Figure 2-4. Revise the section to indicate that elevated selenium is not discontinuous across the site as illustrated by the cluster of orange and magenta dots on Figure 2-4. Figure 2-4 can be interpreted to indicate that elevated selenium occurs within the general core of the chromium plume with the highest concentrations under the compressor station proper. Revise the section to indicate that significantly elevated selenium occurs at wells TW-1, MW-67-225, and MW-66-165 which are all located within the fence line of the compressor station, and therefore, suggestive of a compressor station source. The basis for elevated selenium levels related to colloidal breakthrough mentioned on page 2-4 should be discussed and supported. If not supported, the reference should be deleted. Would all metals exhibit similar levels of colloidal breakthrough? The section indicates that reducing conditions resulting from the remedy will likely limit selenium mobility. This assertion will need to be verified via selenium groundwater monitoring within the plume during the operation of the remedy. Text should be modified to indicate that the regional background concentrations mentioned on these figures (e.g., Figure 2-4) are background concentrations for the regional alluvial aquifer, and are not applicable to bedrock.	The 60% design submittal will honor the text used to describe selenium, molybdenum, nitrate, and TDS in the RFI/RI Vol 2 Addendum (CH2M HILL, 2009x), while accounting for any changes in distribution of these constituents since the RFI/RI was completed. Colloidal breakthrough in the samples will yield variable results based on the amount and composition of the colloids. Language used to describe this concept will be consistent with that used in the RFI/RI. Text will be added to stress that groundwater monitoring will be conducted to verify. Text will be added to indicate that Background Study UTLs listed for selenium, molybdenum, and nitrate were based on unconsolidated aquifer samples and not bedrock aquifer samples.	Okay pending review of the 60% design submittal		Comment resolved.	See Section 2.3 of this BOD Report.
47	DTSC-6	Page 2-4, Section 2.3.1.2 Molybdenum		Groundwater risk values associated with molybdenum should be mentioned, as an MCL does not exist, to assist in evaluating the significance of this constituent. The sentence on discontinuous distribution of molybdenum in the shallow zone wells should be modified to indicate that elevated concentrations (orange and magenta dots on Figure 2-5 – Shallow Wells) cluster to the south similar to the non-discontinuous Mid-Depth Zone. Text should clarify that the elevated molybdenum detected in groundwater is likely related to releases from the compressor station based on historical and current molybdenum use and documented releases. The section should indicate if reducing conditions resulting from the remedy will or will not likely limit molybdenum mobility (as stated in the document previously for selenium – see above).	See response to comment #46 DTSC-5.	Okay pending review of the 60% design submittal		Comment resolved.	See Section 2.3 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
48	DTSC-7	Page 2-4, Section 2.3.1.3 Nitrate		The section discussing the distribution of nitrate should be rewritten to indicate that Figure 2-6 clearly shows that almost all elevated nitrate (including values greater than the MCL) occurs within the confines of the chromium plume, suggesting that nitrate is a contaminant related to PG&E compressor station activities.	The 60% design submittal will honor the text used to describe nitrate in the RFI/RI Vol 2 Addendum (CH2M HILL, 2009x), while accounting for any changes in distribution of these constituents since the RFI/RI was completed.	Okay pending review of the 60% design submittal		Comment resolved.	See Section 2.3 of this BOD Report.
49	DTSC-8	Section 2.3.2, In-situ By-products	Citation of Table 2-2	Should be Table 2-1	This will be corrected in the 60% submittal.	Okay		Comment resolved.	See Section 2.3 of this BOD Report.
50	DTSC-9	Section 2.3.2, In-situ By Products, Page 2-4, paragraph 2,		In the opening statement, qualitatively summarize the important elements of Table 2-2 and do not depend on the reader to review the Table to interpret your sampling trend or results. This critical flaw is throughout the core document. Move first sentence identifying the COPC distribution Figures' locations to the end of the sections. Begin each sentence for each COPC with a qualitative or design statement relating the COPC impact on the design.	Discussion in text will be shifted in the 60% design submittal to emphasize the key points that may be concluded from the statistical summary in Table 2-1.	Okay pending review of 60% language.		Comment resolved.	See Section 2.3 of this BOD Report.
51	HA-7	p. 2-4, Section 2.3.2 (In-Situ By-Products)		It would be helpful to provide further details as to the anticipated behavior of these by-products in the subsurface environment, particularly at the anticipated geochemical interfaces along the flowpaths. While this information has been studied as part of the in-situ testing, geochemical and transport modeling, etc., it would be helpful to provide further discussion to facilitate the understanding of the anticipated behavior of these chemicals and the remedy processes that will control their migration as was discussed during recent TWG exchanges.	A detailed discussion of the generation and attenuation mechanisms at geochemical interfaces along flowpaths was provided in Section 8 of Appendix G in the CMS. The following text will be included in the 60% design submittal: Arsenic is primarily in the As(V) form in most areas of site groundwater. In the pH range of site groundwater, its form in solution is dominated by $HAsO_4^{2-}$. This anion tends to adsorb to the positively-charged surface of iron oxide minerals, which are present in the more oxidizing areas of the aquifer. This adsorption reaction maintains arsenic at concentrations below the UTL in most areas of the site. During the remedy operation of the IRZ, reducing conditions produced by the injection of organic carbon will dissolve iron oxide minerals in the surrounding matrix by reducing the Fe(III) in the oxide to Fe(II), which is soluble. The half-cell redox reaction may be written as: $Fe(OH)_3(s) + 3H^+ + e^- \rightarrow Fe^{2+} + 3H_2O$ with e^- representing electron, $Fe(OH)_3(s)$ as iron oxide (many variations on this formula exist in nature), and Fe^{2+} representing reduced iron or Fe(II). Coupled with this reaction would be another half-cell reaction showing equal oxidation of an electron donor, in this case ethanol going to carbon dioxide: $1/12\ C_2H_6O + 1/4\ H_2O \rightarrow 1/6\ CO_2 + H^+ + e^-$ where C_2H_6O is ethanol, the form of	Noted. Further evaluation will occur during review of the 60% design.	Noted. Further evaluation will occur during review of the 60% design.		See Section 2.3 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					organic carbon to be injected in the IRZ. The combination of organic carbon oxidation and iron reduction is a simplified model version of the family of reactions that occur in the IRZ, but effectively illustrates how iron and arsenic associated with iron minerals get released under these conditions. As the liberated Fe(II) and arsenic move downgradient from the IRZ into more oxidizing conditions, the iron will undergo the reverse reaction of that shown above, and the arsenic will either coprecipitate with the iron or adsorb onto the surface of the newly-formed solid, or both. The representation of these mechanisms in the numerical transport model was described in Appendix B of the 30 percent design Manganese is present in the matrix in the form of various oxides, similar to those of iron. Manganese is liberated around the IRZ in a similar reductive dissolution reaction to that of iron, with Mn(IV) and Mn(III) in the oxide reduced to Mn(II) and released into solution. Manganese is slower to reoxidize than iron, so it will travel further downgradient before the reverse reaction occurs to remove it from groundwater. During transport, Mn(II) is also attenuated by adsorption onto mineral surfaces. The representation of these mechanisms in the numerical transport model was described in Appendix B of the 30 percent design Additional geochemical processes affecting the behavior of dissolved metals occur within the hyporheic zone, the interface between the groundwater and the river. A conceptual level figure detailing these processes was included as Figure G8 in Appendix G of the CMS and discussed at the January 19, 2012 TWG meeting. A model is currently being constructed to evaluate geochemical/hydrological processes governing manganese behavior in the hyporheic zone (groundwater-river interface) as groundwater flows toward the river. This model focuses on Mn, as As is not expected to reach the hyporheic zone. The results of this model will be described in the 60% design and as such will include a more detailed discussion of the geochemical processes governing byproduct fate and transport.				

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
52	DTSC-10	Page 2-5, Section 2.3.3 General Geochemical Indicator Parameters		The section emphasizes the natural occurrence of TDS and sulfate, yet makes no mention of anthropogenic sources. Some text should be dedicated to clarify that the large releases from the PG&E Compressor Station facility would have exhibited elevated TDS and general minerals (e.g., concentrated blow down water from the cooling towers) and that those releases would have mixed with unaffected waters. Please note that salts (Electrical Conductivity) were listed as hazardous waste constituents of concern in the 1996 DTSC Consent Agreement, and were sampled during various phases of PG&E compressor station site characterization and closure activities.	The 60% design submittal will honor the text used to describe sulfate and TDS in the RFI/RI Vol 2 Addendum (CH2M HILL, 2009x), while accounting for any changes in distribution of these constituents since the RFI/RI was completed.	Okay pending review of the 60% design submittal		Comment resolved.	See Section 2.3 of this BOD Report.
53	HA-8a	p. 2-6, Section 2.3.3.1 (Total Dissolved Solids)		As was discussed during recent TWG meetings and conferences, further discussion is needed as to the significance of the variably high concentrations of TDS within the aquifer as this may relate to the efficacy and operation of the groundwater remedy. Is there any component (*e.g.,* chloride, sulfate, etc.) of the TDS that may pose particular concern to remedy effectiveness? Was there any sensitivity analysis performed on the potential effects of density heterogeneity?	The composition of the groundwater has been taken into account in designing the remedy, and information was collected during the two pilot studies to examine effects of water chemistry on the in situ remedy. There are no constituents that posed concern in the design. In particular, Cr(VI) reduction was observed in the presence of elevated TDS concentrations, as presented at the January 19, 2012 TWG meeting. A discussion of this data will be included in the detailed response to comment in the 60 percent design. Variations in density were not applied in modeling the design. The main reason for this is that the vast majority of the groundwater is between about 500 and about 16,000 mg/L TDS, with an average around 5,000 mg/L. The density difference over this range is about one percent, which is not considered significant enough to evaluate density gradients. The areas with TDS greater than 16,000 mg/L are isolated portions of the shallow floodplain and a few deep wells. These areas are limited in extent and none have detectable chromium.	Comment noted. DTSC continues to be concerned with the efficacy of the remedy. However, to date, PG&E has been able to provide reasonable logic to all concerns raised. DTSC will continue to carefully evaluate and monitor PG&E's proposal throughout the design, construction and implementation process.	Comment and response noted.		See Section 2.3 of this BOD Report.
54	Hualapai-33			<u>Additional Technical Considerations</u> It is known that pH affects adsorption rates. Has it been determined how pH varies laterally and vertically within the Topock hydro-geologic system, and is this an issue? Will pH be monitored as part of the system monitoring program?	Average pH values in the remedy area are between 6.5 and 8.5. Most of the pH values that fall between 6.5 and 7.5 are in shallow- and mid-depth floodplain wells, and the remainder are predominantly 7.5 to 8.5, regardless of depth (see Figure 6-1 in the RFI Volume 2 Report). Given these relatively narrow pH ranges, adsorption rates are not expected to be significantly variable on the basis of pH alone. All sampled wells are monitored for pH, and will be monitored for pH throughout the remedy. The effect of pH on Mn sorption will be considered in an expanded discussion on the geochemical parameter sensitivity analyses.	Noted	Comment and response noted.		See Section 2.3 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
55	DOI-19	Section 2.4.1, Paragraph 5, Bullet 1		A summary statement of the findings of the EPNG evaluation of the structural and physical space capacity of the arched bridge should be included in this bullet.	The following text will be added to this paragraph in the 60% design submittal: "In its evaluation report, EPNG concluded that the proposed 12-inch freshwater line load is within the acceptable design loads for the bridge. EPNG recommended that equipment larger than 16 kips not be used in any 18.5 ft long deck section and the bridge deck supports be visually inspected prior to construction".	Okay	Okay pending review of 60% design submittal.	Comment resolved.	See Section 2.4.1 and Appendix G of this BOD Report.
56	HA-8b	p. 2-6, Section 2.4.1 (Land Ownership, Disturbance, and Development)		The Tribe requests further details regarding the proposed types of facilities and activities that will be performed on its property for construction and during remedy operation. As a general principle, the Tribe's preference is for as little remediation infrastructure to be placed on its property as possible. The Tribe and PG&E should consider this in the design phase. FMIT requests a meeting to discuss such potential facilities (i.e., the need for, proposed types, longevity, etc.).	The Tribe's preference is recognized and will be further considered during the development of the 60% design, consistent with the 2006 Easement Agreement and the 2006 Settlement Agreement between the Fort Mojave Indian Tribe and PG&E. A statement to this effect will be included in the 60% design submittal.	Comment noted	Comment and response noted.		See Sections 2.4.1 and 5.3.2 of this BOD Report.
57	HA-9	p. 2.7, Section 2.4.1 (Land Ownership, Disturbance, and Development) & Appendix A-2		PG&E has been discussing with the FMIT the preparation of an aerial map of disturbed areas pursuant to EIR Mitigation Measure CUL-1a-9. In particular, H+A transmitted comments to PG&E on July 5, 2011, expressing concerns on behalf of the Tribe.[3] Among the various concerns discussed was the potential for misuse of such a mapping. Specifically, the classification of lands as "disturbed" could lead to the impression that such areas would be "fair game" for further and additional disturbances, whereas there are other factors that the Tribe believes must be taken under consideration. Accordingly, consultation with the Tribe should always be a prerequisite for such planning regardless of whether the land has suffered disturbance in the past. [3] H+A, 2011. Letter from Dr. L.S. Leonhart, H+A, to Dr. Y.J. Meeks, PG&E, re "FMIT Comments on Mitigation Measure CUL-1a-9, Aerial Map of Disturbed Areas."	Comment noted. Existing mitigation measures require communication/ consultation with the Tribes throughout the design process, as reflected on the project's "Rainbow Schedule."	DTSC understands that the tribe does not believe in the generalization that disturbed areas are less significant to other undisturbed area. DTSC agrees that tribal input throughout the design, construction and implementation phrases of the project is important to the collaborative success of the remedy.	Comment noted. Tribal views regarding the significance of the cultural resources and values adversely affected and the importance of mitigating adverse effects on those resources and values will continue to be solicited through government to government and Section 106 consultations under the Consultation Protocol of the PA (Appendix B) and considered in the decision-making process.		See Section 2.4.1 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
58	DTSC-11	Page 2-6/2-7, Section 2.4.1 Land Ownership, Disturbance, and Development		The Topock 66 Resort and Spa at the Topock Marina is identified as a planned development. DTSC had heard that it had been cancelled, but did recently check the resort website and noted plans for continuing the development as of July 2011. Based on current plans, a source of water for the development (hotel, brewery, pool, water features, greenscape) would be needed and could influence hydraulics in the area. PG&E must acknowledge this issue and evaluate potential impacts of the development on the remedy (e.g., What are potential effects on the remedy if groundwater is pumped from a well located in the Topock Marina area?) and the remedy on the development. PG&E needs to prepare a comprehensive list of all water wells in the Topock area including historical, current, and potential future pumping rates. DTSC had heard that SoCal Gas had requested pumping rights in the area that should be discussed in this section as well as other applicable sections.	As indicated in the response to comment #136 Hualapai-24, the EIR evaluated water use during construction, during operation, and during decommissioning of the remedy, and in each instance, the EIR concluded that the existing entitlement was more than sufficient to serve the remedy project needs. The basin is adjudicated and pumping is controlled by the Colorado River Board. PG&E will request information on the pumping allocations for water users in the Topock area from the Colorado River Board. These would be the maximum allowable pumping rates under the current water rights. Simulations could be conducted to determine if these maximum pumping rates would have any adverse effects on the remedial action. As requested, PG&E will prepare a list of wells in the Topock Area based on available data, and include the list in the forthcoming freshwater evaluation technical memorandum. According to information from BLM (early 2011), SoCal Gas had planned for a well near the water tanks between I-40 and Moabi Regional Park. The well could be up to 500 feet deep and was intended for cathodic protection, and not for pumping of groundwater.	Okay		Comment resolved.	See Appendix J of this BOD Report.
59	HA-10	p. 2-8, Section 2.4.2 (Site Topography and Surface Geology)		On a recent site walk, Tribal members expressed an interest in developing a three-dimensional (3D) physical model of the Site terrain for the purpose of explaining topographic and physical relationships of project facilities to the general Tribal Membership. In turn, PG&E requested the assistance of the Tribe in facilitating this request. It is hereby reasserted that the Tribe is interested in moving forward with this project. In a recent meeting with the Tribal Community, plastic raised-relief maps created by an impression process were displayed for the Needles and Kingman quadrangles. These products were welcomed and characterized as potentially useful if they could be produced on a larger scale, such as for the project area.	PG&E appreciates the Tribe's facilitation and its assertion in this comment. PG&E has initiated work and is coordinating with the Clearinghouse Task Force (CTF) members to deliver on this project.	Comment noted.	Comment and response noted.		Work on the physical model is underway. No changes were made to this BOD report (text/figures/ tables) as a result of this comment.
60	HA-11	p. 2-8, Section 2.4.3 (Soil Contamination Areas)		See previous comment No. 1 regarding soils.	See response to comment #23 HA-1a.	Comment noted.	Comment and response noted.		See Section 1.0 of this BOD Report.
61	DTSC-12	Page 2-8, Section 2.4.3, Soil Contamination Areas		Figure 2-15 is presented to acknowledge soil/groundwater infrastructure overlap. Greater detail, including detailed figures and sampling and soil management plans, will need to be prepared to evaluate how best to proceed.	Additional details will be provided in the 60% design submittal. Also see response to comment #62.	Okay, pending review of 60% design submittal.		Comment resolved.	See Figure 2.4-4 of this BOD Report and draft O&M Manual, Volume 4- Soil Management Plan.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
62	DOI-20	Section 2.4.3.1, Paragraph 2, Bullet 2		In reference to this bullet, please provide a figure or table of areas where remedy facilities will intersect soil contamination areas.	Comment noted. Figure 2-15 will be updated to include a table to list the overlapping areas in the 60% design submittal to address this comment.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See Figure 2.4-4 of this BOD Report.
63	DTSC-13	Section 2.4.3.1, Coordination of RFI/RI Soil Investigation with Remedy Design and Construction		This section did not mention coordination between the soil investigation and the possible use of an infiltration gallery mentioned in Appendix F. DTSC notes that PG&E has reserved this option for future use pending soil RFI results. If PG&E is maintaining this option as stated, the soil RFI work plan should reflect this proposal. In addition, this section mentions that additional soil investigations and opportunistic sampling are independent of design activities for the final groundwater remedy, but that the soil data would be used as it becomes available. PG&E must, as part of the O&M Plan, provide a soil management plan and sampling analysis plan that describes the logic and processes to follow as part of the remedial construction and soil disturbance (e.g., how to sample and handle trenched soils in a potentially contaminated area).	The Soil RFI/RI Work Plan will incorporate the possible use of an infiltration gallery in Bat Cave Wash for disposal of treated remedy produced water into the sampling plan, and will include collection of relevant and adequate data to support the CMS/FS design. The O&M Manual will include sampling protocols and analysis for soil and plan for managing soils during O&M, consistent with the ongoing discussions about displaced material handling protocols between PG&E, agencies, and Tribes (also see response to comment #64 DTSC-14).	DTSC did not note any proposal in the RFI/RI work plan for soil that incorporated the investigation and development for the infiltration gallery in Bat Cave Wash. However, if PG&E is considering such a proposal, DTSC agrees that it can be coordinated through the soil investigation phase.		Comment resolved.	See Section 2.4.3.1 of this BOD Report. Also see draft O&M Manual, Volume 4 – Soil Management Plan.
64	DTSC-14	Page 2-9, Section 2.4.3.1 Coordination of RFI/RI Soil Investigation with Remedy Design and Construction		A bullet should also be included that addresses maximizing retention of soils to address Tribal concerns. The document should clarify and/or provide examples for the following bullets currently included in the text: • Where appropriate, the timing and scope of soil investigation activities will be coordinated to minimize interference with groundwater remedy implementation. • Access restrictions established to protect groundwater remedy infrastructure will consider the need to access soil investigation areas for additional investigation or remediation.	Consistent with response to comment #181 HA-36, a bullet will be added in the 60% design submittal to mention the ongoing discussions about displaced soils handling protocols between PG&E, agencies, and Tribes. The approach and general protocols discussed to date are intended to minimize the amount of displaced material that leaves the site. Specific topics include handling and storage, contamination assessment, long-term disposition of displaced soil, etc. First bullet – an example is if the timing of the soil investigation and groundwater remedy construction coincides, the work will be carefully synchronized so as to minimize interference/obstruction. Second bullet – an example is when access restrictions are established for the protection of groundwater remedy infrastructure (i.e., Category 2 ICs) in certain areas, consideration will also be given to the potential need to access the same area for additional soil investigation or remediation.	Okay		Comment resolved.	Section 2.4.3.1 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
65	DTSC-15	Page 2-9, Section 2.4.4 Surface Water and Wetlands		Figure 2-17: Will the OHWM need to be identified and documented for any Arizona remedy infrastructure (e.g., pipeline) or for the California river bank south of that pictured in Figure 2-17 (e.g., freshwater intake structure). The figure only evaluates a segment of the California floodplain area.	Figure 2-17 is intended to demonstrate compliance with EIR Mitigation Measure AES-2a which states the following: "A minimum setback requirement of 20 feet from the water (ordinary high water mark) shall be enforced, except with regard to any required river intake facilities, to prevent substantial vegetation removal along the riverbank" The requirement for the 20-foot setback from the OHWM is relevant to the aesthetic value from Key View 11. A Key View, according to the EIR, is a vantage point offering a view of some or all of the Project Area from one of the specified points. Each Key View vantage point is located and described in Volume II, Section 4, of the Final EIR. Key View 11 is defined in Table 4.1-1 as "View looking southwest toward the floodplain, IM-3 Facility, and compressor station from Colorado River. View is approximately 300 feet from the floodplain."  Key View 11—View west toward the floodplain, IM-3, and compressor station. *(Photograph taken by AECOM in 2009)* Given the above mitigation directives for AES-2a, the 20-foot setback requirement (hence the need to map OHWM) does not apply to Arizona remedy infrastructure. Further, AES-2a specifically excludes any required river intake facilities. However, it should be noted that the OHWM was identified and mapped (within the project area, in California and Arizona) during the recent wetlands delineation field survey conducted for compliance with EIR mitigation measure BIO-1.	Okay		Comment resolved.	
66	DTSC-16	Page 2-10, Section 2.4.5, 3rd paragraph	This alliance takes many forms and in the Project Area it is form that lacks ironwood (Olneya tesota).	This sentence seems incomplete.	The letter "a" will be inserted between the word "is" and the word form".	okay		Comment resolved.	See Section 2.4.5 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
67	DOI-21	Section 2.4.7		Please update the activities required by the Programmatic Agreement to reflect current status of the stipulations (Access Plan and CHPMP) and reflect that a treatment plan will be developed throughout the design to address any mitigation measures.	The Access Plan and the CHPMP will be updated to reflect their current status in the 60% design submittal.		Okay pending review of 60% design submittal.	Comment resolved.	See Section 2.4.7 of this BOD Report.
68	DOI-22	Section 2.4.7, Last Bullet		Please clarify if a draft paleontological report is under review. It is unclear from the discussion. Also, please verify that the report will be available for review by the agencies.	The paleontological report will be submitted to DTSC once complete. A copy will be provided to DOI at that time.		Response noted.	Comment resolved.	See Section 2.4.7 of this BOD Report. A paleontological report was prepared and submitted to DTSC on December 21, 2012; this report is currently being revised to incorporate comments.
69	HA-12a	p. 2-12, Section 2.4.7 (Cultural Resources)		1st sentence, "Cultural resources occur in areas near some groundwater remedial facilities and will affect design, construction and implementation of the final groundwater remedy." - First, the entire area has been recognized by both DTSC and the state as a tribal cultural property; the issue is not just about some areas near some facilities, but rather impacts to the whole of the area. Second, where and how does this occur? Please provide a map of where design, construction and implementation of these remedial facilities will be located. Third, please give examples of how cultural resource survey information is being used to guide siting and design.	Comment noted. PG&E will continue to outreach and work with the tribes during the design process. The first sentence will be revised to state:"Cultural resources in the area will affect design, construction and implementation of the final groundwater remedy." A map indicating where both remedial facilities and archaeological/historical sites are located will be submitted to the tribes concurrent with the 60% design. Results of the cultural resources survey of archaeological and historical properties (sites) have been uploaded into the Project GIS database. Utilizing GIS, facilities are located with avoidance of historic properties as a primary goal.	Comment and response noted. DTSC will continue to outreach and work with the tribes during the design process.	Comment and response noted. Tribal views regarding the significance of the cultural resources and values adversely affected and the importance of mitigating adverse effects on those resources and values will continue to be solicited through government to government and Section 106 consultations under the Consultation Protocol of the PA (Appendix B) and considered in the decision-making process.		See Section 2.4.7 of this BOD Report. The map indicating where both remedial facilities and archaeological/ historical sites are located was submitted to the Tribes concurrent with the 60% design, but under a separate cover.
70	HA-12b	p. 2-12, Section 2.4.7 (Cultural Resources)		Activities required by the Programmatic Agreement (PA) First bullet – The Fort Mojave Tribe and other tribes (with the exception of Hualapai Tribe) did not sign the PA document as their concerns were not adequately reflected in the PA document. Fort Mojave and other non-signatory tribes have requested of BLM to be consulted under the government–to-government trust relationship that each tribe has directly with the United States as authorized under Executive Order 13175, and numerous Federal and State law, such as National Historic Preservation Act (NHPA), American Indian Religious Freedom Act (AIRFA), etc.	PG&E defers to BLM/DOI.		Comment noted. The 36 CFR 800 regulations (implementing Section 106 of National Historic Preservation Act) are not the only basis for BLM's responsibility to consult with tribes about the actions proposed at Topock. BLM's consultation responsibilities are grounded in the trust responsibility that the federal government bears toward Indian tribes as sovereign governments, which goes back to a variety of treaties, and many laws, executive orders, regulations, presidential memoranda and judicial decisions. Recent examples include the American Indian		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
							Religious Freedom Act, the Native American Graves Protection and Repatriation Act, the Archaeological Resources Protection Act, Executive Orders 13007 and 13175, and memoranda to the executive branch issued by Presidents Clinton, Bush, and Obama. The NHPA is only one piece of the whole corpus of law and policy that drives federal agencies to consult with tribes about a wide range of tribal concerns, notably including tribal religious, spiritual and cultural values they attach to the Traditional Cultural Property/Place (TCP) in the Topock area. The BLM can only determine if an effect is adverse by consulting the tribes that ascribe significance to the TCP. It follows then, in furtherance of BLM's NHPA Section 106 responsibilities and government –to-government trust relationship, that, BLM will conduct its consultations under the Programmatic Agreement's Consultation Protocol (Appendix B) and through the implementation of the Cultural and Historic Properties Management Plan (CHPMP). Consultation will move forward with the tribes to determine if an adverse effect is anticipated for historic properties (i.e., bounded archaeological sites), as well as, for the cultural, religious, and spiritual (intangible) values tribes hold for the TCP within the APE.		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
71	HA-12c	p. 2-12, Section 2.4.7 (Cultural Resources)		Second bullet – The description of implementation of the Cultural and Historic Properties Management Plan (CHPMP) fails to mention that the document is admittedly incomplete. Many of document's sections related to tribal views/perspectives currently are either blank or do not consider or protect the interests of those tribes who ascribe concern to the Area of Potential Effects (APE), referenced in the PA and CHPMP documents. Instead the document has solely an archaeological resource focus. Even through the many years of trying to address this missing link in the Topock process with the agencies and PG&E and the many promises by the decision makers to address this flaw, sadly this remains unchanged and unresolved as this process moves forward,. The final remedy will have many effects on the Mojave people, its aboriginal lands, religious and spiritual values and continued desecration of our Holy Place, surely this significant impact should have risen to the level of grave importance in the design and eventual construction of the final remedy. Only through a complete and knowledge-based understanding from the People who continue their religion and current day practices can such a document help and guide this process in this unique and sacred area. Financial resources were not provided by or to the BLM to adequately capture and reflect these religious and cultural values associated with the cumulative and imminent effects that will be undertaken by the cleanup project. The remedy design documents should acknowledge and provide a framework to solve these missing analytical pieces in such as way as these values can be adequately and timely considered within the design process.	PG&E defers to BLM/DOI.		Comment noted. The comment made that the CHPMP has solely an archaeological resource focus is not correct, nor is the assumption that two remedy design documents (PA and CHPMP) dealing with the implementation of the NHPA Section 106 process do not provide a framework to solve missing analytical pieces in such a way as these values held for the TCP within the APE can be adequately and timely considered within the design process. Additional consultation under the Programmatic Agreement's Consultation Protocol (Appendix B) provides the framework needed to address cultural values of religious and spiritual significance. The Tribes play a pivotal role in this process as only the Tribes can define the cultural values associated with the TCP within the APE. By design the CHPMP is a "living document" that can be modified and updated, as needed, to address new information and ongoing activities related to the Undertaking. Refer to page 33 of the CHPMP, under Section 3.3 Cultural Values/ Ethnographies; see the statement, "BLM will continue to seek additional input regarding cultural values from the Tribes. A contracted study may be undertaken to gather this information and, if provided, will be included in future iterations of the CHPMP. In Section 7.2 on page 77 of the CHPMP is a statement titled, "Accommodation of Tribal Activities and Ceremonies Involving the Topock Maze/TCP that states, "The BLM will continue to work with the Tribes to identify tribal activities and ceremonies that are associated with the Topock TCP. When such activities and ceremonies are identified, BLM will consult		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
							with the Tribes and PG&E to develop treatment measures to accommodate them. Treatment measures may address scheduling of Undertaking work to accommodate ceremonial activities and to mitigate audible and visual impacts." The crux of the matter is that BLM can only determine if an effect is adverse by consulting the tribes that ascribe significance to the TCP. It follows then, in furtherance of BLM's Section 106 responsibilities that BLM can only complete its consultation under the Programmatic Agreement's Consultation Protocol by consulting with the concerned tribes to determine if an adverse effect is anticipated upon the cultural, religious, and spiritual values they hold for the TCP within the APE. If a place is determined to be a traditional cultural place, then all or part of the significance of that place is based on the intangible cultural values of the people whose traditions define the importance. Hence, the BLM, in order to determine if there is an effect to the TCP, must analyze how any given Undertaking affects intangible cultural values associated with that place. The Tribes possess this knowledge and BLM has on several occasions requested that the tribes share this knowledge to the extent that they feel comfortable in doing so, so that their cultural, religious, and spiritual intangible values associated with the TCP within the APE can be protected in a culturally appropriate manner to the maximum extent practicable given federal and state mandates to protect human health and environmental concerns.		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
72	HA-12d	p. 2-12, Section 2.4.7 (Cultural Resources)		Activities required by the Environmental Impact Report Mitigation Monitoring and Reporting Program (EIR MMRP) – As a general statement, the design document must acknowledge that FMIT was not consulted on any of the Mitigation Measures described in the reference bulleted items, nor do we understand the intent of several of the Mitigation Measures and how they are to be implemented. Regardless, the Tribe does appreciate the opportunity to be involved early on in the implementation and refinement of these measures and request to have copies of all the draft reports currently under review (i.e., the Cultural Impact Mitigation Plan (CIMP), Cultural Resources Study, Paleontological Investigation and any others to be developed in the future) provided to the Tribe. This section should be corrected to note that the Tribes, to date, have NOT been part of the CIMP development, despite the Tribes' repeated inquiries.	The bulleted items on the bottom of page 2-12 and on page 2-13 refer to mitigation measures discussed in the certified EIR. PG&E notes that mitigation measures were proposed in the Draft EIR, which was circulated for public review. The Tribe submitted substantial and lengthy comments on the Draft EIR, and it is PG&E's understanding that the Tribe also met with DTSC to discuss mitigation measures. The mitigation measures in the Final EIR were revised in response to the submitted comments from the Tribe and others. The mitigation measures will be implemented at various stages of the final remedy, and not all are required to be complete at the 30% design stage. PG&E acknowledges that the Tribe has been and will be involved in the implementation of specified measures. To date, as chronicled in Table 7-2, PG&E has engaged in numerous outreach efforts and has had many communications with the Tribes. The communications included transmitting documents such as draft disturbed area maps and the proposed methodologies for the Mature Plants and Floristic surveys. As of February 2012, the CIMP outline has been provided to and discussed with the Tribes and the Tribes will have additional future opportunities for input on its contents.	The proposed mitigation measures were provided in the Draft EIR for tribal comments. As a result of those comments, DTSC had several meetings with the Fort Mojave Indian Tribe and revised the mitigation measures for the Final EIR. Although the Fort Mojave Indian Tribe believes that DTSC did not offer sufficient discussions with the tribes on mitigation measures during its development, this is a topic of pending litigation. Please note that DTSC did require PG&E to work with interested tribes on the implementation of specific measures.	Defer response.		
73	Hualapai-35 and TRC-17			While Hualapai and other Tribes believe that the Colorado River is sacred and should be kept clean, Hualapai also believes that there should be an emphasis on protection of spiritual and cultural resources near the Topock Compressor Station. In the 30% Design report, the protection and recognition of spiritual resources was not addressed. Drillers, employees, scientists, and construction workers all must be educated regarding the spiritual importance of the area to the Tribes. If any employee exhibits outward disrespect for the spiritual importance of the area, then those employees should be removed from the project as soon as possible. The Tribes need verification that such an employee program is going to be implemented as part of the project. *[Next sentence appears only in the comment matrix]* In addition, during implementation of the project (construction/operation/maintenance), PG&E should implement and enforce a management plan that addresses human and solid waste in order to more fully protect the site. **TRC Recommendation:** This should be included within in the 60% design report discussions and plans.	Consistent with its obligations under the Programmatic Agreement's Monitoring Protocol, existing PG&E standard practice, and the EIR MMRP requirements, cultural sensitivity training is required of all staff, workers, and contractors engaged in activities within the APE to familiarize them with the sacred nature of the area so that they will perform their jobs in a respectful manner. Consistent with these obligations, PG&E will not tolerate any disrespectful behavior in the field and will remove any staff, workers, or contractors who do not comply with this section. Text will be added in the 60% design report indicating that environmental and cultural/historical resources and other tribal concerns are being considered and protected by PA, CHPMP, CIMP and EIR MMRPs.	Comment and response noted.	Comment and Response noted pending review of the 60% design submittal.		See Section 2.4.7 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
Section 3 Comments—Design Basis and Assumptions									
74	DOI-23	Section 3		DOI acknowledges that the O&M Plan will include details of the proposed monitoring network, sampling frequency, and analytical parameters; however, please include discussion of how chromate and byproduct concentrations will be monitored down gradient of the IRZ and how monitoring data will be used to evaluate system performance and affect changes to system operations (e.g. substrate dosing).	These details will be part of the draft O&M plan. Preparation of that detailed plan is underway and includes these considerations. Partial discussions will likely not provide enough detail to be satisfactory. PG&E suggests a TWG meeting prior to submittal of the plan in the 60% design that includes an agenda item focused on the monitoring plan. Preliminary details at this time would be pre-mature.	Okay pending review of the groundwater monitoring and the O&M Plan	Okay pending review of 60% design submittal, the groundwater monitoring plan and the O&M plan.	Comment resolved.	See draft O&M Manual, Volume 2 – Sampling and Monitoring Plan.
75	HA-13	p. 3-1, Section 3.1 (Summary of Modeling)		Refer to comments on Appendix B.	Comment noted.		Comments noted and addressed separately.		See Appendix B of this BOD Report.
76	DOI-24	Section 3.1/3-2/ Last Paragraph		It is unclear in the depiction on Table 3-1 whether the wells are screened in Layers 2 or 4. It is presumed that they are but the table does not clearly depict this in the column entitled "Preliminary Well Count".	Tables 3-1 through 3-4 will be clarified to better indicate screen zones in each well. Preliminary screen lengths for each model layer are provided in the column "Preliminary Screen Length". If a model layer row does not have a screen length provided in this column, the preliminary design consists of a single screen across two or more of the model layers. Note that the estimated vertical depth of each model layer is provided in the column "Model Layer Thickness". Well design, including placement of screens, screen length, etc., will be updated and detailed during the 60% and 90% designs. It should be noted, that final location and lengths of screens may be modified in the field during installation activities. Additional information regarding the design basis for individual well and aggregate flow rates will be provided the 60% design submittal, including Section 3, Appendix B, and the table footnotes. The discrepancies in the sums of flow rates result from the rounding of per-well or per-screen interval flow rates to appropriate significant digits. These discrepancies will be resolved in the 60% design submittal. Per comment #10 (DOI-9) and #232 (DOI-65), potential inclusion of the Area H well and other changes within the East Ravine will be evaluated based on the latest remedial investigation data available and included in the 60% design submittal. Information will be reflected appropriately in these tables.	Okay	Revised Tables 3-1 through 3-4 are acceptable pending review of 60% design submittal	Comment resolved.	See Tables 3.2-1 through 3.2-3, Table 3.3-1, Section 3.2, and Appendix B.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
77	DTSC-17	Page 3-2, Section 3.1 Summary of Modeling		Request adding contoured chromium plume to cross-sections (especially for B-B'). Contoured chromium maps should also be added to remedy maps to assist in evaluating remedy design.	The vertical delineation of the current chromium plume distribution can be added to the cross-section figures.	Okay		Comment resolved.	See Figures 3.1-2, 3.1-3, 3.1-4, and 3.1-6.
78	DTSC-18	Page 3-2, Section 3.2, In-situ Remediation	Second bullet	The purpose of the Inner Recirculation Loop is stated to be facilitation of groundwater flow through the IRZ. However, it is also noted in Appendix B, section 4.4.2, Riverbank Extraction that the design goal of the extraction wells were to both accelerate groundwater through the IRZ and to capture Cr(VI) located down gradient of the IRZ. DTSC also envisions that the extraction wells should be designed to capture any by-product formation that may be formed as a result of Cr(VI) reduction that would flow past the extraction wells. These goals should be consistent throughout the design document.	Text in section 3.2 will be updated to reflect that the Riverbank Extraction wells will both facilitate the groundwater flow through the IRZ and capture Cr(VI) located downgradient of the NTH IRZ. The Riverbank Extraction wells are also designed to control NTH IRZ generated byproducts in the deeper portion of the aquifer. The Riverbank wells are designed to be screened beneath the naturally occurring reducing rind to minimize negative hydraulic impacts on the reducing rind; and reduce the potential for well fouling in the Riverbank extraction wells caused by the presence of dissolved minerals in the naturally reduced groundwater in the rind. As discussed in response to comment #266 DOI-86, the riverbank extraction wells can be constructed in a manner that would allow them to be modified if observed conditions suggest it is necessary to control Cr6 migration. One approach would be to build the well so that the casing in the shallow unit could be perforated if water needed to be pumped from the shallow zone. Alternative designs will be considered and one selected and presented in the 60% design.	Okay pending review of the 60% design submittal. Please note it was DTSC's understanding prior to the 30% design that the Riverbank Extraction wells were stop gaps to capture not just Cr(VI), but also any byproduct formation from remedy that may expand toward and under the Colorado River. Currently as described, the Riverbank Extraction Wells will not have capture of the resulting by-products, This is an area of interest to stakeholders and agencies since the RAO is to ensure that the "geographic location of the target remediation area does not permanently expand following completion of the remedial action."		Comment resolved.	See Section 3.2.
79	DTSC-19	Page 3-3, Section 3.3, In-situ Remediation	First bullet of page. The stated purpose of the TCS recirculation loop is "to provide hydraulic capture of contaminated groundwater at these locations and to directly treat Cr(VI) under the TCS."	At present, the extent of contamination or the hydraulics of the TCS and East Ravine area is still under investigation. DTSC agrees that the purpose as stated is appropriate for the remedy, but the implementation of the conceptual extraction system may not be sufficient for that purpose. In addition, the measurement of that success will be unlikely for decades.	Comment noted. PG&E recognizes that the TCS and East Ravine areas are still being investigated and that as new information is gathered prior to and after remediation begins, adjustments to the system may be necessary.	Okay pending review of 60% design submittal		Comment resolved.

80	DTSC-20	Page 3-3, Section 3.2.1	Up to 24 injection wells (i.e., NTH IRZ injection wells) situated within 16 locations or clusters also located within the NTH IRZ, that will be used to re-inject carbon-amended water into the aquifer	It is unclear if Appendix B model runs (B-27 to B-30) are results of 75 ft spacing or revised 150 ft spacing. Also, are they running all optional wells or just the proposed 16 locations? If the model is showing Cr(VI) transport running all wells, what will be the fate of the Cr(VI) as proposed in Fig 3-1? Also, what triggers the proposed future provisional wells shown in Fig 3-1? This section should explain or at least mention upfront the provisional NTH IRZ wells that are pictured along the NTH IRZ.	Text will be clarified in the 60% design to differentiate between the 75 ft and 150 ft NTH IRZ well spacing layouts and analysis. The Appendix B model runs (B-27 to B-30) are indicative of the revised 150 ft well spacing – primarily 150 spacing with several 75-foot spaced wells near the center of the line. The flows are reflected in B-26. The provisional wells in Fig 3-1 will be clearly labeled. The need to install and activate the proposed provisional NTH IRZ wells will be based on the monitored performance of the NTH IRZ and the generated reducing zone over time. Further discussion will be included in the 60% design.	Okay, pending review of 60% design submittal		Comment resolved.	See Section 3.2.1, Figures 3.0-1 and 3.1-1, and Appendix L (O&M Manual).
81	DTSC-21	Page 3-3, Section 3.2.1	3rd bullet	The numbers of wells in most figures do not correspond to 24 wells and 16 locations. PG&E should label all figures for clarity. Note: Fig 3-1 provided well IDs, but there are only 16 injection wells. The legend for the figure suggests that those are individual wells and not wells locations. It isn't clear until Table 3-1 which provided well counts at each IRZ. This needs to be more consistent and easier to track.	The presentation and labeling of the NTH IRZ wells will be clarified in the 60% design.	Okay, pending review of 60% design submittal		Comment resolved.	See Figures 3.0-1 and 3.1-1.
82	HA-14	p. 3-3, Section 3.2.1 (National Trails Highway ...)		The locations of the NTH IRZ Extraction Wells are not specified. It is understood that these wells are components of "clusters," but the configuration of a cluster should be depicted schematically somewhere to aid in understanding of how the system operates. What information will determine whether the NTH IRZ well spacing will be at 75 or 150 feet? Will this be determined during drilling or later during start-up operations? How long will it take to make such a determination? How will the monitoring data be used to facilitate such a determination?	Additional details regarding well clusters will be provided in the 60% design documents. Initially the model will be used to select spacing; drilling will not likely lead to spacing changes unless water quality data indicates an absence of a plume, Operational data collected from MW's will be used in conjunction with operational data to determine if more wells are needed. The need for more wells will take anywhere from a few months to several years to determine and will be dependent on the natural system's response and the success of less intrusive system adjustments. A more detailed discussion of monitoring data and its application will be included in the 60% design. These details are not fully developed at this time.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Section 3.2.1.1, Table 3.2-1, and Appendix L (O&M Manual).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
83	DTSC-22	Page 3-3, Paragraph 1, Section 3.2.1.1 Description – NTH IRZ		The paragraph starts out by stating, "The NTH IRZ Extraction Wells will be located far enough away from NTH IRZ Injection Wells to minimize the extraction of reduced water containing organic carbon or dissolved metals. " However, proposed extraction well IRZ-23 is located adjacent to injections wells on the north and south and with a similar well spacing as the rest of the IRZ line. The rationale for placing well IRZ-23 in its location should be specified in this section as should the potential for this well to capture reduced water/organic carbon/ byproducts. The basis for the range of extraction and injection well flow rates mentioned in the section should be cited. Was consideration given to having the IRZ extractors located to the south rather than north to assist with East Ravine/TCS extraction systems to the south?	The language for the NTH IRZ extraction well layout will be corrected. The three northern NTH IRZ extraction wells were positioned to minimize the number of NTH IRZ wells and offer hydraulic control of the northern low concentration end of the chromium plume. Approximately 15 different NTH IRZ well layouts and extraction/injection patterns were considered during the remedial design phase. The original design consisted of 40 wells with approximately 75 ft spacing consistent from North to South along the NTH. The well spacing and injection/extraction pattern then went through several iteration processes until the optimized NTH IRZ well layout was achieved. The NTH IRZ extraction well located in the center of the NTH IRZ line (IRZ-23) was located in this position to maintain/accentuate the eastern flow component of the groundwater. The two closest NTH IRZ injection wells (IRZ-21 and IRZ-25) are 150 ft away from IRZ-23. There is potential for fouling at this location so the monitoring program will take this into consideration. Adjustments can be made to well rates and carbon dosing in this vicinity to alleviate well fouling. Numerous well layouts and rates were considered with the groundwater flow and transport models to develop this optimized well layout. Not all scenarios were included in the design report. Consideration was given to locating the IRZ extractors to the south, however given the limited alluvial thickness in this area and the necessary injection volumes to maintain an effective NTH IRZ. Locating the NTH IRZ extractors to the north proved to be more advantageous in model simulations. Additional information will be added to the 60% design submittal.	In the response, PG&E states: "*Adjustments can be made to well rates and carbon dosing in this vicinity to alleviate well fouling.*" However, DTSC is still unclear how each of those adjustments interplays with the others. DTSC anticipates that information will be provided in the 60% design submittal.		Comment resolved.	See Section 3.2.1.1, Appendix B, and Appendix L (O&M Manual).

84	DTSC-23	Page 3-3, Paragraph 2, 3.2.1.1 Description – NTH IRZ		The paragraph starts out by stating, "The NTH IRZ extractions wells will be constructed using up to 12-inch nominal diameter well casing with one or two screened intervals to target specific intervals of the geologic formation." Which horizons/intervals are being targeted and why?	As described in Section 3.2.5.1, the screen intervals will be chosen based on the portions of the aquifer containing contaminants requiring remediation. Preliminary screen lengths for each model layer are provided in the column "Preliminary Screen Length" in Table 3-1. The preliminary design may consist of a single screen across two or more of the model layers. Well design, including placement of screens, screen lengths, etc., will be updated and detailed during the 60% and 90% designs. It should be noted that the final placements and lengths of screens may be modified in the field during installation activities.	Okay pending review of future design submittals.		Comment resolved.	See Attachment D of Appendix C Design Bulletin (Remediation Well Design and Field Construction Approach).
85	DTSC-24	Page 3-4, Organic Carbon Substrate Amendment System (MW-20 Bench)		The section should reference figures of the proposed system.	Comment is noted. The section will reference the appropriate design drawings and may be supplemented with report figures in the 60% design submittal.	Okay		Comment resolved.	See Section 3.2 (including Section 3.2.1.1 under the heading Organic Carbon Substrate Amendment System).
86	DTSC-25	Page 3-4, Carbon substrate storage		Why did PG&E not discuss the carbon substrate storage tank(s) sizing? This should be included in the design and on P&ID. Also, PG&E highlighted the ethanol system design to minimize fire/explosion during a Hinkley site visit. As PG&E is proposing ethanol as a carbon substrate at Topock, fire/explosion design should also be discussed in the design.	Preliminary carbon substrate storage tank sizes are provided in the Appendix D Equipment List. The carbon substrate tanks located at the MW-20 Bench and Transwestern Metering Station Bench are currently planned to be approximately 20,000 gallons and 3,000 gallons, respectively. Further detail regarding the carbon substrate storage design, including sizing, will be provided in the 60% design submittal. A discussion of fire/explosion protection design requirements, especially those related to the electrical installation, is provided in Section C.4.6 of Appendix C. Additional details will be included in the 60% design submittal.	Okay, pending review of 60% design submittal		Comment resolved.	See Section 3.2.1.1 under the heading Organic Carbon Substrate Amendment System and Appendix C (Section C.5).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
87	DTSC-26	Page 3-5, Tanker Truck Unloading Pad and Portable Tanks		Tanker truck section discussed the construction of a pad to accommodate 110% of one tanker truck volume. Its design will need to be included. If this is included in a drawing, PG&E should reference its location. Similarly, the portable tanks are stated to be from 5 to 1000 gallon capacity, this is a large range. Drawings and diagrams in the final design will need to be more specific.	Comment is noted. The preliminary tanker truck unloading pad location is shown on Drawing C-9 of Appendix D. Additional pad design details will be included in the 60% design submittal. The use and design of portable tanks is provided to allow flexibility in system operation. Portable tanks for reagent delivery will be the exception not the rule. Thus, a range of 5 to 1,000 gallons is provided in the 30% design to accommodate the potential range of carbon dosages to the injection wells and uncertainties at the preliminary design phase. Additional design details regarding the portable tanks will be included in the 60% design submittal.	Okay pending review of the 60% design.		Comment resolved.	See Section 3.2.1.1 (under heading Portable Tanks) and Drawing S-06-03.
88	DTSC-27	Page 3-5, Portable Tanks		The text should elaborate on when portable tanks would be used for specific, targeted injections (How often would it occur? How many times? Where would it occur?). What is the decision point(s) for using a tank rather than installing a pipeline?	Portable tanks may be used in conjunction with substrates that are perishable (e.g., whey) and/or exhibit a long biodegradation half-life to facilitate a low volumetric dose. Portable tanks may also be preferred over pipelines at locations where the carbon injection volume is low enough, injections occur with long rest periods, or long pipelines are expected to pose health and safety, engineering design, and/or long term operation and maintenance challenges. Operational details, including the use of portable tanks for the direct injection of dilute carbon substrate solution at the wellheads, will be included in the O&M Plan. Additional design details regarding how the carbon substrate amendment system will accommodate portable tanks will also be included in the 60% design submittal.	Okay pending review of the 60% design.		Comment resolved.	See Section 3.2.1.1 (under heading Portable Tanks) and Appendix L (O&M Manual, Volumes 1 and 3).

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
89	DOI-25	Section 3.2.1.1/3-5/Organic Carbon Dosing and Delivery Strategy		It is stated that substrate use will be 700 gpd based on ethanol. How different would the flow be based on lactate as the substrate? When will the substrate to be initially used be selected? Please provide an example of how monitoring data will be used to adjust carbon substrate flow rates and frequency of injections. For the example, indicate which monitoring wells would be used, what data will be reviewed, and what would be the rationale to make the adjustments.	Based on the differences in density and organic carbon content between 95% ethanol and 60% sodium lactate, 700 gpd of ethanol is equivalent to approximately 1,100 gpd of lactate. It should be noted that the 700 gpd usage rate for ethanol is a maximum rate; the nominal target rate is 100 gpd. Based on the experience and successful treatment to date, the current plan is to start-up the system with ethanol. The 60% design will discuss the performance monitoring plan, including proposed monitoring well locations, sampling frequency, and target ranges of concentrations. Typically, MWs located within the In-situ Reactive Zone (IRZ) will be used to monitor organic carbon substrate distribution downgradient of the IRZ recirculation wells. Total Organic Carbon (TOC) samples will be collected from these wells and compared to target concentration ranges. If concentrations are too high or too low, adjustments of injection concentration, duration, or frequency, injection flowrates or other operational parameters may be made.		Okay pending review of the 60% design submittal.	Comment resolved.	See Section 3.2.1.1 and Appendix L (O&M Manual, Volumes 2 and 3).
90	DTSC-28	Page 3-5, Organic Carbon Dosing and Delivery Strategy		The basis for carbon substrate flow rates as well as TOC doses should be included in this section. Pilot Test data for the site should be utilized. This comment regarding stating the basis for the design also applies to other components of the remedy (e.g., inner recirculation loop, TCS recirculation loop) Clarify if carbon is planned to be recirculated between IRZ wells as originally proposed in the CMS/FS as it now appears to be a TOC injection only scenario. Distributing carbon across the IRZ transect is of concern if recirculation is not utilized as the floodplain pilot test demonstrated minimal lateral dispersion of a reducing zone. Will IRZ wells be designed with dual screens to assist in drawing carbon outwards from IRZ wells as done in the Upland Pilot Test? Why or why not?	**Organic Carbon Dosing and Flowrate Design** A section will be added to Appendix B in the 60 percent design discussing the results of in situ pilot tests and how these results were used in deriving a target TOC concentration for the remedy and will include a discussion the design principles that were presented at the January 19, 2012 TWG meeting. Organic carbon dosing is designed to achieve sufficient lateral distribution across the spaces between injection locations. As injected water travels away from a given injection well, the organic carbon substrate is consumed. An adequate concentration in the injection solution is required to ensure that there will be sufficient organic carbon substrate to cover the spaces between in the injection points. Modeling was utilized to develop a basis for rate, concentration, and frequency of carbon substrate injection to achieve sufficient organic carbon distribution and chromium treatment. By varying these factors within the solute transport model, a balance was achieved to minimize the potential of the Cr plume migrating past the NTH IRZ. If the TOC carbon substrate	Okay pending review of the 60% design submittal.		Comment resolved.	See Section 3.2 and Appendix B.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					concentration or the injection rate were too low, the solute transport model indicated bleed through of the Cr plume between the NTH IRZ injection wells. Similarly, if the off cycle of the remedial system was too long, the potential of the chromium plume migrating past the residual reducing zone increased. **Recirculation System Design** Several recirculation designs were discussed in the CMS/FS and considered for the NTH IRZ, including the use of dual screen wells (with injection and extraction intervals within a single location), alternating injection and extraction wells along the IRZ, and the 30% BoD proposed configuration with injection wells along the line and minimal extraction wells along the line. As the commenter indicates, one advantage of alternating injection and extraction wells or using dual screen wells is to induce cross-gradients to facilitate lateral organic carbon distribution. However, in practice it is difficult to operate such configurations without extracting organic carbon substrate or treated water; thus complicating system maintenance. For example, organic carbon distribution proved somewhat difficult with the use of dual recirculation wells in the uplands pilot test. A portion of the organic carbon substrate injected into one of the dual screened wells, PTR-1, short-circuited vertically and was extracted by the extraction interval in the same location where the substrate was injected, limiting the horizontal distribution laterally across the deep zone (i.e. to PT-8D). Similarly, difficulties were encountered when using the alternating injection and extraction well design at Hinkley. In that system, it was very difficult to distribute sufficient carbon to treat the space between injection and extraction wells without extracting organic carbon or dissolved metals in treated groundwater and the result was a discontinuous IRZ that produced fingers of treated water downgradient of the IRZ interspersed with gaps where Cr(VI) was not treated. As a result that system was reconfigured to place injection wells along the line and extraction wells on the ends and in minimal places along the line, similar to the design proposed for Topock in the 30 percent design.				

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					The currently proposed design includes continuous operation of injection wells along the IRZ, which will allow for a much greater volume injected and greater radius of influence to be achieved than with the point injections that were applied in the Floodplain pilot test. For comparison, an injection well in the proposed design that receives 20 gpm for a 6 month operational period will receive 5.2 million gallons of water, whereas PTI-1D received 60 thousand gallons in the Floodplain pilot test. A discussion of these considerations will be added to Section 3.2.1.1 on NTH Highway Extraction and Injection Wells in the 60 percent design.				
91	DTSC-29	Page 3-5, Remediation Well Maintenance System		The section indicates that well maintenance reagents could be dosed into the carbon amended groundwater conveyance piping network via the well maintenance reagent delivery systems at the MW-20 Bench. This would seem to invoke special hazardous waste piping criteria (e.g., double- lined) for certain reagents (e.g., acid washes).	As discussed in Section 3.2.5.2, piping materials will be compatible with the characteristics of the conveyed fluids, including any well maintenance reagents and double-walled piping will be used to for any fluids that are California hazardous waste.	See response to item 128.		Comment resolved.	
92	DTSC-30	Page 3-5, Remediation Well Maintenance System/Well Maintenance and Rehabilitation Reagents		The sections should indicate where remediation well maintenance procedures and details will ultimately be located.	Comment noted. Remediation well maintenance procedures and details will be included in the O&M plan to be submitted with the 60% design submittal.	Okay pending review of O&M Plan		Comment resolved.	See draft O&M Manual, Volume 1 – Operations and Maintenance Plan.
93	DOI-26	Section 3.2.1.1/3-5 and 3-6/ Remediation Well Maintenance System and Well Maintenance and Rehabilitation Reagents		The text states that chemical rehabilitation reagents may be injected at the well head and/or dosed into the carbon amended groundwater conveyance piping network. Additional discussion is required on how this will be accomplished in practice since the system is serving two different purposes. Also, please provide additional discussion regarding the affects of the proposed reagents on groundwater chemistry and the reducing environment of the IRZ.	A more detailed discussion of the chemical rehabilitation process will be included in the 60% design. Detailed protocols and safety requirements will be part of the final O&M plan. Acids and biological dispersants are the likely chemicals that will be used to rehabilitate IRZ injection wells. Acids will lower the pH of groundwater, potentially temporarily dissolving Cr(III) minerals that have formed within the screen, filter pack or aquifer within the immediate vicinity of the injection well. Cr(III) dissolved will either be removed from the well during rehabilitation or will re-precipitate as pH is buffered following rehabilitation. The biological dispersant is not expected to impact the groundwater chemistry or reducing environment of the IRZ during rehabilitation.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See draft O&M Manual, Volume 1 – Operations and Maintenance Plan.

Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
94	DTSC-31	Section 3.2.1.2, Design Basis – NTH IRZ, Page 3-6		Define which organic substrate will be used. PG&E state that the selection of the substrate will depend on the balance between the mode of delivery, the substrate properties and the rate of carbon utilization. When can you make assumptions to make this determination? PG&E should have enough experience and information on this critical substrate. Will the design be based on ethanol or lactate and why? Once a substrate is determined to be used, can it be substituted readily to another substrate? What would be the rationale for changing the substrate if geophysical conditions or contaminant reduction is not as successful as anticipated? In the Floodplain ISPT, the purpose was to review the efficacy of reduction without continuous injection of lactate (6 injection events) over a year in a well cluster, and in the Upland, you used a different substrate to demonstrate the efficacy of recirculation over 6 months (using 38K gallons of reagent) in two wells 140 ft apart. The two pilot tests have different parameters and goals, with different substrates. How are the results being used and related back to the remedy? PG&E should provide a discussion to tie in the pilot tests and remedy.	**Organic Carbon Substrate Selection and Implementation** As the commenter notes, the pilot tests evaluated lactate and ethanol organic carbon substrates. Both substrates have similar properties, such as degradation rates. The pilot test results demonstrated that both reagents are effective for chromium treatment. Based on the past success, level of experience, and cost effectiveness of each reagent considered, ethanol was chosen for use in the final remedy, as will be stated in the 60% design. Substrate selection may change over the lifetime of the project as substrate costing varies. In addition, other substrates, such as longer lasting substrates, could be useful for certain situations that arise over the life of the project, and as such documents written to date have preserved the option of using additional substrates. The 60% design will present the performance monitoring plan for evaluating substrate distribution and when different substrate may be needed to achieve sufficient distribution over the course of the project. To the extent possible, flexibility is being incorporated into the design to allow for changes in substrates. Modifications to system equipment, including pumps and flow meters, may be needed to change substrates from ethanol to other potential substrates such as lactate or emulsified vegetable oil. Whey would require more extensive modifications to the substrate storage and dosing infrastructure, given its perishable nature. Changing substrates would also require some system preparation activities, for example, cleaning of the storage tanks and reagent lines. **Organic Carbon Substrate Delivery Design** As the commenter notes, the pilot tests were also used to evaluate reagent delivery and to gather data necessary for full-scale reagent delivery design. With the variable volume point injections conducted in the Floodplain pilot test, the radius to volume relationship and mobile porosity were determined. These basic distribution properties were used in the transport modeling, allowing for analysis of a variety of recirculation system layouts. One of the main objectives of the Uplands pilot test was to test the ability to distribute	Okay		Comment resolved.	See Section 3.2.1.2, Appendix L (O&M Manual, Volume 3), and Appendix B.

<tr><td></td><td></td><td></td><td></td><td></td><td>organic carbon by recirculation with recirculation wells with two screens, one used for injection and one used as extraction at each location. As discussed in the final report, the findings of the study indicated potential issues with distribution of organic carbon substrate in this recirculation design, due to vertical short circuiting between injection and extraction intervals that limited lateral distribution at the middle and deep intervals. Based on this information, the recirculation system for the final remedy does not include recirculation wells with injection and extraction intervals at the same location.

The 60% design will contain a discussion of the pilot test results and how they were used in the full-scale design.</td><td></td><td></td><td></td><td></td></tr>
<tr><td>95</td><td>Hualapai-17</td><td></td><td></td><td><u>Evaluation of First-order Rate Constants to Estimate Remedial Timeline</u>

First-order rate constants have been calculated for Cr(VI) reduction using data from the Upland ISPT. The rate constants can be used for estimating how quickly remediation goals will be met at a site. The rate constant is dependent on TOC concentration, and the Cr(VI) reduction rate constant (k) is determined graphically (Appendix A). From ISPT data, the Cr(VI) reduction rate constant ranges from k = 0.0021 d-1 for TOC =146 mg/L to k = 0.80 d-1 for TOC = 8,050 mg/L (Table 1, Figure 1). The rate Cr(VI) constant varies by two orders of magnitude. This means that the time required to remediate the plume while injecting TOC = 150 mg/L will take 381 times longer than it would take to remediate the plume using 8,050 mg/L.

Data from the Upland ISPT indicates that some of the ISPT monitor wells show Cr(VI) reduction and some wells do not show Cr(VI) reduction in response to ethanol injections. Total organic carbon (TOC) injected into the groundwater system was successful in removing Cr(VI) from the aquifer in the immediate vicinity of certain wells. The wells with successful Cr(VI) removal were mostly located within 20 feet of the TOC</td><td>Kinetics and competition for organic carbon substrate

With regards to the comments on kinetics and competition, a complete response to this comment will be provided in the 60% design. Several key points that will be discussed to address the concerns raised in this comment will include:
The various factors that contribute to the rate of decrease in Cr(VI) concentrations at each location, including the size of the active microbial population and the hydraulics of mixing at locations downgradient or cross-gradient of injection points. These factors confound the first order rate coefficient analysis and can explain the variation in rates observed.
The amount of organic carbon distributed in the Uplands pilot test was greater than necessary due to the nature of the recirculation system tested, making it difficult to draw any conclusions about the relationship between the maximum concentrations observed (as noted in the comment table) and the rate of decreasing Cr(VI) concentrations. Rapid Cr(VI) reduction at locations like PT-7M, PT-7D, and MW-24A was achieved when TOC concentrations were lower than the maximum in the comment table.
As discussed at the TWG meeting, the consumption for organic carbon substrate by various electron acceptors was accounted for in the design through a kinetic model, although the model does not differentiate between</td><td>Comment and response noted.</td><td>Comment and response noted. Further evaluation will occur during the review of 60% design submittal.</td><td></td><td>See Appendix B.</td></tr>

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				injection. Wells further away from injection showed less success in Cr(VI) reduction. Chromium reduction was not successful in ISPT monitor wells where high nitrate and sulfate concentrations were present (Figure A1). In other wells where Cr(VI) removal was successful (wells showing high TOC concentrations), sulfate reduction occurred concurrent with Cr(VI) reduction (Figures A2 and A3), indicating that sulfate reduction is required to completely remove Cr(VI). Injection of TOC creates conditions suitable for sulfate reduction and formation of sulfide minerals (such as pyrite). As sulfate is being reduced, pyrite is being precipitated (probably as colloidal pyrite), and dissolved iron is not present in water samples. When the sulfate is completely consumed, dissolved iron begins to show up (Figures A2 and A3), and manganese concentrations increase dramatically due to the reductive dissolution of naturally present manganese oxides. The data indicate that sulfate and nitrate compete with Cr(VI) for reduction; therefore, it is likely that the proposed injections of low TOC concentrations (100 to 150 mg/L) will not be sufficient to fully remediate Cr(VI) in the Topock plume. The 30% Design report states that the IRZ line along the NTH IRZ will inject a nominal TOC concentration of 100 mg/L (maximum of 500 mg/L). As shown by the rate constants, these low TOC concentrations will take a longer time to remediate the plume than would higher TOC concentrations. In order to remediate the plume more quickly, an alternative may be considered where early in the remediation, high TOC concentrations are injected into the heart of the plume where the highest concentrations are located beneath and northeast of the Compressor Station. Byproducts will be generated by the injection of high TOC concentrations. During the same early periods, low TOC concentrations are injected into the NTH IRZ line in order to remediate the floodplain portion of the plume, and lower byproduct concentrations are generated using low TOC concentrations. Then as the byproducts from the heart of the plume migrate towards the Colorado River, the IRZ line can be turned into an oxidative line to prevent the byproducts from entering the river.	electron acceptors. As presented at the January 19, 2012 TWG meeting, the ISPT data demonstrates in many cases that Cr(VI) reduction occurs concurrently with other reductive processes such as nitrate, iron, and sulfate reduction and is more thermodynamically favorable than sulfate reduction. Some of these topics were discussed at the TWG meeting on January 19, 2012. A complete discussion of the data and concepts presented at the TWG meeting will be included in the detailed response to comments as part of the 60% design. In addition, there will be a discussion of the data from each monitoring location discussed in this comment, so that it is clear how all of the data was evaluated and interpreted and used to inform the current design. The possibility of using higher TOC concentrations in the higher Cr(VI) concentration areas at the Compressor Station could be considered as the system is started up and monitoring data are evaluated; but such changes will be balanced with the relative benefit in IRZ maintenance and the relative cost of by-product generation. The change of the NTH IRZ from a reductive barrier that is used to treat the Cr(VI) that is flushed through the barrier throughout the remedy to an oxidative barrier would be of limited value since the manganese generated in the heart of the plume has a very limited footprint.

96	Hualapai-34			Additional Technical Considerations Have horizontal wells been evaluated as a way to potentially increase the area over which carbon can be introduced into the Cr(VI) plume, without having to increase the number of wells or infrastructure?	Horizontal wells were screened out for use in this application. There would be a number of significant technical challenges with using horizontal wells for this purpose and it is unlikely that horizontal wells would outperform the series of vertical wells currently proposed. It is also unlikely that horizontal wells could be used to replace the deeper wells or the deeper screens in the dual screen injection wells due to significant challenges with constructing a deep horizontal well. An assessment of the applicability of using horizontal wells in lieu of the shallow (vertical) injection wells indicated that difficulties in construction, inherently less efficient screen designs, difficulty in well development, less efficient well performance, difficult well maintenance, and the difficulty of well replacement all make horizontal wells a poor choice for this site.	Comment and response noted.	Comment and response noted.		
97	DOI-27	Section 3.2.1.2/3-6 and 3-7/ Appendix C		The text states that multiple carbon sources may be used during remedy implementation. Please explain how operational data will be used to evaluate substrate performance and what “triggers” will be used to prompt the use of an alternative substrate during remedy implementation.	Operational data collection and how the data will be used to adjust system operations will be discussed in detail as part of the O&M plan in the 60% design. The use of alternative substrates will be included in the O&M plan.		Okay pending review of 60% design submittal.	Comment resolved.	See draft O&M Manual, Volume 1 – Operations and Maintenance Plan.
98	DTSC-32	Section 3.2.1.3, Uncertainties and Assumptions, Page 3-7		Since PG&E proposes the use of adaptive operational approach, provide a general discussion of your adaptive protocol and criteria for adapting/adjusting the system; what is your anticipated adaptive review process that was used in the in situ pilot tests and what differences and how difficult will it be to make changes in the full scale design? What are your initial design criteria, estimated flow rates, carbon concentrations, specifications for each well? Will they vary based on geochemical or other differences?	Preliminary design criteria, including carbon concentrations, estimated flow rates, and well specifications, are discussed in Section 3.2.1.1. Preliminary design flow rates are also provided in Table 3-1. Operational modifications may include adjustments to injection rates, extraction rates, and/or organic carbon loading as discussed in Section 3.2.1.3. The 60% design submittal and O&M Plan will discuss the performance criteria that will trigger modifications to the operational approach, and will present the protocol for implementing such changes.	Okay pending review of 60% design.		Comment resolved.	See Appendix L (Draft O&M Manual, Volumes 2 and 3).

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
99	Hualapai-6			<u>Evaluation and Application of In-Situ Pilot Scale Test Results</u> Section 3.2.1.2 of the report does not appear to adequately address all the results from the pilot studies, and may suggest an incorrect conclusion from these studies. A summary description of both the upland and flood plain pilot studies should discuss not only the positive aspects of the pilot results, but highlight the uncertainties which were also revealed. For example, both ISPT studies show that 1) total organic carbon (TOC) concentrations are unevenly distributed within the IRZs, 2) there is a low overall correlation between ORP and TOC concentrations, and 3) even in the presence of high TOC and low ORP, some monitoring wells still show persistently high concentrations of Cr(VI).	In light of this comment, a discussion of the pilot test data will be included in a detailed response to comments in the 60% design document. In brief, with regard to the three comments: 1) In the Floodplain pilot test, the organic carbon substrate distribution followed a radius of influence/ injection volume relationship typical of injection into a single injection point. Locations that did not receive organic carbon were outside of the radius of influence or upgradient of the injection point. One of the main objectives of the Uplands pilot test was to test the ability to distribute organic carbon by recirculation with recirculation wells with two screens, one used for injection and one used as extraction at each location. As discussed in the final report, the findings of the study indicated potential issues with distribution of organic carbon substrate in this recirculation design, due to vertical short circuiting between injection and extraction intervals that limited lateral distribution at the middle and deep intervals. Based on this information, the recirculation system for the final remedy does not include recirculation wells with injection and extraction intervals at the same location. 2 and 3) Several factors may confound the relationship between TOC distribution, changes in ORP, and Cr(VI), such as hydrogeologic flow conditions, particularly for wells downgradient or cross-gradient of a small pilot test within a larger contaminated area, and lag time for establishment of the microbial population. In addition, as the reviewer commented in a separate comment, the measurement of ORP can be subject to interference and uncertainty which is why it is not used as a primary metric.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
100	Hualapai-7 and TRC-20			<u>Evaluation and Application of In-Situ Pilot Scale Test Results</u> The statement that *"reduction of Cr(VI) from mg/L concentrations (e.g., 3.35 mg/L in April 2006) to concentrations of less than a fraction of a μg/L (e.g., 0.2 μg/L)"* while true for a subset of the ISPT wells is not true for all of the wells. Floodplain ISPT wells PT3D, PT 4D, PT5D, PT6D, PE-1, TW-2D and TW3D all maintained Cr(VI) concentrations an order of magnitude above baseline even in the presence of elevated TOC levels (up to 326 mg/L). **TRC Recommendation:** It is reasonable to expect that local-scale variations may cause requirements (such as TOC concentration) to differ along the actual IRZ line. It is anticipated that a discussion of how system monitoring and designed-in flexibility will be used to 1) identify these areas, and 2) allow for more intense treatment to produce effective chromium reduction along every segment of the IRZ.	It is agreed that there will be local variations in TOC distribution along the IRZs planned for the final remedy. The 60% design will present the performance monitoring plan for evaluating substrate distribution and modifying operations to address areas that are not receiving sufficient organic carbon substrate. With regards to the pilot test data, the distribution of TOC was governed by the radius of influence (ROI) of the injection point (i.e. higher concentrations of TOC and tracer were distributed to monitoring well locations closer to the injection point) and the hydraulic gradient (i.e. outside of the ROI, TOC was distributed to downgradient locations and not to upgradient locations). A more detailed discussion of these monitoring well trends and the reasons carbon distribution as not expected or observed at extraction wells (TW-2D, TW-3D, and PE-1) will be included in the detailed response to comments in the 60% design.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B and Appendix L (Draft O&M Manual, Volumes 2 and 3).
101	Hualapai-8 and TRC-19			<u>Evaluation and Application of In-Situ Pilot Scale Test Results</u> Chromium reduction is dependent on TOC concentration, and the oxidation- reduction potential (ORP) can be used as a surrogate to measure the effectiveness of the carbon-induced reduction. Data from well MW-24A from the Upland ISPT show that TOC concentrations of 100 to 500 mg/L were effective in achieving ORP of -200 to -250 mV necessary for Cr(VI) reduction (Figure 1). However, data from well PTR-1 show that similar TOC concentrations were not effective in that area in achieving the range of ORP needed to cause Cr(VI) reduction. (see also data plots in Appendix A). **TRC Recommendation:** This suggests aquifer heterogeneity exists which may not have been factored into the current model and suggests that local-scale heterogeneity may dominate. It is anticipated that a discussion of how the impacts of heterogeneity will be monitored for during initial startup, and how contingencies to enhance and/or modify the system may be implemented to deal with such situations.	Heterogeneity is addressed in the groundwater flow model by a variable hydraulic conductivity distribution established during the groundwater flow model calibration process. This distribution was based on observed field data and further refined through parameter estimation (PEST). Documentation with respect to the groundwater flow model is presented in CH2M HILL 2005 and 2009. Heterogeneity is also addressed in the solute transport model by simulating the system as a dual domain model. This allows for interaction between the mobile and immobile porosities. The 60 percent design will include a performance monitoring program that will address these concerns and contingency plans. In addition, the detailed response to comments will be included in the 60 percent design and will include an analysis of the relationship between TOC distribution, redox conditions and hexavalent chromium reduction, including the information presented at the January 19, 2012 TWG meeting. With regards to the pilot test data, the data referenced in this comment was collected from a recirculation well, PTR-1, which represents mixing within the well and recirculation pipeline rather than distribution and treatment in the aquifer. As such, this data should not be used to assess in situ	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B and Appendix L (O&M Manual, Volume 2 and Volume 3, Section 2.1).

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					treatment or make predictions for the full-scale system.				
102	TRC-5			Chromium data from the in-situ pilot studies (ISPT) show differing results in response to carbon injections. Some wells showed Cr(VI) reduction, and some wells did not show Cr(VI) reduction. Upland ISPT wells showed different Cr(VI) reduction rates for different TOC concentrations (Figure 1). Data from the Upland ISPT shows that nitrate (NO3) and sulfate (SO4) concentrations may be competing with Cr(VI) for reduction (Figures A1-A3). **TRC Recommendation:** This suggests aquifer heterogeneity exists which may not have been factored into the current model and suggests that local-scale heterogeneity may dominate. It is anticipated that discussions will take place regarding model updates, system monitoring, and designed-in flexibility in order to 1) identify recalcitrant areas, 2) refine the remedy time frames, and 3) allow for more intense treatment to produce effective chromium reduction along every segment of the IRZ.	Local scale aquifer heterogeneities are present in most systems. The groundwater flow model accounted for this heterogeneity by defining a hydraulic conductivity distribution based on available field data and through parameter estimation (PEST) during the groundwater flow model. Aquifer heterogeneities were accounted for in the solute transport model by simulating the model as a dual domain system with mobile and immobile porosities. The combination of a variable hydraulic conductivity distribution with dual domain aids in accounting for the heterogeneities present in the aquifer. It is agreed that there will be local variations in TOC distribution along the IRZ planned for the final remedy. The 60% design will present the performance monitoring plan for evaluating substrate distribution and modifying operations to address areas that are not receiving sufficient organic carbon substrate. With regards to the competition for electrons from ethanol by nitrate and sulfate, this has already been accounted for in the degradation rate for organic carbon used in the model. In reality, the organic carbon substrate will support reduction of a variety of electron acceptors, including nitrate and sulfate; in addition, sufficient organic carbon must be injected to achieve distribution throughout the target area. A summary of the concepts and data presented at the January 19, 2012 TWG meeting on this topic will be included in the detailed response to comments as part of the 60% design.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B and Appendix L (O&M Manual, Volumes 2 and 3).

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
103	DTSC-33	Section 3.2, Uncertainties and Assumptions for most remedial components	An adaptive operational approach is described by PG&E for almost all components of the remedy to be implemented.	Although an adaptive operational approach can be employed during the remedy, PG&E must describe to readers how changes in the specifications will effect and/or impact each component of the remedy. Evaluation metrics (short term measurable performance goals) will have to be developed, which will ultimately affect the redundancy and flexibility, and/or contingency part of the design. Because of the current PG&E approach, it is difficult to make any specific comments on the design including sizing, controls, spare piping, and the P&ID, etc.)	Preliminary design criteria, including carbon concentrations, estimated flow rates, and well specifications, are discussed in Section 3.2.2.1. Preliminary design flow rates are also provided in Table 3-2. These have included both nominal values and operational ranges (i.e., maximum and minimum) for consideration in the design at this stage, which will be further developed as the design progresses. These also consider modifications that may be made during the system operation. The 60% design submittal and O&M Plan will discuss the performance criteria that will trigger modifications to the operational approach, the protocol for implementing such changes, and how elements of the system are designed to accommodate the necessary adaptability.	Okay pending review of 60% design		Comment resolved.	Appendix L (O&M Manual, Volumes 2 and 3).
104	HA-15	p. 3-7, Section 3.2.1.3 (Uncertainties and Assumptions)		This paragraph highlights the relationship between the ability to circulate organic compounds at the NTH IRZ into the floodplain area and the impact of geologic and hydrogeologic heterogeneities within the aquifer. This is an important consideration, the effect of which will remain uncertain until the start-up and operation of the remedy. In order to ascertain the impact of such an uncertainty, it will be necessary to perform monitoring at strategic locations down gradient from the NTH IRZ and to have a contingency plan for addressing the potential for contaminant breakthrough. Such information should be provided in the 60%. Has PG&E performed any simulations based on scenarios assuming hypothetical pathways with higher hydraulic conductivities and then the type of contingency that would be necessary to control such breakthroughs? The Tribe notes that at the Hinkley Site, such a breakthrough occurred along the Central Area IRZ (as discussed in the December 13, 2011, meeting at Hinkley) after 44 months of operation.[4] Has anything been learned as a result of that occurrence that might be applicable to the Topock Site? [4] PG&E, 2012. "In-Situ Reactive Zone Treatment System Overview, Hinkley Gas Compressor Station, Groundwater Remediation Project." See Slide No. 14 "Central Area Treatment System Effectiveness – 44 Months" (8/11)	Heterogeneity is addressed in the groundwater flow model by a variable hydraulic conductivity distribution established during the groundwater flow model calibration process. This distribution was based on observed field data and further refined through parameter estimation (PEST). Documentation with respect to the groundwater flow model is presented in Hill 2005 and 2009. Heterogeneity is also addressed in the solute transport model by simulating the system as a dual domain model. This allows for interaction between the mobile and immobile porosities. The monitoring program will be described in detail in the 60% design. Contingency actions will also be described in the 60% design. The gap that exists in the Hinkley Central Area IRZ barrier is not due to a breakthrough but rather the lack of adequate injection well infrastructure in a portion of the IRZ line. After attempts to fill the gap using higher flowrates and increased TOC loadings failed, a new well was installed. The latest data indicates that the gap is being filled.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B and Appendix L (O&M Manual, Volume 2 and Volume 3, Section 2.1).
105	DOI-28	Section 3.2.2/3-7/ 1st Paragraph		The CMI/RD Work Plan also indicates that the inner recirculation loop provides secondary protection for the Colorado River by controlling the migration of byproducts generated by the IRZ. Please add this discussion.	This discussion will be added as a section in the 60% design submittal.	Okay pending review of 60% design submittal	Okay pending review of 60% design submittal.	Comment resolved.	See Section 3.2.2 and Appendix B.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
106	DTSC-34	Page 3-7, Section 3.2.2 Inner Recirculation Loop		The Inner Recirculation Loop (IRL) is stated to include four carbon-amended injection wells installed near the western margin of the groundwater plume north of I-40, yet some of these wells are not planned as carbon-amended wells and Table 3-4 suggests that all may be freshwater injection wells at some point in time. This section should clarify this issue.	Text will be updated to clarify the operation of the Inner Recirculation Loop wells. The current proposed layout has the northern 2 IRL injection wells receiving water from the Riverbank Extraction wells. The system is modeled without carbon amendment based on the projected chromium concentration from the Riverbank extraction wells; but the system is capable of delivering reagent to the Riverbank flow stream if Cr6 exceeds the target cleanup goal. The 2 southern IRL injection wells are simulated as freshwater injection wells. It is proposed that the IRL layout be flexible to potentially oscillate between freshwater and riverbank extraction water sources to alleviate potential byproduct impacts. Please also see RTC#262 (DOI-84). Additional details will be provided in the 60% design.	Okay pending review of 60% design submittal		Comment resolved.	See Section 3.2.2.
107	DTSC-35	Page 3-7, Section 3.2.2.1 Description – Inner Recirculation Loop		The rationale for having three to five of the River Bank Extraction Wells operated at any given time should be included in this section as should the criteria that would guide one to increase or decrease extraction rates.	This rationale will be included in the 60% design. It will include consideration of the need to: capture potential Cr(VI) concentrations located downgradient of the NTH IRZ, control IRZ by-product migration, accelerate the remediation timeframe through enhanced gradients, and minimize the effects of riverbank extraction on development and maintenance of the NTH IRZ . Monitoring wells will be used to help monitor the effectiveness of the NTH IRZ, and help determine the ideal Riverbank Extraction well pattern to maintain an appropriate balance of these operational goals.	Okay pending review of the 60% design submittal		Comment resolved.	See Section 3.2.2.1 and Appendix L (O&M Manual, Volume 2).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
108	HA-16	p. 3-7, Section 3.2.2.1 (Description – Inner Recirculation Loop)		"River Bank Extraction Wells" This section generally describes the design of the River Bank Extraction Wells, indicating that these 12-inch wells may have two discrete screened intervals. Where will these be screened relative to the natural reductive zone in the rind of the fluvial sediments? What will determine whether one or two intervals are screened? While Table 3-2 indicates a maximum extraction rate of 500 gpm, it appears that the maximum capacity could be 850 gpm total. Is this rate of extraction consistent with the design? Are there any scenarios whereby contaminated groundwater upgradient from the River Bank Extraction Wells could either breakthrough, migrate around, or otherwise escape capture by the River Bank Wells? "Carbon-Amended Injection Wells" – Will injected freshwater also be amended with carbon prior to injection to facilitate chromium reduction?	The river bank extraction wells will be screened in Model Layers 3 and 4. Care will be taken to ensure that the extraction well screens do not intersect the natural reducing zone. No more than two screened intervals are included in any one well. The need for more than one screen is based on a maximum screen length of 40 feet. Refer to Table 3-1. Section 3.2.2.1 indicates that the expected total average river bank extraction flow rate is 150 gpm (based on the individual nominal extraction rates), and that there will be flexibility to increase this flow rate to 500 gpm. Although the sum of individual design capacities is 850 gpm, it must be noted that all the extraction wells will not be operating at full capacity at any given time. This data is consistent with the design of the extraction wells. Based on the projected operation of the system and the model results, breakthrough is not anticipated. The fresh water injection is planned for areas outside the plume and therefore the system does not include a carbon amendment.	Comment and response noted.	Comment and response noted.		
109	DOI-29	Section 3.2.2./3-8/ 21st Paragraph/last line		Add that amendment with carbon will occur if extracted flood plain groundwater chromate concentrations increase above the cleanup level.	This detail will be added to this section in the 60% design submittal.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See Section 3.2.2.1.
110	DTSC-36	Page 3-8, Carbon-Amended Injection Wells		The section indicates that the target dosage concentration for flow from the River Bank Extraction Wells is between zero and 50 mg/L of TOC and that TOC may be added to facilitate treatment of Cr(VI). The basis for the target dose and criteria for adding more (or less) TOC should be clearly explained in this section.	The rationale for this concentration range will be added to this section in the 60 % design. Low concentrations of organic carbon were planned for the carbon amended injection wells in the event that Cr(VI) is extracted at concentrations that require treatment. The low end of the range, 0 mg/L, was included in case Cr(VI) is not present in extracted water and in-situ treatment is not required. The maximum concentration of Cr(VI) anticipated based on modeling results is 13 ppb, below the background concentration of 32 ppb, indicating that treatment of this water is not likely required. Should Cr(VI) treatment be required, low concentrations of organic carbon will be added. Once the reducing zone is established, a low concentration of organic carbon would be required to consume the dissolved oxygen, nitrate, and chromium and to promote iron reduction for potential abiotic reduction of Cr(VI). For reference, approximately 3.4 mg/L of TOC from ethanol would be required to reduce 8 mg/L of oxygen, 2 mg/L nitrate as N, 13 ppb Cr(VI). The upper end of the range was	Okay pending review of 60% design		Comment resolved.	See Section 3.2.2.1.

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					established above this concentration to allow for additional consumption of TOC for cell growth, promotion of reducing conditions in the subsurface, and to accommodate for uncertainties in field implementation.				
111	DTSC-37	Page 3-8, Remediation Well Maintenance System		The rationale for operating the backwash pumps at two times the injection flow rates should be stated in this section. Would another rate be better? May different rates be employed based on responses at specific wells?	The proposed backwashing rate is based on experience gained from the operation of Aquifer Storage and Recovery systems. Backwashing is currently being evaluated on an IRZ well at the Hinkley Compressor Station. Preliminary operating data from Hinkley indicates that backwashing effectively prolongs the injection capacity of the IRZ well. Flexibility in the system operation is planned to allow for variable flows and frequency of backwashing based on system performance. Additional details regarding the backwashing rate and performance criteria for potential in-field adjustments will be addressed in the 60% design submittal and/or the O&M Plan.	Okay pending review of 60% design and O&M Plan		Comment resolved.	See Section 3.2.2.1 and Appendix L (O&M Manual, Volumes 1 and 2).
112	DTSC-38	Section 3.2.2.1, Carbon Amended Injection Wells, Page 3-8		What is the basis for the 50 mg/L? Would it be the same quantity regardless of substrate used? Will the injection rates vary by area or well? What are the rationale for this design?	See the response to comment 110 (DTSC-36) on the basis for the 50 mg/L upper bound on TOC concentrations. The stoichiometry discussed in that response was based on ethanol and would vary slightly if based on lactate (for the example given 5.1 mg/L of TOC from lactate would be required, compared to 3.4 mg/L of TOC from ethanol). This variation is small in comparison with the variability of field conditions. Injection rates and/or TOC concentration may be varied based on area or individual wells. Performance monitoring data will be used to inform the need for changes in the field.	DTSC assumes this to be part of the O&M plan. Okay pending review of future plan.		Comment resolved.	See Section 3.2.2.1 and Appendix L (O&M Manual).

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
113	DTSC-39	Section 3.2.2.1, Remediation Well Maintenance System, Page 3-8		What is the fouling rate anticipated based on historical knowledge?	As discussed in Section 3.2.4.3, to date, no significant fouling has been observed in the pilot IRZ system injection wells at Topock. This may be related to the batch injection configuration used in the Floodplain pilot (limited flow of nutrients through the screen), and the high-concentration ethanol solution used in the Uplands pilot (doubles as a biocide inside the well and related piping). It is also likely that the limited duration of the pilot studies may not have allowed adequate time for fouling to occur to a degree that it impacted operations; however, a longer duration full-scale system will likely have to deal with well fouling. The proposed frequency of well maintenance (e.g. backwashing on a weekly basis) was based on fouling rates observed during the Hinkley pilot test and other full scale experience. More detail regarding the well maintenance program will be included in the 60% design submittal and the O&M Plan.	Okay, pending review of 60% design and O&M Plan		Comment resolved.	See Appendix L (O&M Manual, Volume 1).
114	HA-17	p. 3-8, Section 3.2.2.2 (Design Basis – Inner Recirculation Loop)		On January 9, 2012, PG&E conducted a site walk for tribal participants to examine proposed sites for the inner recirculation loop and other proposed facilities. The Tribe's conclusions with regard to the proposed sites are presented as Attachment B to this comment letter. Of further concern is the siting of monitor well(s) associated with the inner recirculation loop as referred to in Section 3.2.2.3. Once the monitoring network is proposed as part of the 60% BOD, the Tribe requests a site walk to evaluate the acceptability of proposed monitoring sites and will provide comments on the acceptability of the locations proposed.	The Tribe's request for a site walk of proposed monitoring well locations, is noted. PG&E will contact the FMIT and other interested Tribes once the logistics for the site walk are determined.	Comment and response noted.	Comment and response noted.		At the Tribe's request, PG&E held a site walk of the proposed monitoring well locations on July 19, 2012. On July 27, 2012, PG&E received a letter from Dr. Leo Leonhart, on behalf of the FMIT, expressing appreciation for the site walk and documenting various discussions exchanged in the field. The monitoring well network is discussed throughout this BOD report and in draft O&M Manual, Volume 2 (Sampling and Monitoring Plan).
115	DTSC-40	Page 3-9, Section 3.2.3, TCS Recirculation Loop		The TCS recirculation loop will use both the RAV-EXT 1-4 wells and the MID-EX 1-4 wells. It is unclear how balance can be achieved from the COMP-INJ wells.	Text will be clarified and updated in the 60% design report. The nominal extraction rate for the East Ravine wells is 2 gpm, and the nominal extraction rate of the Northeast of TCS Extraction wells is 19 gpm. Therefore by combining the aforementioned extraction rates the nominal TCS injection rate is 21 gpm. The COMP-INJ wells are expected to be more than adequate for this injection rate.	Okay pending review of the 60% design submittal		Comment resolved.	See Section 3.2.3.1 and Table 3.2-3.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
116	DTSC-41	Page 3-9, Section 3.2.3.1 Description–TCS Recirculation Loop Extraction Wells Northeast of the Compressor Station		The section indicates that four extraction wells are anticipated. The section should indicate what would cause the number of extraction wells to increase or decrease. Also see similar comments regarding the basis for flow rates.	The well quantity, spacing, and flow rates were based on the simulated aquifer thickness and associated hydrogeologic characteristics. This system layout and operation was optimized using the groundwater flow and solute transport model. Based on the groundwater flow and solute transport model, the 4 extraction wells in the embayment area operating at a total of 19 gpm were sufficient to hydraulically contain this vicinity. Characterization of this area is primarily defined by MW-59, and there are limited other wells in this vicinity. Installation of the 4 proposed extraction wells will assist in refining the understanding of the hydrogeology of this area. If the aquifer conditions are different than anticipated, the number of extraction wells may need to be adjusted to achieve the desired hydraulic control in this area.	DTSC anticipates additional information (e.g., goal of the recirculation loop, hydraulic and water quality monitoring) to be provided in the 60% design and the draft O&M Manual.		Comment resolved.	See Section 3.2.3.1 and Appendix L (O&M Manual).
117	DTSC-42	Page 3-9, East Ravine Extraction Wells		This section should discuss how the East Ravine remedial approach has changed overtime. The basis for the following statement from the 2009 CMS/FS should be stated in this section, “Initial estimates are that approximately 15 wells, pumping a combined total of up to 10 gallons per minute, would be required to provide hydraulic capture of the area of Cr(VI) in East Ravine bedrock.” The East Ravine extraction system is now proposed to contain four wells pumping two gpm total.	A short discussion of the evolution of the East Ravine design will be added to this section of the 60% design. Data from the ongoing East Ravine groundwater investigation will also be discussed.	Okay pending review of the 60% design and draft O&M Manual		Comment resolved.	See Sections 3.2.3.1 and 2.1.2 and Appendix L (O&M Manual).
118	DTSC-43	Page 3-10, TCS Injection Wells		Based on TCS Injection well locations, DTSC is concerned that westward flow from these wells could push highly contaminated groundwater to the west in an uncontrolled manner. Note that freshwater injection wells to the north are located a significant distance away and that FW-INJ-4, located to the south, is pumping the smallest volume of freshwater. The section should indicate how this issue is being dealt with and, more importantly, how it will be addressed through groundwater monitoring and specific contingency protocols.	This was a critical consideration in the 30% design evaluation. Based on the modeling completed, the potential for westward flow is mitigated by injecting into FW-INJ-4. Although there are not any freshwater injection wells located directly to the west of the TCS injection wells, FW-INJ-4 (50 gpm) injects at more than double the rate than the combined TCS injection rate (21 gpm). This excess injection outside the footprint of the plume combined with the natural eastward flow gradient results in minimal westward flow near the TCS Injection wells. The groundwater flow and solute transport models indicate this eastward flow is maintained. The monitoring and contingency planning will be provided in the draft O&M Manual.	Okay pending review of 60% design and draft O&M Manual		Comment resolved.	See Section 3.2.3.1 and Appendix L (O&M Manual, Volume 2 and Volume 3, Section 2.1).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
119	HA-18	p. 3-11, Section 3.2.2.3 (Uncertainties and Assumptions – TCS Recirculation Loop)		This section indicates that "Construction and cultural resources constraints may affect the design and operation ...." The Tribe would like to discuss specifics as to what parts of the design and operation are thought by PG&E or the Agencies to have been, or will foreseeably be, constrained by cultural resource considerations and the anticipated cost/schedule/performance impact of any such constraints.	The intention of this sentence was to explain that during the design, various constraints will be considered to avoid impacts. There are many elements of the system design – location of facilities, infrastructure, system profiles, etc, that were – and may be further - adjusted to accommodate the site constraints.	Comment and response noted.	Comment and response noted.		
120	DOI-30	Sections 3.2.3.1 and 3.2.3.2		The discussion contained within these two sections regarding the East Ravine Extraction Wells and Design Basis must be revised to reflect uncertainties in bedrock flow conditions resulting from the recent discovery of higher fracture flow conditions at Site H. (See General Comment 9) Given this, the discussion regarding the extraction wells in Section 3.2.3.1 must note that new information from the second phase of the investigation was not fully considered in the 30% design and it therefore can only be assumed that the groundwater production and radius of influence of the East Ravine Extraction Wells will be small. Consideration should be given to further evaluation and possible modification of the East Ravine bedrock remedy in the intermediate (60%) design. It is also recommended that the text in Section 3.2.3.2 be revised as follows: "Investigation of the East Ravine area has been conducted in two phases. The sustainable purge rates of wells drilled during the first phase were low, resulting in a preliminary conceptual model of a fracture flow system with limited interconnectivity and flow volume that was used as the basis for the 30% design. More recently during the second phase, one well location (Site H/ MW-70) exhibited relatively high extraction rates. At the time of the 30% design, it is unknown whether the conditions observed at Site H are isolated or represent potentially higher flow conditions than previously conceptualized for the East Ravine bedrock. ..."	The recently collected data was not considered in the 30% design, but will be included in the assessment and revisions to the system design as reported in the 60% design document. Any new information collected subsequent to the 60% design will be incorporated into the 90% design.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See Section 3.2.3.2.
121	DTSC-44	Page 3-11, Section 3.2.3.2 Design Basis– TCS Recirculation Loop		Maps with the extent of contamination should be included in the document to ensure the extent of the East Ravine plume is defined and to aid in evaluating that the remedy will clean up that portion of the plume.	Comment noted. Figures 2-3a through c depict the approximate extent of the CrVI plume.	Okay pending review of revised figures.		Comment resolved.	See Figure 2.2-1 of this BOD Report.
122	DTSC-45	Page 3-11, Paragraph 2, Section 3.2.3.2 Design Basis– TCS Recirculation Loop		The section indicates that sustainable purge rates of wells drilled during the first phase were too low for injection to be a viable remedial alternative. The basis for this statement should be included in the section as should the second phase data which did identify a higher permeability zone in bedrock.	Comment noted. This section o the 60% design document will include a discussion of the basis of this statement as well as a consideration of recent data collected in the ER/TCS investigation. Also please see response to RTC#10 (DOI-9).	Okay pending review of 60% design submittal.		Comment resolved.	See Section 3.2.3.2.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
123	DOI-31	Section 3.2.4.1/3-11/ 1st Paragraph		The operation of the CIP system requires more discussion. How often will the CIP system be used as this will require shutdown of substrate amended water injection? How much wastewater will it generate? The wastewater flow is not identified in Exhibits 3-5 or 3-7. How does it use the pumps, tanks, and metering equipment of the substrate amendment system?	Current experience with CIP systems for groundwater conveyance piping indicates that circulating a reagent amended water in a recirculation loop is an effective preventive maintenance solution to address problematic scale deposits. The reagents used are those categories of water treatment chemicals approved for use in drinking water systems. Ultimate selection of an effective reagent(s) will require bench-scale testing of actual scale deposits. Operation of the CIP system is expected to occur on an annual basis, but possible as little as once every five years. Operation of the CIP will take place over a limited period of time and be scheduled to take advantage of system shutdown periods. The volume of spent solution is expected to be roughly 10,000 to 40,000 gallons per event. The carbon amended water injection will be temporarily shut off during the CIP event (groundwater extraction will cease and clean water will be used to flush the lines). Each conveyance forcemain will be valved to isolate the wells and create a loop with its associated spare conveyance header which will originate and terminate with the CIP Tank (frac tank). Fresh water will be added to the CIP tank and amendments will be added (per the recommended recipe based on the testing program from the scale deposit samples). The CIP system will operate by recirculating the amended water in a loop. Upon completion, freshwater will be added to flush the lines. The conveyance lines will be valved to facilitate normal operation upon completion of the CIP program.	Okay pending review of 60% design submittal.	Okay pending review of the 60% design submittal.	Comment resolved.	See Section 3.2.4.1 and Appendix L (O&M Manual, Volume 1, Section 5.1).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
124	DOI-32	Section 3.2.5.2/3-13/ 2nd Paragraph/2nd to last sentence		In all likelihood, first flush well rehabilitation water and possible CIP wastewater will have a pH less than 2, rendering it a characteristically corrosive hazardous waste. This would require double walled piping in wastewater transfer lines potentially everywhere. This requires more discussion.	The spent CIP solution will be considered a corrosive material (EPA hazardous waste number D002 [per 40 CFR 261.22]) at a pH less than or equal to 2 or greater than or equal to 12. Bench-test conducted on scale deposits would be conducted to determine suitable amendments and determine the pH of spent solution. An operational constraint that the neat (as-applied) amendment solution exhibit a pH greater than 2 or less than 12 will be considered. Acids have been used for decades in well rehabilitation. Acids are used to dissolve mineral precipitates on the well screen and in the nearby formation like calcium carbonate and sulfate, magnesium hydroxide, iron and manganese oxide, phosphates, silicates, and, of course, mixtures of all of these during well rehabilitation. Of those listed, the carbonates are the most easily dissolved with the resulting release of carbon dioxide. A simple example would be the action of hydrochloric acid on calcite (calcium carbonate). In this reaction, the acid HCl breaks apart the calcite, (CaCO3) into the salt (CaCl2) and carbonic acid (H2CO3) which further breaks down into water (HOH) and carbon dioxide (CO2), which bubbles off. This reaction is carried out by most mineral acids against carbonate deposits and accounts for the rapid evolution of gas during cleaning of wells with this type of deposit. The well water pH is measured as an indication that the acid has reacted with the encrustation to the degree that the acidity of the solution had been lost and all possible reaction has been completed. At the PGE Hinkley Compressor Station, well rehabilitation amendments are added to the well and allowed to loosen scale and deposits for a period of 12 to 72 hours. The pH is measured and verified to be above 2, before the first well volumes are pumped from the well (e.g., first flush). This operational approach will be an option. A second option is as follows, first flush rehabilitation water will be pumped out of the well with a temporary rehabilitation pump through temporary piping, pH neutralized using a permitted mobile treatment unit (if needed), and contained in temporary tanks located near the wellhead. All temporary tanks and piping, as well as the area surrounding the wellhead, will have adequate spill containment.		Okay pending review of 60% design submittal.	Comment resolved.	See Sections 3.2.4 and 3.2.5.2.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
125	HA-19	p. 3-12, Section 3.2.5 (General Design Elements – In Situ Remediation)		General design considerations for the in-situ components as well as all other components of the remedy that involve well construction should consider the eventual need to decommission these intrusive facilities. As mentioned earlier, the Tribe has entered into discussions with PG&E, DTSC, and DOI and other stakeholders in regard to considerations for well decommissioning that would be preferred in deference to the sacred landscape within which these facilities have been or will be constructed. Comments with regard to infrastructure siting alternatives in Attachment B provide further rationale supporting preferences of the FMIT Tribal Community.	The design will take into consideration the component life-cycles and eventual decommissioning process for each element of the remedial system. The design will adhere to any agreements made regarding well and system decommissioning. PG&E will draft a Decommissioning Plan for Remedy Facilities and Restoration, and the Tribes will be consulted prior to the decommissioning of any remediation facility.	Comment and response noted.	Comment and response noted.		
126	DTSC-46	Page 3-12, 3.2.5.1 IRZ Well Design, Number of Wells per Location	In areas with greater saturated thickness within the NTH IRZ, a two well cluster will be employed to facilitate recirculation of groundwater and carbon through the target zone.	Clarity is needed for design of injection wells. Is this saying there will be recirculation between wells or simply recirculation within the inner loop? PG&E has conducted a pilot test using dual screen recirculation wells to increase the reach of carbon dosing. However, the drawings and descriptions are not clear how PG&E intends to run these systems.	A dual screen well will be employed if the saturated thickness exceeds 40 to 100 feet and two screens are necessary to ensure targeted distribution of substrate in each zone. A well cluster will be employed if more than two well screens are required to provide full coverage of the target contaminated zone at locations where the vertical aquifer thickness is more than 110 feet thick. The purpose of the multiple wells per location is to ensure adequate discrete control of the injection fluid into the formation not to promote recirculation within the well cluster.	Okay		Comment resolved.	See Section 3.2.5.1.
127	DTSC-47	Page 3-12, Casing and screen material and type		The section should comment on long term corrosion issues (especially in high TDS waters) as well as fouling issues that may be dependent on the type of casing/screen material selected (also see page 3-13, paragraph 2 of Section 3.2.5.2). Will cathodic protection be utilized?	Comment noted. The 60% design will include a more detailed discussion of materials of construction for the extraction and injection wells.	Okay pending review of 60% design		Comment resolved.	See Sections 3.2.1.1 (under heading Well Maintenance and Rehabilitation Reagents) and Section 3.2.5.1, and Appendix L (O&M Manual, Volume 1).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
128	DTSC-48	Page 3-13, Section 3.2.5.2, IRZ Pipeline Design and Operation	Piping will be single-walled unless it is used to convey: (1) groundwater or remedy - produced water that is California hazardous waste; or (2) concentrated carbon substrate. In these cases, double-walled piping will be used.	Where are the areas that PG&E anticipates to encounter California Hazardous Waste and concentrated carbon substrates? In reviewing the design document, it would appear that PG&E does not believe there will be any California Hazardous Waste and little, if any, of concentrated carbon substrate transference. DTSC believes PG&E should, in addition to the current proposal, use double walled piping for management of any untreated extracted water to protect against leaks due to the cultural sensitivity of the area as well as the possibility of contamination that could be leached from the soils, which have not been completely investigated, to the groundwater.	Based on modeling, groundwater with Cr>5 ppm could be extracted from the IRZ extraction well, IRZ-23. Additional information about the subsurface conditions will be obtained as we start to install remediation wells. With regards to the suggested use of double walled piping for management of extracted water (that are below hazardous waste characteristic level) to protect against leaks due to concerns over the possibility of contamination leaching from the soils (which have not been investigated) to the groundwater, it should be noted that soil data do exist for the AOCs that overlap with the remedy infrastructure as shown in Figure 2-15. Supplemental soil sampling is being planned to complete the soil investigation and current schedule shows completion of the investigation prior to the start of groundwater remedy construction. Further, baseline soil samples will be collected to document baseline site conditions at the time of remedy construction. In addition, the overlapped AOCs are located within the plume footprint for which an active remediation will be implemented for decades. Additional evaluation of the potential for leaks and methods of leak detection and control will be performed and included in the 60% design.	Okay pending review of the evaluation in the 60% design		Comment resolved.	See Appendix C (Design Criteria).
129	DTSC-49	Page 3-13, Section 3.2.5.3, Flexibility and Redundancy		PG&E has proposed in Figure 3-1 many “provisional wells” along the IRZ, however, there are no rationale for these wells, nor are they mentioned in this section or part of the design discussion in 3.2.5. If these wells are proposed as provisional wells, they should be discussed.	Additional details regarding the purpose and locations of provisional wells will be clarified in the 60% design submittal.	Okay pending review of 60% design		Comment resolved.	See Sections 3.2.2, 3.2.3.1, and 3.2.5.3, and Appendix L (O&M Manual, Volumes 2 and 3).
130	DOI-33	Section 3.3/entire section		There is limited discussion of monitoring the fresh water supply for water quality indicators during remedy implementation. Please provide additional discussion of how the fresh water supply will be monitored (i.e. frequency, water quality parameters) to ensure that the water quality remains suitable for use.	The forthcoming O&M plan will include a monitoring plan for the final remedy, which will include discussion of monitoring for the fresh water source.		Okay pending review of O&M plan as part of the 60% design submittal.	Comment resolved.	See draft O&M Manual, Volume 2 – Sampling and Monitoring Plan (Section 5.2, Monitoring of Freshwater Supply Source).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
131	HA-20	p. 3-14, Section 3.3 (Freshwater Supply)		The discussion in this section and on Exhibit 3-3 indicates that in consideration of alternative locations for a freshwater extraction well, a location in the Park Moabi area was ruled out largely on the basis that its hydraulic influence would adversely affect the remedy. This begs a question as to the impact of a potential future private well offsite. What type of assessment was done to consider such a scenario? Additionally, please refer to comments of the TRC regarding the need to consider an alternative freshwater supply for the upgradient injection.	As described in Section 5 (Institutional Controls), model simulations were conducted to determine how close a private well would have to be in order to adversely affect the hydraulic performance of the remedy. Institutional controls are proposed for the area shown on Figure 5-1, to prevent private wells from being built within the area where pumping might adversely influence the remedy. In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Noted pending review of tech memo.	Noted pending review of tech memo.		See Appendix J of this BOD Report.
132	DTSC-50	General Comment on Section 3.3, Freshwater Supply		It is important that PG&E provides a rational and logical decision matrix for the freshwater supply. The decision should be based on objective data and reasoning which would layout and balance the pros and cons associated with each of the three potential freshwater sources prior to selection of the preferred source. The comments below highlight DTSC's issues associated with PG&E's conclusion and should be carefully evaluated and modified for the 60% design.	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Appendix J of this BOD Report.
133	DTSC-51	Page 3-14, 1st bullet	(e.g., a spare header for the conveyance of carbon amended groundwater).	A spare header is mentioned, but they are not reflected in the P&ID. Similar issue for the Clean In Place system.	Comment is noted. Spare headers will be called out in the P&IDs in the 60% and 90% submittals.	Okay pending review of future P&IDs		Comment resolved.	See Appendix D.
134	DTSC-52	Page 3-14, Section 3.3.1, Freshwater Supply Sources		The section introduces potential sources of freshwater supply for the remedial project and favors the HNWR-1 Arizona well and disfavors a California well or river source. Limitations of the California well or river source are summarized, however, limitations associated with the Arizona well are absent. Limitations/drawbacks of the Arizona well must also be mentioned in this section (e.g., excessive pipeline infrastructure, adverse water quality [arsenic, chromium], additional hydraulic effect that could send byproducts or chromium further into Arizona). As indicated previously, PG&E needs to prepare a comprehensive list of all water wells in the Topock area. The water quality of the wells should be tabulated and summarized. Exhibit 3-1 should be updated with this information. The exhibit should also include river water data for comparative purposes. Discussion with community members has indicated that water supply wells exist at the Topock Marina area adjacent to the I-40. If community member information is correct, these wells have not been identified in previous PG&E reports provided to DTSC. Although DTSC agrees with PG&E's criteria for evaluating freshwater supply options, PG&E has not provided sufficient data to suggest that the	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				HNWR-1 well to be the overall superior option. While PG&E argues that using an existing well would avoid disturbance, it fails to account for the extra miles of additional piping which must be trenched and installed outside of an area that is considered the project area. Equally important is that PG&E's current knowledge of the HNWR-1 well is that there are elevated levels of arsenic beyond the MCL, and hexavalent chromium concentrations above the localized concentrations which will be injected into California. Exhibit 3-3 states that "River water is low in dissolved solids, but contains suspended solids, microbes, and trace contaminants, such as perchlorate, pesticides, herbicides, and pharmaceutical compounds. River water could not be injected without conditioning." DTSC currently does not have data suggesting that there are elevated concentrations of the suggested contaminants found within the river water within the project area. The basis for such a statement has not been established. Furthermore, the design document should indicate if disinfection would truly be needed. Will conventional well water require filtration or disinfection? What specific analyses and criteria will be conducted to determine if disinfection and filtration are necessary? DTSC understands that PG&E currently has in-line filters for the water imported from wells Topock 2 and 3. Is the necessary conditioning system similar? The document should respond to these issues. Exhibit 3-3 continues with "Construction of a river intake structure or subsurface infiltration gallery would be likely result in more disturbance than drilling of a well. Depending on where the intake was located, the length of buried pipeline could [be] less than for either of the other two options. Additional disturbance associate with potential conditioning plant construction." DTSC agrees that the needed pipeline WILL be less than for either options. PG&E also states that "much of the river intake construction disturbance could be mitigated if permission could be obtained to mount the river intake from the I-40 or the railroad bridge." Given that statement, PG&E has not demonstrated to DTSC that this design is infeasible, especially for similar design at pipeline bridges. This section also mentions that groundwater in the shallow zone from a "river well" beneath the river would contain water that is geochemically reduced with elevated concentrations of iron and manganese, which could foul the injection wells. First, isn't this issue already a concern for amended injection wells. Won't river bank extraction wells also eventually exhibit reducing					

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				conditions and potentially foul or foul injectors and therefore require a conditioning system? Could the "river well" be designed to preferentially filter oxic water from the river and minimize concerns with reduced water? The document should conduct an in-depth evaluation of the different systems that could be utilized for designing a direct river intake that would minimize or eliminate filtration concerns (e.g., Can a manufactured filter pack be placed over the inlet screen to the intake). What range of filtration systems could be designed to accommodate the remedy? Does infrastructure currently exist for importing water to the station or near the station from a water supplier or alternative source? Can blending water sources be considered to address limitations and utilize strengths of the different options? PG&E must provide a balanced evaluation considering the adverse impacts of the groundwater based on current understanding of the water quality from HNWR-1.					
135	DTSC-53	Page 3-14, section 3.3.1 Freshwater Supply Sources	In addition, pumping freshwater from this area [at Park Moabi] would have an adverse effect on the performance of the remedy.	The section indicates that pumping 600 gpm from a well near Moabi Regional Park would decrease the flux across the IRZ line by about 7%. The report should quantify the significance of this flux decrease. Furthermore, this amount has not been substantiated with the model. Would river leakage mute adverse hydraulic effects if a Park Moabi well was put near the river or on the Park Moabi peninsula? Is this properly accounted for in the model? Furthermore, this amount of change should be easily alleviated by proper engineering of hydraulic movement which PG&E did not discuss. The section concludes by stating, "Because pumping freshwater from a hypothetical well near Moabi Regional Park well PM-03 or an area closer to the Compressor Station would have an adverse effect on remedy performance, the preferred option with respect to this criterion is to pump freshwater from a well in Arizona or from the river." The section should state how far north or west (or east) of Park Moabi a well would need to be located to have minimal adverse effect on remedy performance.	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Appendix J of this BOD Report.

136	Hualapai-24			Water Rights for Fresh Water Wells The source of fresh water for the Topock project is planned to be supplied from one or more wells located in Arizona. The water rights and legal points of diversion for these wells must be presented to the Tribes to prove that PG&E can lawfully divert water from the Mojave Basin aquifer. The riverbank extraction wells, if operated, will undoubtedly draw Colorado River water through the organic layer into the extraction wells. The water rights and legal points of diversions for these extraction wells must be presented to the Tribes to prove that PG&E can lawfully pull water from the sacred Colorado River.	The scope of PG&E's existing water entitlements were described and assessed in Chapter 4.12 of the EIR that was certified by DTSC (and in the Draft EIR that was circulated for review and comment). This analysis included both the amount of water needed for the project and the points of diversion. The EIR concluded, "Any of these points of diversion are permitted" under PG&E's existing Lower Colorado Water Supply Project entitlements. The EIR evaluated water use during construction, during operation, and during decommissioning of the remedy, and in each instance, the EIR concluded that the existing entitlement was more than sufficient to serve the project needs. Given that this issue was fully disclosed and assessed in the EIR, the commenter is referred to that document.	Comment and response noted	Comment and response noted.		
137	Hualapai-25 and TRC-16			Water Rights for Fresh Water Wells Also, the current fresh water supply for the remedy is the single well, HNWR-1. There presently appears to be no alternative for water supply to the site. Are the existing TCS supply wells Topock-2 and Topock-3 intended to provide a contingency source for injection water to maintain a positive groundwater flow? **TRC Recommendation:** Discussion of fresh water supply alternative/contingency should be included in the 60% design report.	Currently, HNWR-1 is proposed as the primary well to supply the freshwater injection system for the groundwater remedy and the compressor station. To date, pumping conducted by the Refuge indicate that HNWR-1 is likely able to supply sufficient water for both purposes (planning is underway for additional pump test at this well). The current supply wells for the compressor station (Topock 2 and 3 wells) would remain connected as a back-up supply, although at present it is not certain that these wells would have sufficient capacity to supply the compressor station, the groundwater remedy, and the other customers of Southwest Water company. Additional discussion about freshwater contingency plans and the results of aquifer testing at both Topock 2 and 3 and HNWR-1 will be provided in the 60% design submittal.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of supplemental fresh water supply information and the 60% design submittal.		See draft O&M Manual, Volume 3 – Contingency Plan for freshwater contingency plans. The Topock-2/3 pump test results are summarized in a tech memo that is included as an attachment to the RTC table in Appendix J The pump tests are also discussed in Section 3.3 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
138	Hualapai-32			Further Considerations for 60% Design Evaluation Fresh-water from other sources and injected into the Site ideally would have water-quality characteristics similar to the aquifer geochemistry corresponding to different levels of the aquifer (shallow, middle, and deep). This means that for injections in the shallow part of the upland aquifer, TDS concentrations of injected water should to be on the order of 2,000 to 4,000 mg/L, for the middle level 4,000 to 6,000, and the for the deep aquifer TDS concentrations need to be 6,000 to 12,000 mg/L, depending on the location. The concern is that disparities in introduced water would result in density-driven fingering of injected waters that would be compounded with the geologic heterogeneities and result in a prolonged remediation time frame.	See response to comment HA-8a. The variation in density over the majority of the site is not considered significant enough to cause density-driven fingering. However, fingering due to aquifer heterogeneity is fairly common, and the monitoring program will be used to detect concentrations that deviate from model predictions due to fingering and other processes. Aquifer heterogeneities were modeled in the floodplain (where data are plentiful) during calibration with PEST. Additional heterogeneities that give rise to unexpected groundwater levels and/or concentrations will be identified by monitoring and incorporated into the model as necessary. The revisions to the model will assist in adjusting pumping or injection rates if necessary to minimize cleanup time.	Comment and response noted.	Comment and response noted.		
139	DOI-35	Section 3.3.1.1/ 3-15/ Last Paragraph		It is stated that the current design flow rate for freshwater injection is 600 gpm. This value does not align with the fresh water extraction flow rates (minimum, nominal, maximum) in Exhibit 3-4. Please explain.	The text will be revised to clarify that the current design and modeled flow rate for freshwater injection is 550 gpm. The freshwater supply extraction flow rates in Exhibit 3-4 included the freshwater usage of 110 gpm by TCS (see footnote a).		Okay	Comment resolved.	See Section 3.3 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
140	DTSC-54	Page 3-15, Quantity of Water Available	"During remedy implementation, several of the Freshwater Injection Wells will be installed in areas where no previous wells have been drilled and hydrogeologic conditions are unknown. If the aquifer is more transmissive than anticipated in these areas, additional freshwater would be needed to create the gradient necessary for remedy operation. On the other hand, if the aquifer is less than transmissive than anticipated, less water would be needed."	DTSC is concerned by the statement that drilling is occurring in areas where no wells have been drilled and hydrogeologic conditions are unknown. All the proposed "FW" wells are located at or in close vicinity to existing wells. Furthermore, groundwater modeling based on site (as well as regional) hydrogeology is controlling remedy design and selection. The cited text must be revised. DTSC does request that PG&E locate the old "resort" well on figures (this well had been noted in older PG&E documents) and indicate what information is available from this well as it is located in the same area as FW-INJ-1.	In the alluvial fan depositional environment of the Topock site, hydraulic properties can vary dramatically over a distance of several feet. The groundwater model grid cells are intentionally made large enough to be able to average this small scale variability, however at the scale of a well, (a foot or so in diameter), there is potential that hydraulic conditions considerably different from average may be encountered. Only one of the proposed FW wells (FW-INJ-2) is nearby a location where aquifer testing has been conducted to estimate hydraulic properties of the aquifer. PG&E is unaware of any aquifer test data or well logs for the former well at the former Rancho Colorado near FW-INJ-1, but will locate and provide all available information for that former well in the 60% design. It is unlikely that any information regarding the former Rancho Colorado well will significantly decrease the uncertainty regarding performance of proposed well FW-INJ-1. Near Well FW-INJ-4 the aquifer pinches out. Well XM-9, drilled in bat cave wash just south of this location, was dry. No aquifer tests have been conducted in this area. The nearest test was a step-drawdown test at TW-1, but this location is outside the influence of that test. There is no way to be certain that the FW wells will be able to achieve the design flows until those wells are installed and tested. PG&E believes the original text accurately captures the uncertainty inherent in predicting the performance of new wells in an alluvial fan environment.	Okay		Comment resolved.	
141	DOI-34	Section 3.3.1.1/ 3-16/4th Paragraph		The 900 gpm flow rate for HNWR-1 is less than the 1,310 gpm maximum flow requirement identified in Exhibit 3-4 for the freshwater supply line. Calculations should be provided to substantiate that there will be adequate yield from this well for the Topock remediation project during peak water demand. Also, flow demand for HNWR's continued use of this well for irrigation needs to be accounted for, and if there is no demand, then it should be documented.	According to information received from US Army Corp of Engineers, well HNWR-1 produced 900 gpm with a pumping water level at 80 feet below land surface during the initial testing. During the subsequent revegetation project, the HNWR-1 well was pumped at rates exceeding 1,000 gpm for periods of 12 hours or more. The well screen extends from a depth of about 92 to 157 feet. PG&E will coordinate with the Refuge on the HNWR's demand for this well and to evaluate the well capacity to meet this and other needs.	Okay.	Okay.	Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
142	DTSC-55	Page 3-16, Quantity of Water Available	"PM-01 was used for several years, but reportedly produced relatively poor quality water with a TDS concentration of 3,000 mg/L. Well PM-02 was tested at 430 gpm but there was no record of the drawdown so no estimate of specific capacity could be made. Both of these two wells had mineralized water. The water from PM-02 was so saline that it was considered unusable and the well was apparently never put into production (LeRoy Crandall & Associates, 1986)."	Park Moabi area: The document should determine where the best location for a well in California might be located. This may be based on geology as well as historical pumping. Pumping data from PG&E test wells (TW wells) as well as IM3 extractors, injectors, etc. should also be cited as they are representative of California conditions. Data from "PMM Supply" from the Background Study must be cited and evaluated. It is suggested that hydraulic data be collected from PM-01 and PM-02 due to higher yields. The section comments (see column to left) on the poor water quality of wells PM-1 and PM-2 even though it is not the appropriate section to be commenting on water quality. More importantly, poor water quality is not defined. The "poor" TDS quality of 3,000 mg/L (note that the 3,000 mg/L value cited appears to be an error as PG&E data indicates TDS ranged from 800 to 1,000 mg/L circa 2005 to 2006 in PM-1) cited may be quite satisfactory for injection during the remedy since the injection area TDS ranges from approximately 1,000 mg/L to 6,000 mg/L depending on depth. The document must discuss desired injection water quality in detail and indicate that IM-3 injection wells have always been injecting treated water with TDS around 4,000 m/L into the FW-INJ-2 locale. The discussion on "poor water quality" should be rewritten for the 60% design. PM-01 analytical data must be summarized and tabulated. See comments above and below regarding PM-01 as the data from this well is not being properly accounted for and summarized. Arizona Wells: All data from Topock 1 must be included in the report including the reason why it was abandoned and replaced with Topock 2 and 3. Other wells in Arizona should be evaluated (see comments above). The results of upcoming hydraulic testing on HNWR-1, Topock 2 and Topock 3 should be provided to DTSC asap and incorporated into this document. The quality of hydraulic testing on Topock 2 and 3 should be stated as it is noted that old pump data are cited to characterize well hydraulics. From the quantity perspective, this section must conclude that the river is obviously the most proven source of water supply in the area and scores above California and Arizona wells.	The PMM Supply well referred to in the Background Study Report is well PM-03. It was considered in the evaluation. This point will be clarified in the text. In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
143	DTSC-56	Page 3-18, Paragraph 2, Water Quality and Potential Need for Pre-Conditioning Prior to Injection	'As noted in Exhibit 3-1, one of the wells drilled at Moabi Regional Park (well PM-02) produced highly mineralized water and was never put into service. The other high-capacity well (PM-01) produced water with a TDS concentration around 3,000 mg/L. Based on the relatively high mineral content of the water, there is some doubt whether a well at Moabi Regional Park would produce water that is geochemically compatible with the injection wells and the aquifer at the Topock site."	The second paragraph discusses "the relatively high mineral content of the water" without discussing quantitative water quality needs for injection. The discussion is poor and misleading as IM-3 injection water of 4,000 mg/L is not discussed and has been operating successfully for over 5 years. The text should be stricken and a balanced evaluation conducted. See comments on "poor water quality" above. Exhibit 3-1 does not cite appropriate information for well PM-01. PG&E sampled this well as part of the background study (November 2009) six times from 2005 and 2006 for a large suite of analytes and identified it as well "PMM-Supply". How PG&E came to overlook this data is concerning as it has direct bearing on Park Moabi supply well evaluation. Exhibit one should be modified to indicate that the casing depth of PM-01/PMM-Supply is 180 feet and not 190 as reported as based on Table 2-1 of the 2009 background study report. The perforated interval should be revised to indicate a dual screen from 28-42' and from 65-180'. Unlike that stated in Exhibit 3-1, PM-01 data for chromium and arsenic are available. Cr(VI) measures about 9ug/L while arsenic is around 2 ug/L. All data should be accurately tabulated in Exhibit 3-1 or an equivalent table. Provide a detailed discussion regarding geochemical compatibility of imported water in the section. Discuss IM-3 injection water quality data in the section as well. Data from the 2009 background study report must be utilized. Figure 2-4 of that report displays a Piper diagram that indicates that the PMM-Supply is geochemically similar to the site as it plots near site wells P-2, MW-10, MW-11, MW-17, and MW-18. This is contrary to what is stated in this section. Piper diagrams must be utilized in the geochemical discussion in this and other appropriate sections. Data tables should be prepared listing all Park Moabi analytical data for water wells. Additional Park Moabi analytical data should be collected as the document indicates that the data base is not extensive (However, note comments referring to existing data from PMM-Supply). The trace metal data discussion in this paragraph must be rewritten as the PMM-Supply data (most extensive and comprehensive dataset for any well evaluated in the freshwater supply section) that was overlooked by PG&E indicates that the water is of high quality. Manganese, iron, and total suspended solids are very low or below low detection limits suggesting that pre-conditioning prior to injection would not be needed. Trace metals are also low including the constituents arsenic and Cr(VI) - see Exhibit 3-1 discussion above. Based on this information, the section	The PMM Supply well referred to in the Background Study Report is well PM-03. It was considered in the evaluation. This point will be clarified in the text. In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				must conclude that the water quality of PPM-Supply well is superior (low minerals, low plugging/fouling potential, low trace metals, and geochemically compatible) to all other water wells.					
144	DTSC-57	Page 3-18, Paragraph 3, Water Quality and Potential Need for Pre-Conditioning Prior to Injection		As previously discussed with PG&E, additional HNWR-1 analytical data should be collected since, as stated in the document, that the well has only been sampled once. Any conclusions regarding the water quality of this well are therefore provisional. Sound decisions cannot be made without adequate data and data evaluation. Data tables should be prepared listing all HNWR-1, Topock 1, 2, & 3 analytical data. Analytical data for other Arizona water wells should also be tabulated.	In coordination with the Refuge, the HNWR-1 well was sampled on February 23 and March 14, 2012, and will be sampled again in April. Data will be incorporated into the forthcoming technical memorandum on freshwater sources evaluation.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.
145	DTSC-58	Page 3-18, Paragraph 4, Water Quality and Potential Need for Pre-Conditioning Prior to Injection		The section should discuss the following issues about hexavalent chromium. First, data regarding chromium should be appropriately summarized (e.g., well data should not be omitted - see PMM-Supply discussions above). The document should note that the HNWR-1 well exhibits a hexavalent chromium concentration about double PMM-Supply. DTSC desires that as low a hexavalent chromium concentration as possible be used for freshwater supply due to its toxic nature and since the uncontaminated aquifer area planned for freshwater injection exhibits very low to nondetect chromium concentrations at depth that increase upward in the aquifer profile (see Figures 2-3 a, b, and c of the document). Chromium added to the deeper portion of the aquifer could result in a potential increased risk/threat as a result of implementing the remedy. The section should acknowledge this concern and include it as criterion used to evaluate freshwater supply sources. The issue is not to simply pick a value below the regional background value of 32 ug/L. The section should conclude that the river would be the superior source of water with respect to hexavalent chromium concentrations as proven by the massive river data base that are typically nondetect for chromium (even excluding non-PG&E data bases).	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.
146	DTSC-59	Page 3-18, Paragraph 5, Water Quality and Potential Need for Pre-Conditioning Prior to Injection		The arsenic section must be rewritten. The section must acknowledge that the regional background arsenic UTL of 24.3 ug/L is inappropriate for the site as a screening criteria for freshwater injection (See DTSC comments on the Revised Groundwater Background Study dated February 29, 2008). The section should indicate that the average concentrations of arsenic in the vast majority of site monitoring wells are below the background UTL of 24.3 µ/L. The section should mention that Figure 2-7 of this document illustrates that arsenic concentrations are approximately 3 ug/L in all portions of the	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				aquifer where freshwater injection is planned. The section should also cite the 2009 regional background report and include Figure 2-7 from that report which illustrates that the highest arsenic concentrations in the region, which are greater than MCLs, occur in the immediate vicinity of well HNWR-1. The section should further state that the background report suggests potential hydrothermal activity in Arizona is associated with the elevated arsenic. DTSC requests that areas outside the area of elevated arsenic and hydrothermal activity also be evaluated for freshwater supply. DTSC has concerns with importing and injecting water containing arsenic above the MCL and above site specific background concentrations on the California side of the river. In addition, DTSC is concerned with ARAR compliance such as meeting Basin Plan standards established by the Regional Water Quality Control Board. DTSC is reluctant and may not be allowed to authorize injection of imported water into the ground that exceeds MCLs and degrades the aquifer. DTSC desires that as low an arsenic concentration as possible be used for freshwater supply due to its toxic characteristic. Typical arsenic (and other analytes) concentrations of river water should be discussed and documented. The section should conclude that based on existing data, well HNWR-1 has the poorest water quality with respect to arsenic in the study area.					

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
147	DTSC-60	Page 3-18, Paragraph 5, Water Quality and Potential Need for Pre-Conditioning Prior to Injection		Arsenic modeling simulations are discussed in this section and suggest that elevated arsenic above MCLs from well HNWR-1 would naturally adsorb to iron oxides in the aquifer matrix when injected into California waters leaving a minimal arsenic footprint. The section must comment on potential well fouling associated with HNWR-1 arsenic (and any other constituents) precipitation into the pores throats of the formation during injection as the section postulates that arsenic is removed in such a manner. The section must clarify how Arizona water that is argued to be geochemically similar in the preceding paragraphs, would then become dissimilar with respect to arsenic when injected in California. The section must indicate why dissolved arsenic is stable in aerobic waters withdrawn from well HNWR-1, but would become unstable when injected into aerobic waters in California. The section should also cite that it was not anticipated in prior documents, that freshwater supply injection would entail injecting water with detrimental constituents at concentrations above an MCL into aquifers containing concentrations less than MCLs.	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.
148	DTSC-61	Page 3-20, Paragraph 1		As stated earlier, there is speculative discussion regarding trace pollutants in the River. River data for the <u>specific area</u> must be cited to support assumptions and quantify any valid concerns. Have trace river pollutants been discovered at the Topock site area? Have these pollutants migrated into the aquifer due to IM-3 pumping or injection? The section must indicate what testing has already been conducted in the Topock area to ensure PG&E's concerns with trace river pollutants have not already adversely impacted the aquifer that we are trying to clean up? PG&E should evaluate its own data set as well as others for the Topock area (e.g., MWD). PG&E must also discuss and evaluate how pumping from freshwater supply wells could draw river water (polluted or not) across aquifers and towards pumping centers. This portion of the paragraph needs to be revised. The paragraph concludes that "water from the river or from a river infiltration gallery is not preferred based on the criteria of water quality." This statement cannot be made without river water data to support it. DTSC recalls that MWD's river data base for the area did not exhibit elevated trace metals and that testing did not detect perchlorate. It would therefore seem that the river would have superior water quality. See comments above on section 3.3.1 Freshwater Supply Sources (Page 3-14) related to freshwater filtration and conditioning. Based on existing information in the document, PG&E will need to	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				make a good faith effort addressing design of a river water conveyance system and any needed conditioning. Conditioning systems already planned for the remedy should be discussed and summarized for comparative purposes. This will allow an educated assessment of the various freshwater sources.					
149	DTSC-62	Page 3-20, 1st paragraph	In addition, water pumped from an infiltration gallery would likely contain elevated concentrations of iron and manganese due to the geochemically reducing conditions present in the fluvial sediments surrounding and underlying the river.	PG&E has not provided fresh water selection criteria on what concentration would be acceptable for the remedy to discount the use of infiltration gallery. Furthermore, in reviewing the concentrations from the California slant wells, the manganese concentration ranged from 200 ppb to approximately 2.5 ppm where most of the higher concentrations are from MW53D. Iron data ranged from 100 ppb to 7 ppm where most of the ppm range data are from the shallow well 52S. Is it possible to design the infiltration gallery to target zones with lower concentrations of unwanted constituents?	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.
150	DTSC-63	Page 3-20, Paragraph 2, Disturbance Associated with Construction	"The river intake structure would likely represent the greatest level of disturbance both during and after construction of any of the three options. Much of the river intake construction disturbance could be mitigated if permission could be obtained to mount the river intake from the I-40 or the railroad bridge."	The section will need to be revised to explain and support the contention that the river intake structure would likely represent the greatest level of disturbance. It is not clear what criteria are being used to make this assessment. Is it volume of soil disturbed? Is it aesthetics? Is it time taken to construct? It is also not clear what PG&E is envisioning for the structure and what range of intake designs exists that would address the needs of the remedy. PG&E should attempt to consider an intake design with as minimal a disturbance as possible. The document should clarify why the freeway or railroad bridge are cited for mitigating disturbance. The section should also comment on why the other bridges to the south are not being considered. Also see comments above on section 3.3.1 Freshwater Supply Sources (Page 3-14) related to freshwater filtration and conditioning.	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
151	DTSC-64	Page 3-20, Paragraph 3, Disturbance Associated with Construction	"Based on a preliminary evaluation of the type and amount of construction for the three identified options, using the existing HNWR-1 well in Arizona is the preferred option. By using an existing well, which has already been proven to provide an adequate quantity and quality of water, additional well drilling would be avoided." "If wells at Moabi Regional Park were selected as the water source, it is likely that several wells would need to be drilled in order to find a sufficient quantity and quality of water."	This section needs to be rewritten pending additional data to be collected for both the PMM-Supply well and HNWR-1 well. In addition, PG&E should also include a better analysis and evaluation of the river intake option. It is premature to select the HNWR-1 well based on the evaluation presented in this document as it lacks specifics with respect to evaluation criteria as well as data to support selection. The section should indicate that the water quality of HNWR-1 has not been proven and that the one sample collected from it so far yields elevated arsenic and hexavalent chromium. The disturbance associated with it also seems significant (significant length of buried pipe and a bridge span). Please clarify how the quantity of water from HNWR-1 has been proven (How many times has it been hydraulically tested? For how long and what rate and drawdown? What is its normal pumping rate? How many hours has it pumped water?) The same questions apply to any well being considered. The section should comment that the PMM-Supply water quality appears satisfactory, if not superior, when compared to other wells. Clarify why several wells would need to be drilled at Park Moabi (clarify the desired pumping rate and water quality for the remedy). PMM-Supply yields superior water quality at relatively high yields. If it still didn't provide sufficient quantity, wouldn't one just install one well in a neighboring area? What happens if HNWR-1 cannot provide a sufficient quantity of water either short term or long term?	As mentioned in response to comment #144 DTSC-57, the HNWR-1 well was sampled, in coordination with the Refuge, on February 23, 2012, and will be sampled again in March and April. Data collected will be summarized in the forthcoming tech memo. As mentioned in responses to comments #142 DTSC-55 and #143 DTSC-56, PMM-Supply well (in the Background Study report) is also called PM-03. Well PM-03 has been sampled on an annual basis and was recently sampled in the December 2011 annual event. Data will be summarized in the forthcoming tech memo. In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.
152	DTSC-65	Page 3-20, Paragraph 4, Disturbance Associated with Construction		This paragraph needs to be rewritten pending additional data and analysis. See previous comments on water quality, disturbance, conditioning, and water compatibility.	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.
153	DTSC-66	Pages 3-20 and 3-21, Preferred Freshwater Supply Option to Carry into Design		This paragraph and Exhibit 3-3 need to be rewritten pending additional data and analysis. See previous comments on water quality, disturbance, conditioning, and water compatibility. Based on the limited evaluation presented in the document, DTSC favors the river intake structure with filtration.	In response to this comment, a technical memorandum will be prepared to present the evaluation of the three potential freshwater sources and PG&E's conclusion.	Okay pending review of TM		Comment resolved.	See Section 3.3 and Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
154	DOI-36	Section 3.3.2/3-22/ Exhibit 3-4		The minimum, nominal, and maximum freshwater extraction and injection flows do not balance. Is this to be interpreted that the injection flow rates relate to well design only? The nominal and maximum design flows for UPGRAD-INF-4 are the same value. Is this a mistake? Per footnote d, the pipeline capacity of 1,310 gpm is based on maximum flow to freshwater (600 gpm) and carbon amended injection wells (600 gpm) (plus TCS usage). The 600 gpm values cannot be gleaned from any information in Exhibit 3-4.	Exhibit 3-4 will be revised to clarify the following points: 1. The minimal, nominal, and maximum flow rates for the wells represent the design flow rates established for each of the individual wells. The total minimal, nominal, and maximum flow rates have been established through groundwater modeling scenarios throughout the remedy duration, and therefore the aggregate flow rates for the minimum and maximum do not balance. The minimum flow rate indicates that one or more injection wells are not used (for example FW-INJ-2). The maximum flow rate scenario indicates that the provisional well (FW-INJ-3) would be in operation. 2. The nominal and max flows of 200 gpm for UPGRAD-INJ-4 as summarized in Table 3-2 are correct. This flow rate was employed in the nominal and maximum scenarios. Under all scenarios, freshwater will be injected into UPGRAD-INJ-4. 3. The current design and modeled flow rate (shown in Appendix B) for freshwater injection is 550 gpm (200 gpm for UPGRAD-INJ-4, 100 gpm each for FW-INJ-1, FW-INJ-2, and UPGRAD-INJ-3, and 50 gpm for FW-INJ-4). In addition, the compressor station has a demand of 110 gpm. The nominal flow rate in Exhibit 3-4 will be revised to 660 gpm. 4. The conveyance pipe for freshwater from AZ will be sized to accommodate the max aggregate flowrate for the entire Outer Loop injection well network (including FW-INJ-4) of 600 gpm (see footnote d of Table 3-2), the max aggregate freshwater flow rate for the Inner Loop injection well network (e.g., UPGRAD-INJ-2, UPGRAD-INJ-3, and UPGRAD-INJ-4 are receiving freshwater at the maximum flow rate) of 600 gpm, and TCS usage (110 gpm). The maximum flow rate in Exhibit 3-4 will be revised to 1,310 gpm.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See Exhibit 3.3-4 of this BOD Report.
155	DOI-37	Exhibit 3-4		The exhibit indicates that a fourth fresh water injection well may be installed, if necessary. Please indicate on a figure possible locations for installation of the fourth fresh water injection well.	If it is not possible to inject a sufficient quantity of water in one of the three primary locations, a fourth injection well may be needed. It would likely be located somewhere near the location where additional injection capacity was needed. Possible locations for this well will be provided in the 60% design.		Okay pending review of 60% design submittal.	Comment resolved.	See Figure 3.0-1 of this BOD Report.

APPENDIX I

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
156	DTSC-67	Page 3-23, Exhibit 3-4, and Page 3-24 1st Paragraph	Superscript of Pipeline capacity, 1310 gpm. "[d] This total includes the maximum flow to Carbon-amended Injection Wells (600 gpm) and Freshwater Injection Wells (600 gpm) plus the maximum for TCS usage (110 gpm)." Also, "to accommodate potential future operational changes associated with the remedy while maximizing the use of existing facilities, the design incorporates the current freshwater supply system for the Compressor Station."	According to PG&E during telephone discussion on February 8, 2012, PG&E is evaluating the fresh water supply infrastructure separately from current TCS usage except for common components such as water storage tank. PG&E stated that the water supply for TCS use will continue to be Topock 2 and 3 wells. However, the cited text suggests the contrary that the design parameters would include TCS operational usage of 110 pgm. See also Figure 3-10 flow diagram from Fresh Water Supply Well (HNWR-01). PG&E should clarify if operational uses at the TCS are accounted into the design. DTSC believes that tying Compressor Station needs into the remedy is outside the project scope and has not been accounted for in previous documents and potentially limits, unnecessarily, selection criteria that should be developed for selecting a freshwater source (e.g., total flow demand for the remedy is stated to be a nominal 250 gpm, but 360 gpm if Compressor Station needs are added to flow demands). There is no apparent need to potentially burden the groundwater remedy with the needs of an unrelated project. If there is desire by PG&E to share infrastructure (e.g., Compressor Station storage tanks), then the infrastructure should be operated or retrofitted to accommodate separate systems, if needed, or replaced by new infrastructure. Exhibit 3-4 should be revised to address these concerns.	The February 8, 2012 discussion was centered around the rationale for certain planned infrastructure (specifically the freshwater supply storage) associated with freshwater supply from Arizona. PG&E explained that for storage, the shared use of the existing TCS freshwater storage tanks (currently receives water from Topock 2/3 wells) minimizes the need for installation of a separate new tank and is consistent with the mitigation directives to use existing facilities where available. In addition, PG&E explained that since the existing tanks also receive Topock 2/3 water, this means that Topock 2/3 well water can serve as a backup to the HNWR well water, which could minimize the need for another well to be drilled in Arizona. This aspect will be verified in the 60% design submittal. Because of its relatively small volume, the Compressor Station water usage does not drive/impact the size/footprint of planned remedy infrastructure (e.g., the 12-inch freshwater pipeline from HNWR well to the existing TCS storage tanks). A new freshwater line is needed to convey water from AZ regardless, and the size of this line is not impacted by the 110 gpm TCS usage.	Okay.		Comment resolved.	

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
157	DTSC-68	Page 3-24, Section 3.3.2 Design Basis for Freshwater Supply System	"To accommodate potential future operational changes associated with the remedy while maximizing the use of existing facilities, the design incorporates the current freshwater supply system for the Compressor Station. The Compressor Station's current water need (approximately 110 gpm) is served by Topock-2 and -3 supply wells in Arizona; the freshwater is conveyed via a pipe crossing the Colorado River on the arch bridge. Coordinating with the Compressor Station's water supply allows for the potential increase in freshwater demand by the remedy to be met with minimal additional infrastructure (see Section 3.3.2.2 for details)."	The document must clarify what is being stated. Are separate pipelines from Topock 2/3 and another freshwater source being proposed? It appears that water from Topock 2/3 is proposed to be mixed with the remedy freshwater in the storage tanks. If this is indeed the case, then the section on freshwater quality must acknowledge this blending of waters and highlight Topock 2/3 water quality. A comprehensive listing of all data from Topock 2/3 is necessary. As DTSC has concerns with elevated hexavalent chromium and arsenic that are also present in Topock 2/3, the mixing of Topock 2/3 water with the freshwater source may also be of concern.	The existing pipeline from Topock 2/3 will remain as is. There is a new pipeline conveying freshwater from the HNWR well proposed in the 30% design. The Topock 2/3 water quality will be presented in the forthcoming Freshwater Water Supply Source Evaluation Tech Memo (see response to comments #142 DTSC-55 and #144 DTSC-57)	Okay		Comment resolved.	See Appendix J of this BOD Report.
158	DTSC-69	Pages 3-24 to 3-25, Section 3.3.2.1 Freshwater Supply Piping Network	With the current preliminary design, the primary benefit of a looped system is having the operational redundancy and flexibility to minimize unplanned downtime over the decades-long life of the remedy. The energy savings associated with a looped system are small given the current design since most of the freshwater injection flow will not require pumping. This could change if the final design is different. As currently designed, the looped segment is less than 2,200 feet long or just over 10% of the total freshwater pipe length (21,200 linear feet).	The desired operational redundancy should be weighed closely against Tribal concerns as the redundant Bat Cave Wash loop is located adjacent to the Maze. The section should also comment on the long term repairs to the Bat Cave Wash segment knowing that periodic storm events can destroy infrastructure located in this particular wash. The reason postulated for the loop is that it would minimize remedy downtime. It is uncertain how big a concern downtime is at this point. A discussion of downtime should be presented that lists disadvantages and assesses if they are critical over the short and long term.	The draft O&M Manual will include a section that discusses pipeline maintenance. The draft O&M Manual is part of the 60% design submittal. In the 30% design, PG&E proposed a looped configuration in the piping, power, and control systems to provide more system reliability. A looped system offers redundancy in critical utility connections which are often difficult to access and repair. With a looped system, most final remedy wells could be served from either direction in the loop, allowing many of the wells to remain in operation while repairs were made to underground utilities. Other benefits of a looped system commonly include reduced energy usage due to lower pressure losses. For this project, the energy savings are small since the primary pumping is for well backwashing; this occurs infrequently and the injection lines are gravity fed so no energy is required.	DTSC will review the design as it becomes available.		Comment resolved.	See Figure 3.0-1 of this BOD Report. The Bat Cave Wash piping corridor has been eliminated; piping is routed through the NTH piping corridor and crosses Bat Cave Wash on two aerial crossings.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				Could the looped system in Bat Cave Wash be replaced with a longer loop that would simply double back in existing trenches?	It is important to note that, in contrast to IM-3 which is designed to reverse the natural gradient in the floodplain, the Final Remedy is designed to enhance the natural groundwater gradients at the site. If the Final Remedy is shut down, the natural gradient will continue to move the chromium plume across the IRZ barrier, but at a slower rate. The NTH IRZ is designed to operate passively for long periods with no carbon substrate injection. Consequently, short periods of downtime will not have a significant effect on the ability of the remedy to meet RAOs. In contrast, relatively short periods of IM-3 downtime during times of low river level can result in a failure to meet the IM-3 goal of gradient control. Therefore the design of the Final Remedy can be more tolerant of failures that would result in short periods of downtime than was possible with IM-3. The remedy design should therefore focus on prevention of failures that could result in long periods of downtime, lasting several weeks or months which, over the life of the remedy, could add significantly to the overall cleanup time. The effects of downtime depend in large part on the location and nature of the failure. PG&E anticipates most failures of mechanical or electrical components can be repaired within a few days to weeks. There will be an appropriate level of spare parts and service capabilities to respond to component failures quickly. Failures of underground piping, power, or control links could take longer to repair due to the difficulty of access. The loop system was one way to provide redundancy in the utility links. Providing redundant piping and conduits in a common trench is another option for including redundancy. In response to DOI's and DTSC's direction (see comment #182), the 60% design submittal will include a modified design to eliminate the Bat Cave Wash segment. It is feasible to loop the system by doubling back in the piping corridors on National Trails Highway and on old route 66 without going through Bat Cave Wash. The main drawbacks are the increased pipe lengths and increased trench widths (e.g., additional pipe lengths of 17,000+ feet for freshwater, 17,000+ feet of electrical conduits, etc.). The drawback will be magnified under an aboveground piping scenario.

PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
159	HA-21	p. 3-24, Section 3.3.2.1 (Freshwater Supply Piping Network)		The first paragraph indicates that of the total 21,700 feet of freshwater piping, approximately 25 percent, will be aboveground and 75 percent underground. What will determine this placement and is a map showing the aboveground vs. underground runs available? Please refer to Attachment B with regard to the Tribe's position on the placement of piping above vs. underground.	Figure 3-1 of the 30% BOD Report shows the aboveground vs. underground piping runs. This figure will be revised in the 60% design to reflect DOI's and DTSC's direction to modify the piping network to eliminate the piping/conduit segment in Bat Cave Wash. PG&E will evaluate the feasibility of additional locations for aboveground piping (in addition to locations already proposed in the 30% design) during the development of the 60% design. In general, the rationale for placing **electrical conduits** underground (versus aboveground) is as follows: <u>High voltage supply lines (from supply source to transformers)</u> – the National Electrical Safety Code (NESC or ANSI/IEEE C2-2007) is the American National Standard to which public or private US electric utility companies adhere to for design, installation, and maintenance of electrical supply lines. The NESC includes safety requirements for three types of utility construction: 1. Rules for Electric Supply Stations and Equipment (Substations) 2. Rules for Overhead Electric Supply and Communication Lines 3. Rules for Underground Electric Supply and Communication Lines Any design that does not conform to the requirements set out by the NESC is considered non-Code compliant. An above-ground, non-overhead, high voltage supply line is an example of non-Code compliant. <u>Low voltage distribution lines (after transformers to wells)</u> – Besides the risk of electrical injuries from contact, long runs of exposed electrical conduit also present additional design and O&M challenges because: 1. When the conduit is above ground and/or exposed to the sun, the wiring in conduit will be subject to extreme changes in temperature. This will cause the wire plastic or rubber covering to become brittle over time, and failures will be much more likely to occur. Repairs will be complex when the runs are long. Failures, depending on where they are, can take hours to days to isolate and weeks to repair. 2. Over long runs, the design will need to accommodate expansion and contraction of the conduit. The wiring does not expand and contract at the same rate as the conduit. This movement, can also lead to	Comment and response noted. DTSC notes that the certified FEIR included impact analysis for underground piping where possible based on information provided by PG&E on the conceptual design. Although DTSC recognizes the Tribes recommendation for siting pipelines and electrical transformers above ground, as discussed with the Tribes during the 3/20 meeting, other factors such as safety and regulatory constraints must be balanced with cultural resource considerations. DTSC agrees that the necessity of the pipeline network within the Bat Cave Wash be reevaluated.	Comment and response noted. The federal agencies have consulted with the Tribes on the 30% design with particular focus on this and related comments. The Tribes comments and the discussions which occurred during consultation meetings were considered in our direction to PG&E regarding modifications to the design including the implementation of the double-back loop along NTH, eliminating the BCW trenching. The federal agencies believe these design modifications take into account the impacts to the site and to some extent reduce the overall affects of the remedy on the cultural, religious, and spiritual values held by the Tribes for the TCP within the APE while recognizing our responsibility for protecting public safety, reducing ecological and visual impacts in the area. DOI, BLM, FWS and BOR are evaluating other options for above ground pipe runs, including in the areas adjacent to Old Route 66 and the Topock Compressor Station.		See Figure 3.0-1 of this BOD Report for piping alignment. PG&E further evaluated placement of piping in the utility corridor (underground or aboveground) during the 60% design development. Results of the evaluation are shown on Figure 3.0-1 of this BOD Report and the rationale is provided in Section C.2.2 of Appendix C (Design Criteria).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					failure. 3. The wire and conduit will need to be larger if aboveground than underground, due to the temperature derating that will be required per code. In some cases, this will require two conduits where the underground design would require only one conduit. Basically, this will increase the infrastructure and footprint required for this installation. For **freshwater and remedy produced water piping**, the rationale for placing them underground (versus aboveground) is to not only avoid increased visual impacts, but also to protect the health, safety, and free movement of humans and animals. It will also protect the integrity of the remedy infrastructure, and minimize remedy footprint and future O&M challenges. There are a number of roadways with a heavy volume of vehicular traffic in the project area, including National Trails Highway in CA, Mohave County Road 10 in AZ, and the Compressor Station access road. Pipelines within the ROW of these roads was all placed underground in the 30% design. If motor vehicle accidents were to occur on these roads, they could cause serious injuries and significant damage to properties and remedy infrastructure (e.g., a car hits a pipe rack or a utility pole). More specifically, aboveground utilities do not have a breakaway component to dissipate the energy exerted from a vehicle crashing into them such as a light pole or a traffic cabinet with a breakaway base. The pipes will remain stationary and cause greater bodily harm to the occupants of a vehicle as well as create a service disruption. Exposed utilities would require a protective barrier of some sort, such as a concrete barrier or enhanced guard rail, which would further increase the footprint. In addition, elevated pipe racks (where vehicular traffic or health and safety preclude a near-ground level installation) would require a structural footing advanced below surface, possibly to a significant depth. Depending on the geotechnical characteristics of the soils, driven pile foundations may be necessary. Further, given the inherent vulnerability of aboveground piping (members of the public have been known to shoot pipes and large rocks or other debris may strike the pipe during a storm event, in addition, pipe will need periodically re-coated) there would be more maintenance of the piping required				

APPENDIX I

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					(compared to underground piping) and therefore more disturbance to nearby habitats as a result of maintenance activities, should piping be installed aboveground. An additional advantage to belowground pipe for the water system is the increased selection of piping materials available. Aboveground piping is limited to metallic materials (ferrous or non-ferrous) due to sunlight and piping durability. Metallic piping is susceptible to corrosion and requires lining and coating maintenance during the lifetime of the project. Belowground piping material, including fiberglass and HDPE, are far less susceptible to corrosion and are in many cases smoother, requiring smaller pipe sizes to transmit water. In the 30% design, the exceptions to underground piping are as follows: • For protection of the old Route 66 roadbed, a short section of pipe and conduits was designed aboveground in the upland area. This is consistent with the existing water injection line from IM3 to the East Mesa. However, it is PG&E's preference to install final remedy facilities in this location belowground, if it can be accomplished consistent with applicable cultural resources protection standards. PG&E is evaluating this and will propose underground facilities along this corridor, if appropriate. • The **freshwater pipe** crossing the Colorado River is placed aboveground on the Arched Bridge because placing this pipe under the Colorado River is more intrusive, complex, and is not necessary. • The **new freshwater pipe** from the Arched Bridge to the existing storage tanks will follow the alignment of the existing freshwater pipe. The reason that both water pipelines will be aboveground is because of their close proximity to PG&E's large, high-pressure gas pipeline.				
160	DOI-38	Section 3.3.2.2/ 3-25/2nd Paragraph		What is the TCS fire flow storage requirement and how is it factored into the design basis for the freshwater storage tank capacity?	The fire flow storage requirement is defined by the California Fire Code and administered by the San Bernardino County. The Code looks at the size and type of buildings and the building materials. More information, including storage requirements will be provided in the 60% design.		Okay pending review of 60% design submittal.	Comment resolved.	See Section 3.3.3.2 and Attachment E (Firewater System Hydraulic Analysis) of Appendix C (Design Criteria) of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
161	DTSC-70	Page 3-25, Section 3.3.2.2 Freshwater Supply Storage		See comments above for section 3.3.2 Design Basis for Freshwater Supply System, Exhibit 3-4, Page 3-22, 23 and 24. Provide some clarification/details regarding the "fire flow storage requirement for the remedy."	See response to comment #160 DOI-38. It should be noted that the fire flow requirements apply to the Station as a whole including remedy buildings.	Okay pending review of 60% design submittal.		Comment resolved.	See Section 3.3.3.2 and Attachment E (Firewater System Hydraulic Analysis) of Appendix C (Design Criteria) of this BOD Report.
162	DTSC-71	Page 3-25, Section 3.3.2.3 Freshwater Injection Wells	"Injection wells will be constructed using up to 14-inch nominal diameter well casing with one or two discrete screened intervals."	The rationale for selecting one or two discrete screened intervals should be explained as should the anticipated location of the screen(s).	The depth and interval of the freshwater injection well screens will be determined in the field after the pilot borehole has been drilled at each respective location. The depth and length of the well screen(s) will be dependent upon the materials or lithology encountered during drilling to insure the well is built in the target aquifer. It is possible that a well may be built with two discrete screened intervals if a fine grained hydrogeologic unit separates two water bearing zones of significant thickness. Wells with two discrete screened intervals could provide flexibility during operation if it is determined injection into one unit versus another, is more effective at meeting the remedy goals. Also see response to comment #76 (DOI-24) (revise Table 3-1 through 3-4).	Okay pending review of 60% design submittal.		Comment resolved.	See Section 3.3.3.4 of this BOD Report.
163	DOI-39	Section 3.4/3-26/ Exhibit 3-5		There are 42 injection/IRZ wells if COMP-INJ-1 and 2 are included, and 40 if not. Exhibit 3-5 indicates 41. There are 13 non-IRZ extraction wells, not 14 as indicated in Exhibit 3-5. Footnote b – It is not clear how 6 months on and 18 months off equates to 30 backwashes per year. This is also not clear from Appendix F. Appendix F indicates that the IM-3 injection wells are backwashed 24 times per year, which is inferred to be a minimum number of backwashes required by the IRZ injection wells. Substrate is not injected into these wells so backwashing of the IRZ injection wells could be considerably more frequent. More discussion is required.	The well count of 41 injection/IRZ wells came from 32 IRZ wells + 4 upland injection wells + 2 TCS injection wells + 3 freshwater injection wells. The well count of 14 non-IRZ extraction wells came from 5 riverbank extraction wells + 8 Northeast of TCS/East Ravine extraction wells + 1 freshwater extraction well. The number of 30 backwashes per year came from the assumption that IRZ wells are backwashed weekly while they are in service, and are backwashed at a less frequent basis while they are not in service. The weekly backwash assumption was based on the Hinkley test at the IRZ well SA-RW-19, and not the IM3 injection wells.		Okay.	Comment resolved.	See Exhibit 3.4-1 of this BOD Report. As shown in the exhibit, there are 32 injection wells (24 IRZ + 4 IRL+ 2 TCS + 2 Freshwater), 4 IRZ extraction wells, 12 non-IRZ extraction wells (5 Riverbank, 5 East Ravine, 2 TW Bench), and 1 freshwater supply well.
164	DTSC-72	Section 3.4 Remedy-produced Water Management		Although this section described in some detail the remedy produced water management approach, the design of the system (e.g. the automatic backwashing system) does not seem to be reflected in the P&ID.	Comment noted. Additional information will be included in the 60% design submittal.	Okay, pending review of the 60% design submittal.		Comment resolved.	See Appendix D of this BOD Report (Engineering Drawings).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
165	HA-22	p. 3-26, Section 3.4 (Remedy-Produced Water Management)		This section indicates that approximately 7.3 million gallons of remedy-produced water (RPW) will be generated annually and provides a preliminary management plan. On p. 3-29, it is suggested that there may be a need for future changes in this plan. Is it likely that one of the future options will include the need for on-site treatment and therefore the construction of a new water treatment plant?	It is possible that in the future, there may be a need for on-site treatment. If and when that need is first recognized, it is anticipated that agencies/stakeholders will be engaged and Tribes will be consulted in accordance with applicable established communications and consultation requirements.	Comment and response noted.	Comment and response noted.		
166	DOI-40	Section 3.4.1/3-27/ 3rd Paragraph		What criteria are used to determine transport of rehab wastewater by pipeline or truck? A pH greater than 2 (not a characteristically corrosive hazardous waste) would be a criterion if remedy-produced water lines are not double lined. (Also see comment pertaining to page 3-13.) It is stated that once rehab water is determined to be suitable to convey in the wastewater lines, it will be pumped using portable pumps tied into the pipeline via tee connections. This implies rehab wastewater will be collected in a tanker truck. This would require secondary containment for the tanker truck at each well. Also, if the wastewater is suitable for conveyance in the pipelines, would it not be directly pumped in to the pipeline using the backwash or groundwater extraction pump? Please clarify.	The regulatory criteria for allowable transport of produced water (from well rehabilitation) by single –walled pipeline is pH>2, dissolved Cr<5 ppm, and dissolved As<5 ppm. At this time, PG&E does not intend to convey water that exhibits hazardous waste characteristics in produced water conveyance pipelines. In practice, well rehabilitation involves removing the existing infrastructure such as the extraction or backwash pump and downhole piping to enable insertion of rehabilitation equipment such as jets and swabbing devices. Therefore, normally present backwash pump would not be available for conveying produced rehabilitation water. First flush rehab water would, instead, be pumped out of the well with a temporary rehab pump through temporary piping, pH neutralized, and contained in temporary tanks located near the wellhead. All temporary tanks and piping will have adequate spill containment, as well as the area surrounding the wellhead.		Okay pending review of 60% design submittal.	Comment resolved.	
167	DOI-41	Section 3.4.2, Paragraph 1, Last Sentence		This statement is very misleading. Although the treated water would be used for a purpose, it will not be returned to the aquifer and could constitute a consumptive use.	The statement is meant to convey the concept that use of remedy wastewater in the cooling towers would preclude the need to pump an equivalent amount of groundwater for cooling water. Thus, the use of remedy wastewater in the cooling towers would not increase the consumptive use of water at the compressor station. This statement will be clarified in the 60% design submittal.		Okay pending review of the 60% design.	Comment resolved.	See Section 3.4.2 of this BOD Report.
168	DOI-42	Section 3.4.2/3-27/1st Paragraph		Indicate that a dedicated infiltration gallery in Bat Cave Wash is not being considered at this time because it is pending the findings of the soil RFI/RI and CMS/FS.	For clarification, the following text will be added to the 60% design submittal: "(note that an infiltration gallery in Bat Cave Wash is not being considered at this time because it is pending completion of the Soil RFI/RI and CMS/FS)"		Okay pending review of the 60% design.	Comment resolved.	See Section 3.4.2 of this BOD Report.

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
169	DTSC-73	Page 3-28, Section 3.4.2 Reuse/Disposal Options and Conditioning, Exhibit 3-6		Exhibit 3-6, Item 2, “Other Constraints” which discusses using the evaporation ponds for discharge should mention that Regional Water Quality Control Board input is required as they regulate the ponds. It should also be noted that these evaporation ponds are outside of the EIR project boundary and additional environmental review may be necessary. The note at the bottom of the exhibit indicates that the Infiltration Gallery in Bat Cave Wash option is deferred until after completion of the Soil RFI/FS and CMS/FS. First, DTSC and a Tribe commented on the Gallery as it affected the soil work plan. PG&E indicated that the Gallery was no longer being considered, and therefore, soil comments related to the Gallery were dropped from further consideration. The note in this exhibit indicates that the soil comments should again be addressed. Notes on Figure 3-1 are different than the notes on Exhibit 3-6. These notes should be clarified and be made consistent throughout the document. PG&E needs to clearly indicate if it is permanently dropping its disposal option at the Bat Cave Wash gallery and Park Moabi sewage ponds from further consideration as part of the remedy design.	Comment noted. The following text will be added to Exhibit 3-6, Item 2, “Other Constraints” (similar to the text in Appendix F, Table F-5, page F-11): As mentioned in the response to DTSC comment #19 (Appendix F, page F-29), PG&E agrees that the TCS ponds are located outside of the EIR project area, but are still inside the Area of Potential Effects (APE). Sending water to the TCS ponds would be done by running a pipe to the existing cooling tower blowdown system. This new pipe would be located on the TCS property. So, no construction would occur outside of the approved project area. The footnote #5 in Figure 3-1 says “Potential infiltration gallery is pending completion of soil RFI/RI and CMS/FS. This footnote is not inconsistent with the footnote on Exhibit 3-6 which states that the infiltration gallery in Bat Cave Wash is not proposed in this submittal (i.e., included in the 30% design), pending completion of the Soil RFI/RI and CMS/FS. The infiltration gallery in Bat Cave Wash is being deferred/ retained and not dropped until after completion of the Soil RFI/RI and CMS/FS. Further evaluation of the Park Moabi sewage pond option will be performed at the 60% design stage, and the evaluation results will be included in the 60% design submittal. Also see response to comment #63 (DTSC-13)	Okay pending review of 60% design submittal.		Comment resolved.	See Section 3.4.2 of this BOD Report.
170	DOI-43	Section 3.4.2.1/3-29/ Exhibit 3-7		First note – please explain why chromium levels in backwash from freshwater injection wells would be high enough to warrant Option 1 or 4 management. Also, it appears you mean option 2 and not 4. With regard to first flush rehab water, the options for disposal are limited to TCS ponds or trucking offsite. This implies dissolved constituents are a major constraint for wastewater reuse (not simply low pH or high solids for which the treatment system has been designed to address). This requires further discussion.	The first note is an older note, a remnant of the drafting process and will be removed from the 60% design submittal. As discussed, the possibility of processing the first flush rehab water at the produced water conditioning plant will be evaluated in the 60% design.		Okay pending review of 60% design submittal.	Comment resolved.	See Section 3.4.2.1 of this BOD Report. Also see Appendix F of this BOD Report.

APPENDIX I

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
171	DOI-44	Section 3.4.2.2		Backwash water from the IRZ injection wells will contain substrate. There should be discussion of possible biofouling of the filters and control measures.	Ethanol is soluble and will not foul the filters. The most potentially fouling water would be produced water from IRZ wells or carbon amended injection wells. As discussed in Appendix F of the 30% BOD, a pilot test has been underway at Hinkley since June 2011 to evaluate backwash frequency and backwash water quality at the IRZ well SA-RW-19. Noted observations from the Hinkley pilot test included: 1) frequent backwashing appears to reduce the buildup of solids (resulting from biomass buildup) and organic carbon in the tested well and 2) the biomass settles quickly in the settling tanks. The Hinkley test is ongoing and the data will be incorporated into the 60% design. In addition, coagulants/flocculants will also be evaluated during the 60% design (see page 3-33 of the 30% BOD) for potential benefits in improving settling of suspended solids in produced water. If the use of these agents is determined to be beneficial, this would require the installation of chemical storage tanks, chemical feed or metering pumps, and controls.		Okay pending review of the 60% design.	Comment resolved.	See Section 3.4.2.2 of this BOD Report.
172	DOI-45	Section 3.4.2.2/3-30/ 1st Paragraph		It is stated that "in the event that the produced water is hazardous, permitted transportable treatment units could be used." Is pH the only criterion for evaluating whether the rehab wastewater is hazardous? Would the permitted treatment units be owned by PG&E to facilitate immediate use, or would the service be subcontracted to a vendor?	The criteria for evaluating whether produced water from rehabilitation is hazardous are 1) pH for corrosivity and 2) dissolved chromium and arsenic for toxicity. There has not been a decision regarding ownership of permitted treatment units or outsourcing of treatment services for this site.		Okay.	Comment resolved.	
173	DOI-46	Section 3.4.2.2/3-30/ 1st bullet		It is stated that "remedy-produced water that has significantly higher concentrations than what exists in the aquifer…" Do you mean higher concentrations of dissolved solids? Please elaborate.	The statement refers to significantly higher concentrations of solids or dissolved constituents (e.g., byproducts) in remedy produced water than in what exists in the aquifer.		Okay.	Comment resolved.	
174	DOI-47	Section 3.4.2.2/3-30/ 1st and 2nd bullet		As indicated in the comment on Section 3.4.1, it is implied that first flush rehab wastewater will be collected in a tanker truck. There is also the possibility of using permitted transportable treatment units (see first comment on Section 3.4.2.2) or using the conditioning plant. Then there is the option to use the wastewater conveyance lines, or truck the wastewater to the conditioning plant, and finally the option to dispose of the wastewater off-site or at the TCS evaporation ponds with or without treatment. Although this will certainly need to be fleshed out in the O&M plan, there needs to be more discussion in 30% design on how this will work in practice with such a complex decision tree.	See response to comment #6 DOI-6.	Okay pending review of the 60% design.	Okay pending review of future documents.	Comment resolved.	See draft O&M Manual, Volume 1 – Operations and Maintenance Plan.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
175	DOI-48	Section 3.4.2.2/3-30/last paragraph on the page		How will temporary fluctuations in water quality result in achieving background water quality? This sentence should be reworded for clarification.	The subject sentence carried forward an important point made in the 2009 CMS/FS, Section 3 (Remedial Action Objectives), and that is in order to attain the RAOs for Cr(VI), substantial movement of groundwater in the target remediation area – either through natural or induced measures - will be necessary, and under active treatment for Cr(VI), it is expected that significant mixing of groundwater in the target remediation area would occur both vertically and horizontally, As a result, water quality and concentrations measured at individual monitoring wells are expected to change during the course of the remediation from concentrations present today. For clarification the second sentence of the paragraph will be revised to read: “Temporary fluctuations in water quality will occur during remedy implementation prior to achieving RAOs. Institutional controls will prevent…”	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See Section 3.4.2.2 and Appendix F of this BOD Report.
176	DOI-49	Section 3.4.2.2/3-32/third bullet from the bottom		It should be made clear that the discussion refers to first flush rehab water only. It should also be indicated that this water will be conditioned as required. There should be mention of secondary containment. A truck loading station in the Maintenance Shop seems odd and should be discussed further.	This text will be clarified in the 60% designed to be unconditioned produced water. Having a truck loading station in Maintenance Shops Area of TCS will give flexibility to handle this water. Specifically, given the proximity of the COMP-INJ-1/-2 and FW-INJ-4 wells, it would not be difficult to pump to the Influent Tanks at the Remedy Produced Water Conditioning Plant. As mentioned in Section C.4.5 (Secondary Containment) of Appendix C (Design Criteria), secondary containment will be sized and designed in conformance with applicable codes and standards. This will be reflected in the 60% design.	Okay pending review of the 60% design.	Okay pending review of the 60% design.	Comment resolved.	See Section 3.4.2.2 of this BOD Report
177	DOI-50	Section 3.4.2.2/3-32/second bullet from the bottom		It is not indicated that produced water conveyance piping will be double walled. If they are not double walled, then the lines cannot be used to convey characteristically corrosive hazardous waste (pH<2). Please discuss.	As indicated in Section C.4.1 (Piping) of Appendix C (Design Criteria), piping materials will be compatible with the characteristic of the conveying fluids and will be single walled unless the pipe is used to convey: 1) groundwater or remedy-produced water that exhibits hazardous waste characteristics or 2) concentrated carbon substrate. In these cases, double-walled piping will be used. At this time, PG&E does not intend to convey water that exhibits hazardous waste characteristics in produced water conveyance pipelines.	Comment and response noted. However, DTSC, in general, prefers the use of double wall piping for untreated waste water. DTSC will consider PG&E’s proposal after review of the leak detection system evaluation in the 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See Appendices C (Design Criteria) and D (Engineering Drawings)

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
178	DTSC-74	3.4.2.2 Conditioning	"Under the management plan presented above, removal of dissolved constituents will not be required because the injected water quality will be similar to the aquifer water quality in/near the Carbon-amended Injection Wells, the IRZ wells, and the Freshwater Injection Wells. Temporary fluctuations in water quality that may occur within the remedy footprint during remedy implementation will ultimately result in achieving background water quality for hexavalent chromium when the remedy is complete, and institutional controls will prevent use of affected groundwater while the remedy is being implemented. Furthermore, contaminant migration to the river that could potentially affect water quality goals or beneficial uses does not occur during remedy implementation through groundwater extraction along the river bank. PG&E believes that this interpretation is consistent with the requirements of the anti-degradation provisions of 40 CFR 131.12 and State Water Resources Control Board Resolution No. 68-16."	Metrics to ensure that "injected water quality will be similar to the aquifer water quality" will need to be developed by PG&E and obtain agency approval. As noted by comments on hexavalent chromium and arsenic related to the freshwater source, DTSC desires that the waters outside the current contaminant plume boundary not be degraded beyond site specific background conditions.	Comment noted. Additional information will be included in the Freshwater Supply TM.	Okay pending review of the Freshwater Supply TM.		Comment resolved.	See Section 3.4.2.2 and Appendix J of this BOD Report.

Alternatives for Siting Infrastructure/Infrastructure Considerations									
182	HA-33			On January 9, 2012, members and representatives of the Fort Mojave Indian Tribe ("the Tribe" or "FMIT") and the Hualapai Tribe participated in a briefing and site walk of the project area led by representatives of PG&E. The purpose of the site walk was to examine the locations of various infrastructure components of the Topock Final Groundwater Remedy in the field. This included proposed pipeline routings, well locations, chemical storage tanks, electrical transformers, etc. In addition to the proposed facility locations presented in the 30% BOD, possible alternative locations were examined and the logistics of changing to these locations were discussed. This site walk was particularly useful and afforded the participants to carry information back to the Tribes for consideration. Subsequently, on January 20, 2012, a meeting and teleconference was held with members of the FMIT Tribal Community as well as representatives of the Hualapai Tribe, Colorado River Indian Tribes (CRIT), and Cocopah Tribe in addition to certain members of the TRC. The following is a summary of the FMIT's comments and conclusions with regard to the particular alternatives presented for infrastructure siting. <u>General Statement</u> The proposed pipeline corridors and groundwater wells are located in and adjacent to areas that are sacred to Native American Tribes. The mere entrance to these areas for purposes other than Tribal activities is itself a desecration of the site and the placement, use and maintenance of project structures (pipeline corridors and groundwater wells) is even a greater desecration. All of these desecrations are unacceptable to the Tribes. However, the following comments reflect our best attempt to address the adverse effects associated with the 30% BOD with the hope that the desecration that is ongoing will be minimized to some degree by our recommendations on how to treat the land. For several of the facilities, including transformers and pipeline routings, it was suggested by PG&E that construction could be either above or underground. In general, the consensus of the Tribal Community was that, whenever possible and despite the undesirable visual impact of such structures, an above-ground configuration would be preferable on the rationale that it would involve less intrusion into the sacred grounds both during construction and eventual decommissioning and dismantling. This is further discussed below. A figure is attached to depict the preferences of the	Comments are noted. As directed by DOI and DTSC, PG&E will modify the piping network to eliminate the piping/ conduit segment in Bat Cave Wash. PG&E will evaluate the feasibility of additional locations for aboveground piping (in addition to locations already proposed in the 30% design) during the development of the 60% design. It should be noted that (in addition to increased visual impacts) a more-extensive above ground pipeline configuration will pose many challenges including health and safety, engineering design, and long term operation and maintenance challenges. Thermal design considerations may require substantial additional footprint to allow for expansion/contraction loops as well as a potentially large support structures (e.g., pipe rack, conduits or cable tray, shade assembly). Further it is likely that significant lengths of pipe racks will need to be elevated to allow the passing of vehicular traffic, adding to visual impacts. Detailed rationale for aboveground vs. underground piping/electrical conduits are also provided in response to comment #159 HA-21. Also see response to comment #183 HA-34 on electrical transformers.	Comment and response noted. DTSC notes that the certified FEIR included impact analysis for underground piping where possible based on information provided by PG&E on the conceptual design. Although DTSC recognizes the Tribes recommendation for siting pipelines and electrical transformers above ground, as discussed with the Tribes during the 3/20/12 meeting, other factors such as safety and regulatory constraints must be balanced with cultural resource considerations. In response to comments received from the Fort Mojave Indian Tribe and Hualapai Indian Tribe DTSC has directed PG&E to modify the design to eliminate the piping/conduit segment in Bat Cave Wash and to replace this with the double-back loop along NTH.	The federal agencies have consulted with the Tribes on the 30% design with particular focus on this and related comments. The Tribes comments and the discussions which occurred during consultation meetings were considered in our direction to PG&E regarding modifications to the design including the implementation of the double-back loop along NTH, eliminating the BCW trenching, an area that is in close proximity to the Topock Maze. The federal agencies believe these design modifications take into account the impacts to the site and to some extent reduce the overall affects of the remedy on the cultural, religious, and spiritual values held by the Tribes for the TCP within the APE while recognizing our responsibility for protecting public safety and reducing ecological and visual impacts in the area.		See Figure 3.0-1 of this BOD Report for piping alignment. PG&E further evaluated placement of piping in the utility corridor (underground or aboveground) during the 60% design development. Results of the evaluation are shown on Figure 3.0-1 of this BOD Report and the rationale is provided in Section C.2.2 of Appendix C (Design Criteria).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				Tribe as presented during the site walk.					
183	HA-34			Electrical Transformers The Tribe was told during the January 9, 2012, site walk that there are seven step-up transformers proposed in order to provide power along the pipeline route to sever the wells and other loads (p. 3-33, Section 3.5.1). PG&E stated it has the option of either installing these transformers in underground vaults or above ground. Since all the remedy's electrical components were not disclosed in the EIR, additional mitigation for impacts to cultural resources and aesthetics may be necessary with either option, The Tribe has considered these options and recommends the following: 1. The design of the electrical system may be overly conservative to require this number of transformers. PG&E should review the electrical component design to determine if the number of transformers can be reduced. 2. In consideration of the invasive activities that would be required to install transformers underground and then to dismantle them at the end of the project, the Tribe recommends that all transformers be constructed above ground even though there may be visual impacts. 3. The Tribe concurs with the siting of the transformer adjacent to the IM3 WTP to the alternative location next to Bat Cave Wash.	PG&E will continue to evaluate and optimize the design of the electrical system, including the precise locations of the transformers, and additional information will be presented in the 60% design. PG&E will consider these comments in formulating the 60% design. Also refer to response to comment #159 HA-21 for rationale for aboveground vs. belowground. In general, PG&E placed transformers belowground due to health and safety concerns similar to piping. However, wherever possible, transformers can be co-located (aboveground) with planned aboveground buildings, e.g., the MW-20 bench. The aboveground building acts as a barrier and provides protection from traffic. With respect to the design of the system, page 3-19 of the Final EIR states generally that the electrical connections will be placed in underground vaults wherever feasible. Counsel for the Tribe has confirmed in discussions with counsel for PG&E that the references to consideration of mitigation measures refers to measures from the EIR, and not additional measures.	Comment and response noted pending review of 60% design	Comment and response noted pending review of 60% design.		The number of transformers was reduced from 7 to 6 after further evaluation. A future provisional transformer was also identified in the event the future provisional well IRL-7 needs to be installed and operated. Their locations are shown in Figure 3.0-1 of this BOD Report.
184	HA-35			Pipeline Routings A number of pipelines are included in the design for the purposes of routing freshwater from the supply well in Arizona (HNWR-1) across the Colorado River to the upland freshwater injection wells and from the floodplain extraction wells adjacent to the western bank of the Colorado River to the upgradient injection wells as part of the inner recirculation loop. Consistent with the recommendation presented earlier with regard to running these pipelines above vs. underground, the Tribe recommends that, wherever possible, the routings should be above ground. In particular, 1. This includes pipelines associated with FW-INJ-4; MID-EX-1,-2,-3, and -4; UPGRADINJ-1,-2-3, and -4. 2. FW-INJ-4 piping would cross Bat Cave Wash, but the Tribe would still prefer that the piping be positioned above ground. 3. The proposed routing of the freshwater pipeline across the Colorado River to the Compressor Station should stay along former Route 66 rather than moving uphill to the El Paso gas pipeline right of way (ROW).	As directed by DOI and DTSC, PG&E will modify the piping network to eliminate the piping/conduit segment in Bat Cave Wash. The details of the pipeline configuration associated with UPGRAD-INJ wells, MID-EX wells and FW-INJ-4 will be dealt with in more detail during the 60% design phase. However, it must be noted that above ground piping will involve many potential challenges such as health and safety, long term operation and maintenance and engineering design issues. Detailed rationale for aboveground vs. belowground is presented in the response to comment #159 HA-21. The comment regarding routing freshwater pipeline crossing the Colorado River along the former Route 66 will be taken into consideration for evaluation during the 60% design.	Comment and response noted. DTSC notes that the certified FEIR included impact analysis for underground piping where possible based on information provided by PG&E on the conceptual design. Although DTSC recognizes the Tribes recommendation for siting pipelines and electrical transformers above ground, as discussed with the Tribes during the 3/20 meeting, other factors such as safety and regulatory constraints must be balanced with cultural resource considerations. In response to comments received from the Fort Mojave Indian Tribe and Hualapai Indian Tribe DTSC has directed PG&E to modify the design to eliminate the piping/conduit segment in Bat Cave Wash	The federal agencies have consulted with the Tribes on the 30% design with particular focus on this and related comments. The Tribes comments and the discussions which occurred during consultation meetings were considered in our direction to PG&E regarding modifications to the design including the implementation of the double-back loop along NTH, eliminating the BCW trenching. The federal agencies believe these design modifications take into account the impacts to the site and to some extent reduce the overall affects of the remedy on the cultural, religious, and spiritual values held by the Tribes for the TCP within the APE while recognizing our responsibility for protecting public safety, reducing ecological and visual impacts in the area.		PG&E further evaluated placement of piping in the utility corridor (underground or aboveground) during the 60% design development. Results of the evaluation are shown on Figure 3.0-1 of this BOD Report and the rationale is provided in Section C.2.2 of Appendix C (Design Criteria).BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
						and to replace this with the double-back loop along NTH.			
185	HA-36			Alternate Injection Well Siting The Tribe considered the alternative locations discussed for the various injection wells associated with the inner recirculation loop. The following are the consensus recommendations. 1. FW-INJ-2 should be placed within the former Route 66/National Trails Highway (NTH) ROW instead of the currently proposed location. It is understood that this placement would require vaulting and that the NTH is a historic landmark. However, a utility vault in a “public highway” is not inconsistent with typical highway purposes, whereas it would be a less impactful desecration than placing it on unpaved Tribal sacred grounds. 2. UPGRAD-INJ-2 and UPGRAD-INJ-3 also are not sited in acceptable locations. As with FW-INJ-2, both should be moved onto the former NTH ROW and installed in vaults. 3. UPGRAD-INJ-4 also is not sited in an acceptable location. The preferred location would be within the median of I-40. However, PG&E stated that siting in the median was denied by Caltrans on the grounds of future plans to widen the I-40 to six lanes. This point needs independent verification and a consultation between Caltrans and the Tribes may be in order for Caltrans to reconsider its options. Therefore, the Tribe requests that an effort to re-approach Caltrans be made by the Agencies in coordination with the Tribes, explaining the conflicts with alternate locations. In particular, the timing of the proposed widening should be considered and evaluated in terms of the temporary use of this area as an injection well site. Assuming that plans for highway widening are sufficiently distant in the future, perhaps the site could be used in the interim and the well abandoned in favor of an alternate location when the road widening project begins. 4. Assuming that Caltrans remains unwilling to grant access for siting UPGRAD-INJ-4 in the I-40 median, the Tribe would prefer its placement within the drainage bottom east of the presently proposed location, as indicated on the attached figure, as opposed to the presently proposed site. **Additional comments/notes from Attachment B Map:** • Do not use this access road for UPGRAD-INJ-2. • Keep FW-INJ-2 in this area, closer to access road. • Remove IM-3 improvement from this area	As discussed at the 3/20/12 meeting with agencies and Tribes, PG&E will modify well locations as follows (in the 60% design) : 1. Relocate FW-INJ-2 as suggested in the Attachment B map of the FMIT’s comment letter. This well will placed in an underground vault. 2. Relocate UPGRAD-INJ-3 to a location closer to the old Route 66. To avoid the So Cal gas pipeline, PG&E propose this well be located on the north side of old Route 66. This well will placed in an underground vault. Relocate UPGRAD-INJ-2 as suggested in the Attachment B map of the FMIT’s comment letter. This well will placed in an underground vault. A new access road connecting to the old Route 66 will be designed in the 60% design for accessing this well. 3. As previously stated, PG&E met with Caltrans early in the design process to discuss the siting of an injection well in the median of I-40. PG&E was informed that siting of a well in the median of I-40 is not acceptable because of a) the median could be used in the future plans for widening of I-40 and b) the health and safety hazard associated with installing and maintenance of a well in the median. 4. Relocate UPGRAD-INJ-4 to the wash located just west of the proposed well location in the 30% design. An access road off the old Route 66 will be designed in the 60% design for accessing this well. PG&E proposes that the pipelines and conduits connected to this well will be installed underground in the roadbed of the newly-constructed road. Since this well will be located in a wash, PG&E proposed to place the well inside a semi-underground vault for easy access and to avoid water from inundating the vault in case of a flow event.	Comment and response noted. DTSC concurs with the modified well locations as proposed.	The federal agencies have consulted with the Tribes on the 30% design with particular focus on this and related comments. The Tribes comments and the discussions which occurred during consultation meetings were considered with respect to the modifications to the design concerning well locations in the upland area as indicated in the response.		See Figure 3.5-9 of this BOD Report.

APPENDIX I

				and restore. • Is the location of UPGRAD-INJ-1 in future Tribal land? • Move UPGRADINJ- 3 to this location. • Move UPGRADINJ- 2 south and grade access road to Route 66. • Ridges in this area not acceptable for wells. • Move UPGRADINJ- 4 to this location.					
186	HA-37			TOC Amendment Storage Tank The Tribe reviewed alternative sites for construction of a 2,500 gallon storage tank for supplying the total organic carbon (TOC) amendment (ethanol) for *in situ* treatment at the "Transwestern Pipeline bench." The Tribe prefers the location along the Compressor Station entrance road, as opposed to the hillside, based on the expectation of less intrusion. **Additional comments/notes from Attachment B Map:** Recommended location for Alcohol tank.	Comment noted. These alternative locations will be reviewed in detail as part of the 60% design.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		After further evaluation, PG&E located the 3000-gallon carbon storage tank against the hillside to maximize the amount of available space for shared use of the Transwestern Bench space by the Topock remediation project and Transwestern gas operations.
187	HA-38			Impacts to Tribal Land As a general principle, the Tribe's preference is for as little remediation infrastructure to be placed on its property as possible. The Tribe and PG&E should consider this in implementing necessary access to the area.	The Tribe's preference is recognized and will be further considered during the development of the 60% design, consistent with the 2006 Easement Agreement and the 2006 Settlement Agreement between the Fort Mojave Indian Tribe and PG&E. A statement to this effect will be included in the 60% design submittal.	Comment and response noted.	Comment and response noted.		After further evaluation and consideration of Tribe's preference, PG&E relocated freshwater injection well FW-1 to outside the FMIT property line. See Figure 2.4-1, FW-1 is the western most well that is located just south of the FMIT property.
188	Hualapai-26			Selection of Remediation Well Locations *UPGRAD-INJ-1*: The pipeline that connects the UPGRAD-INJ-1 well should be above ground as indicated above, as this is the less-intrusive option. The well structure should also be above ground. There are no recommendations for re-locating this well.	As directed by DOI, UPGRAD-INJ-1 will be placed in belowground vault. Please refer to comment #159 HA-21 and #182 HA-33 for considerations regarding above vs. underground piping. For protection of the old Route 66 roadbed, a short section of pipe and conduits was designated as aboveground in the upland area in the 30% design. This is consistent with the existing water injection line from IM3 to the East Mesa. However, it is PG&E's preference to install final remedy facilities in this location belowground, if it can be accomplished consistent with applicable cultural resources protection standards. PG&E is evaluating this and will propose underground facilities along this corridor, if appropriate.	Comment and response noted.	Comment and response noted pending review of 60% design. During consultation meetings with the federal agencies, the tribes expressed their interest to have upland well structures below ground. The design will reflect this preference.		After further evaluation, PG&E proposed underground pipe trench along this segment of Route 66. See rationale in Section C.2.2 of Appendix C (Design Criteria).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
189	Hualapai-27			Selection of Remediation Well Locations *UPGRAD-INJ-2 and 3*: Well completions should be above ground as should connecting pipelines. Locations of these two wells however, are unacceptable. We concur with the Fort Mojave Indian Tribe to re-locate both UPGRAD-INJ 2 and 3 to the former Route66/National Trails Highway right-of-way as this is less intrusive and does not require the construction of a new road, creating further desecration to the area.	As directed by DOI, these wells will be relocated and placed in belowground vaults. Also see response to comment #159 HA-21 and #185 HA-36,	Comment and response noted.	Comment and response noted pending review of 60% design. During consultation meetings with the federal agencies, the tribes expressed their interest to have upland well structures below ground and move *UPGRAD-INJ-2 and 3*. The design will reflect the results of those discussions.		See Figure 3.0-1 of this BOD Report.
190	Hualapai-28			Selection of Remediation Well Locations *UPGRAD-INJ-4*: It is understood that the current locations proposed for remediation wells and infrastructure was initially placed with an attempt to consider both efficacy of the system, and minimizing surface disturbance. However, the current location of injection well UPGRAD-INJ-4 is troubling for two reasons. First, the physical location for this well is very near remnants of the Topock Maze which are still present in this generally disturbed area. Any additional traffic and disturbance in this area, especially over the decades-long time frame of the remediation would very likely result in further degradation of these remaining portions of the maze. In addition, the elevation of this well site is very close to that of the central portion of the maze located south, on the other side of I-40. Therefore, this well location is extremely visible and disruptive when viewed from the maze. We concur with the Fort Mojave Indian Tribe to re-locate UPGRAD-INJ-4 into the drainage east of the proposed location. This location is the preferred choice as it is at best, minimizing adverse effect to the ridge-line above and reduces visibility of well activities in an area that is sacred.	As directed by DOI and as discussed in the 3/20/12 meeting with agencies and Tribes, this well will be relocated to the wash located just west of the proposed well location in the 30% design. An access road off the old Route 66 will be designed in the 60% design for accessing this well. The pipelines and conduits connected to this well will be installed underground in the roadbed of the newly- constructed road. Also see response to comment #185 HA-36. Since this well will be located in a wash, PG&E proposes that it be placed inside a semi-underground vault for easy access and to avoid water from inundating the vault in case of a flow event.	Comment and response noted.	Comment and response noted pending review of 60% design. During consultation meetings with the federal agencies, the tribes expressed their interest to have upland well structures below ground and move UPGRAD-INJ-4. The design will reflect the results of those discussions.		See Figure 3.0-1 of this BOD Report.
191	Hualapai-29			Selection of Remediation Well Locations *FW-INJ-1*: It is understood that FW-INJ-1 is located to the north on the floodplain west of the access road (Route66/National Trails Highway). If this well fails, or is subject to salinity, where will an alternate injection well be placed?	Salinity would not preclude successful completion of an injection well, however, if low permeability aquifer materials were encountered in this area that limited the amount of water that could be injected, additional injection wells could potentially be drilled nearby in hopes of finding better aquifer materials, or an additional injection well could be installed at an acceptable location somewhere between FW-INJ-1 and FW-INJ-2.	Comment and response noted.	Comment and response noted.		Upon further evaluation, PG&E removed the FW-INJ-1 well previously located to the north on the floodplain west of the access road.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
192	Hualapai-30			Selection of Remediation Well Locations *FW-INJ-2*: Well completions should be above ground as should connecting pipelines. Location of this well however, is unacceptable. We concur with the Fort Mojave Indian Tribe to re-locate FW-INJ-2 further into the former Route66/ National Trails Highway right-of-way as this is less intrusive and does not require the construction of a new road, creating further desecration to the area.	As directed by DOI, these wells will be relocated and placed in belowground vaults. Also see response to comment #159 HA-21,	Comment and response noted.	Comment and response noted pending review of 60% design. During consultation meetings with the federal agencies, the tribes expressed their interest to have upland well structures below ground and move FW-INJ-2. The design will reflect the results of those discussions.		See Figure 3.0-1 of this BOD Report.
193	Hualapai-23 and TRC-14			Infrastructure Considerations **Pipelines**: The Hualapai, and others, completed a Topock site-walk on January 9, 2012 of the proposed 30% design pipeline infrastructure. After due deliberation, we concur with the Fort Mojave Indian Tribe to have all pipelines placed aboveground. By doing this, it is hoped that adverse effects associated with the remedy infrastructure will be minimized. Site location data for all pipelines will be maximized in this manner. Additionally, considerable remediation infrastructure, mainly a pipeline, is planned for Bat Cave Wash. Whether buried or at ground-level, this infrastructure will be subject to temporary inundation, scour, or burial as a result of future flood events in the wash. **TRC Recommendation:** It may be appropriate to complete a hydrologic and hydraulic evaluation of Bat Cave Wash to determine water surface elevations at key locations for design storm events of interest, e.g., the 100-yr storm / flood. In general - digital as-built/record drawings, based on accurate field surveys, should be prepared to document the placement of all project infrastructure, particularly subsurface elements. Further, all non-ferrous or non-conductive buried infrastructure (particularly pipelines) should be installed with detection tape or wire. These actions will serve to minimize ground and subsurface disturbance for modifications, repair or future removal. **Transformers:** It is understood that there are plans for 7 to 10 transformers necessary for electrical conversion. Hualapai concurs with the Fort Mojave Indian Tribe in that we prefer all transformers to be constructed aboveground. The design of the electrical system appears to conservative due to the length of each line. We asked that the electrical system be reviewed in regards to possibly reducing the number of required transformers.	As directed by DOI and DTSC, PG&E will modify the piping network to eliminate the piping/conduit segment in Bat Cave Wash. Also see response to comment #159, HA-21 for rationale on aboveground vs. belowground piping/electrical conduits; and response to comments #159 HA-21 and #183 HA-34 regarding transformers.	Comment and response noted. DTSC notes that the certified FEIR included impact analysis for underground piping where possible based on information provided by PG&E on the conceptual design. Although DTSC recognizes the Tribes recommendation for siting pipelines and electrical transformers above ground, as discussed with the Tribes during the 3/20 meeting, other factors such as safety and regulatory constraints must be balanced with cultural resource considerations. In response to comments received from the Fort Mojave Indian Tribe and Hualapai Indian Tribe DTSC has directed PG&E to modify the design to eliminate the piping/conduit segment in Bat Cave Wash and to replace this with the double-back loop along NTH.	The federal agencies have consulted with the Tribes on the 30% design with particular focus on this and related comments. The Tribes comments and the discussions which occurred during consultation meetings were considered in our direction to PG&E regarding modifications to the design including the implementation of the double-back loop along NTH, eliminating the BCW trenching. The federal agencies believe these design modifications take into account the impacts to the site and to some extent reduce the overall affects of the remedy on the cultural, religious, and spiritual values held by the Tribes for the TCP within the APE while recognizing our responsibility for protecting public safety and reducing ecological and visual impacts in the area.		See Figure 3.0-1 of this BOD Report.

APPENDIX I

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
194	TRC-15			It is understood that the current locations proposed for remediation wells and infrastructure were initially placed with an attempt to consider both efficacy of the system, and minimizing surface disturbance. However, some current proposed locations of wells and infrastructure are not desirable for the Tribes. Placement of these structures and wells should be done with consideration to the preservation of the physical archeological resources, as well as in a way to minimize subsurface disturbance. **TRC Recommendation:** We understand that discussions and evaluations are ongoing on this issue with the Tribes, and specific alternate routes and well locations will be included in the 60% design as these discussions reach a conclusion.	Comment noted. As directed by DOI and DTSC, PG&E will modify the piping network to eliminate the piping/conduit segment in Bat Cave Wash, relocate upland wells (except UPGRAD-INJ-1), and place the wells in belowground vaults. An exception is the vault for UPGRAD-INJ-4. Since this well will be located in a wash, PG&E proposes that it be placed inside a semi-underground vault for easy access and to avoid water from inundating the vault in case of a flow event.	Comment and response noted.	The federal agencies have consulted with the Tribes on the 30% design with particular focus on this and related comments. The Tribes comments and the discussions which occurred during consultation meetings were considered with respect to the modifications to the design concerning well locations in the upland area as indicated in the response.		See Figure 3.0-1 of this BOD Report.
Section 4 Comments — Operations and Maintenance Provisions									
195	DTSC-76	Section 4 Operations and Maintenance Provisions		DTSC defers review of this section until sufficient information is provided to allow for a meaningful review.	Comment noted.	Okay.			
196	HA-25	p. 4-2, last para.		This text refers to the preparation of a “sampling and monitoring plan” as part of the 60% design submittal. The Tribe is interested in particular in the monitoring network configuration, including proposed new monitor well locations.	Comment noted.	The sampling and monitoring plan will be provided to the tribes as part of the 60% design review.	Comment noted.		See draft O&M Manual – Volume 2, Sampling and Monitoring Plan

APPENDIX I

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
197	MWD-1	O&M Provisions		Metropolitan recommends that the following items be further developed in the forthcoming Draft Basis of Design Report/60% Design Submittal for the Final Groundwater Remedy because they are not addressed in the 30% Design Submittal. 1. Groundwater Monitoring Program (GMP), 2. Operation and Maintenance Plan (O&M), 3. Contingency Plan, and 4. Transition Plan from IM-3 to full Remedy Metropolitan believes these programs and plans are integral to successfully implementing and operating the remedy and to protecting the water quality of the Colorado River. Specifically, the GMP will need to identify and describe existing new wells that will become part of the program, the purpose of each well in the network, monitoring parameters, and monitoring frequency. Groundwater monitoring parameters should include both water quality and groundwater levels. Remedial Action Objectives (RAO) for water quality (surface and groundwater) and groundwater levels should be defined in the GMP for protection of the Colorado River and other sensitive habitats/sites and for process control measures to optimize elements of the remedy. The O&M Plan developed for the Groundwater Remedy System should be separate from the GMP and identify the means and measures for operating and maintaining the system. The Groundwater Remedy fail or compliance objectives are not met. Time frames should be included in the contingency plan for implementing corrective measures and they should be implemented in such a way that they are protective of Colorado River water quality and other sensitive habitats/sites.	PG&E appreciates MWD's recommendation and is committed to submit an O&M Manual that meets the substantive regulatory requirements. The O&M Manual will include the following: 1. O&M Plan – including routine O&M procedures, maintenance and site management practices. 2. Groundwater/Water Sampling and Monitoring Plan – including monitoring goals, compliance and performance monitoring, sampling methods, and data management practices. 3. Contingency Plan – including the in situ remediation system, compliance monitoring, remedy produced water management system, freshwater supply, power supply, and SCADA. 4. Soil Management Plan 5. O&M Health and Safety Plan Details of the transition from the IM3 system to the final remedy will be provided in the 60% design report.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal and O&M plan review.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal and O&M plan review.		See draft O&M Manual

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
198	MWD-2	O&M Provisions		A plan needs to be fully developed and described in the 60% Design Report on the transition from the currently operating IM-3 Treatment Plan to full operation of the Groundwater Remedy. It is imperative that during the transition the hexavalent chromium plume in the floodplain is not allowed to migrate closer to or beneath the river, particularly if there is a possibility that portions of the plume would move beyond what could be captured by the Groundwater Remedy's Riverbank Extraction Wells. It is important to maintain the hydraulic gradient protecting the river during this transition period. In order to better understand changes in the plume as well as its movement during the transition period, the 60% Design Report should include a chemical reaction and solute transport simulation of the Transition Plan using the project's numerical model. The simulation time steps should be sufficiently small to take into account the hydraulic and chemical changes that are occurring as the elements of the remedy are brought online. The simulation should include the timing of the National Trails Highway In-situ Reductive Zone, extraction of fresh water at the Havasu National Refuge Well, injection of fresh water, activation of the Inner Recirculation Loop and activation of the Topock Compressor Station Recirculation loop. Modifications of the base Transition Plan should also be considered and simulated to better understand and optimize the transition to meet implementation objectives, including protection of the Colorado River's water quality.	The details of the transition from the IM3 system to the final remedy will be provided in the 60% design. During remedy transition and operation, some hexavalent chromium currently in the floodplain will move toward the river bank extraction wells where it will be captured. To the extent possible, the model will be used to evaluate the changes in the plume during the transition period. The shortest time step that is meaningful to model is one month so modeling will be supplemented with monitoring and adjustment during the transition period. As suggested, consideration of alternative sequencing of start-up of the system components will be evaluated to assess whether additional assurance of plume control can be obtained by modifying the sequence of start-up.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Section 7.3 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
199	Hualapai-10 and TRC-6	O&M Provisions		Evaluation and Application of In-Situ Pilot Scale Test Results There is concern that the values of oxidation-reduction potential (ORP) reported in the Topock reports are obtained from platinum-electrode measurements. These platinum-electrode values do not accurately represent the oxidation-reduction potential (Eh) of the subsurface geochemical conditions. Redox couples need to be analyzed (for example, Fe(III)/Fe(II) or Se(VI)/Se(IV) or As(V)/As(III)) in order to track the progress of remediation. The tracking of Eh conditions during remediation will give a more accurate representation of the subsurface redox conditions, and accurate Eh values can be used to describe geochemical speciation through theoretical Eh-pH diagrams. **TRC Recommendation:** It may be appropriate to discuss this during a TWG meeting, and incorporate in monitoring plans within the 60% design report.	The ORP measurements are made with a silver-silver chloride electrode, which is approximately 200 mV less than the standard hydrogen electrode used in reporting Eh values. We agree that this measurement alone provides only an approximate measure of the groundwater redox conditions. Laboratory measurement of redox indicators that will be part of the monitoring program include dissolved oxygen, nitrate, dissolved manganese, dissolved iron, and sulfate. Although more detailed speciation of oxidation state of iron, arsenic and selenium is possible, it is usually not necessary. For example, at the pH range of the site, iron measured in a dissolved iron analysis will likely be comprised of ferrous iron. For arsenic, the driving force for dissolution is the establishment of reducing conditions under which arsenic associated with iron minerals will be released during iron reduction, regardless of arsenic oxidation state. The measurement of dissolved iron and dissolved arsenic concentrations are typically sufficient to understand the establishment of metal reducing conditions and resulting changes in solubility of arsenic.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		
200	Hualapai-18 and TRC-11			Addressing Potential Byproducts, Arsenic, Other Metals The generation of byproducts, including arsenic, barium and manganese, in areas downgradient of the IRZ may be higher than that anticipated by the 30% design report. During the Upland ISPT, arsenic concentrations were reported as high as 97 µg/L in well PT-7D. Arsenic production in well PT-8S appears to be related to the reductive dissolution of manganese rather than sulfate reduction (Figure A2). Increased concentrations of barium in excess of the 1,000 µg/L MCL were observed during the Upland ISPT. **TRC Recommendation:** The monitoring program for the IRZ system should include background and then periodic analysis of Title 22 Metals, possibly annually for a selection of wells, to ensure excessive generation of unwanted byproducts is not occurring. It is anticipated to see this addressed in the monitoring program included in the 60% design report.	PG&E agrees that monitoring of arsenic, barium and manganese are integral components of the performance monitoring program, and these constituents will be included in the plan presented in the 60% design. The monitoring plan will be submitted with the 60% design for review and comment. With regards to the Uplands pilot test data referenced, the elevated concentrations of arsenic and barium measured in the Uplands pilot test were related to the distribution of higher than necessary amounts of organic carbon substrate during that pilot test. Lower concentrations are planned for the final remedy. The commenter is correct that arsenic dissolution is related to metals reduction, rather than sulfate reduction, although iron reduction and the release of arsenic associated with iron minerals may have played a more significant role than manganese reduction. The increase in barium concentrations is likely associated with sulfate reduction and the dissolution of barium sulfate.	Comment noted. Further evaluation will occur during review of 60% design.	Response noted. Further evaluation will occur during review of 60% design.		See Section 2.3 of this BOD Report and the draft O&M Manual – Volume 2, Sampling and Monitoring Plan.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
201	Hualapai-19			Addressing Potential Byproducts, Arsenic, Other Metals In addition, we support further analysis of the potential for increased arsenic concentrations resulting from injection of freshwater containing arsenic such as well HNWR1 which has arsenic concentrations in excess of 10 µg/L.	Additional analysis will be provided in the 60% design submittal.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See draft O&M Manual Volume 2, Section 5.2.
202	Hualapai-20 and TRC-12			Addressing Potential Byproducts, Arsenic, Other Metals Cr(VI) is unstable in the presence of TOC. Many samples which would be collected to monitor the NTH IRZ will also contain TOC as it is the amendment being introduced. Comparison of data from the Upland ISPT suggests field-analyzed Cr(VI) concentrations were greater than laboratory-analyzed Cr(VI) concentrations. This appears to be linked to high TOC concentrations in the water samples (Figure 2). Therefore, there needs to be a discussion regarding the differences between immediate field analyses versus standard laboratory-certified analyses and the possible impact of longer holding times on water samples analyzed for Cr(VI) where TOC is also present. **TRC Recommendation:** This may be appropriate for a TWG discussion. In addition, results of field and standard laboratory analysis should be compared to evaluate if field measurements of Cr(VI) are systematically different from companion laboratory samples. Other potentially unstable constituents should also be addressed, such as Fe(II) and S(II-). This will be important as the monitoring program for the remediation system is being designed.	US EPA methods will be used for all laboratory analyses of Cr(VI). These methods were carefully developed in US EPA laboratories and include detailed protocols for sample preservation to ensure that the target analyte concentrations are not altered during sample transport or storage prior to analysis. In response to this comment, a discussion of the laboratory and field methods for measurement of Cr(VI) will be included in the sampling and analysis section of the O&M plan that will be submitted in the 60 percent design. The impacts of the various reductants mentioned here, TOC, Fe(II) and S(II-) and holding time will be included.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See draft O&M Manual Volume 2 (Sampling and Monitoring Plan), Section 7.1.
203	Hualapai-21			Addressing Potential Byproducts, Arsenic, Other Metals Manganese concentrations might be the most persistent by-product of the remediation. Will manganese travel through the reducing layer beneath the Colorado River, then discharging into the river? What will be the manganese concentrations and loads in the Colorado River? Risk assessment models are needed to describe the effects of manganese concentrations on downstream wildlife and Tribal water users.	The solute modeling indicates that manganese concentrations generated as byproducts will be less than the current manganese concentrations already present in the reducing rind along the river. As noted in the response to comment #258, a more in-depth analysis of the spatial distribution of the reducing rind (Mn concentrations and geochemical redox indicators) will be considered for the 60% design. The net effect on the manganese concentrations in the river will also be evaluated. Additionally, a one-dimensional hyporheic zone model for Mn is also being developed for the 60% design, which will be used to evaluate geochemical/hydrological processes governing manganese behavior near the groundwater-river water interface as groundwater flows toward the river. Risk assessment models are not considered necessary.	Comment noted, please also see response to comment #258.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B.

APPENDIX I

Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
204	Hualapai-22 and TRC-13			<u>The Importance of Detailed and Focused Monitoring Plan</u> With the issues of potential byproducts, uncertainties with respect to heterogeneities in the local geology, and the uncertainties that come with any remediation system, it will be important that the monitoring program for the Topock IRZ be designed to monitor those parameters which modeling and experience indicate may be an issue. More intensive monitoring in the early years of operation would hopefully minimize any negative developments, as well as be able to allow the system to be modified quickly to response to developing conditions. **TRC Recommendation:** It is anticipated that a reasonably detailed monitoring program will be included within the 60% design report.	A detailed O&M plan will be included as part of the 60% design and include information related to organic carbon substrate distribution, chromium removal effectiveness, and by-product monitoring.	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		Also see draft O&M Manual, Volume 1 – Operations and Maintenance Plan and Volume 2 – Sampling and Monitoring Plan.
Section 5 Comments – Institutional Controls									
205	HA-26	p. 5-1, General		Can ICs be developed to further facilitate the intent of FEIR Mitigating Measure CUL-1a-2, which is intended to ensure unrestricted Tribal access to sacred areas? Could an IC address the restriction of access by non-Tribal members to such areas at certain times?	Consistent with the requirements of the Programmatic Agreement, there are access plans in place and/or underway to ensure Tribal access to, and use of, the project area for religious, spiritual, or other cultural purposes. For example, on November 26, 2011, BLM issued a Tribal Access Plan for Federal Properties, the purpose of which is to "assure the rights of Tribes to access their places of spiritual and cultural importance located on federal lands within the boundary of the APE." Access plans must be consistent with existing laws, regulations, and agreements governing property in the project area, including ICs. ICs function to ensure the health of humans and the environment, and to prevent interference with the final remedy by limiting access on specific property until access can be safely provided.	An IC can restrict specific use of the land, but DTSC cannot exclude non-Tribal members to certain areas based on tribal affiliations. ICs are for the protection of human health and the environment and to facilitate operation and maintenance of the remedial system. DTSC will be working with the federal agencies on the enforcement mechanisms of any necessary Institutional Controls at federally owned properties. .	The federal agencies are evaluating potential options for use restrictions for property under our jurisdiction.		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
206	DOI-51	Section 5		Please modify the first paragraph as follows: "Institutional controls (ICs) are a component of the selected final groundwater remedy. These are legal and administrative mechanisms adopted to limit or prohibit activities on specified property that could interfere with the integrity of the remedy or compromise the continued protection of human health and the environment. The target timeframe for having the ICs in place is prior to remedy construction. It is anticipated that most of these controls would remain in place for the duration of the remedy; that is, until the RAOs are achieved. The ROD states that the ICs adopted by the selected groundwater remedy for the Topock site are specified in the *BLM Lake Havasu Field Office Resource Management Plan* issued in May 2007 (BLM 2007) and in the *1994 Lower Colorado River National Wildlife Refuges Comprehensive Management Plan* (USFWS and BOR 1994). These plans restrict surface uses and use of the groundwater on federal lands." In the last paragraph, please remove the sentence, "The land use considerations included in the management plans identified above will be incorporated into restrictions on federal lands." As the first paragraph in this Section already states, the CERCLA ROD for the Topock groundwater remedy specifically states that ICs are imposed on the project area through the applicable federal management plans. Adding this sentence at the end of the Section is not necessary.	The paragraph will be modified as suggested.		Okay pending review of 60% design submittal.	Comment resolved.	See Section 5.0 of this BOD Report.

207	DTSC-77	Page 5-2, Section 5.1, Define Areas for Future Restrictions, and Figure 5-1	The pumping scenarios include high-volume groundwater pumping (e.g., irrigation well) to the northwest at either Moabi Regional Park or along the eastern edge of San Bernardino County leased land, and a domestic water supply well (assuming one household with no lawn or swimming pool) within the BOR property area to the west of the plume and north of BNSF Railroad (APN 50-151-03 on Figure 5-1). Results from these initial simulations suggest an area for Category 1 restrictions as depicted in Figure 5-1.	What are the pumping parameters used? Also, what is the rationale for inclusion of one household with no lawn or swimming pool? Please provide the model simulation runs for evaluation. Finally, in Figure 5-1, DTSC notes that PG&E has identified an area roughly surrounding the remedy infrastructure for Category 1 ICs, but with little rationale.	The pumping scenario included a hypothetical extraction well at Park Moabi pumping at 400 gpm, a typical average rate for golf courses in this region (Source: Green, R.L. 2005. Trends in Golf Course Water Use and Regulation in California. UC Riverside Turfgrass Research Facility. Web publication: http://ucrturf.ucr.edu/). The pumping center was placed at different locations on Park Moabi with pumping rates assigned to model layers 2-4, and plume flow lines were examined. A hypothetical domestic well was also included outside of the plume footprint and placed at different locations to examine the potential for injected recirculation water flow lines to be drawn towards the well. Together, the simulation from pumping of these two hypothetical wells was used to define the area for Category 1 ICs. An additional simulation of the hypothetical domestic well was conducted, with additional features including a pool and lawn. The assumed average pumping rate of 1,440 gallons per day, based on water consumption of a quarter-acre lawn and maximum evaporative losses for pools in the Lake Havasu area The addition of these features makes virtually no difference in the simulation The closest potential domestic well location would eventually intercept freshwater injection flowlines, regardless of the domestic well pumping rate, but the recirculation water flowlines will not pass through the area outside of the IC boundary as shown on Figure 5-1, based on the current remedy configuration. PG&E is contacting the Topock Marina Resort to inquire about potential water use and source. Information obtained will be used to inform the evaluation of ICs in the 60% design. The level of details presented in Table 5-1B is typical at the 30% design stage when infrastructure and pipeline locations on most parcels are still changing. After the locations have been settled on specific parcels, land issues such as legal description, easements and encroachments will be determined and processed. Additional details will be presented in the 60% design submittal.	Okay pending review of 60% design submittal.		Comment resolved.	See Section 5.1 of this BOD Report.
				Furthermore, PG&E did not identify or outline the parcels requiring Category 2 ICs, which may limit potential future development of private parcels including those of the Topock Marina (see table 5-	Section 5.1 defines the area for Category 2 ICs. The level of details presented in Figure 5-1 and the section is typical at the 30% design stage when infrastructure and pipeline locations on most parcels are still				

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				1B). PG&E must adequately identify such impacts on the figure for transparency and evaluation. As stated, Figure 5-1 and the section do not appear to address institutional controls beyond Category 1. For Arizona, modeling in Appendix B indicates the remedy causes flow to Arizona and therefore potential for chromium or byproducts to escape capture during the remedy. Additionally, enhanced pumping in Arizona could exacerbate conditions (e.g., from the planned Topock 66 Resort and Spa). At a minimum, simulation of pumping wells in Arizona must be undertaken (low and higher flow scenarios). Depending on results, additional ICs may be needed in Arizona. Furthermore, PG&E argues that pumping at Park Moabi has detrimental effects on the remedy. If this is true, one would expect a larger area delineated for institutional controls. SoCal Gas had requested pumping rights in the area. If that is true, it should be discussed in this section as well as other applicable sections. Note: Parcel APN 650-151-03 referenced in the text could not be located on Figure 5-1. Please revise the figure or text.	changing. After the locations have been settled on specific parcels, land issues such as legal description, easements and encroachments will be determined and processed. Additional details will be presented in the 60% design submittal. Additional modeling is being done to simulate various pumping scenarios to evaluate freshwater supply sources. That information will be included in the forthcoming freshwater source evaluation tech memo, and will be used to inform the evaluation of ICs (in the 60% design). According to information from BLM (early 2011), SoCal Gas had planned for a well near the water tanks between I-40 and Moabi Regional Park. The well could be up to 500 feet deep and was intended for cathodic protection, and not for pumping of groundwater. The text will be revised to reference APN 650-151-05.				
Section 6 Comments – Preliminary Evaluation of Approvals, Permits, and Easement/Access Requirements									
208	DOI-52	Section 6.1		The Consent Decree should be referenced in this paragraph as well.	Comment noted. The final Consent Decree will be referenced when it is available.		Noted.	Comment resolved.	See Section 5.3.1 of this BOD Report.
209	DTSC-78	Page 6-1, Section 6.2, Anticipated Approvals/ Permits/ Agreements for Access to Non-Federal Lands		PG&E should also consider permits necessary for river intake from pipeline bridge, I-40 bridge, or railroad bridge. Based on location and ease of connection to existing infrastructure, DTSC would prefer to evaluate a river intake from or near the pipeline bridge.	DTSC's preference for evaluation of a river intake from or near the pipeline bridge is duly noted. As mentioned in previous responses, a technical memorandum will be prepared to present the evaluation of the three potential freshwater supply sources (wells in Arizona, River, wells in California) and to present PG&E's conclusion. Should a river intake is needed, PG&E will, in compliance with EIR Mitigation Measure BIO-3b, coordinate and cooperate with USFWS and other fisheries biologists to determine suitable and acceptable location(s) for the intake structure(s) to avoid spawning habitat of special status fish species.	Okay pending review of the Freshwater Supply TM.		Comment resolved.	See Appendix J of this BOD Report.

APPENDIX I

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
210	HA-27	p. 6-1, Section 6.2 (Anticipated Approvals/Permits/Agreements for Access to Non-Federal Lands)		While PG&E has easements for access to the parcel now owned by the FMIT, whether these activities will involve any different or additional presence on this parcel should be clarified and the general statement about the Tribe's preference to limit such activity to the extent practicable should be referenced.	The 2006 Easement Agreement between the Tribe and PG&E covers access as well as activities such as operation and maintenance of facilities. The Tribe's preference is recognized and will be further considered during the development of the 60% design, consistent with the provisions of the Easement Agreement and the 2006 Settlement Agreement entered into between the Fort Mojave Indian Tribe and PG&E. A statement to this effect will be included in the 60% design submittal.	Comment and response noted.	Comment and response noted.		See Section 5.3.2 of this BOD Report.
Section 7 Comments – Compliance with ARARs and EIR Mitigation Measure Monitoring Program									
211	DOI-53	Section 7.0		In July 2011, the Office of Environmental Health Hazard Assessment (OEHHA) of California Environmental Protection Agency published a Public Health Goal (PHG) for hexavalent chromium of 0.02 parts per billion (ppb) or micrograms per liter (µg/L) in drinking water. Although this was not identified as an ARAR or TBC in the DOI ROD, given the high public interest regarding this goal, it may be appropriate to provide a short discussion in this section.	As DOI noted in the comment, although the PHG for hexavalent chromium is not an ARAR or TBC in the DOI ROD, given the high public interest regarding this goal, the following text could be added to Section 7.0 of the forthcoming 60% design submittal: On July 27, 2011, the Office of Environmental Health Hazard Assessment (OEHHA) established a public health goal (PHG) of 0.02 micrograms per liter (µg/L) for hexavalent chromium. The California Department of Public Health and OEHHA describe the PHG as follows: "A PHG is not a regulatory standard. It is only one step in the process of developing an enforceable standard that is set by the California Department of Public Health (CDPH) for drinking water that public water systems must meet. The PHG will contribute to California Department of Public Health's development of a primary drinking water standard (maximum contaminant level, MCL) that is specific for hexavalent chromium. Hexavalent chromium is currently regulated under the 50-micrograms per liter (µg/L) MCL for total chromium in California."	Okay.	Okay	Comment resolved.	See Section 6.2 of this BOD Report.
212	HA-28	Section 7.0		Specific laws relating to cultural concerns should be added to this section as well as applicable State laws. Additionally, State of California Governor Brown has issued directives regarding consultation with Native American Tribal Governments.	PG&E defers to DTSC/DOI Additionally, this section includes a reference to Table 7-3, which sets forth ARARs, including cultural resource laws that are ARARs.	Comment noted. DTSC will comply with all policies established as a result of the Governor's directives.	Comment noted. Within the CHPMP on pages 7 through 10; under Section 1.4 Regulatory Context there is an adequate discussion of Federal Law, ARARs and state law for both Arizona and California.		

APPENDIX I

PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
Section 8 Comments – Project Delivery Strategy/Updated Schedule									
213	HA-29	p. 8-2 et seq., Section 8.3 (Phasing Alternatives/Transition from Interim Measure to Final Remedy)		This section is of particular interest to the Tribe. As discussed in the general comments, the existence of the IM3 WTP on Tribal sacred grounds is causing significant spiritual distress and impact to the well-being of the Tribal Community. The criteria proposed to evaluate transition alternatives (Section 8.3.1) do not rigorously consider alternatives that could lead to a more rapid decommissioning of the IM3 WTP, which is of prime interest to the Tribe. PG&E should state whether there are any scenarios under which it is foreseeable that the IM3 WTP might be restarted after remedy startup and, should there be such reasonably a foreseeable scenario(s), develop a rationale that would support a more rapid determination to decommission the IM3 WTP based on plume control. It is not apparent within this section that such considerations were applied in the transition plan. Also, quarterly submittals of relevant data should be required following the completion of start-up of the National Trails Highway (NTH) In Situ Reductive Zone (IRZ) wells in order to determine progressively the trend towards achieving plume control and when plume control can reasonably be assured. With regard to the expectations of the Tribe, this section misdirects the key consideration of the removal of the IM3 facilities, instead emphasizing the termination of IM3 operations and dismantling of its associated infrastructure. (see p. 8-4, 1st full paragraph) In regard to the IM3 decommissioning decision, it is significant to note that in this same section it is stated that, during the transition from IM3 to the final remedy, the loss of hydraulic control exerted by the IM pumping would not pose a significant concern due to the slow migration rate of the contaminants as well as the capacity of the “reducing rind” to attenuate contaminants before reaching the Colorado River.	PG&E acknowledges the Tribe’s statement of its position regarding the decommissioning of IM-3. These topics are currently being addressed in confidential settlement discussions between the Tribe, DTSC and PG&E, and PG&E defers any response on these issues to those settlement discussions.	Comment noted. Decommissioning of IM-3 is the subject of litigation by the Fort Mojave Tribe.	Defer response.		In response this comment a discussion of criteria for approval for IM3 decommissioning plant has been added to Section 7.4 of this BOD Report.
214	HA-30	p. 8-3, 1st para. Section 8.3.2 (Evaluation of Proposed Transition Plan)		The first line should read “led” instead of “lead.”	The change will be made as requested.	Noted.	Noted.		See Section 7.3.2 of this BOD Report.
215	DOI-54	Section 8.3.3, Last Paragraph		The shutdown of IM-3 and the potential impacts to groundwater, perceived impacts to the Colorado River and, conversely, the potential impacts to the remedy from continued operation is of significant interest to the Tribes and stakeholders. It is recommended that this discussion be significantly expanded.	The details of the transition from the IM3 system to the final remedy will be further discussed in the 60% design as requested.	Okay pending review of 60% design submittal.	Okay pending further evaluation during the review of 60% design submittal.	Comment resolved.	See Section 7.3 of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
216	DOI-55	Section 8.3/8-3 and 8-4/3rd and 4th bullets		The bullets indicate the operations will take 3-6 months. What are the criteria for successful start up necessitating a 3-6 month duration?	An allowance of 3 to 6 months for start up of the freshwater wells is provided in the preliminary design to allow for incremental start up of the extraction well and the injection wells in the uplands. Balancing and measurement of water levels near the injection wells will be required as well as adjustments if necessary. An additional 3 to 6 months is projected to start up the Riverbank and uplands injection wells along with the TCS and ER EW and TCS-IW system. These systems will involve balancing of the respective wells and injection points. In addition, if TOC needs to be added to the Riverbank well water, refinement and operation of the TOC injection components will be needed. There will be multiple wells to balance along with the existing network and system maintenance. Similar activities will be necessary for the ER-TCS loop.		Okay. Further evaluation will occur during the review of 60% design submittal.	Comment resolved.	See Section 7.3 of this BOD Report.
Tables									
217	DTSC-79	Table 3-1, Table 3-2, Table 3-3, Table 3-4		PG&E should provide more description for these tables to clarify if the well count column is also meant to describe the approximate well depth for each of those well? (e.g. Table 3-1, IRZ-1, 1 well with dual screens totaling 40 ft will be installed within the 64 foot layer 1 depth and another well with dual screens totaling 40 ft within the 126 feet layer 3 depth?) Are these proposal based on modeling or convenience since Table 3-1 are all within layers 1 and 3, while river bank extraction wells within Table 3-2 are all within layer 3? The rationale for selecting preliminary screen lengths should be discussed, as should the reason(s) for not establishing the preliminary lengths (well screen length identified as "TBD") in select wells. What screen lengths were used in the groundwater model? What criteria will be followed for locating the particular screen length within the model layer with its specific thickness (especially if the layer thickness is significantly greater than the well screen length)? Clarification is also requested regarding Footnote "d" on Tables 3-2 and 3-3 that indicate all amended water may be replaced with freshwater. What triggers that decision?	Revised Tables 3-1 through 3-4 will be included in the 60% design submittal. The preliminary well count in Tables 3-1 through 3-4 denotes the number of wells are present in each well cluster. Each well location ID may consist of a well cluster of up to two wells. Per Table 3-1, IRZ-1 consists of two dual screen wells. The first well will be screened in the two shallow zones (Layer 1 and Layer 2) and the second well will be screened in the two deeper zones (Layer 3 and Layer 4). The injection flows at each of the injection intervals has been established through groundwater modeling to effectively distribute carbon within the IRZ, and the flow rate may therefore be much less than formation can accept, and a portion of the screen may see little or no flow. These stagnant areas provide ample surface area for unwanted biomass buildup that can exacerbate fouling issues, thus "oversizing" the screen can have a deleterious effect. Therefore, each screen will be a maximum of 40 feet long (a screen length that has been demonstrated to be effective for carbon amended injection). The placement of screens was chosen based on the portions of the aquifer containing contaminants requiring remediation and will likely be modified during the advancement of the remedy design and further modified in the field during installation activities. For the River Bank Extraction Wells only one well per	Okay pending review of 60% design submittal.		Comment resolved.	See Tables 3.2-1, 3.2-2, 3.2-3, and 3.3-1 and Appendix C (Design Bulletin: Remediation Well Design and Field Construction Approach).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					location is proposed. These wells will be a screened in Layers 3 and 4 to minimize the migration of manganese, iron, and other reduced species from the river's naturally occurring reducing rind, which is present in the shallower layers surrounding the river. The purpose of this is to minimize fouling of the extraction well and conveyance piping, as well as minimize the placement of manganese (and other species of concern) within the river's reducing rind into the upgradient groundwater plume via the inner loop injection well network. The rationale behind well screen lengths identified as "TBD" (Tables 3-2 to 3-4) is that the specifications for these future wells will be determined during the 60% design. For modeling purposes, the upland injection wells inject into model layers 1 through 4 (Appendix B, Section 4.4.3). The preliminary screen lengths were chosen based on the initial estimates of thickness of saturated sediments and the thickness of target contaminated zones within the saturated sediment. Well screen lengths will be included in place of "TBD" for the upland injection wells and east ravine extraction wells in the 60% design submittal. It will also be noted where field-encountered aquifer characteristics or other factors may affect the final screen lengths. Footnote "d" on Tables 3-2 and 3-3 attempts to explain that the aggregate minimum and maximum flow rates for each well network and will not be equal to the sum of individual well flow rates. It should be noted that some of the wells could be operating at maximum conditions, while others are operating near the minimum conditions (or not operating at all). Carbon-amended water injections may be replaced with freshwater injections at upgradient locations if it is found that a decrease in carbon dosage is necessary to reduce the mobilization of in-situ by products beyond the plume footprint.

218	DOI-56	Table 7-3 Summary of Identified ARARs, Action Specific, Item No. 48		Please include a discussion of the current well design of the HNWR well in this paragraph.	Based on information provided in a November 24, 2010 electronic mail from Bradley Guay (USACE) to Curt Russell (PG&E), the HNWR well is 10-inch diameter well and extends to a depth of 156.5 ft below land surface with a stick up of approximately 2.75 feet. The upper 116 feet of the well is welded, 10-inch mild steel casing. Between 92 and 116 feet, the steel casing was perforated after installation to open this section of the well to the aquifer. Below 116 feet, a 0.030” slot well screen was installed. The type or material of well screen was specified in the information provided in the electronic mail. The test pump intake was set at a depth of 88 feet. There was no information provided about the grout or gravel pack in this well. Since HNWR well is an existing well, this information will be included in Section 3.3 (Freshwater Supply) of the 60% design submittal and the forthcoming Freshwater Supply Source Evaluation Technical Memorandum.	Okay pending review of 60% design submittal.	Noted. The upcoming report from the USFWS should be used to update the information provided in PG&E’s response when it becomes available.	Comment resolved.	See Section 3.3 of this BOD Report
219	DOI-57	Table 7-3 Summary of Identified ARARs, Location Specific, Item Nos. 5 & 7		The “action” notation should include a reference to the DOI ROD, surnamed by BLM, BOR, FWS and BIA.	A reference to the DOI ROD will be added Table 7-3 as directed, in the 60% design submittal.		Okay pending review of 60% design submittal	Comment resolved.	See Table 6.2-1 of this BOD Report.
220	DOI-58	Table 7-3 Summary of Identified ARARs, Location Specific, Item Nos. 14, 17, & 22		Please update the “action” for the ARAR addressing the PA, Tribal Access Plan, and CHPMP. Additionally, it should be noted that a treatment plan will be developed throughout the design process.	The “action” column will be updated with current information in the 60% design submittal. Treatment measures are contained in the CHPMP and the EIR.		Okay pending review of 60% design submittal	Comment resolved.	See Table 6.2-1 of this BOD Report.

221	DTSC-80	Table 7-3 Summary of Compliance with Identified ARARs		Item 2, 52, 99, 100, 101, 32: Discuss the arsenic MCL and how arsenic concentrations above this level are currently proposed to be injected outside the contaminant plume in the last column on the table. Item 53, 99, 100, and 101: Discuss secondary MCLs of the byproduct manganese in the last column on the table. Item 35: Would this ARAR be in effect if a river intake structure were selected? Item 47: This item states, “Most of the groundwater that is withdrawn will be reinjected into the aquifer. Any groundwater that is withdrawn but not reinjected into the aquifer shall be put to reasonable and beneficial use.” Please clarify/list the water uses of freshwater supply other than for reinjection. These uses do not seem to be accounted for in the design needs for the supply well which is only evaluated as a source for injection. Item 51: Mention that elevated arsenic in Arizona wells may require treatment.	**Item 2** – inserted text is shown in underline typeface, delete text is shown in ~~strikeout~~ typeface: Compliance with this requirement will be achieved by reducing the concentration of Cr(T) in the affected aquifer to a concentration below the federal maximum contaminant level (MCL) for Cr(T) of 100 µg/L. There is no federal MCL for Cr(VI) and the RAO of 32 µg/L (based on the regional background concentration) has been established at the conclusion of remedy implementation. ~~Although~~ ~~c~~ Concentrations of Cr(VI) and arsenic as in situ byproducts may fluctuate above baseline levels within the treatment area during remedy implementation. In addition, as part of the remedy fresh water from a well in Arizona will be injected west of the plume, within the project’s Area of Potential Effects. The naturally occurring arsenic concentration in water from the well exceeds the MCL of 10ug/L, which is typical of water quality in the vicinity of Topock, Arizona . Modeling indicates that arsenic concentrations that may temporarily be elevated by **~~a) the injection of this water and b)~~** the generation from insitu remediation will attenuate under site conditions and return to pre-remedy baseline levels after the end of active remediation. Institutional controls will prevent use of affected groundwater as a drinking water source until the remedy is complete. Groundwater monitoring will be used to track performance of the remedy and verify that RAOs have been achieved at the conclusion of remedy implementation and prior to removing the institutional controls. **Item 32** This item states that “The preliminary (30%) design includes facilities in the jurisdictional water of the US (see Figure 2-16). PG&E will work with the USACE to ensure compliance with the substantive requirements of Section 404 per CERCLA Section 121(e)(1). It is anticipated that a wetland delineation will be conducted in the Spring of 2012.” The DTSC comment does not appear to be relevant to this item. **Item 35** This ARAR applies if the river intake structure has the potential to affect navigable waters on the site.	Agree with Response pending review of the 60% design submittal. However, please note the following concerns : Item 2 – the comparison of UTL, which is the upper end of the background range, with generated concentrations of As above MCL must be carefully evaluated. While in nature, there will be natural variations and some concentration above MCL levels may exist (up to or exceeding UTL), This phenomenon should not be viewed as appropriate to leave chemicals above the MCL after active remediation beyond the current plume boundary because there is within a probability of detecting concentration at the UTL. If the generated concentrations are on par with the mean natural value and occasionally have detection reaching UTL, then the scenario is more like nature.		Comment resolved.	See Table 6.2-1 of this BOD Report. The text shown in bold strikeout typeface in PG&E Response to 30% Design Comment of this comment, is to reflect that in this 60% design, HNWR-1 water is pre-treated prior to injection.

APPENDIX I

Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design

PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					Item 47 The 30% design states that the extracted groundwater is for freshwater injection and for Compressor Station operational use. The Compressor Station currently receives its water from well Topock-2 and 3 in Arizona. **Item 51** The Arizona Action-Specific ARAR (A.R.S 49-282.06(A)(2)) states that “To the extent practicable, provide for the control, management or cleanup of the hazardous substances in order to allow the maximum beneficial use of the waters of the state”. PG&E understands that this ARAR applies to the control, management, or cleanup of hazardous substances in the State of Arizona. The 30% design does not involve treatment or cleanup in Arizona. The DTSC comment does not appear relevant to this item. **Item 52** – inserted text is shown in <u>underline</u> typeface, delete text is shown in ~~strikeout~~ typeface: Compliance with this requirement will be achieved by reducing the concentration of Cr(T) in the affected aquifer to a concentration below the state maximum contaminant level (MCL) for Cr(T) of 50 µg/L. There is no state MCL for Cr(VI) and the RAO of 32 µg/L (based on the regional background concentration) has been established at the conclusion of remedy implementation. ~~Although c~~ <u>C</u>oncentrations of Cr(VI) and arsenic as an in situ byproduct may fluctuate above baseline levels within the treatment area during remedy implementation. <u>In addition, as part of the remedy fresh water from a well in Arizona will be injected west of the plume, within the project’s Area of Potential Effects. The naturally occurring arsenic concentration in water from the well exceeds the MCL of 10ug/L, which is typical of water quality in the vicinity of Topock, Arizona . Modeling indicates that arsenic concentrations that may temporarily be elevated by</u> **~~a) the injection of this water and b)~~** <u>the generation from insitu remediation will attenuate under site conditions and return to pre-remedy baseline levels after the end of active remediation.</u> Institutional controls will prevent use of affected groundwater as a drinking water source until the remedy is complete.	Item 52 – The modeling result which suggests that Arsenic will attenuate and not be mobile in any extensive direction beyond the injection well remains to be proven. DTSC agrees that the pilot test appears to support that conclusion; however, it will become PG&E’s liability if the remedy creates an Arsenic plume that does not attenuate with time or distance. PG&E must develop robust monitoring and contingency plans to ensure that arsenic will be under control during the remedy. PG&E’s response is noted and DTSC will review the 60% design submittal when available.			

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					Groundwater monitoring will be used to track performance of the remedy and verify that RAOs have been achieved at the conclusion of remedy implementation and prior to removing the institutional controls. **Item 53 –** inserted text is shown in <u>underline</u> typeface**:** There is no secondary MCL for Cr(VI) or Cr(T). Secondary MCLs are community acceptance standards for constituents that may adversely affect the taste, odor, or appearance of drinking water. <u>Concentrations of insitu by-products (arsenic, manganese (secondary MCL of 50ug/L)) may fluctuate within the treatment area during remedy implementation</u>. An institutional control will be enforced throughout the chromium plume area during implementation of the remedial action to prohibit use of the groundwater as drinking water source.	Item 53 - PG&E is correct that there is no secondary MCL for Cr(VI) or Cr(T). However, despite PG&E's statement that secondary MCLs are "community acceptance standards," they are nevertheless a regulatory standard for California drinking water. Although PG&E states that there will be ICs to prevent use of affected water for drinking water, the basin plan, which is an ARAR, dictates that the water is designated for beneficial uses. Therefore, ICs are not to change the designation of which the clean-up standards at remedy completion must be based.			
					Item 99 – inserted text is shown in <u>underline</u> typeface**:** Compliance with this requirement will be achieved by reducing the concentration of Cr(T) in the affected aquifer to a concentration below the federal and state MCLs of 100 µg/L and 50 mg/L respectively which represent the chemical concentrations in drinking water considered safe for human consumption. There are no MCLs or MCLGs for Cr(VI) and the RAO of 32 µg/L (based on the regional background concentration) has been established at the conclusion of remedy implementation. <u>Concentrations of Cr(VI) and in situ byproducts (e.g., arsenic, manganese) may fluctuate above baseline levels within the treatment area during remedy implementation. In addition, as part of the remedy fresh water from a well in Arizona will be injected west of the plume, within the project's Area of Potential Effects. The naturally occurring arsenic concentration in water from the well exceeds the MCL of 10ug/L, which is typical of water quality in the vicinity of Topock, Arizona . Modeling indicates that arsenic concentrations that may temporarily be elevated by</u> ~~**a) the injection of this water and b)**~~ <u>the</u>	Item 99 –The action specific ARAR designated the site ground water to be beneficial for municipal and domestic water supply. PG&E should ensure that the water quality will be properly restored to ambient conditions not just for Cr(VI) but also for any chemicals that will be generated or introduced.			

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					<u>generation from insitu remediation will attenuate under site conditions and return to pre-remedy baseline levels after the end of active remediation</u>. <u>Modeling also indicates that manganese generated from insitu remediation does not exceed the upper tolerance level of background manganese concentration at the site</u>. The final groundwater remedy includes an institutional control to restrict use of the groundwater for potable use until the remedy is complete. Groundwater monitoring will be used to track performance of the remedy and verify that the RAOs have been achieved at the conclusion of remedy implementation and prior to removing the institutional control. **Item 100** – inserted text is shown in <u>underline</u> typeface: Surface water sampling in the Colorado River near the site show concentrations of Cr(T) less than the federal and state MCLs of 100 µg/L and 50 mg/L (drinking water supply standards). Surface water sampling in the Colorado River also show concentrations of Cr(VI) less than the California Toxics Rule criteria of 11 µg/L (protection of freshwater aquatic life). Reducing Cr(VI) concentrations in groundwater by implementation of the remedy will increase the level of certainty that surface water quality will continue to remain below these levels. PG&E will prepare an O&M Plan, Progress Reports, and a Corrective Measure/Remedial Action Completion Report. The remedy is intended to restore groundwater to the regional background Cr(VI) concentration of 32 µg/L, thereby addressing any contribution by PG&E affecting potential beneficial uses. The operation of the River Bank Extraction Wells will prevent migration of contaminants to the Colorado river that could impact beneficial uses or result in a failure to meet surface water quality objectives <u>The remedy is also designed and will be implemented to control the generation and migration of insitu by-products (arsenic, manganese). The MCL for arsenic is 10ug/L and the secondary MCL for manganese is 50ug/L. In addition, as part of the remedy fresh water from a well in Arizona will be injected west of the plume, within the project's Area of Potential Effects. The naturally occurring arsenic concentration in</u>	Item 100 - Similar to above, under basin plan and ARAR compliance, PG&E is also obligated to restore the groundwater to ambient conditions not just for Cr(VI) but also for any chemicals that will be generated or introduced.			

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					water from the well exceeds the MCL of 10ug/L, which is typical of water quality in the vicinity of Topock, Arizona. Modeling indicates that arsenic concentrations that may temporarily be elevated by **~~a) the injection of this water and b)~~** the generation from insitu remediation will attenuate under site conditions and return to pre-remedy baseline levels after the end of active remediation. Modeling also indicates that manganese generated from insitu remediation does not exceed the upper tolerance level of background manganese concentration at the site. **Item 101 –** inserted text is shown in underline typeface: PG&E will prepare an O&M Plan, Progress Reports, and a Corrective Measure/Remedial Action Completion Report. Although concentrations of Cr(VI) and insitu by-products will fluctuate inside the footprint of the remedy during implementation, at the conclusion of the remedy the RAOs will be achieved. In addition, as part of the remedy fresh water from a well in Arizona will be injected west of the plume, within the project's Area of Potential Effects. The naturally occurring arsenic concentration in water from the well exceeds the MCL of 10ug/L, which is typical of water quality in the vicinity of Topock, Arizona. Modeling indicates that arsenic concentrations that may temporarily be elevated by **~~a) the injection of this water and b)~~** the generation from insitu remediation will attenuate under site conditions and return to pre-remedy baseline levels after the end of active remediation. Modeling also indicates that manganese generated from insitu remediation does not exceed the upper tolerance level of background manganese concentration at the site. Therefore, the remedy will comply with the substantive provisions of the SWRCB Resolution 68-16 that requires maintenance of the highest water quality consistent with maximum benefit to the people of the State, and with the substantive provisions of SWRCB Resolution 92-49 that require restoration of background water quality.				

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
222	DTSC-81	Table 8-1		DTSC understands that this is a cross reference table copied from the CMI/RD work plan. However, please note that the target dates for document submission have clearly changed. PG&E should update the table accordingly. Please also note that the table referenced other tables that are not in the 30% design (e.g., Table 4-5 for content of various design submissions). DTSC suggests a checklist format with locations within the document instead of the proposed table. The checklist can allow reviewers to know that the specific item has been completed and its location within the document at a glance.	PG&E will update the target dates in Tables 8-1 and 8-2 to reflect current schedule at the time the 60% design is submitted. In response to DTSC's comment, PG&E proposes to include a table similar to Exhibit 1-3 of the Revised CMI/RD Work Plan.	Okay pending review of the 60% design submittal.		Comment resolved.	See Tables 7.2-1, 7.2-2, and 7.2-3 of this BOD Report.
Figures									
223	DOI-59	Figure 2-17		This figure shows IRZ wells locations in the floodplain. Previous documents have noted that the wells would be located along the National Trails Highway (NTH) or possibly in the floodplain. Please justify the location of the wells within the floodplain area rather than along the NTH.	For safety reasons, PG&E has located the IRZ wells out of the NTH traffic lanes, on the road shoulder where available. Where road shoulder is not readily available, such as on the east side of NTH north of the MW-20 bench, PG&E has located wells in areas that minimize removal of vegetation and mature plants. The proposed well locations on Figure 2-17 accomplished both of these objectives.	Okay pending review of 60% design submittal.	Okay.	Comment resolved.	See Figures 2.4-6 and 3.0-1 of this BOD Report.
224	DOI-60	Figure 3-1		Building "M" is incorrectly labeled in the inset map according to the legend description which includes "L" but not "M". Please review and revise as necessary.	This figure will be revised in the 60% design submittal.	Okay	Okay pending review of the 60% design submittal.	Comment resolved.	See Figure 3.0-1 of this BOD Report.
225	DOI-61	Figure 3-1		Notes 1 and 3 should indicate Appendix D not C for the engineering drawings. Also, in the legend under Pipeline for Remedy, the words "pipeline" and "pipe" should end with (s) to indicate these may not be single pipelines.	This figure will be revised in the 60% design submittal.	Okay	Okay pending review of the 60% design submittal.	Comment resolved.	See Figure 3.0-1 of this BOD Report.
226	DTSC-82	Figure 3-1		Where would FW-INJ-3 (future well) potentially be located. Please summarize how this well came to be an optional well in the document.	See response to comment 155 DOI-37.	Okay pending review of 60% design submittal.		Comment resolved.	See Figure 3.0-1 of this BOD Report.
227	DOI-62	Figures 3-4 through 3-9		Please define the model layers on each figure.	The model layers will be further labeled to reflect the corresponding hydrogeologic units displayed in the cross-sections.		Okay pending review of the 60% design submittal.	Comment resolved.	See Figures 3.1-2 through 3.1-7.
Appendix B – Groundwater Modeling									
228	DOI-63	Appendix B Cross Sections		The proposed well screens should be identified on the cross sections.	Well screens will be added to the wells presented in the Appendix B cross-sections.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Figures 6.4-3 to 6.4-8.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
229	HA-31			This appendix provides an overview of groundwater flow model development, but does not present sufficient detail to understand various decisions that were applied to arrive at the final model configuration on which the final remedy design was based. For example, how was the model calibrated, specifically what was the basis for assigning individual parameters over the range of available field data? What constraints were applied? What is the range of uncertainty? Between the time that the 2005 flow model was developed and the appearance of this new flow and transport model, little specific information on model development was presented to stakeholders, only the results. What configurations were considered to arrive at the design presented? What was/were the goal(s) of model optimization? Within these comments, the Tribe has emphasized the importance of siting to avoid impacts and desecration to sacred areas. Were any constraints applied to consider such avoidance? Were any scenarios considered that specifically addressed a startup strategy that would allow for a more rapid release of the IM3 WTP? Regardless of the answers to these questions, the Tribe is disappointed that the development of this model, the basis for design, was not communicated with the Tribes, Agencies, and Stakeholders in a transparent way. The Agencies should direct more open discussions and information exchange in this regard moving forward and particularly during remedy startup.	The calibration procedure was explained in CH2MHILL 2005 and describes the assignment of hydrogeologic parameters. The flow model was calibrated against (a) long term average groundwater levels, (b) average monthly floodplain levels responding to fluctuating river levels, (c) short-term responses to pump testing events, and (d) plume development over time. The autocalibration program PEST was employed to refine the calibration and to reduce effects of uncertainty in each calibration target. The solute transport model was based directly on the original flow model and honors all of the hydrogeologic parameters and boundary conditions. With respect to the uncertainty in the solute transport model, a sensitivity analysis was conducted with respect to the simulated parameters in section 6 of Appendix B. Text can be added to expand on the associated uncertainty. Several configurations were considered in the development of the groundwater flow and transport model. Well locations were carefully selected first by avoiding culturally or otherwise sensitive areas to minimize impact. This included closely evaluating delineated areas and avoiding sensitive areas during well placement. The next criteria was to optimize the well locations to minimize the number of necessary wells while still maintaining effective treatment to minimize the remedial timeframe. A careful balance of these criteria were evaluated until the optimal well layout was established. Several of these scenarios were presented prior to submittal of the 30% design report to reflect the reasoning We welcome open discussions and feedback regarding the remedial system design.	DTSC is perplexed as to the origin of the comment that the model development was not communicated with the Fort Mohave Indian Tribe. Based on review of our records, DTSC has facilitated several discussions on the model over the years so that questions associated with its development and use could be addressed. Some of these meetings held after the 2005 model calibration included the August 19, 2008 discussion on the use of the 5 layer models in the remedial selection process, the January 22, 2009 meeting at USGS office in San Diego, a two day meeting on September 1 and 2, 2011 on input parameters, and the October 18, 2011 meeting specifically on the modeling basis, uncertainties and results as it was applied to the remedy design. In addition, DTSC notes that we have responded to many questions raised by the FMIT via email on this same topic. However, DTSC acknowledges that the solute transport model included in the design is far more complex in nature than the original flow model, but such complexity is not unexpected. As always, DTSC will continue to facilitate meaningful discussions between PG&E and Tribes and/or Stakeholders regarding this matter.	Comment and response noted. DOI acknowledges the complexity of the fate and transport model, and to a lesser extent, the flow model and has requested the PG&E included further discussions in the forthcoming Fresh Water Technical Memorandum and the 60% design submittal. The agency encourages continued Tribal participation in the upcoming Consultative Working Group and Technical Working Group meetings planned throughout the design process.		See Appendix B, Section 4.
230	HA-32			Additionally, the Tribe notes that the TRC has provided a number of comments on model uncertainties, scenarios, etc. (Attachment A). The Tribe wishes to underscore these comments and approves them on behalf of the FMIT.	Comment noted. PG&E have responded to the TRC comments in Attachment A, and included those responses in this table.	Noted	Comment noted		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
231	DOI-64	App. B, Section 2.2		The first paragraph of this section discusses the primary components of the groundwater flow system, citing five items. The conceptual hydrogeological site model should address each of these items in order to provide the framework necessary for development of the numerical flow model. DOI believes that it is important that the conceptual site model be thoroughly documented so that the basis of the subsequent mathematical model can be understood and critically assessed. This section, and in particular Section 2.2, is very abbreviated, with no discussion of several of the items called out in the first paragraph, and no basis for appreciating the hydrogeologic complexity of the site. Furthermore, while it is recognized that groundwater flow modeling has been ongoing at the site for many years, with comprehensive documentation, fate and transport modeling has not been previously presented. This model represents a significant revision warranting a more thorough discussion of the conceptual hydrogeologic and contaminant fate and transport site model as the basis for the numerical model in this section.	Conceptual model section will be expanded to provide a more thorough treatment of the subject at the beginning of the appendix for the 60% submittal.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 2
232	DOI-65	App. B, Section 2.2, 2nd paragraph		This section mentions the occurrence of groundwater only in the alluvial aquifer at the site. Groundwater is also known to occur in consolidated bedrock. Previous to the discovery of contamination in bedrock groundwater in the East Ravine, bedrock groundwater was discounted as a potential contaminant migration pathway. With the East Ravine findings, the occurrence of groundwater in bedrock should be discussed in this section of the conceptual model. In doing so, it should be noted that limited information exists on the nature of the fracture flow and groundwater flow directions in the East Ravine area. Studies are ongoing. Also, with the recent findings at Site H in the East Ravine, PG&E should avoid statements that fracture flow in the bedrock is necessarily of limited flow rate and radius of influence.	Text will be added to discuss the groundwater in bedrock based upon the studies conducted to date. This will include discussions of how the bedrock groundwater behaves in the East Ravine area as well as conditions observed at Site H. Refer to response to comment #10 DOI-9.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See Appendix B, Section 2.2.
233	DOI-66	App. B, Section 3, 2nd paragraph, last sentence		This section of Appendix B refers the reader to Section 3.1 of the main report for a summary of the updates to the groundwater flow model, while Section 3.1 of the main report refers the reader to Appendix B for the same information. DOI recommends that the most detailed discussion of the modeling, including the conceptual hydrogeologic and fate and transport models, and the model code selection and implementation descriptions be presented in Appendix B, with the important concepts summarized in Section 3.1 of the main report.	The reference of the groundwater flow model details should have pointed to Hill 2005 and 2009. The solute transport model code selection and the groundwater submodel code selection are explained in detail in Appendix B. Further information with respect to the conceptual hydrogeologic and fate and transport models will be added to Appendix B. Appendix B will serve as a comprehensive documentation of the model. Section 3 will provide a summary level discussion that highlights primary design-related modeling conclusions.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Section 3.1 of the BOD Text and Appendix B.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
234	DOI-67	App. B, Section 3.3, 1st paragraph, 2nd sentence		There appears to be a typographical error in this sentence. It appears "is' should be replace with "of".	Text will be edited.	Ok	Ok		See Appendix B, Section 4.3.
235	DOI-68	App. B, Section 3.3, 1st paragraph, 3rd sentence		It is not apparent that a north-south oriented grid is necessarily aligned with the direction of groundwater flow, which is northeastward over much of the area.	This sentence will be deleted in the 60% submittal.	OK.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 4.3.
236	DOI-69	App. B, Section 3.3, 1st paragraph, last sentence		This section states that the submodel domain boundaries are constant head boundaries, while Section 3.4 states that the boundaries are constant flux boundaries.	Text will be corrected. Boundary conditions are constant flux cells.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 4.3.
237	DOI-70	App. B, Section 3.3 2nd paragraph		This section refers to the thickness of layers in the "solute transport submodel", but this section is actually discussing the groundwater flow submodel domain. This is potentially confusing. Also, it is unclear by what is meant by the statement that the upper four layers in the southern bedrock portion of the model "…no longer are consistent with the alluvial portions of these layers to the north". In what way are they not consistent? Please clarify.	Text will be revised to reflect a single flow and transport submodel. South of the bedrock contact, the upper four layers in the groundwater flow submodel represent bedrock, whereas to the north of the bedrock contact, the 4 layers represent the alluvial aquifer. Therefore the hydraulic conductivities vary within the layers to represent the different lithologies. Text will be changed to make this point more clear.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 4.3.
238	DOI-71	App. B, Section 3.4		The use of constant flux boundaries seems reasonable if the distances from the boundaries to aquifer stressors (e.g., pumping and injection wells) are sufficient so as not to inappropriately constrain fluxes at the boundaries. In this regard, DOI would like assurance that the model is appropriately simulating boundary conditions under remedial action conditions in two areas; west and north of the fresh water injection wells and along the eastern boundary nearest the fresh water supply well in the HNWR. Also, please clarify what is meant by the statement "The final boundary conditions simulated in the submodel domain are the well cells which represent the proposed extraction and injection locations for the various remedial scenarios."	Because the submodel was extracted from the regional flow model, the boundary conditions reflect the actual pumping conditions within the model domain. Therefore the fluxes at the boundaries are not inappropriately constrained. The text will be modified to identify the three types of boundary conditions within the submodel. The sentence quoted in the comment represents the third type of boundary condition.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 4.4.
239	DOI-72	App. B, Section 3.5, last sentence		Please revise the last sentence to say "All hydraulic conductivity values in the submodel were assigned on the basis of the ORIGINAL groundwater flow model properties", if in fact, this is the case.	The hydraulic conductivity values in the submodel are the exact same values in the regional groundwater flow model from which the submodel was extracted. Text in the 60% submittal will be edited to reflect the suggested sentence.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 4.5.
240	DOI-73	App. B, Section 4.1, 3rd bullet		Change "on" to "of"	Text will be changed.	Okay	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 6.1.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
241	DOI-74	App. B, Section 4.2.1		This section addresses mobile and immobile porosity. Please provide more support for this assumed value for this important parameter. Simply referring to the cited textbook is not sufficient. Please provide a detailed discussion of why a textbook value is reasonable for this model. Provide a discussion on how sensitive the model results are to this assumed parameter. If highly sensitive, which DOI expects, are there ways to better estimate the conditions for this site, rather than solely relying on textbook values?	Site in situ pilot tracer studies, along with breakthrough of IM3 injection water, were also used to estimate mobile porosity. Text will be added to document these site-specific sources of data and how they were used to estimate porosity.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 6.2.1.
242	DOI-75	App. B, Section 4.2.2		DOI has previously been told by PG&E that calibration of the fate and transport model is infeasible because it is not possible to reliably simulate the generation of the current plume from its release in BCW. However, this section seems to be saying that the mass transfer coefficient parameter was somehow evaluated by adjusting it to produce “reasonable plume movement”. This concept is not clear and warrants further explanation.	It is correct that the calibration of the fate and transport model is infeasible because it is not possible to reliably simulate the generation of the current plume from its release in BCW wash. The mass transfer coefficient was developed based on literature values and models of similar dimensions and aquifer properties, and testing with the model. Small scale and short term plume movements were evaluated with a range of mass transfer coefficients. The text will be updated accordingly.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 6.2.2.
243	DOI-76	App. B, Section 4.2.4		DOI had understood that this relationship of Cr (VI) degradation with TOC concentration was based on observations during the in-situ pilot tests, however no mention is made of that in this section. Please amplify on the basis for these critical assumptions and why 0.1 ppm is the point at which this process occurs. DOI has understood that the target TOC concentration for the IRZs is 100 ppm.	A section will be added to Appendix B discussing the results of in situ pilot tests and how these results were used in deriving a target TOC concentration for the remedy. A more detailed discussion of the various TOC target and trigger concentrations used in the model will be included in the 60% submittal.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 3.4.1.
244	DTSC-83	Appendix B, Page 9, 4.2.4 Chromium Reduction	To account for this, the model assumed hexavalent chromium reduction/precipitation whenever the injected carbon exceeds a concentration of 0.1 parts per million (ppm). At the same time, a carbon half-life of 20 days was assigned to account for the degradation of the injected carbon over time.	Up to this point, Arcadis has provided a logical rationale for the parameters selected for the solute transport model. However, no rationale was provided for the parameters cited in the quoted text. This section should provide examples or reference specific sections of other documents that verify the 0.1 ppm carbon concentration is an appropriate value for the completion of chromium reduction (as well as the point at which arsenic and manganese begin to sorb and precipitate).	Refer to response to comment # 243, DOI-76. Additional detailed discussion of byproduct generation will be added to Section 4.2.6 of Appendix B and attenuation mechanisms will be detailed in 4.2.7 of Appendix B.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 3.4.1.
245	DOI-77	App. B, Section 4.2.5, 3rd sentence		The sentence seems to have a typographical error. Is the intent of the sentence to say that, for initial conditions, the Cr (VI) concentrations in the mobile and immobile portions of the aquifer are in equilibrium?	Yes, the revised sentence is “The initialized hexavalent chromium distributions are the same in both the mobile and immobile aquifer portions.”	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 6.2.5.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
246	DTSC-84	Appendix B, Page 9, 4.2.5 Chromium Reduction		The initial hexavalent chromium contaminant plume maps (B-13 to 16) will need to be updated to include all recent data including the highest concentration detected to date in well MW-68-180 (22,000 ug/L) located on the compressor station. It will be interesting to see if this new concentration affects cleanup model runs.	Plume maps will be updated with plume characterization data collected through January 2012.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 6.2.5. Plume maps were updated with plume characterization data collected through February 2012.
247	DOI-78	App. B, Section 4.2.6, last paragraph		The first sentence appears to actually be two separate sentences. The relationship of Cr (VI) reduction, Mn and As generation, and Mn and As persistence in dissolved form would benefit from a concentration versus TOC concentration plot that shows all three constituents. It appears from the various sections of text, and the referenced CMS-FS plots that Cr (VI) reduction begins when organic carbon concentration is above 0.1 ppm, Mn and As dissolution begins at about 10 ppm, and Mn and As precipitation begins at about 0.1 ppm.	Yes, it should be adjusted to two sentences and corrected. Within the model, both Mn and As generation/ dissolution will occur in the presence of any degrading TOC and is not limited by TOC concentration. However with respect to precipitation, Arsenic will not precipitate in the presence of TOC above a concentration of 0.1 ppm. Manganese will have active sorption in the aquifer independent of TOC concentration. The controlling function for Manganese sorption is Mn concentration as it is simulated using the Freundlich isotherm. In order to present conservative (worst-case) Mn transport, there is no active precipitation in the solute transport model to serve as a mechanism to remove Mn from solution. Additional detailed discussion of byproduct generation will be added to Section 4.2.6 of Appendix B and attenuation mechanisms will be detailed in 4.2.7 of Appendix B.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Sections 3.4.3, 5.3, and 5.4.
248	DTSC-85	Appendix B, Page 10, 4.2.6 Byproduct Generation		The section discusses generation rates for byproduct arsenic based on organic carbon dosage during hexavalent chromium reduction. Mention of the specific arsenic species and geochemical mechanisms is requested to assist with understanding stable arsenic species in both reduced waters as well as aerobic. Please also discuss how arsenic is generated naturally in aerobic, nonreducing environments and what mechanisms and species exist in those environments.	Concepts presented in the response to comment #51, HA-7 will be provided in the text for the 60% submittal. Additional details on various arsenic species in other environments outside the IRZ will also be included.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Sections 3.4.3 and 5.4.

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
249	DOI-79	App. B, Section 4.2.6, 1st paragraph and Section 4.2.7, 1st paragraph, last paragraph		The assertion is made here that Mn migration will be limited outside the reactive zone where Cr (VI) is treated, and that the model-predicted attenuation profile is consistent with observed Mn attenuation across the floodplain. This concept has been often stated in discussions with PG&E consultants, i.e., that dissolved Mn is generated in the treatment zone but then will quickly adsorb outside the carbon area and dissolved concentrations will rapidly decline down gradient. However, the results of the fate and transport modeling depicted on Figures B-31 through B-34 do not seem to support this conclusion. The extent of the generated Mn plume grows continuously during the 30-year simulation period both within the floodplain and in the upland areas where carbon-amended water is injected. The plumes extend well beyond the areas where injected carbon is simulated to occur. Please reconcile these seemingly contradictory conclusions.	To introduce a level of conservatism, it is assumed that manganese sorption will occur, but manganese will not precipitate in groundwater. This will essentially retard the movement of manganese in groundwater, but will not remove manganese from groundwater. This allows the manganese to persist in the groundwater and only be minimized through dilution or remedial extraction. It is also important to note that the Mn represented in the model is also sourced from naturally occurring Mn in the rind which migrates into less reduced sediments in layers 3 and 4 and only attenuates by dilution and sorption – not via precipitation. This represents a conservative assumption that will be reconsidered in the 60% design. The rind concentrations will be reassessed and modified as necessary (refer to response to comment # 258, DTSC-91). Arsenic and manganese will be described separately in terms of attenuation and precipitation, with arsenic being more limited in overall mobility than manganese. More detail will be provided on the attenuation mechanisms for byproducts in Section 4.2.7 of Appendix B. The conceptual model, to be expanded at the beginning, of Appendix B will provide an overview of these concepts.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Sections 5.3 and 5.4.
250	DOI-80	App. B, Section 4.2.7, Item c, page 13		Item (c) says that the concentrations of sorptive forms of iron were scaled back by three orders of magnitude from the measured values in fine-grained materials. Item (d) says that iron values measured for coarse-grained materials were slightly less but of the same order of magnitude as the fine-grained. It then concludes that “These results confirm selection of the strong and weak site iron concentrations as best representations of the iron concentration and form in the aquifer soil.” DOI is not clear on which results have been confirmed and are being used; the scaled-back values or the measured values for coarse-grained materials. If the scaled-back values are used, is this being done as a conservative measure?	Item (d) will be clarified to state that difference in iron concentration between the fine and coarse fractions was about three orders of magnitude, in agreement to the assumptions in item (c).	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	No longer applicable. See updated discussion in Section 5.3.2 of Appendix B.
251	DOI-81	App. B, Section 4.2.7, Item G		Please explain this sentence: “Field isotherms matched the model isotherms when sorptive iron was scaled back by 10% - field and model isotherms were for silt/clay soil.”	Field sorption isotherms were developed by measuring the concentration of manganese in the soil and in the groundwater for samples recovered from the alluvial aquifer fine grained soil. The sorption isotherm developed from this field data matched the modeled isotherm within 10%.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 5.3.2.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
252	DTSC-86	Appendix B, Page 11, 4.2.7 Byproduct Adsorption and Precipitation	"Manganese and arsenic will sorb to iron minerals present naturally in the aquifer outside of the reactive zone, across the floodplain, and to these newly-formed iron minerals."	How then is arsenic stable at elevated concentrations in aerobic environments? Arizona wells have elevated arsenic above MCLs. Anomalously high arsenic concentrations are noted in aerobic well MW-12 coexisting with the chromium contaminant plume. Will the model allow the elevated arsenic that is measured at MW-12 and in Arizona (e.g., Sanders well) to persist in model results?	Arsenic is stable in aerobic environments due to natural geochemical equilibrium established over an extended time period, and in the presence of a continual ongoing source of arsenic (such as due to hydrothermal activity in AZ). This ongoing source over geologic time periods can result in saturation of arsenic sorption capacity in the aquifer. The text from Appendix B that this comment refers to discusses arsenic generated by the transient geochemical conditions in the IRZ. The solute transport model is designed to simulate the relative effect of arsenic generated by the biogeochemical conditions induced by the NTH IRZ, and also to simulate the fate of the arsenic naturally present in the freshwater supply well that is injected into the freshwater injection wells. The model does not include anomalously high arsenic concentrations at MW-12 or the Sanders well.	Okay		Comment resolved.	Note that as directed by DTSC on December 31, 2012, PG&E added into the 60% design, a pre-treatment system to polish Arizona groundwater to California standards prior to injection. Therefore, the fate and transport of naturally-occurring arsenic associated with freshwater injection is no longer applicable, as the freshwater source will be treated for arsenic, and has been removed from the 60% design.
253	DTSC-87	Appendix B, Page 12, 4.2.7 Byproduct Adsorption and Precipitation, Paragraph 1, Line 1.		Please cite the wells being evaluated for manganese so the reader can follow along and evaluate the assessment presented here.	The wells that were evaluated for Mn attenuation include MW-20 (adjacent to the river), MW-39, MW-30, MW-36, and MW-31 (away from the river). The concentrations of manganese and iron were evaluated in these wells under IM-3 pumping conditions. These wells will be identified in the 60% design document update to Appendix B.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 5.3.
254	DTSC-88	Appendix B, Page 12, 4.2.7 Byproduct Adsorption and Precipitation	"The field data provides a validation of the conceptual model used as the basis for attenuation in the byproduct fate and transport model."	The section must also then cite that field data also raises concern with manganese due to its long term persistence.	The long-term persistence of manganese is generally associated with persistent reducing conditions. Under less reducing conditions, manganese concentrations decline gradually with time. The field data demonstrates this. The text in the 60% design will include this expanded discussion.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 5.3.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
255	DTSC-89	Appendix B, Page 13, 4.2.7 Byproduct Adsorption and Precipitation, Item (e).		The section indicates that manganese and arsenic were added to the model at low to high concentrations to simulate conditions. It seems that actual concentrations should have been utilized. The document should include a listing of the actual concentrations used in the model to allow for review and ensure they are representative.	The naturally occurring Mn and As simulated in the model was discussed on page 15 section 4.2.8. These values were average representative values that will be refined in the 60% design.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 6.2.8, for discussion of manganese. Note that as directed by DTSC on December 31, 2012, PG&E added into the 60% design, a pre-treatment system to polish Arizona groundwater to California standards prior to injection. Therefore, the fate and transport of naturally-occurring arsenic associated with freshwater injection is no longer applicable, as the freshwater source will be treated for arsenic, and has been removed from the 60% design.
256	DTSC-90	Appendix B, Page 15, 4.2.7 Byproduct Adsorption and Precipitation	"An evaluation of the concentration trends for manganese across a transect of wells from the east (along the river) to the west (toward National Trails Highway) shows that as groundwater moves through less reducing geochemical conditions (away from the river), the concentration of manganese attenuates. The attenuation profile is simulated in the model by an analysis of manganese concentrations along a similar transect, moving from west (along the IRZ at National Trails Highway) to the east (toward the river)."	The first sentence indicates that manganese attenuates away from the river (away from less reducing conditions). The second sentence seems to say that manganese attenuation will occur towards the river. Clarification is requested.	Text will be clarified to indicate that manganese more readily attenuates in less reducing conditions. In this case, the discussion compares Mn attenuation away from the river (under IM-3 pumping conditions, where the gradient direction is reversed and Mn in the reducing zone adjacent to the river is pulled into a more oxic environment away from the river, and deeper) to the Mn attenuation simulated under IRZ conditions (where Mn generated in the IRZ migrates downgradient into a more oxic zone toward the river). This appears to be contradictory but the discussion compares current observations of Mn attenuation (under IM-3 pumping conditions) to Mn attenuation under IRZ conditions.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 5.3.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
257	DOI-82	App. B, Section 4.2.8		It appears from the discussion that the evaluation considered only naturally occurring Mn in the floodplain and not As. Please explain why the naturally occurring As component was limited only to the fresh water injection sites in the simulations. Why is As treated differently from Mn?	The mechanisms that govern arsenic mobility were analyzed in the same way in both freshwater injection wells and in IRZ injection wells. The difference lies in the predicted behavior of arsenic in these two areas, rather than the way in which they were analyzed. In the freshwater injection areas, arsenic from the freshwater supply is injected into the wells and the model predicts its attenuation with distance from the injection points. In the IRZ areas, arsenic is generated as organic carbon is consumed, and then attenuates within the organic carbon footprint via the same mechanisms that it attenuates with away from the freshwater injection wells. Any arsenic generated in the NTH IRZ is readily precipitated outside of the carbon footprint or once the carbon is consumed. The model predicts that byproduct arsenic will not reach the Colorado River or the river bank extraction wells.		Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment resolved.	Note that as directed by DTSC on December 31, 2012, PG&E added into the 60% design, a pre-treatment system to polish Arizona groundwater to California standards prior to injection. Therefore, the fate and transport of naturally-occurring arsenic associated with freshwater injection is no longer applicable, as the freshwater source will be treated for arsenic, and has been removed from the 60% design.
258	DTSC-91	Appendix B, Page 15/16, 4.2.8 Naturally occurring Manganese and Arsenic	"To simulate a naturally occurring conservative manganese concentration distribution in the rind, an additional simulation was performed under ambient (nonpumping) conditions. This assumed the rind was present in model layers 1 and 2, and extends approximately 250 ft on either side of the surface water features, as well as under the surface water features and marshland."	There appears to be no basis for utilizing the manganese rind simulation as exiting data do not support a manganese rind extending 250 feet away from the river in model layers 1 and 2. Fluvial wells nearest the river (MW-28-25, MW-28-90, MW-34-55, MW-34-80, MW-34-100, MW-52S, MW-52M, MW-52D, MW-53M, MW-54-85, MW-54-140, MW-56S, MW-56M, MW-56D, etc.) do not yield the high manganese (> 2 mg/L Mn) that is depicted adjacent to the river and under the marsh in modeling figures (e.g., Figure B-31). Figure 2-8 of the report also shows the lack of high (> 2 mg/L) manganese. Wells with elevated manganese near the river (e.g., MW-22, MW-32-035, MW-53D) are associated with highly brackish, saline (and even brine) waters atypical of site conditions. Figure 2-8 suggests that elevated manganese may be a function of depth and, therefore, related to the chemically stratified nature of the aquifer. The model must be modified to represent site conditions and the section rewritten.	Elevated concentrations of both Mn (Figure 2.8) and Fe (Figure 2.9) indicate the presence of a reducing zone extending away from the river. Anaerobic core study data suggest that although this area is generally reducing, the reducing conditions are naturally distributed with pockets of weaker and stronger reducing activity. Also, manganese content of the fluvial matrix is variable, so that in some areas that indicate reducing conditions that would support dissolved manganese(indicated by strongly negative ORP and the absence of Cr(VI)) , the observed Mn concentrations are relatively low. It is also possible that Mn concentrations are lower in parts of the shallow zone immediately adjacent to the river due to the presence of the hyporheic zone (groundwater/surface water mixing zone), which serves to deliver oxic river water that can dilute aqueous Mn concentrations and/or oxidatively precipitate Mn. A more in-depth analysis of the spatial distribution of the reducing rind, including spatial distribution of geochemical indicators, will be considered for the 60% design to more fully illustrate the extent of the reducing zone. The Mn transport model results indicate generated-byproduct Mn concentrations within the range naturally measured in the floodplain. The text will be modified in the 60% design to place this in better context with the actual background Mn concentrations observed. Additionally, a	Okay pending review of the 60% design submittal.		Comment resolved.	See Appendix B, Sections 2.3, 6.2.8, and 8.

Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					one-dimensional hyporheic zone model for Mn is also being developed for the 60% design, which will be used to evaluate geochemical/hydrological processes governing manganese behavior near the groundwater-river water interface as groundwater flows toward the river.				
259	DTSC-92	Appendix B, Page 16, 4.2.8 Naturally occurring Manganese and Arsenic	"With respect to arsenic, the primary naturally occurring arsenic that was simulated was associated with the proposed freshwater injection. Groundwater extracted from HNWR-1 located in Arizona was assumed to have a naturally occurring arsenic concentration of 17 ppb. This concentration was continuously applied to all of the simulated freshwater injection wells to evaluate the potential impact of the naturally occurring arsenic."	Why was 17 ppb arsenic used for HNWR-1 when Exhibit 3-1 and Appendix A1 state a value of 15 ppb? Recommend updating this value after a robust data set is attained. Please indicate if the model, if applied in its current form, would conclude that injected arsenic would attenuate within the aquifer if reinjected back into the HNWR-1 area.	The freshwater arsenic concentration will be updated to reflect all available data for future solute transport modeling runs. The solute transport model was developed as a tool to analyze the relative impact of arsenic potentially generated by the NTH IRZ and the introduction of a freshwater water source with a known arsenic concentration into the upgradient freshwater injection wells. This solute transport model is not designed to be a tool to evaluate background arsenic behavior in the vicinity of HNWR-1. Also refer to response to comment #252 DTSC-86.	OK pending review of 60% design submittal.		Comment resolved.	Note that as directed by DTSC on December 31, 2012, PG&E added into the 60% design, a pre-treatment system to polish Arizona groundwater to California standards prior to injection. Therefore, the fate and transport of naturally-occurring arsenic associated with freshwater injection is no longer applicable, as the freshwater source will be treated for arsenic, and has been removed from the 60% design.
260	DOI-83	App. B, Sections 4.4 and Figures B-17, B-18, and B-20		The text and figures are very confusing in this section. The text appears to talk about two different optional configurations of NTH wells, one with a 150-foot spacing and one with a 75-foot spacing. The figures jump from one configuration to the other with no explanation. The figure titles speak only of the "conceptual remedy" or "remediation design locations", without distinguishing between the two apparent options discussed in the text. DOI understands from the text that PG&E is proposing the 150-foot spacing configuration design as the remediation design. The text and figures need to be revised to clearly distinguish between the remediation design and the alternative option considered but not selected. DOI recommends that Figure B-17 show the remediation design configuration of 150-foot well spacing, and that the cross section location figure (B-18) and the cross section (B-20) depict this remediation design configuration. A separate new figure can then be introduced showing the 75-foot well spacing configuration, with the title clearly stating this is as optional layout that was considered but not selected.	The text and corresponding figures will be clarified with respect to the NTH IRZ well spacing. The provisional wells will be removed from Figures B-18 and B-20. Figure B-20 will be brought to Section 3 with the provisional wells included.	OK pending review of 60% design submittal.	OK pending review of 60% design submittal.	Resolved pending review of 60% design submittal.	See Appendix B, Section 6.4, and Figures 6.4-1 to 6.4-8.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
261	DTSC-93	Appendix B, Page 17, 4.4 Remediation Design		Request adding contoured chromium plume to cross-sections (Figures B-18 through B-24). Identify the natural reductive zone on Figures B-19 and possibly B-20. Illustrate the actual screened zones that were used in the model run to allow comparison to Tables 3-1 to 3-4 and eventually to actual emplaced screen depths. What criteria will guide screen placement during drilling? Figure B-17: The flow rates associated with the IRZ wells pictured on Figure B-17 are not the same as those rates called out in Table 3-1. This difference should be discussed or corrected.	The cross-sections will be updated to reflect the chromium plume delineation and proposed screen intervals. Screen placement will be guided by the lithology encountered during drilling. Screening over the more permeable sections of the aquifer will produce better flow and encourage development of the IRZ. The IRZ well flow rates shown on Figure B-17 will be corrected to correspond to the nominal rates in Table 3-1. Flow rates will be reviewed for consistency and explanations will be included in the 60% design submittal.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B and Table 3.2-1 of the BOD Report.
262	DOI-84	App. B, Section 4.4.1		The discussion of fresh water injection wells conflicts with DOI's understanding of the different purposes of the FW-INJ wells and the UPGRAD-INJ wells. DOI understood that the FW-INJ wells receive only fresh water, while the UPGRAD-INJ wells receive both carbon-amended water and fresh water. The text of 4.4.1 identifies wells UPGRAD-INJ-3 and UPGRAD-INJ-4 as fresh water injection wells. In reviewing the design document, DOI could find no information that suggests that wells UPGRAD-INJ-3 and UPGRAD-INJ-4 would be used differently than the other UPGRAD-INJ wells.	The well names can be updated to reflect their function in the model and the text will be clarified. Because the FW-INJ well located within I-40 was no longer a viable option, it was relocated to the UPRAD-INJ-4 location. The two northernmost upgradient injection wells (UPGRAD-1 and 2) receive the water extracted from the riverbank extraction wells. The freshwater injection wells (FW-INJ-1, 2 & 4, and UPGRAD-INJ-3 & 4) receive freshwater from HNWR-1. Additional modeling can be conducted to evaluate the impact of using different patterns of freshwater and riverbank water injections into UPGRAD-INJ-1, 2, 3, & 4. Please see Exhibit 3-4 footnote c indicating that wells UPGRAD-INJ-1 and UPGRAD-INJ-2 may be used for injecting carbon-amended water or freshwater. The remaining upland wells will be used as freshwater injection wells. The proposed setup is expected to successfully create proper hydraulic conditions, so that the chromium plume moves through the treatment zone at the designed direction and rate.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittals.	Comment resolved.	See Appendix B (Section 6.4) and Section 3 of the BOD Report.
263	DOI-85	App. B, Section 4.4.1		Editorial Comment. The new section entitled "Freshwater Injection" should be included within the text between the current 4.4.1 and 4.4.2.	The text will be updated.		Okay pending review of 60% design submittals.	Comment resolved.	See Appendix B, Section 6.4.7.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
264	DTSC-94	Appendix B, Page 17, 4.4.1 National Trails Highway IRZ	"By extracting at these locations the natural west to east flow gradient is generally preserved to encourage flow through the reduced groundwater."	Extracting 200 gpm at the northern end of the IRZ would seem to have a significant effect on east-west flow. Section 3.3 indicates that pumping a remote well at Park Moabi would have adverse effects on the remedy. Please provide figures with flow lines to help visualize system flow. Please indicate why dual screen recirculation wells were no longer considered for the IRZ. They would generate no net flow along shorter segments of the NTH IRZ.	Extracting 200 gpm from the northern portion of the NTH IRZ, and 100 gpm from the central portion of the NTH IRZ allows the groundwater to flow from west to east to encourage flow through the NTH IRZ. Injection of fresh water upgradient of the IRZ, coupled with extraction from the AZ side of the river, forms the greatest flushing force through the IRZ. Switching the fresh water source to the Park Moabi area would diminish the flushing force through the IRZ, as the pull from the east would be lost and the pull from the west would lower the eastward flux of injected water to some degree. This will be explained more thoroughly in the freshwater supply evaluation technical memorandum and summarized in the 60% submittal. A more detailed discussion regarding dual-screen recirculation wells is included in the response to comment #94 (DTSC-31): As discussed in the final pilot report, the findings of the study indicated potential issues with distribution of organic carbon substrate in this recirculation design, due to vertical short circuiting between injection and extraction intervals that limited lateral distribution at the middle and deep intervals. Based on this information, the recirculation system for the final remedy does not include recirculation wells with injection and extraction intervals at the same location.	Okay pending review of tech memo and 60% design submittal.		Comment resolved.	See Appendix J of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
265	DTSC-95	Appendix B, Page 19, 4.4.1 National Trails Highway IRZ	"A conservative simulated arsenic concentration of 17 ppb was introduced into all 5 freshwater injection wells. Due to the relatively high precipitation potential in this aquifer, the footprint of the impacted groundwater in the vicinity of the freshwater injection wells is fairly limited and actually reaches steady state conditions after several years where the arsenic footprint no longer expands. "	The section calls out "high precipitation potential". Please define this term. Will precipitation of the arsenic lead to well fouling? Details of the simulated arsenic precipitation model should be shared in the document. What transformations are occurring to specific arsenic species? Will pH adjustment of the freshwater be needed as originally envisioned in the 2009 CMS/FS? Angled borings/wells should be considered for this project due to logistical and cultural constraints. Angled wells for FW-INJ-3 do not appear to have been considered.	The high precipitation potential refers to the potential for arsenic to be removed from groundwater through interaction with the aquifer matrix minerals upon injection of the freshwater. This will be clarified in an update to Appendix B. Details of the arsenic precipitation model will be provided in an updated conceptual model discussion to be added to Appendix B for the 60% design. pH adjustment is not considered necessary for the freshwater injection. In the 2009 document, the need for pH adjustment was mentioned as a design consideration. Angle drilling of large diameter wells presents many serious difficulties. The drilling equipment for large diameter boreholes is not designed to drill at anything other than very slight angles off of vertical. At slight angles, the horizontal offset between the well head and the screened interval would be a few tens of feet. Other problems include difficulty in keeping a straight borehole, keeping the borehole from caving, placement of annular materials, installation of pumps and injection tubing, and rehabilitation of the well using swabs and bailers. A more complete discussion of the possible advantages and drawbacks of angle wells will be provided in the 60% design.	Okay pending review of 60% submittal.		Comment resolved.	Note that as directed by DTSC on December 31, 2012, PG&E added into the 60% design, a pre-treatment system to polish Arizona groundwater to California standards prior to injection. Therefore, the fate and transport of naturally-occurring arsenic associated with freshwater injection is no longer applicable, as the freshwater source will be treated for arsenic, and has been removed from the 60% design.
266	DOI-86	App. B, Section 4.4.2		DOI has concerns about the proposal to construct the riverbank extraction wells with capability of only extracting from the deeper portions of the aquifer. While it is understood that contaminated groundwater in the floodplain area is predominantly deep, there are areas where Cr (VI) contamination is present in samples from shallow wells east of NTH (Figure 2-3a). In DOI's view, one of the important reasons to incorporate the riverbank extraction wells in the selected remedy was to provide a "backstop" to the in-situ remedy that could be operated to capture any contaminated water that might otherwise reach the river. While it may prove to be unnecessary to extract water from the shallow zone, DOI would prefer to preserve the option of doing so without additional well installation later if it proves to be necessary. PG&E should evaluate well construction options for the riverbank extraction wells that would allow for pumping of water from the shallow intervals if deemed necessary in the future during system operation and monitoring.	While there is Cr(VI) present east of the NTH IRZ, it is anticipated that this impacted water will be readily treated in the existing shallow reducing rind. This is only applicable to existing Cr concentrations east of the NTH IRZ line, the Cr concentrations upgradient (west) of the NTH IRZ is anticipated to be treated by the NTH IRZ. The riverbank extraction wells were originally designed to be a backstop for the deep groundwater below the reducing rind. Screening wells in the reducing rind could lead to potential well fouling by the naturally occurring Mn. However, the riverbank extraction wells can be constructed in a manner that would allow them to be modified if observed conditions suggest it is necessary to control Cr6 migration. One approach would be to build the well so that the casing in the shallow unit could be perforated if water needed to be pumped from the shallow zone. Alternative designs will be considered and one selected and presented in the 60% design.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittals.	Comment resolved.	See Section 3.2, Appendix D2, and Appendix B (Section 6.4.2).

267	DOI-87	App. B, Sections 4.4.2 and 4.4.3		This section states that reinjection of the water extracted from the riverbank extraction wells would be limited to two injections wells, presumably UPGRAD-INJ-1 and UPGRAD-INJ-2, although not specifically identified by number in the text. DOI understood that all of the UPGRAD-INJ wells would receive both carbon-amended water from the riverbank extraction wells and fresh water. In reviewing the design document, DOI could find no information that suggests that wells UPGRAD-INJ-1 and UPGRAD-INJ-2 would be used differently than the other UPGRAD-INJ wells. Why was injection of the riverbank well water limited to only these two wells in the simulations?	The text will be clarified to explain the function of the proposed wells. It is currently simulated that only the northern 2 upgradient injection wells (UPGRAD-INJ-1 & 2) will receive riverbank extraction water. The remaining two wells will receive freshwater injections. Alternative injection approaches are being considered as part of the 60% design and will be presented in the 60% document.	Okay pending review of 60% design submittal.	Okay pending review of the 60% design submittals.	Comment resolved.	See Appendix B, Section 6.4.
268	DTSC-96	Appendix B, Page 19, 4.4.2 Riverbank Extraction	"Along the west side of the Colorado River, a series of extraction wells were simulated with the goal of both accelerating groundwater through the NTH IRZ and to also capture any hexavalent chromium located downgradient of the NTH IRZ. The proposed layout of the riverbank extraction wells consists of 4 wells screened in model layers 3 and 4 (beneath the naturally occurring rind) with the option to add a fifth well if necessary. The simulated total extraction rate of 150 gpm was utilized for the solute transport model runs."	Please provide capture zone analysis, including associated figures, for the riverbank system for all layers modeled. Is the riverbank system capturing the entire plume east of the floodplain during the life of the remedy? Also document that the riverbank extractors were created to capture any generated byproducts throughout the life of the remedy. The document should discuss higher pumping rates up to 640 gpm as originally envisioned for the riverbank system in the 2009 CMS/FS. Why send imported freshwater to the inner recirculation loop when site water is available and higher rates should achieve cleanup faster? Layers 3 and 4 are proposed for pumping, presumably since they are beneath the "naturally occurring rind". The reductive zone must be clearly defined and carefully plotted on maps and cross-sections to ensure that systems are properly designed. The rind appears to be part of the remedy, yet is not properly addressed in the document. What will trigger adding a fifth well? Why was the fifth well eliminated from the original design?	Capture zone figures and an expanded discussion for the Riverbank Extraction wells will be provided with the 60% design. Pumping rates were reduced in the Riverbank Extraction wells in an attempt to reduce the impact on the naturally occurring shallow reducing rind and to minimize pumping stress on the NTH IRZ caused by higher flowrates in the floodplain. Higher pumping rates in the floodplain proximal to the NTH IRZ will lead to faster groundwater velocities between the IRZ and the Riverbank Extraction wells. This increases the hydraulic stress on the NTH IRZ in the direction of groundwater flow and increases the potential for an incomplete remedial barrier, as demonstrated in the 300 gpm model run (Figure B-46). Pumping the Riverbank Extraction wells at a reduced rate increases the potential for a comprehensive IRZ to develop along the NTH IRZ to enhance remediation of the Cr(VI) impacted groundwater. The extent of the naturally occurring reducing zone will be delineated in both plan view and cross-section in the 60% design. The fifth riverbank extraction well will be considered based on the hydraulic performance of the other 4 Riverbank Extraction wells and monitoring well data. The fifth well is not operated in the 30% design because adequate capture was achieved by just operating the other 4 extraction wells.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 6.5.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
269	DTSC-97	Appendix B, Page 19, 4.4.2 Riverbank Extraction	"These wells will potentially pull down the groundwater from the naturally occurring rind, so consideration was taken to keep the extraction rate at a reasonable level."	Clarify why pulling down shallow water with the deeper extractors should be minimized/kept to "reasonable levels".	There are two major reasons for minimizing the downward pull of the riverbank wells. 1. The naturally occurring reducing rind typically contains elevated manganese and iron concentrations that could contribute to well fouling and provide a source of manganese and iron into layers 3 and 4. 2. The naturally occurring reducing rind provides ideal conditions for Cr(VI) precipitation in the event there is breakthrough past the NTH IRZ in Layers 1 and 2. Thus the riverbank extraction wells are designed with due consideration given to minimizing potential impacts to the naturally occurring reducing rind.	Okay		Comment resolved.	
270	DTSC-98	Appendix B, Page 20, 4.4.3 Uplands Injection		Briefly describe how fouling in amended wells will be mitigated.	Wells will be periodically rehabilitated to physically or chemically remove fouling deposits on the well screen, filter pack and/ or in the near well formation. Well fouling mitigation procedures are addressed in more detail in Sections 3.2.1.1, 3.2.2.1, and 3.2.3.1 for the different components of the in-situ remediation system. In addition, proactive backwashing of the wells will be used to control fouling before it occurs.	Okay.		Comment resolved.	
271	DOI-88	App. B, Section 4.4.4		Please identify the four extraction wells and two injection wells by number in the text. DOI presumes they are Mid-EX-1 through -4 and comp-inJ-1 and comp-inJ-2, shown on Figure B-18. While this may seem obvious in this case, the previous discussions of the UPGRAD-INJ injection wells led to confusion. This can be avoided by explicitly identifying wells by number when discussing them.	Text will be clarified to reflect how the simulated wells will be operated.		Okay pending review of 60% design submittals.	Comment resolved.	See Appendix B, Section 6.4.2.
272	DOI-89	App. B, Section 4.4.5		Identify the extraction wells by number in the text. DOI presumes they are RAV-EXT-1 through RAV-EXT-4.	Text will be updated to reflect the associated well names.		Okay pending review of 60% design submittals.	Comment resolved.	See Appendix B, Section 6.4.5.
273	DOI-90	App. B, Section 4.4.6		Identify the injection wells by number in the text. DOI presumes they are comp-inJ-1 and comp-inJ-2, and FW-INJ-4.	Text will be updated to reflect the associated well names.		Okay pending review of 60% design submittals.	Comment resolved.	See Appendix B, Section 6.4.6.
274	DTSC-99	Appendix B, Page 21, 4.4.6 Topock Compressor Station Injection	"Water from the extraction wells northeast of the Compressor Station and the East Ravine Extraction wells is treated and injected into two wells located in the immediate vicinity of the TCS."	Briefly describe how extracted water is being treated prior to injection.	The water extracted from the TCS and East Ravine wells will undergo carbon substrate amendment addition prior to being re-injected. The word "treated" will be revised to "amended with carbon substrate".	Okay.		Comment resolved.	See Appendix B, Section 6.4.6.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
275	DOI-91	App. B, Section 4.5, 2nd sentence		This section states that groundwater flow under ambient conditions is primarily west to east, however, flow over much of the plume area is north to northeastward toward the river based on the contours on Figure B-25.	The sentence will be deleted.		Okay pending review of 60% design submittal	Comment resolved.	See Appendix B, Section 6.5.
276	DTSC-100	Appendix B, Page 21, 4.5 Flow Conditions		Figure B-25 illustrates simulated groundwater contours, but it is not clear which model layer is being presented. Separate figures for each model layer are required. Flow line figures are also requested for each layer.	Figure B-25 is for Layer 1. Flow figure for each layer will be provided in the 60% design report.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 6.5.
277	DOI-92	App. B, Figure B-28		Figure B-28 is missing. Figure B-27 is included twice.	Correct, Figure B-28 will be provided to show the Layer 2 simulated Cr results.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittals.	Comment resolved.	See Appendix B.
278	DTSC-101	Appendix B, Page 22, 5. Solute Transport Results 5.1 Hexavalent Chromium	"By year 30 of the simulated transport run, the majority of the hexavalent chromium plume in all four model layers has been remediated. The only exception by year 30 is the portion of the hexavalent chromium that is initialized in the bedrock in the vicinity of the East Ravine extraction wells."	The design documents should indicate what the total estimated time is to clean up (meet RAOs) based on the results of the most current model run. Modeling times should be extended until RAOs are met. The document should also mention that the "Year 30" runs for all layers do not show complete cleanup to RAOs in the alluvial aquifer.	In the 60% design, the model runs will be continued until RAOs are achieved in the alluvial aquifer. Total projected time to cleanup for the alluvial aquifer in each layer will be presented.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 7.1.
279	DOI-93	App. B, Section 5.1, 2nd sentence		There are no results shown for 5 years.	Agreed, the 5 year reference will be removed from the text.	Okay	Okay pending review of 60% design submittals.	Comment resolved.	See Appendix B, Section 7.1.
280	DOI-94	App. B, Section 5.1 and Figure B-29		It is not clear why the NTH IRZ fails to control Cr (VI) plume migration at the northern end. Please explain why the system cannot be adjusted to correct for this without having to rely on the riverbank extraction wells.	The northern end of the NTH IRZ consists of 3 extraction wells. These wells both supply the NTH IRZ injection wells and also maintain the eastward flow component towards the Colorado River. They are screened in the lowest concentration portion of the plume and hydraulically control the plume when they are actively pumping. When the IRZ "rests" for 18 months between TOC injection events, these wells are not pumping and the low concentration plume migrates a short distance past the wells. The low concentration mass that progresses past the northern NTH IRZ in model layers 3 and 4 is readily captured by the riverbank extraction well and is diluted below 32 ppb with the other riverbank extraction wells before it is injected into the upgradient wells. Model simulations will be conducted in the 60% design to analyze alternatives to better control migration of the Cr(VI) plume to the north end of the IRZ.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	See Appendix B, Sections 7.1 and 10.9.

APPENDIX I

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
281	DTSC-102	Appendix B, Page 22, 5.1 Hexavalent Chromium, and Figures B-27 to B-30	The sections of the plume that are initialized on the east side of the NTH IRZ and the low hexavalent chromium concentrations in the vicinity of the NTH IRZ wells that are not treated by the NTH IRZ, are hydraulically controlled by the riverbank extraction wells.	The validity of this statement is difficult to determine based on the representative snap shots of the model provided in Figures B-27 to B-30. One might expect that the northern NTH IRZ extraction wells would be able to adequately intercept the hexavalent chromium plume, however, as demonstrated in the transport model figures, a sizable portion, albeit at low concentrations, does escape past the extraction wells towards the river and Arizona between 18 months and Year 20. Perhaps, PG&E should use particle tracking and resulting flow lines to illustrate the anticipated hydraulic movements surrounding the Northern portion of the IRZ. DTSC also recommends showing the current plume outline on these figures for reference.	Refer to response to comment #280 DOI-94. The NTH IRZ extraction wells only operate for 6 months during a two year period and are not designed to fully hydraulically control the low concentration northern Cr plume. The northernmost riverbank extraction well assists in capturing the northern tip of the Cr(VI) plume.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 7.1.
282	DTSC-103	Appendix B, 5.2 Manganese		The section or elsewhere in the document should discuss the manganese secondary MCL as well as USEPA's 2004 health advisory for manganese to provide significance to the manganese discussion. Is there an ecological risk associated with manganese? PG&E should mention some contingency measures being utilized at Hinkley to control manganese byproduct migration (i.e., pumping impacted manganese wells and injection into dry wells or infiltration gallery to precipitate manganese within vadose zone soils).	Manganese was one of 13 general chemical parameters evaluated for potential risk in the GWRA and was not identified as posing a potential ecological risk, based on data available at the time of that evaluation (ARCADIS 2009). The SMCL and USEPA's 2004 health advisory for manganese are both below the UTL of the naturally occurring concentration of 1.32 mg/L manganese in groundwater and the range of average concentrations up to 9.26 mg/L found in the floodplain. In this situation where the naturally occurring concentration is higher than a concentration protective of human health and ecological receptors, any activities conducted that maintain conditions consistent with the naturally occurring background concentration would not result in any increase in site related potential adverse impacts to either human or ecological populations Concentration is the key to evaluating potential adverse impacts to biological species. Concentration is a function of the amount of manganese present (i.e. – mass) along with the flow rate and volume of water carrying that manganese. The proposed design and associated modeling indicates that manganese generated will not increase the concentration of manganese in groundwater to exceed the UTL of background concentrations. Therefore, implementing the proposed design would not create additional adverse impact (exceeding background conditions) to species potentially contacting the manganese concentrations in groundwater. Because the proposed treatment does not increase concentrations above naturally occurring background, the proposed	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix L (O&M Manual).

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					treatment does not present a concern for additional adverse impacts for either direct contact by humans consuming groundwater, or for indirect contact by humans or ecological species contacting manganese discharged from groundwater to surface water. As suggested, a discussion of contingency measures will be included in the 60 percent design in the event that manganese concentrations exceed naturally occurring concentrations.				
283	DTSC-104	Appendix B, Page 22, 5.2 Manganese		The manganese figures and text need to be revised. See previous comment on Appendix B, 4.2.8 Naturally occurring Manganese and Arsenic, Page 15/16. DTSC does not concur with the current write up. Based on existing data presented, the section should conclude that manganese byproduct formation will occur and impact upland areas around amended injection wells as well as the majority of the floodplain with elevated concentrations for greater than 30 years. Figure 3-34 (Layer 4 Simulated Manganese Transport) suggests that the manganese plume is still expanding after 30 years. Would manganese concentrations and plume footprint continue to expand after 30 years? Include model runs that show when manganese levels return to baseline conditions.	Manganese is continuously generated in the presence of carbon. Additionally, the simulated sorption of Mn only retards the movement of Mn in the aquifer, there is no mechanism that removes Mn from groundwater in the solute transport model. In the 60% design the manganese behavior in the solute transport model will be evaluated to reflect the potential of Mn oxidation.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 5.3.3.
284	DTSC-105	Appendix B, Page 22, 5.2 Manganese, and Figures B-31 to B-34	The manganese runs take into account both the simulated naturally occurring manganese as well as potential manganese generated as a byproduct from carbon amended injection wells.	This presentation is simply confusing. Although it is PG&E's hypothesis that there would be a potential for high concentrations of manganese in the fluvial sequence, there is little objective data to support this "simulated naturally occurring manganese." If it is PG&E's intention to show the effect of Mn flux resulting from remediation, PG&E should begin with actual measured data and simulate the sequence over time as with Cr(VI). Although PG&E would also like to conclude that the remedy would not increase "the load" of manganese in the formation, it is questionable if these graphics would accomplish that either.	The simulated naturally occurring manganese distribution was meant to represent an average naturally occurring Mn distribution. Observed concentrations ranged from 1 to 9 ppm. The manganese distribution will be re-evaluated based on available site data to refine the solute transport modeling. Due to the limited data density, in particular to the east of the river, assumptions have to be made based on the observed concentration data and the operating conceptual model that explains the presence of Mn in the floodplain sediments.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 7.2.

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
285	DOI-95	App. B, Sections 4.2.7, 5.3 and 6.5		Section 4.2.7 discusses arsenic attenuation and states that arsenic attenuates primarily through sorption processes. However, Sections 5.3 and 6.5 refer to arsenic precipitation in discussing the rapid As plume attenuation. In general, the discussions of Mn and As generation and attenuation must better explain why they behave similarly or differently during transport, and provide the basis for why they are being simulated differently. Also, DOI requests that the results of the As simulations be provide for the 0.5xBase precipitation simulation in map form so that the potential As plume could be assessed.	Text will be clarified to explain how arsenic and manganese are simulated. Results for the 0.5 X Base precipitation for Arsenic will be provided.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	Note that as directed by DTSC on December 31, 2012, PG&E added into the 60% design, a pre-treatment system to polish Arizona groundwater to California standards prior to injection. Therefore, the fate and transport of naturally-occurring arsenic associated with freshwater injection is no longer applicable, as the freshwater source will be treated for arsenic, and has been removed from the 60% design.
286	DTSC-106	Appendix B, Page 23, 5.3 Arsenic		See previous comments regarding arsenic. Include model runs that show when arsenic levels return to baseline conditions. As with all modeling, appropriate monitoring will need to be conducted to verify model results. Contingency measures will need to be identified in the event that modeling proves inadequate.	Additional figures will be generated to show the recovery of the arsenic levels to baseline conditions after the active remediation is completed. Contingencies will be discussed in the 60% design document.	Okay pending review of 60% design submittal.		Comment resolved.	Note that as directed by DTSC on December 31, 2012, PG&E added into the 60% design, a pre-treatment system to polish Arizona groundwater to California standards prior to injection. Therefore, the fate and transport of naturally-occurring arsenic associated with freshwater injection is no longer applicable, as the freshwater source will be treated for arsenic, and has been removed from the 60% design.
287	DTSC-107	Appendix B, Page 23, 6. Sensitivity Analysis		The rationale for conducting sensitivity analysis 10 years out should be stated. An analysis near the end of cleanup (end goal) would also seem appropriate.	The 10 year timeframe for the sensitivity analysis was selected because it provided a reasonable snapshot of the influence of the varied parameter on the plume transport. Analyzing the sensitivity at early or late times in the run potentially masks the impact of the parameter variance. Simulation results toward the end of the remedial timeframe where plume mass is still present (approximately 30 years of simulated transport) will be provided in the 60% design in order to summarize the long term impact associated with parameter variations.	Okay pending review of 60% design submittal.		Comment resolved.	See Appendix B, Section 10.

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
288	DTSC-109	Appendix B, Page 25, 6.3 Riverbank Extraction Rates		A range of 0 to 300 gpm riverbank extraction rates were evaluated. Please also evaluate 640 gpm as originally proposed for Alternative E in the 2009 CMS Report.	Increasing to 640 gpm will significantly increase the byproduct impact in the uplands as can be seen in the comparison of the 150 gpm and 300 gpm runs.	Okay.		Comment resolved.	
289	Hualapai-9			In the modeling portion of the 30% design report (Appendix B), the time frame for clean-up of the Cr(VI) plume was modeled to be 30 years. Parameters for input to the remedy model came partly from the ISPTs at the Topock Compressor Station. During the different ISPT studies, carbon concentrations in the injected fluid ranged from 1,000 to 10,000 mg/L. In contrast, carbon concentrations in the remedy model ranged from 50 to 100 mg/L (many orders of magnitude lower). Therefore, the modeled results really cannot be compared to the ISPT results. The groundwater remedy, when constructed, will be a large experiment with many unknown parameters. This might be expected given the geochemical and hydrological complexities at the site. However, the Tribes and stakeholders should be made aware of the uncertainties that exist in the project, and a range of dates should be presented, rather than a promise for a 30-year completion.	A more detailed discussion of the uncertainties will be added to the text.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B, Section 11.
290	Hualapai-1 and TRC-1			<u>Addressing Uncertainty</u> The modeling discussion does not address or evaluate predictive uncertainty. The fact that the modeling report does not mention "uncertainty" suggests that an integral part of the modeling evaluation is missing here. It is important to utilize the model to address the uncertainty of model inputs (such as porosity, hydraulic conductivity, storage, river leakage, sorption, dispersion, Cr(VI) reduction rates, etc.) which could be evaluated in terms of variations in number of remediation wells, impacts from by-products, and estimated total duration of the cleanup. **TRC Recommendation:** It is anticipated that a reasonably detailed discussion of how uncertainly has been evaluated would be included in the 60% design report.	As with all mathematical models of natural systems, it is limited by factors such as scale, accuracies in estimated hydraulic properties and/or boundary conditions, and the underlying simplifications and assumptions incorporated into the models. These factors result in limitations to the model's appropriate uses and to the interpretations that may be made of simulation results. The flow model calibration procedure was explained in CH2MHILL 2005 and describes the assignment of hydrogeologic parameters. The flow model was calibrated against (a) long term average groundwater levels, (b) average monthly floodplain levels responding to fluctuating river levels, (c) short-term responses to pump testing events, and (d) plume development over time. The autocalibration program PEST was employed to refine the calibration and to reduce effects of uncertainty in each calibration target. This calibration procedure resulted in a highly heterogeneous distribution of hydraulic conductivity to represent the natural system. With respect to the solute transport model, uncertainty was addressed by conducting a detailed sensitivity analysis on various solute transport parameters. This sensitivity analyses can be utilized to address the uncertainty in the model by providing a range of remedial timeframes associated	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B, Section 11.

APPENDIX I

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					and relative impacts of by-products. Additional text can be added to the 60% design report to expand on the uncertainty associated of the predictive model.				
291	Hualapai-2 and TRC-2			Addressing Uncertainty Certainly one expects deviations between model simulated and actual system responses in drawdown, groundwater flow direction and gradient. Has the model been utilized to evaluate contingencies (aside from simply adding wells) to respond to potential changes in the system outside of those specifically shown by current model results? **TRC Recommendation:** Using a range of possible flow parameters in the model runs may illustrate potential responses in the actual groundwater system which should be monitored for during initial operation and startup. If this has already been done or is ongoing, a discussion of this analysis and results should be included in the 60% design.	The calibrated groundwater flow model provided a representative highly heterogeneous representation of the natural system. This calibration processed was described in detail in CH2MHILL 2005. Therefore, additional calibration will not be performed. Several different remedial alternatives were evaluated using the groundwater flow and solute transport model. By varying the remedial scenarios based on the amount of wells, well locations, flow rates, and well spacing, the effectiveness of the different layouts could be compared. For example, numerous runs were conducted with respect to the NTH IRZ where the system was optimized to minimize the potential for the plume to migrate past the NTH IRZ. Additional text can be added to the 60% design report to expand on the various components that were evaluated in order to arrive at the optimized remedial strategy.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B, Sections 6.4 and 10.
292	Hualapai-3			Evaluating Effects of Local-scale Geologic Heterogeneity Using the Model Local-scale geologic heterogeneity will likely dominate the effectiveness of the simulated proposed carbon injection treatment. This is typical and even expected in most groundwater cleanups, especially in fluvial systems. It does not appear that the current model incorporates the representative elementary volume (REV) to capture the local heterogeneities in confining layers, etc., especially using Mod-Flow. The model should be used to generate a range of probable cleanup times. Modeling parameter estimation tools such as PEST could be used to help estimate at least the effects of parameter uncertainty on predicted cleanup times.	The concept of REV is defined as the minimum volume over which aquifer parameters reflect their macroscopic values and do not fluctuate over small-scale changes in matrix properties (Bear, 1972). The model cells contain macroscopic average values that were originally estimated during flow model calibration (CH2M HILL 2005 and response to comment 116), and therefore support the REV concept. There is no continuous confining layer documented in the numerous well logs compiled for the site and presented in the RFI Volume 2 report, but there are heterogeneities inherent in the alluvial and fluvial materials. PEST was used in the original flow model calibration to help account for these heterogeneities. Clarifications about the modeling parameters will be provided in the 60% design. Transport parameters will be further evaluated through a sensitivity analysis to represent uncertainty in the transport model to provide a range of cleanup times in the 60% Design Report.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B, Sections 4, 10, and 11.

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
293	Hualapai-4 and TRC-3			<u>Evaluating Effects of Local-scale Geologic Heterogeneity Using the Model</u> A thorough discussion is needed to address the uncertainties associated with subsurface heterogeneity and model parameterization and the associated confidence ranges for the number of wells, duration of cleanup and by-product concentrations over impacted areas. **TRC Recommendation:** It is anticipated that a reasonably detailed discussion of how uncertainly has been evaluated would be included in the 60% design report. Questions to address in refining the accuracy and precision of the model include: what are the geological, geochemical, or hydrologic heterogeneities that might be anticipated? How would these affect the design details? What are the reasonable ranges of time to achieve clean up the plume?	Heterogeneity is addressed in the groundwater flow model by a variable hydraulic conductivity distribution established during the groundwater flow model calibration process. This distribution was based on observed field data and further refined through parameter estimation (PEST). Documentation with respect to the groundwater flow model is presented in Hill 2005 and 2009. Heterogeneity is also addressed in the solute transport model by simulating the system as a dual domain model. This allows for interaction between the mobile and immobile porosities. Additional discussions regarding uncertainty will be included in the 60% design.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B, Sections 4 and 11.
294	Hualapai-5 and TRC-4			<u>Evaluating Effects of Local-scale Geologic Heterogeneity Using the Model</u> With any drawdown scenario, it is reasonable to anticipate that the system will be stressed beyond the conditions against which it has been calibrated likely causing deviations between the simulated and actual conditions. **TRC Recommendation:** In the subsequent design documents, there should be discussion on contingencies in the remedial design (other than additional wells) to account for the reasonably anticipated deviations. This may include a discussion on how <u>predicted</u> drawdown, and extent, magnitude, flow direction and/or gradient may differ from actual drawdown impacts (especially at distance from the injection/ extraction wells) using a range of possible flow parameter values.	The system has not been under the proposed stresses simulated in the model so we cannot calibrate to these proposed conditions. By calibrating to the current conditions a baseline is established to build upon. The model is just used as a tool to guide decisions, not to be used as a factual predictor. As the remedy is put in place, the system should be carefully monitored to evaluate the effectiveness.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		
295	Hualapai-11 and TRC-7			<u>Addressing Uncertainties in Model Parameters and Assumptions</u> The current flow model assumes steady-state flow conditions, and appears to assume that the seasonal water table fluctuations from such factors such as variable recharge, river leakage and variations in time and distance between gaining and losing areas are not important. **TRC Recommendation:** The model should be used to assess transient boundary conditions on the simulated predictions and model simulation runs.	While there are variations in such parameters recharge and river stage, the pattern of groundwater flow is consistent. By developing a long term steady state average condition, the model is able to take into account the fluctuations in the system	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
296	Hualapai-12			<u>Addressing Uncertainties in Model Parameters and Assumptions</u> A uniform model grid of 25x25 feet is specified throughout the entire sub-model domain. Given that injection and extraction well points will be on the order of one foot, corrections need to be made to the simulated heads at and near these injection/extraction wells to account for these differences. It is not clear that the current model account for this.	Focused figures were not generated to display water levels at the well points. For the purpose of solute transport modeling, the head is averaged over the entire cell to demonstrate the hydraulic influence. While water levels at the exact location of the well will vary based on injection or extraction rates, the model averages the hydraulic impact over the cell to simulate the hydraulic influence.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		
297	Hualapai-13 and TRC-8	Modeling		<u>Addressing Uncertainties in Model Parameters and Assumptions</u> Density dependent flows were not simulated, yet groundwater levels are typically corrected for both temperature and salinity (which DOES increase with depth at Topock). Would the operation and performance of the proposed remedial system (i.e. number and distribution of wells, pumping rates, etc.) be different if temperature and salinity effects were considered in the modeling? **TRC Recommendation:** Salinity differences should be accounted for in the modeling for the 60% design. At a minimum, a discussion should be included if it is anticipated that salinity variation will not be a factor, based on sensitivity calculations.	Language will be added to the 60% design explaining how temperature and salinity differences will have a negligible impact on the proposed remediation system. The flow of water will be more controlled by the natural heterogeneity of the aquifer, not the potential deviations in temperature and salinity.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B, Section 11.
298	Hualapai-14 and TRC-9			<u>Addressing Uncertainties in Number of Installed Wells</u> Discussion on page 18 of the Appendix B: “Development of a Groundwater Flow and Solute Transport Model” indicates that one of the driving forces behind the potential increase in the number of wells installed within the NTH (National Trails Highway) IRZ is based upon reducing the production of by-product: *“the spacing of the NTH IRZ wells is decreased, the carbon injection concentrations can potentially be lowered as well to reduce generated byproducts”* This statement indirectly addresses uncertainty in the system and raises concerns that additional wells will be placed prior to a thorough evaluation that additional wells will be effective. **TRC Recommendation:** A discussion of the rationale and decision points to be used to install additional NTH IRZ wells should be included in the 60% report. This discussion should include how the IRZ installation and/or monitoring data will be used in this decision process.	Text will be expanded in the 60% design to further explain the sensitivity analyses conducted to optimize the well locations, rates, and carbon concentrations. A balanced system that will optimize the Cr(VI) reduction while minimizing the potential for byproducts, and minimizing the remedial system footprint is the goal of the transport modeling.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B, Sections 6.4 and 10.

Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
299	Hualapai-15			<u>Addressing Uncertainties in Number of Installed Wells</u> For example, monitor well 3-D within the ISPT floodplain study indicated that chromium reduction was not efficient until carbon levels above 100 mg/L where achieved. This raises doubt about the effectiveness of lower carbon concentrations in sufficiently reducing Cr(VI). In addition, multiple examples from the ISPT data indicate that sustained chromium concentrations can persist in the presence of lower TOC concentrations. A thorough analysis of the correlations of TOC levels, achieved ORP values and Cr(VI) concentrations measured during the ISPT studies would provide insight into the range of carbon injection concentrations that are capable of reducing Cr(VI) and preventing undesirable concentrations of byproducts from forming. Prior to implementation of additional remedial wells, modeling efforts could be used to understand how additional extraction wells would impact byproducts produced in the NTH IRZ. Results from such an analysis could be used to determine appropriate byproduct action thresholds which would be used justify additional remedial wells.	This topic was discussed at the January 6 and January 19, 2012 TWG meetings. A discussion of the pilot test data will be included in a detailed response to comments in the 60% design document. Detailed discussion of the monitoring plan and how data is used will be in 60% documents.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B (Section 3.4) and Appendix L (O&M Manual).
300	Hualapai-16 and TRC-10			<u>Evaluation of the Impact of River Bank Extraction on the Organic Rind</u> In 30% Design Modeling Appendix B, sensitivity analysis of riverbank extraction wells showed that the clean-up time was not affected by riverbank extraction rates of zero. Are the riverbank extraction wells just a contingency in case Cr(VI) is detected in the Colorado River, or can the remediation proceed with zero riverbank extraction rates.*[Next four sentences appear only in the comment letter]* The potential for destruction of the organic rind would be much less if the riverbank extraction wells did not stress the groundwater system near the river. Operation of the riverbank extraction wells will certainly pull oxidized river water through the rind, which over time could reduce the ability of the rind to naturally reduce Cr(VI). In addition, Anaerobic core tests show that there is sufficient reducing capacity in the "rind" to remove a significant portion of Cr(VI) in the plume. Long-term impacts of flushing were not described **TRC Recommendation:** It may be appropriate to discuss this during a TWG meeting. A more detailed discussion of scenarios where the river bank extraction wells will (or will not) be utilized would be anticipated in the 60% design report.	The riverbank extraction wells are not a contingency in case Cr(VI) is detected in the Colorado River. Riverbank extraction wells will both facilitate the groundwater flow through the IRZ and capture Cr(VI) located in the floodplain downgradient of the NTH IRZ. The riverbank extraction wells are also designed to control NTH IRZ generated byproducts in the deeper portion of the aquifer. The riverbank wells are designed to be screened beneath the naturally occurring reducing rind to minimize potential negative hydraulic impacts on the reducing rind and reduce the potential for well fouling in the riverbank extraction wells caused by the presence of dissolved minerals in the naturally reduced groundwater in the rind. Hydraulic analyses indicate the riverbank extraction wells primarily pull water from the deep aquifer (Model Layers 3 and 4) below the river and reducing rind. Limited extracted water comes from the shallow aquifer (Model Layers 1 and 2) and the largest fraction of captured shallow groundwater comes from upgradient (west) of the riverbank extraction wells. As per comment to DTSC-96, capture zone figures and an expanded discussion for the	Comment and response noted.	Comment and response noted. Further evaluation will occur during the review of 60% design submittal.		See Appendix B, Section 6.5.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					riverbank extraction wells will be provided in the 60% design. The naturally occurring reducing rind provides ideal conditions for Cr(VI) precipitation in the event there is breakthrough past the NTH IRZ in the shallow portion of the aquifer. Thus the riverbank extraction wells are designed with consideration given to minimizing potential impacts to the naturally occurring reducing rind.				
Appendix C – Design Criteria									
301	DOI-96	Appendix C.7		This section should identify criteria for selecting above ground versus underground piping.	The criteria will be added to this section in the 60% design submittal.		Okay pending review of 60% design submittals.	Comment resolved.	
302	DOI-97	Appendix C, Attachment A		This attachment shows general respiratory and fermentative reactions but it should also discuss 1) how substrate dose relates to lowering redox potential, causing fermentation processes that are critical to hexavalent chromium reduction, 2) how an optimal dose can achieve hexavalent chromium reduction while minimizing byproduct production (reduced manganese and arsenic), 3) arsenic reduction and increased mobility of arsenic, and 4) that the primary mechanism for hexavalent chromium reduction is abiotic reactions with ferrous iron and sulfide.	Appendix C (Attachment A) will be expanded to capture the following points: Within an IRZ, many reductive processes will be stimulated. The amount of organic carbon substrate applied to the injection points is determined by the amount needed to achieve lateral distribution. Concentrations of TOC will be highest at the injection point and decrease with distance, and the arsenic and manganese generated is a consequence of that distribution of organic carbon, as discussed in detail in Appendix G of the 2009 CMS/FS. It is agreed that abiotic pathways such as reduction by Fe(II) may be faster than direct biotic mechanisms for Cr(VI) reduction (e.g., Wielinga et al., Environmental Science and Technology, 2001). Fe reduction is expected to occur under active Cr(VI) reduction conditions, producing mixed Fe/Cr precipitates that sequester Cr(VI). Thus, we do expect that both Cr(VI) reduction mechanisms will be occurring simultaneously. To optimize the tradeoff between organic carbon distribution and byproduct generation, design parameters such as well spacing, recirculation flowrates, and injection concentrations can be varied. The first step of this process was taken with the reactive transport modeling that supported the IRZ design (Appendix B). This optimization process will continue during operation as monitoring data is collected, evaluated, and used to modify operations of the system. A monitoring plan detailing how this will be done will be included in the 60 percent design.	Okay pending review of 60% design submittal.	Okay pending review of 60% design submittal.	Comment resolved.	

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
303	DTSC-110	Appendix C, Page C-2, 3rd Bullet	Non-mechanical excavating methods within TCS are mandatory and requirements will be described in more detail in the intermediate design submittal.	PG&E has asserted that this is a company policy for years and DTSC has been requesting this policy to be documented for nearly as long. DTSC does not understand why the inclusion of this policy should be deferred to the 60% design.	Comment noted.	DTSC awaits submittal of the PG&E policy.		Comment resolved.	
304	DTSC-111	Appendix C, Page C-3, C.1.4 Concrete Vaults	Vaults will be precast concrete sections conforming to PG&E Standard K-35.	What is this standard? PG&E should provide all design standards, in whole, if they are applicable to the remedy.	The draft technical specifications (part of the 60% design submittal) will list applicable standards (e.g., ASTM, ANSI, PG&E), applicable codes (e.g., Uniform Building Code, Uniform Fire Code) and other requirements. There are more than 120 specification sections and each section references one or more standards. PG&E Standard K-35 is a standard for concrete vault cover.	Okay pending review of information to be submitted in the 60% design submittal.		Comment resolved.	
305	DTSC-112	Appendix C, Page C-7, C.4.1 Piping	piping materials will be compatible with the characteristic of the conveying fluids and will be single walled unless the pipe is used to convey: (1) groundwater or remedy-produced water that is California Hazardous waste; or (2) concentrated carbon substrate. In these cases, double-walled piping will be used.	As stated earlier, because of the cultural concerns associated with the project area and the incomplete soil investigation, DTSC would prefer that double wall pipes be used for any untreated water conveyance.	Based on modeling, groundwater with Cr>5 ppm could be extracted from the IRZ extraction well, IRZ-23. Additional information about the subsurface conditions will be obtained as we start to install remediation wells. With regards to the suggested use of double walled piping for management of extracted water (<u>that are below hazardous waste characteristic level</u>) to protect against leaks due to concerns over the possibility of contamination leaching from the soils (<u>which have not been investigated</u>) to the groundwater, it should be noted that soil data do exist for the AOCs that overlap with the remedy infrastructure as shown in Figure 2-15. Supplemental soil sampling is being planned to complete the soil investigation and current schedule shows completion of the investigation prior to the start of groundwater remedy construction. Further, baseline soil samples will be collected to document baseline site conditions at the time of remedy construction. In addition, the overlapped AOCs are located within the plume footprint for which an active remediation will be implemented for decades. Additional evaluation of the potential for leaks and methods of leak detection and control will be performed and included in the 60% design.	DTSC will review evaluation of 60% design submittal.		Comment resolved.	

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
306	DTSC-113	Appendix C, Page C-9, C.4.5 Secondary Containment	Where required, secondary containment systems will be sized and designed in conformance with applicable codes and standards.	When will this be defined? Since the locations of major infrastructures have already been proposed in the 30% design, PG&E should be able, at this point, to decide what components will need and where these secondary containment systems will be required.	Example elements defined with secondary containment in the 30% design submittal are: - The solid/liquid separator area (see dwgs A-7 and M-7) - The remedy produced water conditioning building containment is discussed in Appendix C, Section C.4.5 - The influent water storage tanks (see dwgs C-17 and C-18) - The truck loading/unloading area at the MW-20 bench (see dwg C-9) - The truck loading/unloading area at the Transwestern Bench (see dwg C-10) f) Carbon amendment process buildings (see dwgs C-9 and C-10) h) Carbon substrate tanks (See Section 3.2, p-3-4) Additional details will be provided in the 60% design.	Okay pending review of 60% design submittal.		Comment resolved.	See Section C.5.5 of Appendix C (Design Criteria) and Appendix D (Engineering Drawings)
307	DTSC-114	Appendix C.11 Construction Requirements		DTSC recognize that more detailed sequence will be in the 60% design, however, it would be helpful to have a general idea of the construction sequence.	An updated project schedule with more detailed sequence will be provided in the 60% design submittal.	Okay pending review of 60% design submittal.			

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
308	Hualapai-36 and TRC-18			Considerations for Implementation and Construction Presently, the project site is impacted by noise from the compressor station, river traffic noise, the interstate highway (I-40) and the BNSF railway (and possibly other less significant sources). At many, but perhaps not all locations, the additional noise from groundwater contamination remedy implementation will not be problematic. However, there may be locations of cultural significance and use where this is not the case. The existing noise standards quoted in the 30% BOD Appendix C (Design Criteria), indicate, for CA facilities, that based on San Bernardino County criteria, a noise level of 70 dB is permissible. We take issue with this, as the 70 dB A-weighted equivalent energy level of 70 dB as stated in the San Bernardino County Development Code of 2007 (Section 83.01) is for an affected land use that is industrial. **TRC Recommendation:** This design criterion may be appropriate for areas such as the existing compressor station itself. However for other land uses, this criterion needs to be re-examined and likely revised downward.	PG&E appreciates the Tribe's comment and notes the TRC's recommendation. PG&E has not completed the detailed project design at this stage. In the 30% design, major process equipments were located within buildings which will attenuate process equipment sound emissions. Pumping equipments were also located in belowground concrete vaults which will attenuate the sound emissions. PG&E will continue to evaluate potential means and methods to further lower noise emissions by the remedy as the design progresses and throughout the equipment procurement process. Additional information will be provided in the 60% design, As stated in the Tribe's comment, the noise environment at the project site is currently dominated by a number of noise sources, and "at many, but perhaps not all locations, the additional noise from groundwater contamination remedy implementation will not be problematic." For other areas, PG&E does not anticipate off-site sound levels from long term remedy operation to result in a substantial permanent increase in ambient noise levels above existing noise levels (see Section 4.91.5 of the Final EIR). In fact, in some areas, a source of noise will be eliminated when the IM facilities are decommissioned and the land is restored, as part of implementing this remedy. PG&E will implement the EIR mitigation measures on noise (NOISE-1, NOISE-2, and NOISE-3) and incorporate them in the project design, construction, and operational phases. These measures include best management practices for reducing noise levels during construction and a method to inform/ communicate to alert Tribes and nearby receptors of project activities that could generate noise, and to manage/ resolve any complaints. The EIR notes that implementation of NOISE-3 would achieve the normally acceptable exterior noise standards for places of worship. The San Bernardino County Development Code 83.01.08 establishes the exterior noise standards for land uses as a place of worship at 55 dB Leq daytime and 45 dB Leq nighttime (Leq is the equivalent average hourly noise level). The noise criteria in the EIR were appropriate.	Comment and response noted.	Comment and response noted.		

APPENDIX I

Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
Appendix D – Plans (Engineering Drawings)									
309	DOI-98	Appendix D, Drawing G-6		There is an influent flow from the Bat Cave Wash Remedy. This is not discussed anywhere in the design package. Influent wastewater flow from the TCS and East Ravine systems is not shown. Why are solids transferred to the liquid/solid phase separators by vacuum truck? Would this process not be continuous enough to warrant dedicated piping?	The remedy produced water main that runs through Bat Cave Wash is shown on drawing G-6 (Appendix D), at the upper left hand corner. There is a parallel main that runs along National Trails Highway. A cross reference to site plans will be added in the drawings. There is no produced water pipe from the East Ravine extraction wells since those will not be backwashed automatically. The TCS injection wells (COMP-INJ-1/-2) are shown on the drawing connected to the produced water pipe. The solids loadings are anticipated to be low; therefore vacuum truck was designed for transferring solids. If actual operating conditions differ, automation could be considered.	Okay pending review of 60% design submittals.	Okay pending review of 60% design submittals.	Comment resolved.	
310	DOI-99	Appendix D, Drawing G-6A		Although small in volume (0.1 MG/yr), extraction well rehab water should be shown in the table for completeness.	This will be added to drawing G-6A in the 60% design submittal.		Okay pending review of 60% design submittals.	Comment resolved.	
311	DOI-100	Appendix D, Drawing G-9		It appears CIP water can be directly used in carbon amended injection wells. Under what conditions?	CIP water will be treated like first flush rehabilitation water. Because the characteristics of the wastewater will not be known until it is pumped back out of the well, some of this water will likely be hauled by a truck to the central treatment system initially (versus transporting through pipelines). Possible reuse scenarios will be examined after water quality is determined.		Okay pending review of 60% design submittals.	Comment resolved.	
312	DOI-101	Appendix D, Drawing -10		It appears Line 202 (third from the top of the drawing) should be North NTH IRZ Injection Leg 1 – 23.	The comment on Line 202 is duly noted. The label should read “North Nth IRZ Injection Leg 1-23”. However, it must be noted that IRZ-1, IRZ-5 and IRZ-9 and IRZ -23 are designated as extraction wells (See Figure 3-1 and Section 3.2.1) and will not be used to inject carbon-amended water into the aquifer.		Okay pending review of 60% design submittals.	Comment resolved.	
313	DOI-102	Appendix D, Drawing C-4		Injection wells should be shown on the drawing (the symbol is in the legend).	The change will be made in the 60% design.		Okay pending review of 60% design submittals.	Comment resolved.	
314	DOI-103	Appendix D, Drawings C-25 and 26		The pipeline profiles are missing on the drawings.	The profiles will be shown in the 60% design submittal.		Okay pending review of 60% design submittals.	Comment resolved.	
315	DOI-104	Appendix D, Drawings I-5, I-10-, I-13, and I-15		DOI reviewed the fresh water system P&ID (Drawing I-5), which showed freshwater output going to facilities on Drawings I-10, I-13, and I-15. Drawings I-10 and I-14 identified no inflow from Drawing I-5, but I-13 did. One of these lines should go to the freshwater injection P&ID, which does not exists.	These drawings will be clarified in the 60% design submittal.		Okay pending review of 60% design submittals.	Comment resolved.	

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
316	DOI-105	Appendix D, Drawing M-11A		Where is the influent line? Also, please explain the notation "future borehole dia after re-drill". Is the drawing depicting potential future well diameters as wells are periodically replaced in the same location?	The influent line is shown in the center of the diagram (the backwash and injection share a common line that join together outside the well casing). For clarity, a call out will be added in the 60% design submittal. The wells will be drilled in two passes because of the size and depth of the boring – 1) a pilot hole to record the lithology and perform geophysics; 2) reaming the boring to place the casing and filter/gravel pack.		Okay pending review of 60% design submittals.	Comment resolved.	
317	DOI-106	Appendix D, Drawing M-13A		According to Table 3-1, all single screened wells are for layer 1, and dual screened wells are for layers 1 and 3. Why is packer shown above layer 1 for the single screen well but not the dual screen well?	For the single screen injection wells, the packer is used to help support and centralize the down-well piping and appurtenances. In the dual screen wells, the primary purpose of the packer is to isolate the two target zones of the aquifer (while providing the support and centralization as a secondary purpose). Standardization of the packer equipment simplifies the spare parts inventory.		Okay.	Comment resolved.	
318	DOI-107	Appendix D, Drawing M-13D		Has this sheet been put in as a place holder to be completed in the 60% design? Please explain.	That is correct. Details will be added in the 60% design package.		Okay pending review of 60% design submittals.	Comment resolved.	
Appendix F – Remedy-produced Water Management Technical Memorandum and Response to Comments									
319	DTSC-115	Appendix F, Remedy Produced Water Management		Can PG&E define the rehabilitation event – In a common rehabilitation event – you have acid washing then swabbing and jetting. Do you anticipate equipment replacement? What is the respective down time of that well?	Over time, wells will exhibit a progressive loss in specific injectivity and specific capacity. If routine backwashing does not correct the decline or loss, more extensive or aggressive rehabilitation will be required. A common rehabilitation event consists of first, using various tools and techniques to agitate the well to remove and loosen the plugging material, such as wire brushing, swabbing, surging and the use of acids/chemicals and second, removing the plugging material from the well by airlifting or pumping. In addition, testing can also be conducted before and after a rehabilitation event to identify the zones that are most plugged (before the event) and to understand the effectiveness of the rehabilitation (after the event). Testing techniques could include video surveys, spinner surveys, and aquifer tests. At the start of a rehabilitation event, the equipment (pump, connecting pipe) will be removed from the well and will be replaced if significant wear or corrosion is noted; otherwise, equipment will be replaced based on a replacement schedule developed in the O&M plan. A well could be out of service for 1 to 2 weeks during a rehabilitation event. Down time is usually dependent on the ease of access to the well, the ability to efficiently manage	Okay pending review of the 60% design and O&M Plan submittal.		Comment resolved.	See Appendix F of this BOD Report.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design
PG&E Topock Compressor Station, Needles, California

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
					produced water, the well depth and diameter, the amount of pre and post testing that is required, the severity of capacity loss or plugging, and the number of rehabilitation techniques utilized during the event.				
320	Hualapai-37	Appendix F		1. Evaluate how the remedy-produced water management system will perform in relation to how much time the remediation process will take; i.e. 30 years – 60 years. Appendix F provides a list of options for disposing of the remedy-produced water, and no definitive water management alternatives were presented. Given the uncertainties, it is difficult to describe the anticipated performance of the remedy-produced water management system. Infrastructure such as pipelines, pumps, and valves would be expected to wear out, and these components would be replaced as part of routine maintenance. However, the expected life of the injection and IRZ wells cannot be predicted over the 30 to 60 years of the remediation project. It is possible that re-injection of unclean water (i.e. remedy-produced water that has not been fully treated or cleaned) might reduce the overall life of the wells, requiring the drilling of replacement wells, thereby prolonging the time period necessary to complete the groundwater remediation.	Appendix F presents a management plan that is flexible to support, and not constrain the remedy over the anticipated multiple decades of operation. Having more than one reuse and/or disposal option available is critical for this remedy over the long haul. The design basis for the remedy produced water conditioning system is 30 years. A Draft O&M manual will be included in the 60% submittal with information about routine maintenance activities, sampling, testing, equipment replacement schedule, etc. for the conditioning system as well as maintenance activities for wells (backwash, well rehab). Injection well performance will be monitored (e.g., specific injectivity) and evaluated, and well maintenance will be performed in a timely manner to prevent reduced well life	Comment and response noted.	Comment and response noted pending review of the 60% design, including the groundwater monitoring and contingency plans.		See Appendix F and the draft O&M Manual of this BOD Report.

321	Hualapai-38	Appendix F		<u>2. Are the stated estimates for required conditioned water (7.3 MG per year referenced on Table F1) viable for the remediation remedy? According to the document (page F-2) "a variable that will have a significant impact on the volumes produced is the frequency of backwash events…" Please review data for reliability. What are the consequences of increased backwashing to the existing water tables with a projected run-time of 30 to 60 years?</u> The estimated annual volume of remedy produced water is shown to be 7.3 million gallons per year (Mgal/yr). This translates to about 22.4 acre-feet per year (af/yr). There is a significant amount of uncertainty in the number of IRZ wells and frequency of backwash and well-rehabilitation events; therefore, it seems that the design should consider a range of values. In any case, 22.4 af/yr is a significant amount of water, considering that the groundwater flow model (CH2M HILL, 2005) indicates that 10 af/yr of groundwater flows into the west side of the model domain, the subsurface outflow from the Mohave Basin is 5 af/yr, and Mohave Basin discharge to the Colorado River is 603 af/yr. If the remedy-produced water were removed from the Mohave Basin water budget (for example, on page F-9 by trucking off-site or evaporation through TCS ponds), the loss of water to the aquifer would represent a substantial loss of the water budget. Accordingly, PG&E should ensure that every measure is exercised to minimize this water loss.	The groundwater levels at the Topock site are controlled by the Colorado river. The quantity of water being discussed as remedy produced water is insignificant in comparison to the water available from the Colorado River. The average annual flow of the river below David Dam is nearly 10 million af/yr. The river is in communication with the aquifer at Topock. If the aquifer were drawn down below the level of the river, recharge from the river would rapidly replenish the aquifer. Note that PG&E currently pumps over 200 af/yr from the IM-3 wells on the river bank just to maintain a minimum landward gradient. The aquifer reaches steady state within a matter of hours to days when IM-3 pumping is started or stopped. Even though the volume of water generated by well maintenance is insignificant in terms of the basin-wide water balance, it is PG&E's desire to minimize the volume of water trucked away or discharged to the evaporation ponds.	Comment and response noted. DTSC agrees that water is a valuable resource and should be preserved within the local water basin to the maximum extent possible.	Comment and response noted pending review of the 60% design, including the groundwater monitoring and contingency plans.		See Appendix F of this BOD Report and the draft O&M Manual, Volume 2, Sampling and Monitoring Plan and Volume 3, Contingency Plan.
322	Hualapai-39	Appendix F		<u>3. Please evaluate backwash byproducts as they relate to remedy-produced water (conditioning) that is possibly reused by blending it with carbon-amended water and then injecting back into carbon-amended IRZ wells as described on page F-13.</u> The document indicates that the backwash water will have elevated concentrations of Cr(VI) and byproducts (As, Fe, and Mn). It is further indicated that the well-rehabilitation water will have pH values potentially less than 2. It is proposed that this remedy water will be re-injected into IRZ wells after pH neutralization and filtration of solids. However, there does not appear to be a contingency plan addressing the potential for handling remedy-produced water that could contain high concentrations of contaminants. Approaches outlined in Appendix F assume that the remedy-produced water will be non-hazardous and can be re-cycled.	Please note that the text that this comment refers states that the wells, receiving the injected water, will have elevated levels of byproducts, carbon, and <u>possibly</u> chromium. Injection wells need similar water to the formation water to not cause adverse geochemical reaction. Therefore, pH adjustment of water generated during acid treatments is anticipated to be required. Removal of dissolved constituents (byproducts and low levels of chromium) will not be needed because after blending backwash water with the water from the riverbank wells, the injected water quality will be similar to the aquifer water quality in/near the injection wells. Injection well performance will be monitored (e.g., specific injectivity) and evaluated, and well maintenance will be performed in a timely manner to prevent reduced well life. Based on experience at Topock and Hinkley, PG&E anticipates that the routine backwash water will be non-hazardous. This will be verified and confirmed via monitoring at startup and during operations.	Comment and response noted.	Comment and response noted pending review of the 60% design, including the groundwater monitoring and contingency plans.		See Appendix F of this BOD Report and the draft O&M Manual, Volume 2, Sampling and Monitoring Plan and Volume 3, Contingency Plan.

APPENDIX I
Response to Comments on Draft Basis of Design Report/Preliminary (30%) Design
Groundwater Remedy Revised Basis of Design Report/Intermediate (60%) Design

					Well rehab water can be thought of as having two distinct water quality characteristics – one at the beginning (first flush) and the other at the end of the rehabilitation process. The first flush water can be low in pH (acid is used to dissolve mineral deposits), and contain high concentrations of solid materials and rehabilitation chemicals. As the flushing continues, the water quality becomes more similar to backwash water. By careful management of the acidification process, it is possible to maintain pH >2 in the first flush water so that no hazardous waste is expected to be generated. Note that the preference for disposal of first flush rehab water are the TCS evaporation ponds or off-site disposal (trucking offsite to permitted disposal facility is an approach presented in Appendix F). However, monitoring of water quality will be conducted during rehabilitation events. Care will be taken to maximize recycling/reusing of produced water onsite and minimize the amount of water needed to be trucked offsite.				
				In addition, re-use by blending with carbon-amended water could consume carbon that is intended for remediation of the Cr(VI) due to the presence of byproducts such as ferrous iron and sulfide; therefore, target carbon concentrations might not be achieved in the remedial system.	Ferrous iron in the injected water will not consume the amount of organic carbon needed for the remediation of Cr(VI), in fact it is a product of the carbon injection. Carbon would be consumed by oxidized species, not by reduced species such as ferrous iron and sulfide. As discussed in response to comment #51 HA-7, the combination of iron reduction and organic carbon oxidation that produce the reducing conditions in the IRZ for remediation of Cr(VI) will occur thermodynamically as follows: $Fe(OH)_3(s) + 3H^+ + e^- \rightarrow Fe^{2+} + 3H_2O$ $1/12\ C_2H_6O + 1/4\ H_2O \rightarrow 1/6\ CO_2 + H^+ + e^-$ where C_2H_6O is ethanol, the form of organic carbon to be injected in the IRZ.				
				As with any engineering design, the remedy-produced water treatment system should be designed for the worst-case scenario.	It is not clear as to "the worst case scenario" mentioned in this comment. It is typical that groundwater remediation systems are designed to anticipated conditions and, through the use of contingency planning, provided with adequate flexibility for adjustment after startup and operations.				
				At the top of page F-15, "if strict water quality requirements are mandated for re-injection options, removal of dissolved constituents (such as arsenic, manganese, iron, calcium and	See 1st paragraph of this response.

Item	Comment Number*	Section/Page	Reference Text	30% Design Comment	PG&E Response to 30% Design Comment	DTSC Response to 30% Design Comment	DOI Response to 30% Design Comment	Final Comment Resolution	Where Responses are Reflected in the 60% Design Documents**
				selenium) may be required." Note that Cr(VI) is not mentioned in this list of constituents. As described above, re-injection of unclean water (i.e. remedy-produced water that has not been fully treated or cleaned) might reduce the overall life of the wells, requiring the drilling of replacement wells.					
323	Hualapai-40	Appendix F		<u>4. If Cr(VI) is not effectively removed from the aquifer, what is the contingency plan if the backwash contains high concentrations of Cr(VI)?</u> If the backwash contains Cr(VI), Appendix F proposes to add carbon (ethanol) to the backwash water before re-injection, which will supposedly reduce Cr(VI) to Cr(III) after re-injection. However, with an automated backwash and re-injection system (as proposed), it is not clear whether there would be monitoring of Cr(VI) concentrations in backwash water. A contingency plan was not presented for treatment of backwash water containing Cr(VI) concentrations.	Backwash water quality will be monitored; the draft O&M Manual will propose a monitoring frequency. As indicated in response to comment #321 Hualapai-39, removal or treatment of dissolved constituents (including Cr(VI)) in the injected water will not be required because after blending with water from the river bank wells, the injected water quality will be similar to the aquifer water quality in/near the injection wells. Because the water is being injected along with carbon amendment in to an already reduced geochemical environment around the injection wells, any Cr(VI) in the injected water will be rapidly reduced within a short distance of the injection well. Injection well performance will be monitored (e.g., specific injectivity) and evaluated, and well maintenance will be performed in a timely manner to prevent reduced well life.	Comment and response noted. DTSC agrees that the pending contingency plan is an important document that will require careful evaluation.	Comment and response noted pending review of the 60% design, including the groundwater monitoring and contingency plans.		See Appendix F of this BOD Report and the draft O&M Manual, Volume 2, Sampling and Monitoring Plan and Volume 3, Contingency Plan.
