Responses to Comments on the Basis of Design Report/Preliminary (30%), Intermediate (60%), and Pre-Final (90%) Design Submittals
(on CD-ROM only)

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
General Comments											
1	MWD	Non-design	Other	General		The Metropolitan Water District of Southern California (Metropolitan) appreciates the leadership and commitment from DTSC and DOI to resolve outstanding issues and to move this project forward in a timely manner. Implementing the final remedy is vital to ensuring protection of Colorado River water quality. Under current drought conditions, Metropolitan has increased reliance on Colorado River water to serve nearly 19 million residents in the southern California coastal plain.	Comment noted. PG&E concurs with MWD.		The Federal Agencies appreciate the continued involvement and support from MWD.		DTSC – Comment Noted
2	MWD	Non-design	Other	General		Metropolitan recognizes the significant efforts from all project stakeholders interested in streamlining the design review process. We are hopeful that the proposed design decision making process (i.e., RTC protocol) will ensure that all comments are carefully considered, while providing guidance for resolving outstanding design issues. We appreciate that our comments from the 60% design were appropriately addressed. In the interest of meeting the project timeline, if our new comment has already been addressed and/or incorporated, please provide a reference to the final resolution to explain if no further action will be taken to amend the final design.	Comment noted.		Comment noted.		DTSC- Comment Noted
3	MWD	Non-design	Editorial	General		Review the acceptance of edits between the Basis of Design Report/Pre-final 90% Design Submittal and the redline version of the Basis of Design Report. Check all footnote references and citations for accuracy, including footnotes 8 through 10 in the Basis of Design Report/Pre-final 90% Design Submittal.	References and citations to footnotes 8 through 10 will be revised and updated to 7 through 9 accordingly.				Comment resolved.
4	ADEQ					The installation of groundwater wells and the continued monitoring of hydraulic and hydrologic conditions and groundwater quality with respect to hexavalent chromium (Cr VI) and, more recently, remediation byproducts on the Arizona side of the Colorado River have been, and continue to be, important to this agency and others. The technical, practical, and sensitive importance has been documented previously by several entities. For the record, ADEQ supports the technical and practical components that have led PG&E to the proposed locations of MW-X and MW-Y. With the recent confirmation that the increasing concentration of Cr VI in MW-55-120 are statistically significant, ADEQ echoes the DTSC's sentiments expressed during the TWG meeting that more than two additional monitor wells on the Arizona side of the Colorado River are ideal. However, ADEQ will heed to the compromise of two additional monitor wells on the Havasu National Wildlife Refuge (HNWR) peninsula, as long as the VRP decision criteria outlined in 2007 continue to be met: • Exceedances of the total chromium Arizona Aquifer Water Quality Standard (AWQS) of 100 micrograms per liter (μg/L) do not occur; and • Cr VI concentrations are not detected above the regional natural background concentration of 32 μg/L. Once the groundwater remediation system is operational, the WRP will have additional decision criteria that will need to be met such as: • Remediation system byproducts are not to be detected above their respective AWQSs; and • Changes in groundwater quality parameters are not to be determined statistically significant. Specific groundwater quality parameters and preferred statistical analysis methods and bounds will be outlined at a later date. ADEQ acknowledges concerns expressed by the various Tribal stakeholders regarding the cultural significance of the HNWR peninsula as well as the region as a whole. ADEQ recognizes that federal agencies have primary jurisdiction over the HNWR and a decision on whether to drill on the peninsula, and where, will be made through the federal consultation and approval process. ADEQ's mission is to protect human health and the environment and requests to remain a participant in the consultation process to advocate the continued protection of our residents and environment.	Comment noted.				This RTC was discussed at the July 23, August 18, and August 26 TWG meetings. DTSC/DOI – Comment noted. The Agencies will provide final direction to PG&E with respect to MW-X and Y
5	DTSC-1	Non-design	Editorial	Certification Page		DTSC maintains that the draft design document should be certified by a licensed professional to verify that the design was prepared and considered by a professional with adequate expertise.	Agree, the certification page will be completed for the final design.	For future reference, DTSC will be requiring compliance with the California Business and Professions Code requiring name and license number for engineer in charge			Comment resolved. PG&E to add "PG&E will comply with the California Business and Professions Code" for all document submissions.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
								for draft documents or name, license and stamp for geologists on draft documents.			
6	DTSC-2	Design	Editorial			Please ensure design for the contingency Fresh Water Pretreatment System is incorporated into the site design throughout the document. PG&E can insert marker or qualifier that those parts are contingency design, but the design should be incorporated so that reviewer can see how the system is incorporated site wide.	The contingent Fresh Water Pretreatment System was incorporated throughout the documents, e.g., 90% BOD text/figures/ tables, engineering drawings (function code 13 with a marker as “contingent”), O&M Manual Volume 3 (Contingency Plan), and C/RAWP (Section 5, Construction Contingency Plan).				Comment resolved.
7	DTSC-3	Non-design	Process			DTSC observed statements in the basis of design document that referenced a final design (100%) to be prepared. Although DTSC acknowledge that a revised 90% basis of design document based on comment resolution will be produced for agencies deliberation as basis for DTSC’s CEQA evaluation and approval, DTSC did not envision that version to be called 100%, and more importantly, that there will be a follow-up comment process. Therefore, any remaining design decisions should be incorporated into the 90% for review and consideration and not deferred to the 100%.	Comment noted. Text and figures will be revised to reference the “100% design” as the “final design”. PG&E understands that there will not be a comment/ review process for the final design.		DOI envisions a DOI/DTSC review of a redline version of the 90% design package with incorporated changes. As the lead regulatory agencies, DOI and DTSC are responsible for ensuring that resolutions to comments resulting from the RTC process are appropriately incorporated into the final design package and we will review a redline to ensure this occurs. Once the agencies have accepted the redline revisions, the design package will be issued as a Final BOD/Design Submittal and C/RAWP.		Comment resolved.
8	DTSC-4	Design	Editorial and Process			In DOI and DTSC’s directive letter dated April 4, 2014, PG&E was directed to incorporate the removal of all underground utilities and infrastructures to the extent practicable at the time of remedy decommissioning and required PG&E to incorporate this directive into the decommissioning plan as part of the 90% design. Based on PG&E’s November 7, 2014 reply to Tribal inquiry on this matter, DTSC does not concur that PG&E has satisfied this directive in Attachment T to Appendix I of the 90% design. PG&E must prominently carry this directive into the remedy decommissioning and restoration plans at the end of remedy. Document revision required.	The document will be revised in response to this comment. As directed, PG&E will add a dedicated section on decommissioning in the executive summary of the BOD. The new section was provided during the 90% RTC period and included in	**Attachment A** must be revised to acknowledge agencies April 2014 direction to PG&E to incorporate the removal of all underground utilities and infrastructures to the extent			**Attachment A** was revised to address DTSC’s comment and incorporated DTSC’s edits.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							Attachment A of this RTC table (referred to herein as the final RTC table). All attachments can be found at the end of the table. It is important to note that at this time in the design process and before the remedy is constructed, steps to decommission any remedy components, that will occur decades into the future, will have to be general and conceptual. Descriptions of the conceptual decommissioning steps provided in the 60% RTC #6 (Attachment T of Appendix I) reflects this fact. Any additional details should be considered speculative best guesses, and are subject to change at the time of remedy decommissioning. PG&E has and will continue to reiterate its commitment to remove of all underground utilities and infrastructures to the extent practicable at the time of remedy decommissioning. See also RTC #12 DTSC-8.	practicable at the time of remedy decommissioning. Citing the actual letter is requested. DTSC has also edited PG&E's August 5, 2015 **Attachment A** Decommissioning Section. Those edits should be included in the final document. Finally, a groundwater SEIR is currently being prepared and will evaluate the Tribes current desire to remove all underground utilities and infrastructures to the extent practicable at the time of remedy decommissioning. Therefore, reference in Attachment A to the 2011 EIR language regarding abandonment in place and removal of only above grade facilities will likely need to be amended in the future as part of the upcoming SEIR assessment.			
9	DTSC-5	Design	Monitoring			DTSC has made comments on the uncertainty and difficulty in estimating the number of wells this particular remedy may require over the duration of the project (e.g., see 60% design RTC 225 and 632). Even commenting on a provisional, "next step" well can be difficult (e.g., see 60% design RTC 136 and 137 regarding wells IRL 6 and 7) and DTSC is no longer pursing very detailed information for certain provisional wells as potential well locations and associated circumstances can be too variable. DTSC does believe the 10 provisional, unassigned wells called out in the 90% BOD is good planning, but realizes that it is just a place holder. Ten to twenty percent of the total number of wells may be a more realistic upper bound. DTSC reiterates that wells should be minimized on this site due to cultural concerns, but that the need for the well must be based on technical necessity.	Comment noted.				
10	DTSC-6	Design	Monitoring			The Tribes have noted concern with the presence of Monitoring Wells X and Y on the Arizona peninsula. DTSC wishes to note the importance of these wells as sentry wells for the remedy which will purposely accelerate groundwater flow towards Arizona. Fundamentals on capture zone analysis and associated sentry wells can be found in *A Systematic Approach for Evaluation of Capture Zones at Pump and Treat Systems* (USEPA 2008). DTSC could not approve the remedy without sentry wells. The remedy would have to be drastically modified (groundwater flow in the area would have to move in an opposite direction - towards the west) if sentry wells were to be eliminated. These wells need to be installed early to establish baseline concentrations for water quality	Comment noted. Also note that discussion of sentry (sentinel) wells is provided in Sec 4.3.3.3 of O&M Vol 2.				This RTC was discussed at the July 23, August 18, and August 26 TWG meetings. Agencies to provide direction to PG&E based on input received.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						constituents (e.g., baseline chromium concentrations) so any naturally occurring trends can be observed before remedy start up. This will assist in determining if the well has been adversely affected by the remedy.					
11	DTSC-7	Design	Monitoring			Lessons learned from the in-situ remedial actions at the PG&E Hinkley Compressor Station should be shared with the CWG/TWG. Tribes had requested this information and PG&E was not able to find the time to schedule it. This information would appear valuable and directly applicable to the Topock site as the contamination and remedial measures are quite similar. As PG&E has recently planned to replace fouled injection wells at Hinkley, a summary of the events that led to that decision should be discussed as wells as preventive maintenance that will be conducted at Topock to alleviate the need to replace wells so quickly. Manganese migration that has exceeded threshold limits at sentry wells should be discussed as well as the Manganese Mitigation Plan that has been developed and as of November 2014 includes active extraction and infiltration dry wells to address the exceedances. Expansion of the plume at Topock via excessive byproduct migration is unacceptable and as it would likely result in significant footprint, infrastructure and costs in order to mitigate. PG&E should identify additional Hinkley topics for discussion at an upcoming TWG meeting.	An educational webinar was held by PG&E on July 7, 2015 to provide an overview of the In-situ Remediation of chrome-six utilizing a similar technology to that under design for the Topock site, and will cover infrastructure, geochemistry, management of byproducts, rate of chromium remediation, and lessons learned.	Hinkley presentations by PG&E and the RWQCB staff on July 7 and 8, 2015 respectively were informational and appeared to be well received by Tribes, agencies, and stakeholders.			Comment resolved.
12	DTSC-8	Design	O&M			The 90% should be revised to readily indicate that all subsurface remedial infrastructures will eventually be removed as part of decommissioning and not be abandoned in place. At a minimum, a section on site decommissioning should be included in the executive summary and should briefly describe the decommissioning process envisioned for the remedy. More decommissioning details should be provided in a dedicated section even though it is understood that a decommissioning plan will be prepared much later in the remedial process. Language contained in Attachment T in Appendix I is not adequate and difficult to find. PG&E should address how certain portions of the remedy may be decommissioned prior to remedy completion if agencies believe they are no longer needed. For clarity, PG&E should list all remedial structures that they believe cannot or should not be removed at the end of the remedy. For example, will horizontal casings installed under the freeway be removed or left in place.	As directed, PG&E will add a dedicated section on decommissioning in the executive summary of the BOD. The new section was provided during the 90% RTC period and included in **Attachment A** of the final RTC table. It is important to note that at this time in the design process and before the remedy is constructed, steps to decommission any remedy components, that will occur decades into the future, will have to be general and conceptual. Descriptions of the conceptual decommissioning steps provided in the 60% RTC #6 (Attachment T of Appendix I) reflects this fact. Any additional details should be considered speculative best guesses, and are subject to change at the time of remedy decommissioning. PG&E has and will continue to reiterate its commitment to remove of all underground utilities and infrastructures to the extent practicable at the time of remedy decommissioning. A conceptual list of	PG&E should note that portions of the remedy may be decommissioned prior to remedy completion if agencies believe they are no longer needed. See also response to RTC # 8.			See RTC #8 DTSC-4. Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							remedy features that may not be removed was provided in the executive summary as directed. The new decommissioning section also mentioned that a future Bird Impact Avoidance and Minimization Plan will be prepared (prior to decommissioning) based on surveys conducted prior to decommissioning.				
13	FMIT	Design and Non-design	General	Also, in reference to ARAR Table 6.2-1		The Project burdens the traditional religious practices of the Tribe. The burdens are not merely defined by restrictions to physical access and such intrusions as visual and auditory insults to the Tribal members, but includes the continuing and now expanded degradation and desecration of the Traditional Cultural Landscape. The Agencies and design documents should more fully reflect the breadth of the statutes (including RFRA and AIRFA) and the Project's impacts on the Tribe. As reflected elsewhere, consultation under the NHPA continues to be mostly about producing documents, rather than focusing on process inclusion of the Tribe in actual decision-making. Some recent efforts to consult with the Tribe on the continually expanding scope and intensity of impacts is appreciated, but has not been reflected in the design documents.	PG&E defers to the agencies on consultation with Tribes.	Tribes have been consulted throughout the remedy selection and design process. This remedy was specifically recommended by FMIT as compared to other technologies evaluated. Tribal input have been incorporated into the design including injection and monitoring well locations, pipeline alignments, soil storage and staging areas, access routes, etc.	DOI and BLM acknowledge that the site investigation and remediation activities will have an adverse effect to the Traditional Cultural Property from these actions. However, DOI and DTSC, as the regulatory agencies responsible for cleanup, are the decision makers on the project and disagree that the Tribes have not had many opportunities to provide significant input to the agencies. Tribal input is always taken into consideration before decisions are made by BLM and DOI. Design changes have been included at each phase of the process based on input from the Tribes. Furthermore, the BLM is exploring a National Register nomination for the Topock TCP (in response to unavoidable	In its response, DTSC maintains that the "… remedy was specifically recommended by FMIT as compared to other technologies evaluated. Tribal input have [sic] been incorporated into the design including …" This is misleading. First, the Tribe's preferences in regard to the nine alternatives presented in the CMS/FS document were clearly outlined in a comment letter dated February 26, 2009. In that letter, the Tribe clearly expressed its preferences among the alternative remedies in terms of priority. The Tribe's first preference was Alternative A ("No Action" or "Natural Attenuation"). Second was Alternative B ("Monitored Natural Attenuation"). After that, and in consideration of PG&E's preference for Alternative E ("In Situ Treatment with Freshwater Flushing") and believing that this technology would be the least disruptive of the engineered remedies to Tribal interests based on the information presented in the CMS/FS, the Tribe agreed that it could support Alternative E, as	Once again Agencies would like to affirm our commitment to continue working with all Tribes and Stakeholders to see that the cleanup is accomplished in a manner that minimizes impacts to cultural and religious values and resources as well as biological resources.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)

Groundwater Remedy Basis of Design Report/Final (100%) Design

PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
									impacts) and are consulting with tribes on the National Register eligibility of the Clay Gathering Area -- all in response to purported impacts to their sacred landscape. The BLM has been following the guidelines documented in the CHPMP and PA which require that sites be evaluated for the National Register if they cannot be avoided. Thus in such cases a report must be produced and tribes must be consulted. Additionally, all cultural documents are reviewed by Tribes and their concerns are factored into revisions. Tribes were also heavily involved in the development of the Programmatic Agreement although only one tribe signed the document. The agencies hope that all Tribes are more involved during the upcoming revision of the Cultural Historical Property Management Plan (CHPMP). The remedy must be implemented in a timely fashion and we will continue to work with all Tribes and Stakeholders to see that this is accomplished in a manner that minimizes impacts	then proposed. For example, the Tribe clearly expressed a preference for above-ground piping installations, a design detail which we are now informed will not be implemented for various reasons. And in fact, Alternative E, during the progression from 30% to 60% to 90% design, has significantly increased in complexity and associated impacts, as reflected by the need for a Subsequent EIR. Second, it may be true that certain preferences of the Tribe have been incorporated into the design on a selected basis, some of the most significant and impactful ones remain such as underground utilities and MW-X and MW-Y sitings. Indeed, some of these have been characterized in the CEQA process as significant, unmitigable and irreversible. Further, DOI also acknowledges that "… the remedial activities will have an adverse effect to the Traditional Cultural Property …." Accordingly, it is misleading and disingenuous for DTSC to make such a blanket claim that it has incorporated the Tribe's input into the design, when changes that would reduce significant religious and cultural impacts were not adopted and the project has substantially evolved from that originally proposed and approved. More generally, both the DTSC and DOI responses sidestep the thrust of the Tribe's comment regarding how the project will limit its ability to exercise and	

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
									to protect cultural and religious values and resources as well as biological resources.	enjoy religious freedoms guaranteed under Federal statutes. The Tribe acknowledges that certain design changes have been made on a selective basis, however many of the more impactful features of the design have not. Overall in most instances, the response clearly reflects single-mindedness in achieving technical objectives without commensurate consideration of important cultural issues, whenever such matters come into conflict.	
14	FMIT	Non-Design	CEQA/EIR			The documents still do not set out the *process* as to how CEQA and other environmental review requirements will be met when changes occur during the decades-long operation of the remedy. Nor is there a description as to how the tribes will be appraised of proposed or actual changes and how the tribes will be meaningfully included in the environmental review to determine whether potential impacts, both individually and cumulatively, are significant (This is an open issue that was be carried forward from the 60% BOD to the 90% design.)	PG&E defers to DTSC for response to this comment.	CEQA evaluates the potential environmental impacts of a project in totality. That is why CEQA evaluations use conservative, but realistic estimates, of the project activities during its evaluation. Future allowable modification of the project will be bounded by the scope of the impacts evaluated in the completed CEQA document for the project. Changes with impacts beyond those evaluated in the completed EIR review will be separately evaluated after PG&E puts forth a change proposal and discussion with agencies. DTSC will comply with the requirements of CEQA. Tribal involvement will be maintained through our standard periodic meetings (e.g. CTF, CWG, and TWG) and any other required outreach		Thank you for the commitment to continue Tribal involvement throughout the project. We also note that any environmental review considered after July 1 2015 will need to comply with the provisions of AB 52 (Gatto). The Tribe requests that AB 52 consultations occur with FMIT for all work related to the remediation effort. Please consider also the response at RTC #29 FMIT- 15.	DTSC response: Request noted. DTSC will comply with applicable and relevant requirements of AB52 as procedures are developed by the Governor's Office of Planning and Research and DTSC, as applicable to the project.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
								under CEQA requirements. There is no plan to dissolve or end the current periodic meetings. Tribal involvement will be extended through field monitoring opportunities pursuant to mitigation measures, and SOPs (e.g. well screen calls). Currently, agencies cannot foresee any significant project changes that the Tribes would not be notified or be a participant in its decision making process based on existing meeting and input structure provided in the 90% design document.			
15	FMIT-1	Non-design	Other			On April 4, 2014, the Agencies issued final directives to PG&E on "outstanding issues of the response to the 60% BOD report." Among the "outstanding issues" was whether the pipeline would be designed as a buried or above-ground facility. The Agencies ultimately directed PG&E "to continue to design the pipeline system for below ground pipeline placement, following the alignment in PG&E's 60% Design proposal." This decision purportedly was based on input received from PG&E, the Tribes, and [unidentified] stakeholders as well as other such significant criteria as ecological impacts, construction impacts and long-term maintenance and safety concerns." The letter states that [FMIT[1]] expressed "... a *revised preference* for below ground piping for the area adjacent to Maze Loci B ... [and] a preference for aboveground placement of the remaining portions of Pipeline A." [Emphasis added.] These statements grossly misrepresent and deemphasize FMIT's position as stated in the March 6, 2014, cover letter as well as the conditions of use comments in Enclosure A of that letter. First, the March 6 cover letter clearly states that "... the comments and preferences as expressed in [this letter] do not in any way constitute an endorsement or acceptance of the design ... many of the adverse impacts associated with this project are permanent and irreversible." However, after several meetings and site walks, the Tribe yielded to the persistent arguments of PG&E regarding asserted "safety issues" associated with an aboveground pipeline along this route, as well as to the realization of potential further damage to *in situ* materials that could result from road cuts that might be necessitated by placing above-ground infrastructure on an access route. Accordingly, after re-iterating its preference for above-ground routing, FMIT yielded to an *acceptance* of the proposed below-ground construction, with the conditions that: (1) no further disturbance would occur to the *in situ* materials on either side of the roadway, and (2) all below-ground piping be removed after remedy completion. And, as correctly indicated in the Agencies' letter, FMIT did express preference for aboveground design, with the exception of the spur piping to IRL-4.	PG&E will review and consider the Tribes' response (dated Sept 18 and 21, 2015) to PG&E's evaluation of the MW-X/Y White Paper (dated August 14, 2015). PG&E anticipates that additional discussion on a proposed path forward (including model improvements and timing) to occur at a future TWG.	DTSC would like to thank the Tribes for their continued input on this investigation and cleanup project. DTSC understands through repeated statements by the Tribes that this area is culturally and spiritually significant. Contrary to Tribal perceptions, inputs from the Tribes weigh heavily in DTSC's decision process. DTSC considers many criteria in our decision including long term maintenance, health and safety, visual impacts, as well as cultural impacts. That is	DOI and BLM met with the Tribes on several occasions regarding the pipeline placement and considered aboveground pipeline segments as design options. DOI developed a pipeline matrix to assist in the analysis of each segment in determining whether the above ground option could be considered. DOI and DTSC directed PG&E to further analyze options for aboveground versus below ground placement for each main segment of the pipeline. PG&E	As claimed by DTSC, can the agency cite one important example of how Tribal input has weighed "... heavily in DTSC's decision process?" [Emphasis added.] There has rarely been any discussion with the Tribe of the weighing of various factors, on summary conclusions that the Tribe's input was considered. With particular regard to the decision on the installation of proposed monitor wells MW-X and MW-Y in Arizona, which are sited on the cultural property known as Amut ahar, the Tribe has taken all reasonable measures to objectively assess the technical need and justification for these wells, including	Please see Agencies' direction letter dated April 4, 2014, on above ground/ belowground pipeline infrastructure. DTSC/DOI – In response to the yellow highlighted section, PG&E must also include language in the Executive Summary that they will work with landowners on decommissioning preferences.

[1] Referencing letter from Dr. Leo S. Leonhart, Hargis + Associates, Inc., on behalf of FMIT to Mr. Aaron Yue, DTSC, and Ms. Pamela Innis, DOI, re "Fort Mojave Indian Tribe Comments on Alternative Pipeline Routings and Proposed Soil Storage/Staging Areas for the Topock Compressor Station 60% Groundwater Remedy Design," April 6, 2014.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						FMIT further notes that the Agencies' letter also misrepresents the March 10, 2014, letter[2] from the Hualapai Tribe, and the March 13, 2014[3], letter from the Cocopah Tribe, both of which indicate a preference for above ground placement of the last portion of the pipeline route from IRL-3, west along former Route 66 to FW-1 ("F to H to I"). The Tribe has repeatedly appealed for above-ground infrastructure, both verbally and in numerous written comments and letters regarding the 30% and 60% design documents. This preference is rooted in the need to protect the sanctity of the sacred landscape and preserving it for future generations. Contrary to the Tribe's appeals, the present design for the remedy calls for *nearly the entire pipeline routing*, roughly *5 linear miles* to be placed below ground. This decision raises the question as to the *specifics* of the Agencies' criteria apart from the generalities mentioned above that override FMIT's expressed preferences. And it further raises an issue as to whether there were individuals responsible for weighing in on cultural matters involved in such decisions. And finally, what level of commitment there is to completely remove the pipeline once the remedy is completed and how enforceable is that commitment?		why DTSC expended much resources and efforts to meet and discuss these matters with Tribes to seek resolutionAs claimed by DTSC, can the agency cite one important example of how Tribal input has weighed "… heavily between parties. In response to Tribal concerns, agencies directed PG&E to prepare visual simulations of pipeline options which were discussed at several meetings. Ultimately, however, the agencies must make a decision to move forward with the project, even though the decision may not be satisfactory to the Tribes. In the case of the various segments of piping, DTSC understands that the Tribes acknowledged PG&E's needs to install the pipelines underground and that there would be greater disturbance with piping located below ground. DTSC has also requested PG&E to commit in the design document to remove all infrastructures at the end of the remedy.	provided a detailed comparison that is included in the 60% Design Response to Comment. Additionally, visualizations were made for the segments and presented for discussion at the meetings. The Agencies considered all input in their direction to PG&E. We do acknowledge the Tribes preference for aboveground piping however, when considering safety and constructability, visual impacts, impacts to undisturbed areas, potential impacts to biological resources, as well as impacts to the cultural area, our direction to PG&E in our 4/4/14 letter was to carry forward the below ground placement of the pipeline system in the 90% Design, following the alignment in PG&E's 60% Design proposal. Our direction specified that, based on additional input from the Tribes, PG&E shall remove all underground utilities and infrastructures to the extent practicable at the time of remedy decommissioning.	engaging the expertise of the TRC, including the TRC's presentation of a some 60-page white paper, which proposed a program of further testing and evaluation that could address the suitability of the well sites. While the decision remains under consideration, it appears that PG&E has essentially rejected the findings of the white paper and its recommendations, based on limited findings that were never intended to address the specific matter of the wells. It is hoped that the agencies will give due consideration to this good faith analysis. In its response, DTSC asserts that "Ultimately, however, the agencies must make a decision to move forward with the project, even though the decision may not be satisfactory to the Tribes." This language seems to imply that the Tribe is in some way opposed to implementing a groundwater remedy. This is not at all the case. Indeed, the Tribe is extremely concerned over the level of contamination that has been spread throughout the site and its sacred lands. Accordingly, the Tribe represents and speaks for the lands, animals, plant life and all things above and below ground and presents comments to make PG&E and the agencies aware of the nature of its disturbance and requests various design modifications to lessen

[3] Letter from Mr. Edgar Castillo, Topock Project Manager, to Mr. Aaron Yue, DTSC, and Ms. Pamela Innis, DOI, re "60% Pipeline and Soils Staging Matrices," March 13, 2014.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
								Finally, DTSC does have cultural resource experts that provide us with input for consideration in our decision making.	See also RTCs #36 FMIT/TRC, #37 Hualapai/TRC, #38 Cocopah/ TRC, and #39 Chemehuevi/ TRC.	its impacts on the TCP and in concert with the PA, CHPMP, CIMP and related documents that state "Avoidance" is the first consideration. Both responses also seem to prioritize visual impact reduction over reduction to other cultural aspects prioritized by the affected community - the Tribe. Relative to the direction of infrastructure removal at time of decommissioning, the Tribe remains concerned about the enforceability of "to the extent practicable" and requests that some performance criteria to determine practicality be considered and adopted prior to final design acceptance. Please see RTC #16 FMIT-2.	
16	FMIT-2	Non-design	Other			As was further expressed in FMIT's letter of March 6, 2014, the March 10, 2014, Hualapai letter and the March 13, 2014, Cocopah letter, any below-ground piping should be removed following the remedy completion. And indeed, this was called for in the April 4, 2014, letter from DTSC/DOI to PG&E. Specifically, PG&E was directed to "... remove all underground utilities and infrastructure to the extent practicable at the time of remedy decommissioning. This directive shall be incorporated into the decommissioning plan as part of the 90% Basis of Design." ~~[Emphasis added.]~~ Despite this directive and contrary to comments made by the FMIT, CRIT, Hualapai, Chemehuevi, and Cocopah Tribes, PG&E apparently believes that it has fully responded to this issue, referencing a narrative presented in Attachment T (to the RTC). However, in regard to "System Components Decommissioning," this narrative provides for either removal or abandonment in place as part of the decommissioning. There is no explicit commitment to actually remove underground infrastructure, as DTSC and DOI directed and as the Tribes' requested. Thus we assume that PG&E prefers that the ultimate decision, which will occur tens of years after construction, remains solely within its own discretion. This is unacceptable to FMIT. Perhaps one reason why PG&E feels it has the freedom to provide only a vague commitment at this time is the qualification "to the extent practicable" in your letter. The Tribes' letters made it quite clear that complete removal is expected. As to practicability, if there are compelling reasons why removal is not practicable, then this needs to be justified in detail in the narrative and performance criteria outlined, and must be consistent with all requirements of California Environmental Quality Act ("CEQA") and the National Environmental Policy Act ("NEPA") equivalent analysis. Moreover, if there is reasonable justification as to the impracticability, then such disclosure needs to be made now. Also, an enforceable commitment must be made that the Tribes will be brought in for consultation prior to abandonment. Again, I wish to remind you that the Tribe will be resident in the Mojave Valley, our historical and cultural homeland, well into the future, far beyond the implementation of this Topock Project. It is therefore critical that the full and proper design, implementation, and decommissioning be established at this time so that our – and your – successors understand how to proceed in the future. This process needs to be spelled out now in the final remedy document to better reflect the Tribe's understanding of this agency directive, not down the road when most of us will no longer be part of the project and left to someone else's interpretation. Fort Mojave will be here still overseeing this	Please see RTC #12 DTSC-8. DTSC and DOI have the ultimate decision making power over the Project and its decommissioning, including the removal of remedy facilities. PG&E understands the Tribes expect "complete removal." PG&E is committed to following the agencies' direction regarding removal in the April 4, 2014 directive letter. As noted in RTC #12 DTSC-8, decommissioning will occur decades from now. PG&E will follow the state and federal requirements that apply to the Project during decommissioning. These requirements include the EIR		Section 5(A) of the Programmatic Agreement (PA) states that "All facilities and appurtenances related to the Topock Remediation Project are to be removed as soon as practicable upon attainment of cleanup standards and a determination by DOI that removal of such facilities is protective of human health and the environment. All such removal will be planned in consultation with the Signatories, Tribes and Invited Signatories, following the guidelines in Appendix B." DOI and the Bureaus , along	As discussed in recent meetings of the TWG, the Tribe understands that a commitment to remove ALL infrastructure as part of decommissioning may not be practicable or may cause more disruption than leaving it in place. However, the Tribe believes from the examples cited in the TWG, this represents more of an exception than a rule. The Tribe understands that it may well be the Agencies decision as to the final disposition of the infrastructure, but notes that PG&E's statements in the BOD lacked firm commitment, and that the direction received from the Agencies on April 4, 2014, was rather explicit in this regard as referenced in the comment. and must be fully and accurately reflected in	A dedicated section (see **Attachment A** of the final RTC Table) that describes the decommissioning process envisioned for the proposed remedy will be added to the Executive Summary of the Final BOD. This RTC was discussed at the August 19 TWG meeting. See final resolution in comment 15 above.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						cleanup for many generations to come, we need an enforceable removal process and criteria in place now as part of the remedy design documents.	mitigation measures, the PA, and the CHPMP. PG&E does not currently know whether it will be infeasible to remove certain remedy components and cannot provide the Tribes with such information. Any guess regarding future conditions that may make complete removal of the remedy infeasible would be just that—a guess. A more detailed decommissioning plan will be prepared in the future, and will address the feasibility of removal of remedy infrastructure.		with DTSC and PG&E, will evaluate the removal of infrastructure in the decommissioning plan to determine if doing so is protective. As stated in part D of this same section, prior to decommissioning of any remediation facility, the Federal Agencies will consult with all Signatories, Tribes and Invited Signatories during the development and review of related plans.	the final design and CEQA documents. Also, as a landowner the Tribe must be consulted on what happens on its land and requires that at the end of the remedy that all features of the final remedy be removed from its property. The Tribe, as landowner, not the agencies or PG&E, shall determine what "to the extent practicable" means to their respective management practices at project decommissioning especially on lands owned by the Tribe.	
17	FMIT-3	Non-design	Other			It has been eight years since the Tribe submitted a letter to the Arizona Department of Environmental Quality (ADEQ) regarding PG&E's plans to construct wells on the Arizona shore. At that time, the Tribe expressed serious concerns about the plan and opposition to the proposed installation of a well in the area then referred to as "Site 1." Site 1 was characterized at the time as "sensitive," and part of a named Mojave sacred place known as Amut ahar (White Clay). It is the area below the present land surface that relates to the named sacred area, including sediments below this area and any previously dredged areas. Any consideration of wells or other components in this area- also must be consistent with all requirements of CEQA, NEPA-equivalent analysis and the National Historic Preservation Act ("NHPA"). Nothing has changed to amend that characterization of the sacred area. On April 16, 2007, Tribal representatives met with representatives of ADEQ and the Arizona State Historic Preservation Office ("Arizona SHPO") to further discuss this issue. This resulted in Arizona SHPO's transmittal of a letter to ADEQ affirming that the proposed Site 1 was indeed a named traditional historic place and opining that "... the construction and monitoring of these [proposed] drill sites would negatively impact the characteristics that make these properties eligible for inclusion in the State Register of Historic Places." In turn, ADEQ transmitted a letter to PG&E, emphasizing the Tribe's objections, particularly to the Site 1 location. Despite the finding of Arizona SHPO, the BLM subsequently issued an opinion that the proposed drilling at Site 1 "... would result in No Adverse Effect to sites listed or eligible for listing on the National Register of Historic Places." It is interesting to examine the events leading to this conclusion. Specifically: • BLM met with FMIT on July 17, 2007, to argue that the Site 1 area was "under water" until the U.S. Bureau of Reclamation placed dredge materials there in 1962. • Following this, BLM asserted it did not hear further from FMIT re its and therefore BLM was uncertain as to whether FMIT maintained its position and did not consult further with us. • BLM claims to have conducted further research as to whether "... Site #1 was in the vicinity of any known gathering place," but failed to make such a determination to our knowledge. The source and outcome of the "research" remain unidentified to us. • On September 7, 2007, BLM claims to have met with representatives of the Colorado River Indian Tribes ("CRIT") from the Topock and Golden Shores vicinity. BLM claims that the CRIT representatives "... informed the Federal agencies that there are no sites of traditional or cultural use or importance in the vicinity of Site #1 to the Mohave [sic] people, at least historically." On March 6, 2008, FMIT Chairman Williams wrote again to BLM pointing out serious shortcomings in the NHPA Section 106 consultation process and the fact that the BLM had been rather	PG&E will review and consider the Tribes' response (dated Sept 18 and 21, 2015) to PG&E's evaluation of the MW-X/Y White Paper (dated August 14, 2015). PG&E anticipates that additional discussion on a proposed path forward (including model improvements and timing) to occur at a future TWG.	DTSC thanks the Tribe for adding some detail and clarifying the Tribes concern with the area in question. DTSC is aware that the Arizona SHPO had requested information from the Tribes and on February 4, 2008, SHPO concluded that no substantial information was provided to support the Tribes position. DTSC is also aware that the Arizona SHPO is currently recommending additional consultation on the installation of wells X and Y. DTSC strongly disagrees with the Tribes portrayal that the Arizona wells lack technical basis. DTSC offers the following discussion to hopefully clarify the misconceptions. For this remedy, wells MW-X and	DOI disagrees with the Tribe's characterization regarding the consultation related to the installation of wells at Site 1 in 2008, as set forth in the FMIT's comment. In 2007 through 2008, BLM engaged in extensive consultation with the Tribes regarding Site 1. On many occasions during this time period, BLM requested from the Tribes information that might support the eligibility of Site 1 for the National Register. On January 24, 2008, BLM concluded that "DOI/BLM does not currently have evidence that the vicinity of Arizona Well No. 1 contains any documentable historic properties eligible for inclusion on the	As discussed thoroughly during the TWG RTC review process, the Tribe understands the position as presented by PG&E with regard to the need and basis for siting the monitor wells MW-X and MW-Y on the Arizona shore. Likewise, the Tribe hopes that the Agencies fully understand and appreciate the Tribe's opposition to the intrusion onto that culturally-sensitive area. Moreover, the Tribe hopes that PG&E and the Agencies will some objectively consider (1) the possibility that further analysis on this issue is warranted as presented in the TRC's "White Paper," and (2) some thinking "out of the box" as to the possibility of some alternative for assessing the effectiveness of hydraulic capture of the remedy, noting that the purpose of the monitor wells is to provide a	This RTC was discussed at the July 23, August 18, and August 26 TWG meetings. DTSC/DOI response to highlighted section: The rational of the proposed MW-X and Y wells has not been to address some future contingency. As explained in various meetings with the Tribes, the purpose of those wells is to directly monitor the down gradient effect of the remedy. Nevertheless, in deference to Tribal cultural concerns, The Agencies have considered the various proposal made by the TRC on behalf of the Tribes to further evaluate the geological understanding of the area prior to making a decision on the installation of MW-X and Y. Our direction letter to PG&E will lay out our expectations.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						confrontational with the Tribe, "challenging and den[ying] [the Tribe's] beliefs and concerns," and requesting further consultation on the matter. And on March 7, 2008, FMIT legal counsel wrote to the Advisory Council for Historic Preservation ("ACHP") requesting full review of the record and consultation with the Tribe and BLM on the matter. Finally, on March 10, 2008, the Yavapai-Prescott Indian Tribe ("Yavapai') sent a letter supporting FMIT's position in regard to the Site 1 drilling. Ultimately, PG&E proceeded to construct the wells in 2008 over the Tribes' objections and contrary to the recommendations of Arizona SHPO and ADEQ. And among the approvals and authorizations they cited was the May 10, 2007, letter from ADEQ, without mention of the discussions and proceedings that occurred subsequently. Despite the flagrant disregard for the Tribe's legitimate concerns and the misrepresentation of approvals from the State of Arizona, PG&E is now planning the construction of two additional wells in Arizona to the north of the location of monitor well MW-54 (at Site 1), an area which is still within the sacred place affirmed by the discussions with the Arizona SHPO back in 2007. FMIT has made the CWG aware of this fact during recent meetings. Additionally, the Tribe has discussed this with DOI in the context of the Cultural and Historic Property Management Plan (CHPMP) meetings and consultations as recently as February of this year. Still it seems that both the Agencies and PG&E remain steadfast in their position as to the necessity of constructing wells at these locations, notwithstanding the significant adverse impacts and lack of valid supporting technical and environmental analysis. The Hualapai Tribe requested that the TRC perform a technical evaluation of the need for MW-X and MW-Y. In summary, the TRC has concluded that the need for these wells in the proposed locations is not justified on technical grounds. Specifically, the TRC notes that the proposed locations might be too far north to capture any potential migration of hexavalent chromium ("Cr(VI)"). While DOI has argued that the modeling shows a pathway toward these locations in the event of a contaminant (Cr(VI)) breakthrough, the TRC points out that the model may be flawed in regard to discretization of hydraulic conductivity values beneath and adjacent to the River. Accordingly, in the opinion of TRC, the groundwater flowlines from the California side would deflect further to the south. The 90% BOD states that the purpose of monitor wells MW-X and MW-Y is to address a contingency involving the detection of elevated concentrations of Cr(VI) at those locations. As expressed in the strategy, if such conditions were to arise, it would trigger a discussion as to a need to construct additional slant wells under the river. The Tribe's review of the documents failed to reveal any other rationale explaining why such a contingency would be realistic, particularly considering that the design concept involves the line of In-Situ Reactive Zone ("IRZ") wells and a line of River Bank wells, both intended to intercept the eastward movement of the Cr(VI) plume, and additionally the expectation that the floodplain will be cleaned up in a rather short timeframe, based on model simulations. Moreover, this does not account for known information about the reductive properties of the naturally-occurring "rind" of reducing sediments that envelopes the River as well as the fact that, in the time it has been monitored, Cr(VI) has not been detected in the River. Finally, if Cr(VI) has not been detected in the River or at monitor well MW-54 on the Arizona shore, with riverbank extraction, it would be even less likely that there would be plume migration beneath the River from west to east into the area of the proposed MW-X and MW-Y monitor wells. At the recent CHPMP meeting, DOI indicated that it was concerned about using the MW-X and MW-Y wells also to monitor hydraulic capture of the plume. This was presented in the context of gradient control in reference to the hydraulic effects of the River Bank extraction wells and the pumping at freshwater well HNWR-1A. Certainly, this is an effect that should be first examined using simulations. Also, a notion of the drawdown effects can initially be gained from monitoring wells MW-54 and the TCS wells 2 and 3. Further, given the large surface water body between HNWR-1A and the proposed monitor wells MW-X and MW-Y locations, it is quite likely that any drawdown associated with pumping of HNWR-1A would likely be dampened by the constant recharge source short of the radial distance to MW-X and MW-Y. The above-referenced section of the 90% BOD indicates that PG&E held discussions with the Agencies regarding this technical issue during the development of the 90% BOD report. Presumably other issues important to the Tribe were discussed during this timeframe as well. The Tribes should have been included in such discussions. In summary, the Tribe asserts that the construction and monitoring of wells MW-X and MW-Y would be impactful to the cultural and religious values of the landscape.		MW-Y are a critical part of the monitoring program. DTSC would be extremely reluctant to approve the remedy design without them. The reason is that PG&E's remedy intentionally accelerates groundwater flow to the east towards Arizona. This is in direct opposition to the current interim measure which pulls outboard contamination back to the west towards California. So wells MW-X and Y are proposed to monitor the outboard, downgradient portion of the remedy and make sure untreated chromium contamination does not escape the remediation zone and continues on towards Arizona. Additionally, the wells would also be monitored for byproducts (e.g., arsenic, manganese) that would be generated by the remedy's in-situ treatment zone. USEPA's 2008 guidance document titled, Systematic Approach for Evaluation of Capture Zones at Pump and Treat System, refers to these types of monitoring wells as, "sentinel wells". Without these sentinel wells, there would be no direct way to confirm that the Arizona	[National Register]." The Arizona SHPO then concurred with the January 29, 2008 BLM finding of "no historic properties affected" in their correspondence of February 4, 2008 (see **Attachment B** of the final RTC table). As BLM explained in a February 29, 2008 letter to the FMIT, it is problematic to define the area as a Traditional Cultural Place (TCP) when insufficient information regarding discrete boundaries and locations has been provided by Fort Mojave Indian Tribe. However, in response to the Tribes concerns with proposed well MW-X and -Y, BLM has re-initiated consultation on the proposed Arizona wells to evaluate the National Register eligibility of the area. Related to this action, on May 1, 2015, BLM sent a letter to the Tribes requesting that the information needed to further evaluate the clay gathering area be provided by mid-July. It should be noted that Arizona Department of Environmental Quality (ADEQ)	contingency for another contingency in order to determine whether a further contingency may be necessary. As also discussed during the TWG, the Tribe does not approve of any new wells on the peninsula. While one well is better than two, no wells are better than one. Monitor well MW-54 is already on the peninsula. Moving MW-Y to the road is better than at its proposed location, but still represents an intrusion into the area and the important strata at depth. Fort Mojave provided a letter dated July 10, 2015, to BLM Field Manager, Kim Liebhauser related to adverse effects to cultural properties related to the siting of proposed Monitoring wells, which further supports its evidence of Amut ahar, a named Mojave place and the Traditional Cultural Area (TCA) elated to the lower river region of Mohave Valley, AZ. A response from BLM and in consultation with AZ SHPO is still pending. While the Tribes understand that wells maybe important to control the spread of the contamination, the reasoning used for the need of these wells has not been provided beyond the need to support the model, which is insufficient justification for the permanent adverse effects to this area and the TCP in general. There needs to be concrete justification and an exhaustion of other methods to	DOI/BLM will continue to consult with the Tribes on this issue until a final decision is made. It is important to note that DTSC does not completely agree with the technical basis or statements made by the TRC in their white paper and their rebuttal to PG&E's response. However, for the purpose of promoting progress on this project, DTSC will not debate those disagreements here.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						Moreover, the purpose of and technical justification for these wells has not been well established, and therefore the Tribe is opposed to their emplacement at the proposed locations, which are within both a named place, a Tribal sacred area and, within the Havasu National Wildlife Refuge.		groundwater is adequately guarded and if the assumptions used in the design are correct. In addition to monitoring for contaminant data, the proposed wells would also monitor hydraulic data and determine if the groundwater flow in the area responds to the remedy as anticipated. The current level of understanding of groundwater flow in Arizona is minimal (e.g., many monitoring wells exist on the California side, yet only two monitoring locations – MW-54 and MW-55 – currently occur in Arizona that allow for collection of reliable water level measurements). Data obtained from the Arizona wells would be incorporated into the groundwater model to improve its predictive capabilities. It is important to note that Arizona Department of Environmental Quality (ADEQ) sent a letter to DTSC and DOI on March 26, 2015 supporting the importance of these sentinel wells as part of their design review comments. Finally, as echoed in the PG&E Topock March 18, 2015 Technical Work Group Meeting,	(letter to DTSC dated March 26, 2015 on the 90% BOD) has pledged its support for the "technical and practical components that have led PG&E to the proposed locations of MW-X and MW-Y". DOI and BLM will continue to consult with the Tribes and AZ SHPO in resolving this issue and anticipate further technical discussions during 90% Design comment resolution.	secure similar data for the placement and number of wells in this location that is shown to clearly outweigh the impact to the sacredness of the area.	

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
								many more Arizona monitoring wells would be added to the monitoring program for this type of remedy as standard practice absent Tribal concerns. DTSC believes that MW-X and MW-Y represent the minimum number of wells the agency believes would be necessary for the monitoring needs of the remedy.			
18	FMIT-4	Non-design	Other			In its March 6, 2014 letter[4], the Tribe provided a table summarizing the acceptability of, and concerns about, PG&E's proposed staging areas and soil processing and soil storage areas. The table provided by the Tribes' indicated the preference and acceptance (or non-acceptance) of each of 29 areas proposed for such purposes with specific conditions for use. Based on various discussions and site walks to each of these areas, the Tribe has, at multiple times and specifically in their comment letter, expressed strong objections to the use of Areas 6, 7, 12, and 13, which are so-called "upland staging areas." In the April 4, 2014, joint letter from DOI/DTSC[5], PG&E was directed "... to consider all the information in the [Tribes'] revised matrix, communications from the Tribes in meetings, and design comments to identify the minimum number of preferred storage and staging locations necessary in the 90% design for the Agencies [sic] consideration." It has been argued by others that these areas underwent prior disturbance, and therefore potentially represent areas that may be preferable to other, undisturbed areas. However, the Tribe has surveyed these proposed work areas, and, despite past desecrations, noted that these areas continue to hold tribal cultural significance and values, and conclude that further disturbances are unacceptable. In fact, the Tribes have yet to hear from BLM as to the disposition of their original Tribal Cultural Values Assessment (TVCA) report and the acceptability of the alternative methodology proposed by the Tribes' to document their findings. Also, amongst these areas is the location of an "Exclusion Area" which encompasses areas 6 and 7. Most of the areas identified in the TCVA, should fall under new discoveries in the already accepted and approved PA and CHPMP documents. This must be resolved prior to the final remedy design acceptance and approval by the agencies. It appears that Areas 6, 7, 12, and 13, despite the Tribes' preferences and the direction from DOI/ DTSC, still remain under consideration by PG&E.[6] However, PG&E included an evaluation of options that could be employed in lieu of using these areas. The Tribe, a landowner, strongly prefers the implementation of "Alternative Approach Option 1" as described in Table 1 of that evaluation, and under its rights as a landowner objects to the implementation of any other alternative. Under a 2006 Settlement Agreement with the Tribe, PG&E has expressly agreed to "honor Tribal concerns to the maximum extent practicable." (2006 FMIT-PG&E Settlement, Sec. VIII.A.) As to FMIT property, an easement agreement, recorded in 2006 pursuant to that same settlement, only grants rights to PG&E for the purpose of "conduct[ing] its legally-required Remediation" including, among other things, "to install, access, use, operate, maintain, modify, upgrade and remove any and all additional Remediation-related Facilities required by the DTSC or another agency or governmental body with jurisdiction over the Property or the Remediation." Thus, Tribal concerns must be honored to the maximum extent practicable and, as to FMIT	PG&E has participated in discussions with the agencies and Tribes, including the FMIT, on this topic at several TWG and other meetings and site visits since March 2013. In response to comments from Tribes and DOI and through further discussions to resolve these comments, a number of the proposed staging and soil storage areas were removed from further consideration. PG&E thoroughly evaluated alternative approaches to avoid the use of the proposed Upland areas, which the FMIT objects to, but the alternatives would have adverse effects on worker safety, and public safety, and create potential nuisances, environmental impacts, and construction schedule delays that would outweigh the benefits of eliminating those areas. Use of the Upland areas (Areas #6, 7, 12, and 13), which are in close proximity to the	DTSC understands that there are Tribal sensitivities to the use of all areas within the project site, and did receive Tribal input objecting to the use of several staging areas as pointed out in your comment. DTSC and DOI, however, have attempted to seek a balance in Tribal preference with the necessities of the cleanup project by hosting discussions and conducting site visits to identify suitable areas for the soil staging and storage areas. The agencies have also proposed to the Tribes during the TWG and site walk of October 19 and 20, 2014 to map and reduce the amount of areas to be used within each of those proposed staging locations prior to providing	The Federal agencies have received written comments and met with the Tribes on several occasions regarding the staging areas for the remedy. In the DTSC/DOI Direction letter of April 4, 2014, DOI provided direction to PG&E to eliminate Sites 15, 16 and 19 from further consideration based on Tribal input. It is unfortunate that areas 6, 7, 12 and 13 are located in areas of tribal cultural significance and values while being optimum locations for construction of the remedy and decommissioning of the IM-3 facility. The agencies, however, must also consider the information provide by PG&E	While worker and public safety are of paramount importance to the Tribe as well, the Tribe believes that, with proper planning and management, PG&E can safely operate with alternative storage and staging areas in deference to the Tribe's legitimate cultural issues at the proposed sites. Again, DTSC maintains that it must "... seek a balance in Tribal preference." The DTSC has decided to direct PG&E to consider whether it can perform construction and decommissioning without using those areas. It is no surprise therefore that PG&E concluded that the work could not possibly be done without using those areas, and that the benefits of using those areas "... would outweigh the benefits of eliminating [them]." It is not appropriate for PG&E to attempt to balance the effects and	This RTC was discussed at the July 23 TWG meeting.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						property, may otherwise be overridden *only if expressly required by DTSC or the federal government*. Absent further agreement by the Tribe or an express order by DTSC or DOI to PG&E, the Tribe will allow only the implementation of "Alternative Approach Option 1."	remedial infrastructure in the Upland, is required for efficient, successful and safe implementation of construction activities and will be beneficial for a number of reasons set forth in RTCs #860 FMIT/TRC, #861 Hualapai/ TRC, #862 Cocopah/TRC, and #863 Chemehuevi/TRC . The FMIT comment refers to the 2006 Settlement Agreement between the Tribe and PG&E. As the FMIT note, PG&E agreed to "timely and meaningfully consult with the Tribe and . . . honor Tribal concerns to the maximum extent practicable." PG&E understands that the FMIT objects to the use of Areas 6, 7, 12 and 13 and has considered the information provided by the FMIT regarding staging and soil storage areas, as described above, and believes it has fulfilled its Settlement Agreement obligations. PG&E disagrees that it cannot use the FMIT's property for remedy-related uses absent an "express order" by DTSC or DOI. As noted by the FMIT, the easement gives PG&E the right to use the FMIT property for "conduct[ing] its legally-required Remediation." Approval of the design and the C/RAWP by DTSC or DOI would obligate PG&E to carry out the remedy as proposed therein and would be sufficient to show that use of the FMIT's property for staging and soil storage is necessary for PG&E to conduct its legally required remediation.	direction to PG&E on the supplemental 90% design. As a result of Tribal input, the agencies directed PG&E in our April 4, 2014 letter to eliminate the use of sites 15, 16 and 19. DTSC understands that BLM is working with the Tribes on a treatment plan related to the TCVA. Nevertheless, agencies have charged PG&E with the responsibility to evaluate if construction and decommissioning can be done without the use of areas 6, 7, 12 and 13. It is PG&E's belief that the uses of those areas are necessary.	regarding the health and safety of the public and workers, the environmental impacts from additional traffic and schedule in making our decisions. Therefore, areas 6, 7, 12 and 13 should remain as options for staging during construction; however PG&E should minimize their use to the extent practicable. See also RTC #26 FMIT-12.	benefits of its project components. The Tribe requests that an alternative(s) be studied in the SEIR that excludes these objectionable staging areas, just because it was disturbed by earlier Interim Measures (IM) doesn't mean the land has lost its cultural integrity. As has been relayed in many meeting venues, the Fort Mojave Tribe was not consulted with during the earlier IM 1, 2 and 3, project disturbances by BLM. Had it been consulted, this subject conversation wouldn't be happening. But because it didn't occur then, we are being asked to allow further cumulative adverse impacts to the TCP. The "after the fact" consultation/environmental analysis does not give PG&E, DTSC/DOI a ride for free card. Since all impacts cannot be eliminated, then reduction to the bare minimum should be the focus. Again, this is a situation between want and need. The tribe did not waive its right to comment on the remedy design and potential impacts of such and so offers these final thoughts on the project use, cumulative effect and future implementation of the final design. As to PG&E's interpretation of the easement, there is an express requirement that "Remediation," a term defined to mean "investigation and remediation activities on and at the Property," be "legally required." Thus, the	

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							PG&E also notes that under the 2006 Settlement Agreement, the FMIT agreed to not to "oppose PG&E's efforts that are subject to [the] Agreement to remediate the chromium plume at the Topock Compressor Station," and that both PG&E and the FMIT are obligated to cooperate with state and federal agencies "in ensuring that the selected Groundwater Remedy and Soils Remedy become operational and are certified as complete." (2006 PG&E/FMIT Settlement Agreement, VI.B.2.d; 2012 PG&E/FMIT Settlement Agreement § VI.C.)			activities themselves on the Property must be legally required, not that PG&E can engage in any activity that it wants or it feels it needs that is related to the overall remedial action required by DTSC and DOI.	
19	FMIT-5	Non-design	Other			The Tribe notes that PG&E has considered the alternative design concepts proposed by the TRC[7] for the utility crossing at Bat Cave Wash as presented with the December 23, 2014, directives from DOI/DTSC[8]. The location of this proposed crossing is on FMIT property at the location of the current Bat Cave Wash bridge crossing. PG&E has previously considered the need to extend its utilities across Bat Cave Wash at this location. In lieu of PG&E's earlier proposal to construct an aerial crossing, it is now proposing a design involving a raised structure over box culverts. This design will accommodate installation of piping and conduits above the wash channel. In addition to that design, PG&E provided an analysis in the Supplemental 90% of the alternative designs proposed by the TRC[9]. Characterizing the TRC designs as "ford crossings," PG&E rejected such designs based on essentially the following reasons: • This type of design allegedly had been rejected by both Agency direction and Tribal preference at the 30% design phase. • The design would drastically alter the road profile, thereby altering PG&E's design criteria. • Such a facility would be overtopped by a 25-year, 24-hour design storm, again violating PG&E's design criteria. In contrast to PG&E's position, the Tribe responds point-by-point as follows: • Design review as established for this project is a progressive process. As such, more details regarding the proposed design have unfolded at each review stage. Details regarding the nature of the current design proposal for this crossing were not presented at the 30% design. As stated earlier, it was instead an aerial crossing that was proposed. Not that the Tribe would have preferred such a structure, but it is not appropriate for PG&E to suggest that the Tribe would have preferred the current design without consideration of reasonable alternatives. Alternatives related to this design were not previously presented. • The Tribe recognizes that the alternative design would alter the road profile, though the term "drastically" has not been substantiated by PG&E. That is the point of creating a design that is compatible with the existing landscape and avoiding an obtrusive structure. Based on what	After further deliberation and consideration of all 90% comments received on this topic, PG&E changed the design of the northern BCW crossing to involve a) keeping the existing access road and b) burying the piping/ conduits within BCW and up-gradient of the existing access road. Similarly and concurrently, PG&E also changed the design of the southern BCW crossing to remove the aerial crossing and bury piping/conduit within BCW. The revised design was provided during the 90% RTC period and included in **Attachment C** of the final RTC table.	**Attachment C** illustrates that the new pipeline alignment "I" will travel through many AOCs and SWMUs (i.e., SWMU-1, SMWU-5, SWMU-9, Station Perimeter, Storm water Piping, AOC-1, extension of AOC-4, AOC-13, and AOC-21) including waste disposal/ discharge/ treatment areas in Bat Cave Wash and the lower yard. Therefore, enhanced opportunistic sampling pursuant to C/RAWP (Table 5.5-1) is required as well as general added caution due to the increased potential for		The Tribe appreciates PG&E's adoption of an alternative design at the Bat Cave Wash crossing and maintaining the natural setting in the design process.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						was presented by the TRC in December of 2014, the vented ford design results in little / no change to the road crossing profile. The Tribe notes that at the February 19, 2015, TWG meeting, PG&E disclosed that there was not even the current crossing structure present at this location prior to 2004 and prior to the construction of the IM-3 treatment plant. The current crossing structure was installed by PG&E without consultation with the Tribes and without a CEQA document. We understand that previous access was unimproved access. • What is inviolable about deviating from the referenced design storm, other than it is inconsistent with PG&E's arbitrary design criterion (25-year return period, 24-hour duration storm)? During the February 19, 2015, TWG meeting it was also disclosed that the referenced PG&E design criteria were established *ad hoc*. Also, the referenced design criteria (Appendix C, 90% BOD Report) do not indicate a 24- hour duration storm, instead they related to a reference storm of duration equal to the time of concentration ("TOC") within the watershed. For the relatively small tributary watershed above this location, TOC would likely be considerably less than 24 hours. Considering that the project may extend well beyond a 25-year timeframe or that a storm of a magnitude greater than a 25- year average recurrence interval could occur during the operational period of the remedy, or even on two successive days in the operational period, the 25-year criterion does not afford full assurance that the road will not flood out. At the same meeting, PG&E pointed out that a ford would likely be overtopped every year. While this would likely involve increased maintenance on an as-needed basis, its advantage is in providing a less intrusive structure across the landscape. It may also be a cheaper alternative. Also at the meeting it was pointed out that continued use of a bridge structure over an extended period, might somehow constrain FMIT's future preferences regarding its eventual removal on its own property. Finally, improving accessibility in a manner that would invite more users onto its property, is not a preference for the Tribe. The landowner's preference should be provided great weight here as outlined above pursuant to settlement and easement terms. During the meeting, DTSC explained its position that, despite the Hualapai's December 3, 2014, letter[10] requesting consideration of various alternative crossing designs as presented by the TRC, that the joint DTSC/DOI letter of December 23, 2014,[11] directed PG&E to proceed with its own preferred design for the crossing, because the Agencies had not received (written) direction from FMIT, the property owner. This is a rather insulting position that the Agencies are presenting to FMIT. Recognizing that FMIT is indeed the property owner, and that the Hualapai Tribe deferred to FMIT on the decision after presenting some alternative designs, why would the Agencies not direct PG&E to consider presentations of the alternatives or even an open discussion of them at a TWG meeting? The agency letter maintains that it considered "... all input received to [that] date." Should we then conclude that the alternative designs prepared by the TRC and presented by Hualapai were considered and dismissed without notice to or consultation with the Tribes or FMIT, the landowner? FMIT did not directly respond in writing, expecting that some type of analysis would be included in the Supplemental 90%. Indeed it was, but only to the extent that any alternatives would be dismissed. The Tribes were also told that consideration of a buried utility crossing was rejected at the 30% design stage and, therefore, PG&E did not consider burying the utility trench at the crossing. This is also misleading considering that the earlier designs were considering burial of utilities along the axis of Bat Cave Wash, not at one location transverse to the wash, such as the location under discussion. As for the issue of site access, FMIT was told at the recent TWG meeting that the area is already accessible from the west by one other route. The FMIT position should be abundantly clear: Because of the reasons of the impacts, not only to the FMIT property, but also to the unique cultural resources downstream from the crossing, the Tribe vigorously objects to the design proposed in the Supplemental 90% design document. FMIT requests to discuss/consult on this further with the agencies, including considering an alternative involving keeping the existing crossing and burying the utility trench within the wash.		encountering contaminated media. Finally, detailed trench logs are requested for this pipeline segment as well as other segments passing through soil investigation areas. Appropriate sections of the document should be revised to incorporate the requested changes.			
20	FMIT-6	Non-design	Other			Figure 3.5-9A of the 90% BOD report depicts "Proposed Access Routes for Remedy Features – California." Considering the attendant impacts that would be projected from ongoing incursions for the purposes of monitoring and maintenance along these routes over the lengthy period of remedy	PG&E will be discussing this comment, and its response to this	DTSC will be communicating with FMIT directly		Please note that the Tribe is only asking for consideration and	The agencies will provide direction to PG&E, see response

						performance, the Tribe proposes, to the extent practicable, consideration of a policy of *access by foot traffic only* ("ABFTO"), wherever and whenever possible. This would not only lessen the severity of the impacts to the sacred areas, but might also establish a spirit of respect, if not reverence, for the landscape. Again, the Tribe requests to discuss the logistics of this proposal with the agencies and PG&E prior to final design.	comment, directly with counsel for DTSC and counsel for the Fort Mojave Indian Tribe.	regarding this matter.		further discussion as to the practicability of applying ABFTO to avoid impacts to certain sensitive areas in accordance with the PA, CHPMP, CIMP and Access agreements which recommend "Avoidance" as the first step. Relative to PG&E's comment, a brief discussion between counsel occurred in which positions were restated but no agreement reached. The Tribe therefore requests further discussion of this matter.	to comment 69.
21	FMIT-7	Non-design	Other			Considering the status of the remedy design, the Tribe's technical consultants spent considerable time reviewing the technical specifications and drawings as presented in the 90% BOD document. Particular consideration was given to whether the designs provide for optimal configurations to achieve the Tribe's preferences for minimizing the impacts of the design. In doing so, our reviewers noted several instances where the drawings were inconsistent with the written specifications. While the written specifications allow for a range in the minimum spacing between pipelines, the application to the drawings appear inconsistent. While this may seem simply a matter of fixing one or the other, this problem confounded the Tribe's technical review. An example is that the pipe spacing between similar water line sizes was inconsistent on Sheet C-07-102, where in Section H1 the space between water lines ranged from 8 to 10 inches, but in Section A10, the spacing ranged from 4 to 6 inches. The Tribe's preference is the minimum feasible separation that results in the narrowest trench and a minimum of disturbance. The Tribe offers the assistance of our technical personnel to assist in achieving this goal, if requested by the Agencies and/or PG&E. Design drawings and specifications become part of the bid package for contractors performing the work and eventually their field guidance. If the information provided to contractors is inexact or inconsistent, there is a high risk that the contractors may opt for a design or location that is not optimal, while still potentially conforming to the contract. This example further underscores the importance of impact minimization at the design stage and the presence of Tribal Monitors. This also supports the Tribe's comments requesting for a clear framework for Tribal participation in the construction and implementation of the groundwater remedy moving forward.	Pipe and conduit spacing and configurations within trenches will be reviewed for consistency and revised as needed during the final design. This goal of this effort will be for consistency in final documentation and to minimize the disturbance impact of the trenches.			This item was discussed with PG&E engineering staff during a recent TWG meeting. FMIT is satisfied that PG&E has committed to reconciling conflicting information between design narratives and drawings.	This RTC was discussed at the July 23 TWG meeting.
22	FMIT-8	Non-design	Other			During the approval of the Groundwater FEIR and then subsequently throughout the reviews and discussion of the groundwater remedy design, the Tribe was told that the cap on the number of boreholes is 170. Likewise, the Tribe has repeatedly emphasized that each such intrusions desecrates the landscape individually and cumulatively. Now, Tables ES-2A and ES-2B provide "estimated" borehole counts and construction information, respectively. Examination of Table ES-2A indicates that the borehole count could very well exceed the 170 well count. This is confirmed in Line 41 of the table, where PG&E makes an allowance for up to 20 additional boreholes for monitor wells that may be needed at "unidentified locations." Figure ES-4A illustrates the entire layout of infrastructure incorporating the proposed monitor and remediation wells as well as the existing wells that will be incorporated into the design. Needless to say, simple examination of this figure reveals a disturbing level of impact to the landscape. PG&E has said that it expects the utility of some wells to be ineffective during the project lifetime. And accordingly, PG&E plans to "replace" wells at the "same locations" if they remain essential to remedy performance. However, these "replacement wells" will not be the same borehole, but will be in a *new* borehole near – but not in – the already counted borehole thereby making a farce of	Regarding well replacement, Section 4.2.2.5 of the O&M Manual Volume 1 states	As stated in the 60% RTC to DTSC-101, "DTSC based the number of wells on estimates provided by PG&E at a stage when the remedy was quite conceptual. While every effort should be made to minimize the total number of wells, if necessary, wells should be installed for an identified	DOI defers to DTSC regarding the well count found in the FEIR. In response to your concerns stated in the last paragraph, it is true that the project is a technically driven project that must ultimately result in cleanup remedies implemented to protect human	The Tribe fully understands and appreciates the realities of wear-and-tear of material components over time. The comment is intended to highlight the Tribe's continuing concern over these intrusions into sacred grounds and the potential spiritual implications of the infrastructure. 170 is a significant number, but	This RTC was discussed at the July 23 TWG meeting.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						the alleged 170 well count. Again, this creative math represents further intrusions into the landscape, one that has not been the subject of the required environmental analysis. Finally, it is evident that the soils investigation will superimpose another level of intrusions including both borings and trenches upon what has already been projected for the groundwater program increasing further the direct and cumulative impacts to the area. It seems that the project is being dominated by a technical mindset, one in which the overarching view is to collect whatever information may be desired, largely regardless of the impact to the cultural and environmental resources. Despite claims to the contrary, and the occasional compromise or impact reduction, there appears to be no real effort to constrain the level of site disturbance, and again, no one at the decision making level has the professional qualifications and experience to consider a proper and reasonable balance between the competing interests. DTSC and BLM have recently brought on archaeologists to the project, which should have allowed a qualified experienced new set of eyes and viewpoint to understand the concerns raised by the Tribes. However, the views of those experts seem to be focused mainly on the archaeological aspects and not the tribal cultural values. Those archaeologists have not been able to consider the full picture of the remedy design impacts, because they have been limited by their specific tasks, time dictated in their respective contract/ employment or lack of qualifications beyond archaeology. This is an issue the Tribes have raised face-to-face in meetings, such as the recent consultation meeting with DOI on January 23, 2015.	"Wells that cannot be restored to a condition that is satisfactory to fulfill the given well objective using routine or non-routine maintenance methods…. may require replacement. Well replacement entails the construction of a new well within a new borehole, and should be considered as the least desirable option to achieve the given objective of a well. The location of replacement wells will be determined based on the evaluation of available remediation system performance data (e.g., current hydraulic gradient and water quality data, as well as model predictions), accessibility, and agency-approved work plans and compliance documents. If it is determined after further evaluation and discussions with agencies that a replacement well is warranted and that the most suitable location to achieve the well objective is within the area of the original well location, well replacement will proceed under the scope of this O&M Plan..." In addition, the FEIR addresses this same well replacement concept and the associated well count, with the following language: "One option would be for existing wells to be abandoned and replaced with an entire new well. The new well would be located close to the existing well, within the areas currently designated in the FEIR (see Exhibit 3-4 above).	purpose and not be artificially bound by the specific well counts for the design." Please recall that DTSC has been explicit during the CTF, CWG and TWG meetings that the well count from the certified EIR was based on PG&E's estimate prior to completion of the East Ravine and Topock Compressor Station sampling. DTSC will evaluate impacts of additional wells in the subsequent EIR. DTSC express grave concerns regarding the Tribes' statement that the project is "…dominated by a technical mindset, one in which the **overarching view is to collect whatever information may be desired, largely regardless of the impact to the cultural and environmental resources"** (emphasis added). DTSC acknowledges that the project is located in a culturally significant area; however, DTSC is mandated to protect human health and the environment. In the process we try to protect the biological and cultural resources to the extent possible; however, infrastructures are needed to achieve the necessary cleanup. Impacts are unavoidable. Agencies and PG&E	health and the environment. It is unfortunate that the project occurs in a location that of such significant cultural and spiritual importance to the Tribes. There will be cultural and biological impacts resulting from the groundwater remedy and the efforts by DOI, BLM, DTSC, and PG&E to minimize/ mitigate those impacts should not go unrecognized (see the following documents: CIMP, PA, CHPMP, MMRP from the 2011 Groundwater Remediation EIR). DOI and BLM believe we have a very qualified and knowledgeable archeologist and an experienced tribal liaison dedicated to this project. Both of these people have worked with Tribes on similar projects for many years. As noted in our May 1, 2015 letter to the FMIT, the BLM Arizona Deputy Preservation Officer also has advisory role. Accordingly, we believe the BLM has the appropriate federal cultural resource preservation expertise to fulfill its responsibilities.	even a lesser number is a concern. Further, the Tribe's comment represents an appeal to extend every consideration towards not increasing the number of wells beyond the prescribed number in the FEIR.	

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)

							Unless the new well encountered different geologic conditions and/or has significantly smaller capacity than the well it replaced, there would be no net change in the total number of existing wells. If the new well has significantly smaller capacity, it might be necessary to replace an existing well with two new wells under certain conditions" (see FEIR, pages 3-26 and 3-27). Replacement wells put in the same location as original wells would not be counted as additions to the estimated number of wells disclosed in the EIR. See also 60% RTC #606 FMIT-169 for references to the evaluation of environmental impacts of well replacement in the FEIR.	have been very mindful of Tribal concerns with remedy and monitoring wells and have held several meetings and conducted several field visits (including multiple trips for the same proposed well) to evaluate the proposed well location(s) and consider alternative locations more acceptable to Tribes. This has included trips and/or discussions regarding, at a minimum, the following wells: FW-1, FW-2, MW-S, MW-HH, MW-II, MW-10D, MW-11D, MW-V, IRL-4, MW-DD, MW-EE, IRL-3, IRL-2, MW-BB, MW-I, MW-P, MW-AA, IRL-1, MW-CC, MW-Z, location of IRZ wells along the road, location of River Bank extraction wells and provisional wells, and East Ravine extraction wells, and wells MW-X and MW-Y. These efforts have been conducted to attempt to minimize impacts to cultural and environmental resources identified by Tribes as well as to notify Tribes of the need for particular wells. DTSC would like to point out that even during the April 2015 TWG meeting, it was pointed out to the Tribes that the agencies would have installed many			

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
								more sentry wells to ensure the safe and effective operation of the remedy, but it is due to the understanding of the Tribal concerns that the agencies are self-limiting the proposed sentry wells to two in Arizona.			
23	FMIT-9	Non-design	Other			As has been said many times by the Tribe over the years, because to Tribal people there is a sanctity associated with this landscape, and because the Tribe holds religious and spiritual connection and ceremony to the Topock area, noise control and abatement is essential. It is equally important to recognize that adverse impacts arise both from audible and inaudible energy. Vibrations, high and low frequency waves, etc. are all impactful to the spiritual setting of the landscape, regardless of the presence of Tribal members. As you are aware, the ambient noise levels across the landscape arise from a number of sources including the Interstate highway, railroad, compressor station operations, and nearby recreational areas and enterprises. The construction activities and eventual operational activities associated with the remedy will add incrementally and cumulatively to these existing sources. Treatment of noise levels is addressed in PG&E's Cultural Impact Mitigation Program ("CIMP") in CUL-1a-8h. In the 90% BOD document, compliance with noise standards is addressed in Appendix C, Section C.11. This section cites San Bernardino County Code, Division 3, Chapter 83.01.080, which exempts "temporary construction, maintenance, repair, or demolition activities between 7:00 AM and 7:00 PM, except on Sundays and federal holidays." Clearly this part of the code is potentially less stringent than the protocols and practices established in the CIMP. Again, the Tribe expects that PG&E will work earnestly to achieve practices that go beyond the minimum civil standards. Appendix C addresses design standards in general and should not be limited to codes. Reference to that County Code must be struck throughout the 90% BOD document as inconsistent with governing project requirements. Moreover, the project documents must commit to resolving Tribal noise concerns that might arise during project construction and implementation – beyond simply referencing the existence of a Noise Coordinator.	San Bernardino County Development Code, as well as the Mohave County Zoning Ordinance, noise and vibration standards are applicable legal requirements that PG&E cannot ignore. Because these standards were part of the EIR analysis and incorporated directly into Mitigation Measures NOISE-1 and NOISE-2, as well as indirectly into Mitigation Measure NOISE-3, PG&E also cannot delete references to the County code (in whole or in part) in the project documents. According to the Tribe, it is "important to recognize that adverse impacts arise both from audible and inaudible energy." PG&E agrees with the EIR, which recognize that even with mitigation, the "values associated with the Topock Cultural Area cannot be reconciled with additional project-related noise," and thus concludes the project will have a significant an unavoidable impact. (EIR, Vol. 2, at p. 4.9-24; see also EIR, Vol. 1 at p. 4-118 [responding to FMIT's concern that tribal values were not addressed in the EIR]; id. at p. 4-127 [responding to FMIT's request not to rely on the County's		DOI believes the CIMP noise protocol and the EIR noise mitigation measures adequately address the FMIT concern.	By continuing to cite conflicting noise standards, the intent of the Basis of Design report remains ambiguous and open to interpretation and possible future disagreement. The Tribe requests the addition of language to the effect that, when and where there is a conflict among the various noise standards, the most stringent (most noise restrictive) shall apply. Further, the Tribe notes that in addition to current standards, CEQA allows for the provision of project-specific standards. See CEQA Guidelines section 15064(d). The Tribe requests that such standards for outdoor worship be developed and considered in the SEIR.	DTSC Response: Comment noted. Noise impact evaluations are based on established regulatory thresholds. Noise impact is a resource area that DTSC will consider in the upcoming SEIR.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							noise standards]). This analysis included consideration of ambient noise and vibration. (EIR, Vol. 1 at p. 4-123.) PG&E commits to constructing the remedy in a manner that is safe, compliant with the law, respectful as possible given the fact that unavoidable impacts exist, and expedient, and has committed to numerous steps, above and beyond those required by the San Bernardino County Code to address the Tribes' concerns. As the Tribe notes, the EIR requires compliance with Mitigation Measure NOISE-3 and the CIMP protocols for noise (CUL-1a-8h) to minimize noise impacts on the Topock Cultural Area to the extent feasible. The EIR also analyzed the cumulative impacts of adding the project's noise to the existing noise in the environment. (EIR at p. 6-38.) That analysis acknowledges that the project "would generate noise that could expose the Topock Cultural Area (a place of worship for Native Americans) to levels that . . . would conflict with Native American values associated with this resource" and notes that those impacts are significant and unavoidable. (EIR, Vol. 2, at p. 6-38.) . Regarding commitment to resolving Tribal concerns, PG&E has proposed protocols in addition to designating a Noise Disturbance Coordinator. Section 2.8.4 of the CIMP CUL-1a-8h (Noise Protocols)				

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							states "[s]hould a concern about the actual noise generated by remedy construction arise, PG&E disturbance coordinator will thoroughly investigate and resolve the issue. A qualified acoustical consultant (Institute of Noise Control Engineering [INCE] Board Certified or Professional Engineer in Acoustics) will evaluate all reoccurring disturbances for compliance with applicable standards. All noise complaints and resolutions will be recorded, tracked, and reported to DTSC in the quarterly compliance reports." Further, Section 2.8.5 of CIMP includes the following specific communication protocols with nearby noise-sensitive receptors and the Tribes: • A detailed project schedule is established and published for all stakeholders. • Monthly notification to Agencies and the Tribes of scheduled field activities. During periods of extensive construction activity, these notifications will be issued more frequently – weekly and/or daily, as appropriate. • After issuing these notifications, notify the nearby noise-sensitive receptors and Tribes of any schedule changes. • Provide an open-				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							communication process for Tribal representatives to seek more information about Project noise-generating activities. PG&E welcomes Tribal input on timing of Project noise-generating activities and on potential noise-reducing methods. • The contact information for the disturbance coordinator will be posted in a conspicuous location near the construction areas. This information will also be mailed to all nearby noise-sensitive receptors and Interested Tribes. • In addition to the communication methods described above, PG&E will consider posting construction schedule information at the information kiosk (CUL-1a-3c). PG&E also will consider and may decide to use additional communication processes. The CIMP noise protocol and the EIR noise mitigation measures go beyond the County's noise requirements, but do not conflict with the County's noise standards, which also are applicable to the project. Accordingly, no revision to Appendix C, Section C.11, which mentions both the EIR noise mitigation measures as well as the County noise standards on which the EIR relied,				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							is required.				
24	FMIT-10	Non-design	Other			The Tribe is concerned that there are a number of developments that have occurred and are planned within the Park Moabi Area, which comprises parcels of land leased by private developments from the U.S. Bureau of Land Management ("BLM"). To date, there has been considerably greater development within the present Park Moabi lease area than originally envisioned by the Tribe. Presently, the C/RAWP proposes an option for the "Use of Staging Areas at Moabi Regional Park."[12] This option is offered by PG&E as an alternative to using staging areas 6, 7, 12 and 13 on the FMIT property, sites which the Tribe has indicated are unacceptable due to cultural impacts. PG&E points out that these areas "... were not originally intended for temporary facilities or as a support zone for construction in the Upland because they were not adjacent or central to the primary work zone in the Upland." It had previously been suggested by PG&E that these areas could serve as construction headquarters and a main temporary equipment and materials laydown area. The memo now indicates that use of these areas for the added purposes of replacing the aforementioned proposed staging areas might result in their expansion to accommodate the added purposes. The memo concludes that in PG&E's view this option, along with the other alternatives evaluated, "... would outweigh the benefits of eliminating those areas [on FMIT property]." It is unacceptable that PG&E would be making such decisions that adversely impact cultural resources identified by the Tribe, particularly in light of PG&E's limited rights on FMIT property. It seems as though PG&E is asking to have *both* an expanded Park Moabi present and the staging areas that are unacceptable to the Tribe. This is unacceptable to the Tribe and is why consultation is necessitated. Similarly, the Tribe must be involved in the terms for any lease amendments prior to lease finalization. Moreover, if such areas were dedicated to such uses, regardless of whether they are slated for the original purposes or expanded to accommodate the additional uses as described above, are there provisions within the property lease(s) that would control future developments? The Tribe is concerned with the precedent established by the original situation involving seemingly continual expansion of the lease associated with the regional park. The limits of the added infrastructure associated with the remedy must be explicit within the terms of the lease and guard against mission creep. Moreover, at the present time, it appears that the proposed developments in the Park Moabi area do not adequately address the treatment of the nearby cultural resources or the open-ended nature of the potential and alternate sewer, fire water, and water connections. When would these environmental effects be considered if not now? How would their potentially significant environmental impacts, including cumulative impacts, be considered? Some of these areas are outside the Area of Potential Effects and project boundaries. When will these aspects be handled pursuant to the Programmatic Agreement? These seem to be critical path items requiring Tribal participation.	Please see RTCs #860 FMIT/TRC, #861 Hualapai/ TRC, #862 Cocopah/TRC, and #863 Chemehuevi/TRC, for response to the proposed use of Areas 6, 7, 12, and 13. PG&E defers to DOI/BLM for response on Tribal consultation and Park Moabi lease(s). PG&E defers to DTSC for response on environmental review and the project boundary, and to DOI for response on APE and PA.	DTSC is conducting a subsequent EIR (SEIR) to evaluate whether the additional remedy design features that were not considered or were changed since the conceptual design used for the 2011 certified FEIR may have new significant impacts from those disclosed in the 2011 certified FEIR or increase the severity of the impacts disclosed in that document. This upcoming SEIR analysis will consider the use of Park Moabi for the remedy and determine whether use of that area will have new significant impacts	DOI and BLM appreciate the concerns of the Fort Mojave regarding the ongoing development of the Park Moabi area. The lease agreement with San Bernardino County and the associated use by the concessionaire are not part of this project and will not be address as part of the design review. The FMIT may contact BLM directly regarding the Park Moabi lease. A cultural resources inventory of the operations and staging areas was conducted in January of 2015. Tribes were present during the archaeological fieldwork. BLM is evaluating the information provided in the survey report and will work with the Tribes regarding potential impacts to cultural resources. The Area of Potential Effect changes have been discussed between the agencies and the tribes at several recent technical and cultural meetings. Consultation with the Tribes and SHPO will occur once the	The Tribe appreciates DOI's invitation to contact BLM to discuss issues related to the types of development permissible on its lessee's parcel. The Tribe looks forward to further discussion and consultation regarding both the potential impacts to cultural resources which is required by the PA and other documents and the amendment of APE boundaries. The Tribe reiterates its request for the agencies to allow meaningful discussion of these important issues and not leave them to the very end of the project process.	This RTC was discussed at the July 23 TWG meeting. RTCs related soil storage and construction staging areas were also discussed at the July 23, August 19, and August 26 TWG meetings.

[12] See C/RAWP Appendix W, "Technical Memorandum: Proposed Use of Certain Areas for Construction, Staging, and Soil Storage at PG&E Topock Compressor Station," Option 2, p. 7.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
								beyond those disclosed in the 2011 certified FEIR.	boundaries of the amended APE are determined.		
25	FMIT-11	Non-design	Other			The Tribe recognizes that the PG&E Project organization listed in various organizational charts throughout the documents are living documents. However, because of the potential for conflicts in communications to arise in the field during construction and remedy implementation, clarification of reporting contacts for Tribal Monitors is essential. Clear lines of communication and lines of authority are critical for successful implementation of Tribal Monitoring. For example, the CHPMP and the C/RAWP document outline that Tribal Monitors provide "Daily Reports" to the designated "Site Supervisor" and /or "PG&E's On-Site Project Manager" (or designee). The C/RAWP organization chart and related document text uses different terminology that indicate that the "Site Operations Manager" will be responsible for contacts with site visitors and observers. The "On-Site Project Manager" must be identified, if Tribal Monitors need to coordinate with this individual. Additionally, the Tribal Monitors need to be able to communicate with the person having authority to stop construction or otherwise modify the field activities as appropriate if such actions are warranted in order for cultural resource protection purposes.	Comment noted. The project organization language in the final C/RAWP will be made consistent. The "On-Site Project Manager" and "Site Operations Manager" refer to the same position. The final C/RAWP will use the term Site Operations Manager exclusively. Tribal monitors will be able to communicate directly with the Site Operations Manager or his designee, as described in the C/RAWP. Tribal monitors will also be able to communicate directly with the Construction Manager. The Construction Manager, Site Operations Manager or their designee will have authority to stop construction. Any modification to field activities would only be implemented after a complete compliance review.			This is an important provision that will assure proper and efficient communications through the construction and operations phases of the project. If a "complete compliance review" is necessitated, the Tribe must be a participant in the process. Please keep in mind that, due to the complexity of the project work schedules, the Tribal monitoring duties will necessarily be shared among the participating Tribes. The Tribes have established an intertribal communication network for information exchange. Accordingly, the compliance review must allow time for this intertribal communication to take place.	Comment noted.
26	FMIT-12	Non-design	Other			FMIT has been working with BLM and the other Topock participating Tribes for the past two years on the previously mentioned Tribal Cultural Values Assessment (TCVA) document that was provided to BLM in September 2013, and an amended version of the TCVA was subsequently submitted on February 18, 2014. On April 2, 2014, BLM directed PGE "to go forth with a field inspection of the findings" in the TCVA. That letter summarized certain discussion during a conference call held on December 2, 2013, between BLM, PG&E and the cultural resource management firm hired by PG&E, Applied Earthworks (AE). As stated in the April letter, during the December 2nd conference call, as a "preliminary, interim measure," BLM had instructed PG&E: • To create a methodology for conducting a field check of the findings identified in the CVA; to develop protocols/guidance on what will be • Recorded/confirmed as an archaeological manifestation; to develop criteria for distinguishing sites from isolates; and to identify the • Archaeological manifestation of the Topock Maze. The April 2nd letter also directed AE, based on the "discussion items" in the passage quoted above, to develop a "study plan" to be used "to guide the field effort to evaluate the archaeological potential of the findings identified in the CVA." The Tribes received written notification of this direction from BLM to PG&E and AE by letters dated April 9, 2014. Subsequently, the Tribes were provided, with a "Study Plan" dated April 25, 2014 prepared by AE. At a CHPMP meeting held on June 4, 2014, the Tribe informed BLM, PG&E and others, that the draft "Study Plan" dated April 25, 2014, is not acceptable given that it misses the point of the TCVA. The sites that the Tribe had identified in the TCVA are important to the Tribes for their cultural value. The strictly archaeological methodology proposed by AE in its Study Plan would yield a fragmented perspective that would fail to consider the range of cultural values associated with the Topock landscape.			In April 2015, BLM provided a new proposal to the Tribes concerning the process for recordation of tangibles and intangibles associated with the Traditional Cultural Property in the area prescribed in the TCVA. The purpose of the Draft Proposal for Documentation of Tribal Cultural Values in response to the TCVA was to acknowledge special values to tribes over and above the traditional archaeological	On August 4, 2015, the Topock Tribal Work Group presented to the BLM, DOI, and PG&E; a Counter Proposal to the BLM's April 2, 2015, draft proposal during the CHPMP meeting. Within this document, the importance of protecting the intangible cultural heritage related to the Topock area was identified and explained. During the August 4 presentation; the BLM, DOI and PG&E all expressed a need to review the document, which the Tribes agreed was appropriate. The Counter Proposal document strategy basically followed	BLM received the Tribes alternative TCVA proposal at the August 4 CHPMP meeting. BLM provided a final response on October 6, 2015

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						The Tribes offered to develop an alternative methodology for following up on the TCVA and provided a letter and document captioned "Recommended Approach for Inspecting Cultural Locations Identified in the Tribal Cultural Values Assessment" in August 2014. Although the Tribes have meet with BLM/DOI/ PGE and others during the course of two years, we still have not had a response to the Tribal documents referenced above. Until we have an official response, we cannot move forward or provide our comments or opinions on prioritizing which sites are to be addressed first. We need to have BLM's decisions on the numerous items we have discussed during the CHPMP meetings. This issue is of grave concern to the Tribes and since it related to implementation of the MMRP for the Groundwater FEIR, it is there to address the cultural impacts of the remedy implementation and its affects/effects to the TCP and the participating tribes. BLM's response is time critical: The final design and construction of such remedy is imminent, and the Tribes are once again a missing link. The Tribe's input into the process does not get added until it is too late and critical decisions will have be made by the Agencies without addressing the tribal cultural values and cultural resources that exist within the remedial footprint where the final remedy design will be implemented. We are at a critical time in the design stage of the Topock Project, and the decisions of BLM/DOI regarding this TCVA document are pivotal to the ability of the project to proceed. It behooves the Agencies to respond and address this tribal concern now, not later or down the road. The FMIT requests (1) an official response to the TCVA submitted November 21, 2013, and as amended February 18, 2014; (2) consideration of the Tribal alternative methodology that was recommended by the Tribes as part of the BOD; and (3) whatever CEQA measures would be applied to address this impact prior to project finalization.			manifestation s on the landscape. BLM anticipates meeting with the Tribes in the near future.	BLM's April 2, 2015, Draft Proposal, except that the Tribes would conduct the study and control the indigenous or Tribal Intellectual Property which resulted. From further discussions immediately after the presentation, the Tribes identified that there would be no impacts to the upcoming soils investigation work plan implementation schedule. At present, no response has been received from the agencies related to this Counter Proposal. BLM, did indicate via email from Renee Kolvet, that more time was required for BLM to respond, most likely in October 2015. To facilitate and not delay the implementation and schedule of either the Groundwater FEIR and SEIR documents, the tribes have begun the implementation of the Counter Proposal on FMIT lands in a good faith effort to ensure progress is being accomplished.	
27	FMIT-13	Non-design	Other			The Tribe holds firm to its holistic belief that the land and water as well as all other earthly components are connected. For reasons of schedule, the implementation of soil and water remedy components of this project had been implemented on independent timelines by the Agencies. Regardless of the reasons for such logistics, technical rationale dictates consideration of the interrelationship between these two programs. For example, the Tribe is aware that there may be important information to the conceptual groundwater model that might arise from sampling the pore waters in the Colorado River at the mouth of the East Ravine. Yet this sampling and the resulting information will not be available until the next phase of implementation of the soils remedial investigation. While it is obviously too late to change the remedy bifurcation, the Tribe would like assurance that soil information has been thoroughly considered and integrated as appropriate within the groundwater remedy design.	Much effort was put into integrating the soil information into the remedy design and coordinating with the Soil RFI/RI program to minimize duplication and disturbance. This integration is evident throughout the BOD, the O&M Manual, and the C/RAWP. Examples include: • Section 2.4.3 (Soil Contamination Areas) of the 90% BOD discusses the status of the soil investigation effort and the coordination between the soil			The Tribe appreciates PG&E's effort to date to integrate soil information into the groundwater remedy design. Moreover, the Tribe understands that information from the soil remedial investigation will be generated during the groundwater remedy implementation schedule. Of course, should such data collection provide information applicable to any aspect of the remedy design, it may be necessary to adjust as appropriate to that information. In such instances, the Tribe	This RTC was discussed at the August 19 TWG meeting.

							the planning for confirmation sampling to minimize duplication and disturbance. • The Soil Management Plan (Volume 4 of the O&M Manual) establishes procedures and protocols to ensure that the management and disposal of potentially contaminated soil derived from the soil investigation areas that are generated during groundwater remedy implementation is handled in a manner that is protective of human health (including construction workers) and the environment within the framework of appropriate federal, state, and local requirements, and consistent with United States Environmental Protection Agency (USEPA) guidance. Regarding implementation of site cleanup activities, PG&E commits to carry out the work as expedient as possible. To that end, PG&E submitted additional details on the construction and start-up sequence in anticipation of construction activity in 2016, during the 90% RTC period and included in **Attachment D** of the final RTC table. This sequencing plan

							provides for start-up of system elements while construction proceeds. This approach will provide more time for data analysis and design refinement while still completing the overall program within the originally planned schedule. See also RTCs #72-75.				
28	FMIT-14					At the recent meeting of the CWG, a high-level schedule was presented, titled "Groundwater Remedy Design, Construction, and Initial Start-Up Schedule." The schedule addressed the general activities such as design, construction, CEQA Review, etc. One particular timeline on the schedule that caught the Tribe's attention is labeled "Ongoing Consultative Work Group/Tribal Communication and Tribal Consultation." This timeline is shown in brown and is a continuous line throughout the project duration. While the Tribe appreciates recognition of the need for ongoing communication and consultation, there are certain milestones in the process that in particular necessitate formal consultation. The Tribe notes that the schedule marks certain decision points where design, work plan, and CEQA approvals occur, there likewise should be definite milestones marking the timing of input from Tribes that would be used in making such determinations. Moreover, the Tribes are entitled to consultation at the Government-to-Government level pursuant to Section 106 of the National Historic Preservation Act ("NHPA"). As such, the Tribes should not be lumped with the CWG. The Tribe also strongly believes that a timeframe and performance criteria for the decommissioning of the Groundwater Remedy should be developed now. The Tribe is concerned if these items are put off into the distant future, that the concerns of the Tribe and its elders may be ignored and forgotten—"out of sight and out of mind" and left to someone's future interpretation who has no idea of the importance and seriousness of Tribal affiliation to this sacred place to the Mojave peoples. Consultation should begin immediately on developing those criteria.	The completion criteria/ performance standards for the remedy are presented in the BOD (Sections ES-2 and 1.2.1) and the O&M Manual (Section L.4). The current projection of remedial timeframe is also presented in the BOD. Once the completion criteria/ performance standards are met to the satisfaction of the agencies, PG&E will submit a plan to decommission the remedy in accordance with the CD and CACA. As stated in RTC #12 DTSC-8, PG&E will add a dedicated section on decommissioning in the executive summary of the BOD. It is important to note that at this time in the design process and before the remedy is constructed, steps to decommission any remedy components, that will occur decades into the future, will have to be general and conceptual. Descriptions of the conceptual decommissioning steps	DTSC anticipates that Tribal involvement beyond the 90% design will continue. DTSC believes that the current forum to gather input (CTF, CWG, TWG and specially arranged Tribal meetings) affords Tribes with many opportunities to consult with DTSC. DTSC does not envision the cancellation of the aforementioned meetings. Moreover, DTSC has offered, and did meet with Tribes on specific issues or concerns as requested. Furthermore, there are adopted mitigation measures in the certified 2011 EIR that provides additional opportunities for the Tribes to voice their concerns during remedy construction and operation outside of the meetings stated above. Please also note DTSC comment 8 requested PG&E to provide commitment to decommission all remedial	The Tribes have been afforded multiple opportunities for National Historic Preservation Act consultation pursuant to the Programmatic Agreement's Consultation Protocol throughout the design process. DOI and BLM will continue to consult with the Tribes through the comment resolution process should specific topics necessitate this (e.g., reinitiating consultation pursuant to the PA's Consultation Protocol on the Arizona wells) or should a Tribe request consultation on specific issues. We also will be working with the Tribes and Signatories and Invited Signatories in revising the CHPMP in the future. The timeframe for decommission the remedy is based on achievement of the remedial action objective and cannot be determined at this time.	As a landowner within the project area, FMIT must be apprised of any and all changes to the remedy that occur in its land, particularly those that have the potential for impacts. We reiterate our concerns regarding a decommissioning plan being done sooner than later after the remedial years have been completed. Developing even a conceptual plan now that documents Tribal priorities, goals and performance standards - followed up at a later time by a more detailed plan - would be more consistent with CEQA requirements and superior to a wholly deferred plan. See also RTC 15 FMIT-1. PG&E states its understanding that that there will not be a comment/review process for the final design. The Tribe remains concerned that the final design be considered in some transparent way, such as at least in the SEIR analysis.	A dedicated section (see **Attachment A** of the final RTC Table) that describes the decommissioning process envisioned for the proposed remedy will be added to the Executive Summary of the Final BOD. DTSC response to highlighted section: The final design will be made available to all stakeholders and Tribes once completed by PG&E. DTSC will also provide the draft SEIR for review during the 45-day comment period.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						Additionally, the Tribe is aware that design review is a progressive process, and that this current review represents review at the *pre-final* stage of design. So it is likely that further design modifications will be made between now and the final ("100%") design and subsequent agency approval later this year. So in order to truly assess the project's significant impacts, there will be a need for Tribal participation beyond this 90% review stage. The "high-level" schedule indicates tribal consultation terminates with the submittal of comments on the 90%. After this time, the schedule refers to a period of "Comment Resolution" extending through (approximately) mid-June 2015, with the 100% to be completed by (approximately) mid-July 2015. CEQA review of design is estimated to be completed in early August 2015. Tribal input/review during each of these timeframes is essential and needs to be specifically identified in the schedule for that input to be truly timely and meaningful. In short, moving forward, there is a need for continuing and substantive Tribal input during final design, construction, and implementation of the groundwater remedy. The documents do not necessarily reflect that need.	provided in the 60% RTC #6 (Attachment T of Appendix I) reflects this fact. Any additional details should be considered speculative best guesses, and are subject to change at the time of remedy decommissioning. In general, high level schedules presented at CWG meetings are based on best available info at the time and are subject to change. Changes to the schedule are announced by the agencies. The latest version of the project schedule is posted on the DTSC website www.dtsc-topock.com. As for design modification between now and the final design, PG&E will present all anticipated design modifications for agencies, Tribes, and stakeholder review and comment during the 90% comment resolution period. Design modifications that are accepted by the agencies will be incorporated into the final design. As noted in RTC #7 DTSC-3 and RTCs #56-59, PG&E understands that there will not be a comment/ review process for the final design.	infrastructures at the end of the remedy.	DOI and BLM anticipate continued tribal communication throughout remedy construction as well and look forward to working with Tribal monitors and representatives to ensure that resources are protected.		
29	FMIT-15	Non-design	Other			As mentioned above, there were a number of items that the Tribe had commented in regard to the 60% BOD report, but resolution was deferred to the 90% BOD report. Our review noted that there were such items that were not properly addressed or for which the final comment resolution has been considered "resolved." In the former instance, it is explained that the 90% BOD document does not require revision.[13] For many dispositions of the Tribe's comments, the characterization of the resolution is questioned by the Tribe: (1) Who made the determination that the item is "resolved"? (2) In instances where the Tribe indicated that resolution at the 60% stage was "... pending review of 90% design," it is appropriate to consult with the Tribe(s) to affirm whether the item is indeed resolved. Accordingly, the Tribe's enclosed comments speak to whether PG&E's determinations of resolution are accurate. These may require consultation to truly resolve.	With respect to the question as to the determination that a comment was "resolved," that determination was made after discussion of the comment in comment resolution meetings, which occurred between September 2013 and		DOI concurs with the PG&E account of the 60% Design RTC process. Sections of the design package that were deferred, noted at the 60% RTC stage as "... pending review of 90% design,", were	Comment considered resolved while noting that the SEIR must consider the final design. See also RTC 28 FMIT-14.	Comment considered resolved while noting that the SEIR must consider the final design

[13] See, for example of "Not applicable" in Table I-1, Item No. 7, last column.

							February 2014. PG&E, Agencies, Tribes, and stakeholders participated in those meetings. The final 60% Master RTC table with attachments was sent to everyone on April 18, 2014. To PG&E's knowledge, no comments were received on the RTC table nor were there expressed disagreements with the resolution recorded in the RTC table at the time. Additionally, PG&E anticipates that the comments for which resolution was marked "pending review of 90% design" were either addressed in the 90% design or will be addressed through the 90% RTC process.		to be taken under consideration by the commenter/ interested party during the 90% BOD/Design Package and C/RAWP review.		
30	Hualapai					Native plants are an important part of the life cycle, sustaining the diet for humans and animals, as well as providing sources of healing. There is a need to protect native plants at Topock and foster their growth in the face of the onslaught of activities at Topock. The Hualapai Tribe has suggested garden plots at the site where native plants can be nurtured for replanting as part of restoration and decommissioning, but this suggestion was rejected by PG&E.	Creating gardens for native plants would increase the project footprint and require substantial material and labor inputs. This approach would only be justified where many more plants were needed for restoration than have actually been estimated. The anticipated restoration plant need can more technically and economically be met using existing commercial plant facilities in the area with locally collected seeds.			Nurturing of native plants could go hand-in-hand with restoration of the effects of the groundwater remedy; for example, native plants could be planted in restoration areas, plants could be used to prevent erosion of long-term soil stockpiles, which would also help to keep the soil alive. Clean soil from the project could be stored at staging area 5, and the soil could be contoured against the western hillside, covered with clay for protection, and native plants seeded upon the protected soil. With occasional watering, it seems like an efficient way to care for the displaced soil and to nurture native plants at the same time. This comment is considered unresolved.	DTSC response: Protection and avoidance of native plants is a priority during the remedy construction and through operation and maintenance of the remedy. DTSC will consider the mitigation measures necessary as part of the SEIR. Hualapai's preference is noted.

31	Hualapai					Geothermal water is sacred to the Hualapai Tribe, and pumping of geothermal water from well HNWR-1 is a desecration of this precious resource. We believe that the geothermal water at HNWR-1 comes from the sacred hot springs of the Black Mesa area (Warm Springs Wilderness Area), and that our ancestors performed ceremonies in the same water that now is being proposed for pumping and extraction. We believe that this geothermal water is a finite resource, floating on cool water near the confluence of Warm Springs Wash and the Mohave Valley. Pumping of water from well HNWR-1 will deplete this limited sacred resource, and when it has been depleted, it will take thousands of years to replenish. The Hualapai Tribe requests that water-quality and temperature conditions of the freshwater source wells should be monitored over time during implementation of the groundwater remedy, and the geothermal water should be treated with respect, for example by allowing the water to cool before being injected into the groundwater remedy.	Clarification provided during April TWG: Hualapai suggests that geothermal water is sacred, and the temperature of water pumped from HNWR or Site B will be elevated and should be cooled, if possible by natural means, before being used for industrial purposes. Response to clarified comment: High ambient temperatures during most of the year will prevent significant natural cooling of water pumped from HNWR or Site B. However, monitoring of water quality and temperature of freshwater will be conducted during groundwater implementation as discussed in Appendix L, Volume 2, Section 5.2 and Table 5.2.4.			Hualapai Tribe requests to be notified if water temperature from the freshwater well increases significantly. This comment is considered resolved pending verification of the notification procedure within 100% design.	This comment is considered resolved pending verification of the notification procedure within 100% design.
32	Hualapai					In regards to the proposed monitoring wells on the Arizona side of the Colorado River (MW X-Y), the Hualapai support FMIT in regards to their specific cultural affiliation through nomenclature. Hualapai oppose any wells being placed in that sacred traditional cultural property. We have attached a technical memo in this regard.		See RTC #17 FMIT-3.	See RTC #17 FMIT-3.	The historical aerial photos show that the proposed locations for these wells is a sacred place because it is of both land and water, 	RTCs related on MW-X/Y were discussed at the July 23, August 18, and August 26 TWG meetings. DTSC/DOI Response: See response to RTC #17

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
										 Within a confluence. Hualapai believe, even in contemporary times, that confluences and the landscape near-by are sacred. We agree with the Fort Mohave Tribe that this is a significant cultural place where no wells should be drilled.	
33	Hualapai					Use of soil storage and staging areas during the remedy will contribute dramatically to the overall cumulative impacts and destruction of the cultural landscape. We have worked diligently with the agencies to define acceptable storage and staging areas. However, storage and staging are still proposed within some of the most sacred areas of the cultural landscape, and we find this frustrating that despite objections from the Tribes, these staging areas remain as part of the proposed remedy. In regards to areas being selected, prior to consultations, during consultations and outside of consultations for staging and or construction and arsenic monitoring wells, we would like to take this opportunity to remind the agencies that the Advisory Council on Historic Preservation commented back in 2011, (December 5, 2011 Federal Property Management Section, Office of Federal Agency Programs, ACHP) that in regards to expertise, the "details…are best specified by those experts at the local and state level with the most familiarity with the site." Consultations as specified by Section 106 of the National Historic Preservation Act (NHPA), 16 U.S.C. § 470f, requires that, prior to approving the expenditure of any federal funds on undertaking with the potential to affect historic properties, or prior to issuing any license or other authorization for such an undertaking, the federal agency must engage in the consultation process mandated by NHPA section 106, a process that has been implemented through regulations issued by the Advisory Council on Historic Preservation, (36 C.F.R. part 800). We are aware that DTSC takes the perspective that the DTSC is not subject to S106, however there are best practices to consider, and continued consultation is of prime importance for the Hualapai. Specifically to storage and or construction staging areas, Tribal knowledge and preferences as specified by tribal experts at times, were not being considered by the agencies. For example, there were instances in which the Tribes, as a group, made decisions early-on and some of these decisions have been superseded by the DOI. In particular areas # 6 thru 8 were specified (January 14, 2014) as not acceptable, and that 16, was noted as not acceptable because it is too close to Loci B.	See RTC #18 FMIT-4.	See RTC #18 FMIT-4.	See RTC #18 FMIT-4.	As areas #6, 7, 12, and 13 are going to remain as options for staging, Hualapai formally states for the record, that 'Avoidance' still remains the most preferred option. We consider this RTC# 33 closed but not resolved.	RTCs related soil storage and construction staging areas were discussed at the July 23, August 19, and August 26 TWG meetings. The Agencies have provided a direct response to the Tribes regarding staging areas. DOI and will provide further direction to PG&E on staging and storage area usage.
34	Hualapai					After completion of the groundwater remedy, it is necessary that all elements of the remedy should be removed and decommissioned, and the land should be returned to its original condition. While the Tribes have previously indicated that decommissioning of wells and subsurface casings may cause additional damage to the earth, we feel that new technologies will be developed in the future that will provide for decommissioning of wells with less disturbance. In addition, many of the states (e.g. Kentucky and North Carolina) have mandated that abandoned wells must be decommissioned and removed. Therefore, we need to allow for flexibility in well decommissioning on a case-by-case basis, and in the event of future well decommissioning regulations in California, we should not allow these remedy wells to be grandfathered, hence bypassing any new requirements.	See RTC #12 DTSC-8.			The Basis of Design report language continues to incorporate uncertain plans for remedy infrastructure removal, for example, deferring to priorities and decisions of future land and agency managers. The granting of	See above for decommissioning.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment (*Please provide sufficient detail, include specifically what you are looking for*)	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
										easements for remedy infrastructure construction should include explicit requirements for the future removal of that infrastructure. It is realized that much of the detail for these issues cannot be made with certainty at this point, therefore this comment remains unresolved.	
35	Hualapai					In regards to cumulative impacts and our growing concern for the integrity of the entire Topock Cultural landscape, on December 16, 2013, Hualapai and other tribes presented a draft conceptual cultural resources mitigation document containing specific mitigation measures that Hualapai felt did address the intent of CEQA and actually mitigated to some degree cultural, religious, social and economic impacts, (reference CEQA § 15002(h), 15123(b)(3), 15270, and 15124(d)(1)(c), yet the DEIR as it is presented, did not address any of our suggested mitigations. We again, present these mitigation recommendations in this comment letter, with one additional suggestion. Also on September 5th, 2014, in a letter to DTSC and DOI (HDCR File 2014-741) Hualapai commented that "…analysis of the role of social change has been largely absent in prior CEQA analyses relative to Topock and has resulted in the minimization of certain potential impacts to the Tribe and its members, such as those related to noise, visual and aesthetics, among others and a failure to seek out, consider and analyze tribal views of significance and impacts for specific resources and impacts." We have again, attached those mitigation requirement here and hope that future activities at Topock could take into consideration CEQA to the extent that CEQA regulations require EIR's to define mitigation measure per the spirit of the law in regards to mitigating cumulative impacts. These are:[1] 1. Methods or plans to reduce, offset, or eliminate adverse project impacts. Action taken to avoid, reduce the severity of, or eliminate an adverse impact. Mitigation can include one or more of the following: 2. Avoiding impacts. 3. Minimizing impacts by limiting the degree or magnitude of an action. 4. Rectifying impacts by restoration, rehabilitation, or repair of the affected environment. 5. Reducing or eliminating impacts over time. 6. Compensating for the impact by replacing or providing substitute resources or environments to offset the loss. Mitigation measures affecting Resources of Tribal, Cultural, Religious, Social, and Use Values: 1. A biological survey of riparian habitat associated with the Topock Cultural landscape shall be conducted (by PG&E with tribes and or tribal representatives) bi-annually to document vegetation characteristics and conditions in order to determine if there are any long-term impacts of the project on the riparian habitat, and to determine if the project revegetation process is functioning. The findings of all biological surveys shall be submitted to the Tribes. These surveys should occur every year from start of soils remediation selection through the life of the remediation project in its entirety. 2. If any grading, clearing, brushing, or construction occurs during the bird breeding season (approximately February 15 through August 31), a qualified biologist, with tribal assistance, shall conduct a survey of the habitat to determine whether there are active bird nests in the area, including raptors and ground nesting birds. The survey would begin not more than three days prior the beginning of work. If an active nest is observed, a minimum 300-foot buffer (500 feet for raptors) would be established using temporary fencing. The buffer would be in effect as long as work is occurring and until the nest is no longer active. 3. All disturbed areas, including storage piles, which are not being actively utilized for construction purposes, shall be effectively stabilized to suppress dust emissions using typical methods such as: water, organic stabilizers / coverage with a tarp or other suitable material, or vegetative ground cover. All on-site unpaved roads and off-site unpaved access roads shall be effectively stabilized to suppress dust emissions using water or organic stabilizers. All land clearing, grubbing, scraping, excavation, land leveling, grading, cut/ fill, and demolition activities shall be effectively controlled		DTSC appreciates the input from the Hualapai regarding proposed mitigation measures to the draft soil investigation EIR. Those comments have been responded to as part of the final soil investigation EIR. DTSC will also consider any input from Tribes during the subsequent EIR comment period for the groundwater remedy design.		Hualapai will wait to receive a response as a part of the final soil investigation in regards to how agencies DTSC and PG&E are going to incorporate these suggested mitigation measures. Hualapai considers this RTC#35 un-resolved.	DTSC Response: Proposed Mitigation Measures are considered based on threshold of impacts in CEQA evaluation. Mitigation Measures will be considered in the SEIR if warranted.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment (Please provide sufficient detail, include specifically what you are looking for)	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						of fugitive dust emissions utilizing application of water and/ or by presoaking. 4. When soil or similar materials are transported off-site, all material shall be covered, or effectively wetted to limit visible dust emissions, and at least six inches of freeboard space from the top of the container shall be maintained. All operations shall limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at the end of each workday. Use of blower devices is expressly prohibited. Following the addition of materials to, or the removal of materials from, the surface of outdoor storage piles, said piles shall be effectively stabilized to suppress fugitive dust emissions utilizing sufficient water or organic stabilizers. Within urban areas, track out of mud or dirt onto public roads shall be immediately removed when it extends 50 or more feet from the site and at the end of each workday. Any site with 150 or more vehicle trips per day shall prevent carryout and track-out of mud or dirt onto public roads. 5. Physical disturbance within the Project area will occur to significant trails and will cut-off the ability of participating tribes to travel physically and spiritually along these trails. In consultation with participating tribes, extant trails in Topock Cultural Landscapes should be field mapped, and preserved by qualified cultural resource personnel with the assistance of participating tribes and or tribal representatives. Low-level aerial photography and video photography should be used to document trails that are within the APE and throughout the Topock Cultural Landscape. It appears from present information that certain trail corridors can be preserved, including routes to Spirit Mountain, Boundary Cone, and the Needles. 6. Physical disturbance within the Project area will occur to significant cultural resources including but not limited to, stone circles, rock cairns, stone scatters, trails, tool refining stations, spiritual teaching areas, minerals etc. In consultation with participating tribes, the entire Topock Cultural Landscapes should be field mapped, and preserved by qualified cultural resource personnel with the assistance of participating tribes and or tribal representatives. 7. Tribal Interpretive Centers. Provide financial support for tribal interpretive centers on tribal lands that describe, educate, and engage tribal communities in disseminating and preserving traditional cultural identity through tribal languages. Provide support through grants and phased funding, for tribal interpretive facilities/museums, language programs, and healthy food systems. Resulting programs could then be components for continued outreach and education to stakeholder/agency staff with linking cultural information at Topock. Grants to be phased over life of the remediation project. 8. Continue on-going reasonable compensation for tribal participation in monitoring, attending meetings, and participating in project development, as with the present Consultative Work Group, Technical Work Group, Clearinghouse Task Force, and subcommittee involvement. Funding support to continue through the life of the remediation clean-up project. 9. Create a trust fund for a Cultural Preserve at Topock. This would help in attempting to preserve the Topock Cultural Landscape in view of the encroaching Park Moabi tourist facility. Future generations. 10. Funding for increased security measures around the Topock Cultural Landscape. Due to tourism and increasing numbers of visitors to the Topock area. This also relates to recent vandalism at Grapevine Canyon. We do not want this to happen at Topock. 11. Funding support for education and technical training for tribal members. In conjunction with all of the above, provide for full higher-education tribal scholarships (two per educational year per participating tribe) for biology and / or ethnobotanical degrees, archaeology, hydrogeology, and museum studies. 12. Create a collaborative land management working group to include tribal and agency members to discuss; plan; and implement a long-term landscape management plan for the Topock Remediation Project area.					
36	FMIT/TRC	Design	Infrastructures		Overall Comment	The Tribes have repeatedly voiced a strong preference for aboveground installations of the remedy infrastructure, both verbally and in numerous written comments and letters regarding the 30% and 60% design documents. This preference has remained unchanged and is rooted in the strong desire to protect the ultimate condition and continuity of the subsurface of this sacred area, preserving it for future generations. Regardless, the ultimate decision for this remedy has placed essentially all ~5 miles of pipeline corridor below ground. This situation will result in permanent and irreparable adverse cumulative impacts throughout the Topock cultural landscape over the life of the project and into the future. Given the magnitude of the impact of this decision, the Tribes should be provided with a summary of the detailed, technical basis for this decision, which was deemed to override cultural and spiritual considerations.		See response in DOI column.	DOI and DTSC respectfully refer the Tribes to RTCs 159, 182, 183, 184, 185, and 188 - 193 from the 30% Design, RTCs 1, 8a & b, 9, 434a, 850, 852, 855, and 865 from the 60% Design, the DOI/ DTSC Direction letter to PG&E dated April 4, 2014	In spite of the consultation and the RTC processes at 30% and 60%, the fact is that the cumulative disturbance footprint of the project has only gradually taken form as the design has progressed, has grown as that designed changed and has only gradually become evident to Tribal staff	DTSC response: See 4/4/2014 direction letter to PG&E . Additionally, see RTCs #8 DTSC-4, #12 DTSC-8, and #16 FMIT-2. The Tribes have been afforded the opportunity to use the TRC and technical consultants to clarify technical

44	FMIT/TRC	Non-design	Process		Overall Comment	Numerous examples exist within the 90% BOD report indicating that many final design decisions will be determined post the design phase of the project. For example the final locations of many wells and pipeline runs, determination of whether the system is OPS, determination regarding the need and installation of provisional wells, and decisions on the timing and use of monitored natural attenuation are just a few of the many examples of final design decisions that will be made after			DOI concurs with the PG&E response.	The Tribe as a landowner, Indian Tribe with religious connection to the project property and a	A similar RTC (RTC #46) was discussed at the August 18 TWG meeting.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)

Groundwater Remedy Basis of Design Report/Final (100%) Design

PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						the finalization of the project design. Specific referenced examples of these post design phase decisions found throughout the 90% BOD report have been provided (1a-1s) and are found as an attachment to this comment. This list should be considered as some examples found in the report but is not intended to be considered comprehensive. Please clearly discuss how data collected post the design phase of the groundwater remediation could result in changes to infrastructure locations that are different than the locations presented within the BOD reports. In addition please clearly outline how the Tribes will be involved in final design decisions that are made post approval of the 100% BOD report. Any future deviations from the infrastructure locations determined during the design phase necessitates Tribal involvement at a level that has been established during the design process. Therefore please clearly describe how the Tribes will be part of data review post design phase and the forum in which Tribes will be involved in design phase decisions made after finalization of the BOD report.	Discoveries made during construction and start-up could result in changes to infrastructure locations. These include discovery of human remains or burials, previously unidentified potentially significant cultural, historic, or paleontological resources or listed species, groundwater quality data or soil data, etc. See Table 5.1-1 of the Construction Contingency Plan (Section 5 of the C/RAWP) for a listing of potential contingencies due to issues that may arise during construction and start-up, and proposed mitigation. As mentioned in Table 5.1-1, the lack of site-specific subsurface data (e.g., certain groundwater quality data, certain hydrogeologic data, supplemental geotechnical data, soil conditions) during design could lead to later discovery during construction of site conditions that render the design non-compliant with codes, laws, regulations and/or engineering standard of practice, planned well locations and/or constructions fail to meet the project objectives, etc. Typically, these subsurface data would be collected during the design phase. Here, these subsurface data were not collected during design to minimize ground disturbance prior to	DTSC will continue periodic consultative workgroup meetings, technical workgroup meetings, and the clearinghouse taskforce meetings. Although the frequencies and duration of these meetings may be adjusted based on need and number of agenda items. In addition to regular meetings and construction oversight, DTSC may also meet with the Tribes when requested regarding specific issues. Furthermore, DTSC has also adopted specific mitigation measures as part of		government entity reiterates its strong desire to be included along with DOI and DTSC as primary parties to whom communication is addressed if material deviation from work plan and design documents, MMRP action specific, and location specific ARARs occur. The current proposed use of monthly progress reports and periodic uploads to SharePoint is not a sufficient level of involvement when it comes to decisions that could result in permanent disturbance to the Sacred landscape or Tribal property. PG&E should remain mindful of its independent legal obligations under the 2006 Settlement Agreement to consult with FMIT and to provide all non-attorney-client privileged material information, documentary or otherwise, to the Tribe contemporaneously with its receipt or development by PG&E.	DTSC Response: Tribal comment noted.

Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							construction. The only exceptions to the curtailment of intrusive filed data collection were the alternative freshwater evaluation and the potholing for underground utilities. The curtailed data collection efforts have been combined with construction and/or soil investigation activities. To minimize the potential for uncertainties in the conceptual site model to cause unnecessary disturbance (that is, to avoid constructing unnecessary infrastructure), measures such as scheduling data collection at planned Category 1 well locations early in the construction schedule (see Section 3.2.1.3 of C/RAWP) and combining the collection of geotechnical data with the upcoming soil investigation were proposed. Communication and outreach are key elements of all phases of remedy implementation. A summary of communication procedures and protocols to be used during the construction and startup, as well as operation and maintenance of the groundwater remedy is presented in Table 2.3-1 of the C/RAWP and Exhibit L2.2-1 of the O&M Manual, respectively. The communication procedures and protocols are intended to be used by the PG&E Topock project team to inform and/or seek input from agencies, stakeholders, and Tribes; to seek approvals from	the 2011 certified FEIR that include additional Tribal coordination during the construction and O&M phase of the project (i.e. CIMP). Finally, if agencies determine that changes to operation are necessary based on Five Year reviews, DTSC will also notify the Tribes for input.			

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							agencies; to resolve issues; and to comply with certain requirements. The summary is a compilation of PG&E's obligations for formal communication to certain parties during this phase of work that is specified in various directives from, and agreements with, State and Federal Agencies, state and federal laws, Memoranda of Understanding ("MOUs") with certain Tribes, the 2006 Settlement Agreement with the FMIT, and other required project documents. In general, communications occur in two forms -- routine (regular periodic communication) and non-routine (communication when the project experiences unexpected changes during construction, startup, or O&M). Examples of routine communication include monthly progress reports during construction and start-up, and quarterly progress reports during O&M submitted to DTSC and DOI and Tribal outreach, including, for example, regarding scheduled field activities. Examples of non-routine communications include requests for a work variance in the event of a material deviation to the C/RAWP or design documents. For example, during construction, routine monthly progress reports will be a key tool for PG&E to inform agencies, stakeholders,

							and Tribes of work completed, forecasted work, issues encountered, actions taken to rectify problems/issues, personnel changes, variance requests to the agencies to deviate from design documents or C/RAWP, agencies' actions, etc. See Exhibit 2.6-2 of the C/RAWP (Monthly Progress Report Template) for additional details. The monthly reports will be submitted to DTSC and DOI, and posted on a SharePoint site for access by Tribes and stakeholders (Section 2.6.4.2 of the C/RAWP [Retention and Reporting]). In addition, PG&E will continue to conduct outreach with the Tribes under the terms of any MOUs in effect with various Tribes, the 2006 Settlement Agreement with the FMIT, protocols specified in the CIMP, and additional protocols under communication-related EIR mitigation measures, including, but not limited to: • CIMP § 2.1: Protocols for continued communication. • CIMP § 2.3: Protocols for the review of cultural resource-related documents throughout the design, construction, and operational phases. • CIMP § 2.10: Protocols for Tribal notification in advance of project-related activities. • CIMP § 2.12: Protocols for Tribal Monitors to				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							observe ground disturbing activities. • EIR Mitigation Measure CUL-1a-4: PG&E will continue to work with the representative members of Tribes through the Technical Review Committee during final design and remedy construction, at which time DTSC will determine the committee's status. • PA Appendix C – Monitoring Protocol/CHPMP §§ 6.6.4: Protocols for Tribal Monitors to observe ground disturbing activities. PG&E currently holds monthly meetings with Tribes to address current issues and provide a forecast of upcoming activities. Other communications may take place depending on purpose of the communication and type of information to be exchanged. Tribes are welcome to request discussions of specific topics or information that are of interested to the Tribes during these information exchanges. In the event of a material deviation from the design documents and/or C/RAWP due to discovery of site conditions discussed above, PG&E will formally submit a request for work variance to the agencies (see Table 2.3-1 of C/RAWP and Exhibit L.2.2-3 of the O&M Manual). In response to comment #907 JDS-1,

							PG&E will also notify the FMIT when a work variance request for material deviation on the FMIT property is submitted to the agencies. Such requests and agencies' actions will be included in the monthly progress reports.				
45	Hualapai/TRC	Non-design	Process		Overall Comment	Numerous examples exist within the 90% BOD report indicating that many final design decisions will be determined post the design phase of the project. For example the final locations of many wells and pipeline runs, determination of whether the system is OPS, determination regarding the need and installation of provisional wells, and decisions on the timing and use of monitored natural attenuation are just a few of the many examples of final design decisions that will be made after the finalization of the project design. Specific referenced examples of these post design phase decisions found throughout the 90% BOD report have been provided (1a-1s) and are found as an attachment to this comment. This list should be considered as some examples found in the report but is not intended to be considered comprehensive. Please clearly discuss how data collected post the design phase of the groundwater remediation could result in changes to infrastructure locations that are different than the locations presented within the BOD reports. In addition please clearly outline how the Tribes will be involved in final design decisions that are made post approval of the 100% BOD report. Any future deviations from the infrastructure locations determined during the design phase necessitates Tribal involvement at a level that has been established during the design process. Therefore please clearly describe how the Tribes will be part of data review post design phase and the forum in which Tribes will be involved in design phase decisions made after finalization of the BOD report.	See above	See above	See above	Hualapai reiterates the need to be included (along with DOI and DTSC) as a primary party in communications regarding all project design changes, or work variance requests including material deviations from the design documents and/or C/RAWP due to discovery of changed site conditions as discussed in these earlier comments (at left). Communicating these changes needs to occur as soon as it is known that a change needs to be made. Hualapai needs to be included in those discussions via informing a tribal monitor, or email or telephone calls to designated points of contact. Once the change has been approved then a formal document can be forwarded to Hualapai.	A similar RTC (RTC #46) was discussed at the August 18 TWG meeting. DTSC Response: Tribal comment noted.
46	Cocopah/TRC	Non-design	Process		Overall Comment	Numerous examples exist within the 90% BOD report indicating that many final design decisions will be determined post the design phase of the project. For example the final locations of many wells and pipeline runs, determination of whether the system is OPS, determination regarding the need and installation of provisional wells, and decisions on the timing and use of monitored natural attenuation are just a few of the many examples of final design decisions that will be made after the finalization of the project design. See above	See above	See above	The Tribes reiterate the desire to be included along with DOI and DTSC as primary parties that communication is addressed to if material deviation from work plan and design documents, MMRP action specific, and location specific ARARs occur. The current proposed use of monthly progress reports and periodic uploads to SharePoint is not a sufficient level of involvement when it comes to decisions that could result in permanent disturbance to the Sacred landscape.	A similar RTC (RTC #46) was discussed at the August 18 TWG meeting. DTSC Response: Tribal comment noted.
48	FMIT/TRC	Design	Infrastructures		Overall Comment	The treatment of noise during the construction period is well developed in the CIMP (CUL-1a-8h in Appendix H of the C/RAWP), but this is at odds with language regarding exemption for San Bernardino County noise regulations as stated in Appendix C-11 of the 90% BODBOD Report. The Appendix C-11 criteria need to be stricken from the BOD Report. Noise impacts related to backup generators, TEGs, pump and emitter operation at the water evaporation ponds need to be quantified, as this facility will have cumulative negative impacts on the soundscape at the Topock Maze and the Topock cultural landscape.	Please see RTC #23 FMIT-9. As with other equipment, equipment at the ponds are designed/specified to comply with the noise design criteria (Section C.11 of Appendix C). The ponds are located on the Refuge; therefore, the operational noise criteria is 60 dB(A). In addition, the operational noise will also comply with applicable San Bernardino County Development Code 83.01.080 for acceptable exterior noise standards for place of worship, which is 55 dB(A) Leq daytime (7 a.m.-10 p.m.) and 45 dB(A) Leq nighttime (10 p.m.-7 a.m.) (Leq is the equivalent average hourly noise level) (See EIR, Vol. 2, p. 4.9-24 [DTSC 2011]). The noise			The comment response is unsatisfactory because cumulative project noise impacts remain unquantified and unknown. Therefore, this comment remains unresolved. See also Tribal comment at RTC 23 FMIR-9. While not requesting additional mitigation, the Tribe respectfully disagrees with PG&E's opinion on nexus particularly considering cumulative effects under CEQ A and notes the agencies have an independent obligation to fully consider all project impacts.	DTSC Response: Comment noted. Noise impact evaluations are based on established regulatory thresholds. Noise impact is a resource area that DTSC will consider in the upcoming SEIR.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						Sound power levels of new electrical generation equipment at the TCS need to be quantified, in relationship to sound power levels of existing equipment at the TCS.	measurement locations will be at the edge of the Maze closest to the subject facilities and at the short-term ambient noise measurement locations (ST-1, ST-2, and ST-3) in Exhibit 4.9-2 of the certified EIR (DTSC 2011). The noise design criteria are consistent with the noise mitigation measures in the EIR and supplemented by protocols to reduce auditory impacts in the CIMP. PG&E must implement the EIR mitigation measures and the CIMP protocol. Designing equipment to meet the design criteria prevents the equipment from creating direct and cumulative impacts more severe than those disclosed in the EIR. For this reason, the noise generated by various pieces of equipment does not need to be individually quantified. The TCS, including its new electrical generation equipment, is not part of the project. Although the remedy project's equipment may increase ambient noise levels, the project's contribution to cumulative noise impacts would remain as disclosed in the EIR. Additional mitigation measures to control noise from the TCS would lack a nexus to the proposed project.				
49	Hualapai/TRC	Design	Infrastructures		Overall Comment	The treatment of noise during the construction period is well developed in the CIMP (CUL-1a-8h in Appendix H of the C/RAWP), but this is at odds with language regarding exemption for San Bernardino County noise regulations as stated in Appendix C-11 of the 90% BODBOD Report. 52	FMIT/TRC	Design	Infrastructures		Overall Comment	The BOD Report, the C/RAWP, the CIMP, the CHPMP, and the project plans and specifications should have sections that clearly and consistently identify the coordinate systems (and any scale factors) being used on the project as they relates to both horizontal and vertical coordinates. Also, there should be a set of 5 to 10 +/- vertical and horizontal control points established throughout the site where the various users of various GPS and other positioning instrumentation can check their equipment at any time to verify that the instrumentation is working correctly. These steps will help to reduce incorrect positioning during construction and during the operational life of the project when it comes to field positioning. Sites selected shall be chosen to be free, as much as possible, from construction/operations/maintenance disturbance, with a clear view of the sky in all directions, and free, to the greatest extent possible of nearby walls of surfaces likely to create multi-path positioning errors. Information on locations and coordinates shall be made available to all Tribes and stakeholders.	Sufficient monuments currently exist at Topock to provide for 'land survey' accuracy. An additional monument(s) would introduce unnecessary new ground disturbance. Section C.2.1 of Appendix C lists the project vertical and horizontal datum. Temporary control points will be placed and surveyed in during construction and will be included in the as-built drawings. Handheld GPS units using the same coordinate system which PG&E uses can provide the necessary accuracy non-surveyors would require. Additional details on the coordinate system which PG&E and its contractors will use can be added to the BOD (e.g., Section C.2.1 [Site Civil Datum] of Appendix C [Design Criteria]) and/or C/RAWP (e.g., Section 4).		DOI concurs with the PG&E response.	The Tribe will consider the utility of the conventions described by PG&E.	DTSC Response: It is PG&E's responsibility to construct the remedy system in compliance with all applicable requirements and prescribed mitigation measures.
53	Hualapai/TRC	Design	Infrastructures		Overall Comment	The BOD Report, the C/RAWP, the CIMP, the CHPMP, and the project plans and specifications should have sections that clearly and consistently identify the coordinate systems (and any scale factors) being used on the project as they relates to both horizontal and vertical coordinates. 56	FMIT/TRC	Choose an item.	SOPs		Overall Comment	At present, there appears to be little or no explicit future role for the Tribes when it comes to review of significant (to the Tribes) changes that may occur during the bid-, construction-, start-up-, or operations & maintenance periods of the project. This should be remedied with a standard operating procedure, protocol or some other suitable document that contains appropriate and acceptable language to remedy this situation. The following elements should be included. Tribal consultation will be conducted beginning after finalization and Agency approval of the 100% Topock Groundwater Remediation Project Basis of Design (BOD) Report, Construction/Remedial Action Work Plan (C/RWAP), and construction plans & specifications, referred to herein as the 100% Documents, and continue to be in effect and applicable to all remedy activities, including operations and maintenance activities, through completion of remedy decommissioning. Prior to the approval of the 100% Documents, there has been an opportunity for Tribal Representatives to review the remedial design documents and provide input in the form of review comments. Tribal participation and consultation during the development of these documents was crucial in ensuring that adverse effects on cultural, archaeological, and historical resources were either avoided or minimized to the extent practicable. This level of Tribal participation during the preparation of the 100% Documents has reduced the level of cultural impacts associated with the implementation of the groundwater remedy during the planned construction and operation & maintenance (O&M) periods. Continuation of that participation at a similar level is essential. Additionally, the Tribes should have an agreed-upon role and level of involvement in the review of data collected during remedy construction and O&M, after Agency approval of the 100% Documents, because that information may be relevant to changes to the remedy implementation or to remedy O&M that may be made going forward from the time of that Agency approval. It is expected that, during remedy well installation and testing, after system start-up, and during remedy operation, data will be collected and analyzed to evaluate whether the groundwater flow, geochemical, and solute transport models do not differ significantly from the conceptual site model with respect to the hydrogeologic characterization or remedy performance. If there are significant differences, the groundwater flow model, geochemical model, and/or the solute transport model will be updated and recalibrated. In addition data will be collected from monitoring and injection	PG&E appreciates the comment and understands that the Tribes are concerned about continued involvement in the project post design approval. The Tribes have and continue to be important stakeholders for the project. As mentioned in RTCs #44 FMIT/TRC, #45 Hualapai/TRC, #46 Cocopah/TRC, and #47 Chemehuevi/TRC, PG&E will continue to implement the adopted mitigation measures, which include multiple requirements for Tribe monitoring and outreach/coordination with Tribes during project implementation, including the protocols for continued communication and tribal communication set forth in the CIMP that is required pursuant to EIR Mitigation Measure CUL-	See RTCs #44 FMIT/TRC, #45 Hualapai/TRC, #46 Cocopah/TRC, and #47 Chemehuevi/ TRC above.	As noted by PG&E, there are several existing documents that provided guidance and protocols for continued communication and consultation with the Tribes. Should specific topics necessitate additional Section 106 consultation during comment resolution or construction (e.g., reinitiating of consultation pursuant to the PA's Consultation Protocol on the Arizona wells) or should a Tribe request consultation on specific issues such consultation will be conducted pursuant to the PA. BLM and DOI will be working with	Relative to PG&E's comment on review of final design, please see Tribal comment at RTC 28 FMIT-14. The Tribe also is of the understanding that DOI will discuss specific project mitigation with the Tribe once the final design is completed.	A similar RTC (RTC #58) was discussed at the August 18 TWG meeting. DTSC Response: Tribal comment noted.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						wells to establish baseline conditions and to provide insight into whether and why future modifications to the remedy or to its O&M will be required to optimize the remedy performance. The Tribes will be on a footing equivalent to other stakeholders regarding communications concerning the review of data collected during construction of the groundwater remedy well network, model updates and monthly progress reporting. This communication will help further reduce cultural impacts associated with the implementation of the final groundwater remedial design. In addition, consultation with the Tribes will be held prior to deviating from the 100% Documents, especially concerning changes that could result in ground-disturbing activities in locations other than those specified in the 100% Documents. When planned/anticipated change(s) to the 100% Documents arise, notification of such will be communicated in writing (email or letter) by a designated PG&E representative to Tribal representatives, who will determine if, from their perspective, the change(s) is (are) significant. If the change(s) is (are) deemed significant, a timely consultation between PG&E and the Tribal Representative(s) will occur. PG&E will evaluate the results of the consultation, and render a decision, which will be recorded and communicated to Agencies, Tribes and Stakeholders, and entered into the Agency records. If the Tribes disagree with the decision, they will communicate for the record their objections to PG&E and the Agencies.	1a-8, as well as additional protocols under communication-related mitigation measures in the EIR as well as under federal communication-related measures. Many existing documents including the CIMP, the PA, the CHPMP, the C/RAWP, the MOUs with Tribes, and the 2006 Settlement Agreement with the FMIT, contain requirements or protocols for consultation and/or communication with Tribes in various phases of the project, including during construction, operations and maintenance, and decommissioning. PG&E does not believe that an additional or new document on interaction/communication with the Tribes is necessary. PG&E defers to DOI/BLM on parts of this comment related to Tribal consultation. Regarding review of the final (100%) design mentioned in the 3rd paragraph of the comment, PG&E understands that there will not be a follow-up review and comment period of the final design (see RTC #7 DTSC-3). Please see RTCs #44 FMIT/TRC, #45 Hualapai/TRC, #46 Cocopah/TRC, and #47 Chemehuevi/TRC for responses related to progress reports and data collected during construction, startup, and O&M.		the Tribes in revising the CHPMP in the future as well.		
57	Hualapai/TRC	Choose an item. Continuation of that participation at a similar level is essential. Additionally, the Tribes should have an agreed-upon role and level of involvement in the review of data collected during remedy construction and O&M, after Agency approval of the 100% Documents, because that information may be relevant to changes to the remedy implementation or to remedy O&M that may be made going forward from the time of that Agency approval. It is expected that, during remedy well installation and testing, after system start-up, and during remedy operation, data will be collected and analyzed to evaluate whether the groundwater flow, geochemical, and solute transport models do not differ significantly from the conceptual site model with respect to the hydrogeologic characterization or remedy performance. If there are significant differences, the groundwater flow model, geochemical model, and/or the solute transport model will be updated and recalibrated. In addition data will be collected from monitoring and injection wells to establish baseline conditions and to provide insight into whether and why future modifications to the remedy or to its O&M will be required to optimize the remedy performance. The Tribes will be on a footing equivalent to other stakeholders regarding communications concerning the review of data collected during construction of the groundwater remedy well network, model updates and monthly progress reporting. This communication will help further reduce cultural impacts associated with the implementation of the final groundwater remedial design. In addition, consultation with the Tribes will be held prior to deviating from the 100% Documents, especially concerning changes that could result in ground-disturbing activities in locations other than those specified in the 100% Documents. When planned/anticipated change(s) to the 100% Documents arise, notification of such will be communicated in writing (email or letter) by a designated PG&E representative to Tribal representatives, who will determine if, from their perspective, the change(s) is (are) significant. If the change(s) is (are) deemed significant, a timely consultation between PG&E and the Tribal Representative(s) will occur. PG&E will evaluate the results of the consultation, and render a decision, which will be recorded and communicated to Agencies, Tribes and Stakeholders, and entered into the Agency records. If the Tribes disagree with the decision, they will communicate for the record their objections to PG&E and the Agencies.					at the August 18 TWG meeting.
58	Cocopah/TRC	Choose an item.	SOPs		Overall Comment	At present, there appears to be little or no explicit future role for the Tribes when it comes to review of significant (to the Tribes) changes that may occur during the bid-, construction-, start-up-, or operations & maintenance periods of the project. This should be remedied with a standard operating procedure, protocol or some other suitable document that contains appropriate and acceptable language to remedy this situation. The following elements should be included. Tribal consultation will be conducted beginning after finalization and Agency approval of the 100% Topock Groundwater Remediation Project Basis of Design (BOD) Report, Construction/Remedial Action Work Plan (C/RWAP), and construction plans & specifications, referred to herein as the 100% Documents, and continue to be in effect and applicable to all remedy activities, including operations and maintenance activities, through completion of remedy decommissioning.	See above	See above	See above		This RTC was discussed at the August 18 TWG meeting.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						Prior to the approval of the 100% Documents, there has been an opportunity for Tribal Representatives to review the remedial design documents and provide input in the form of review comments. Tribal participation and consultation during the development of these documents was crucial in ensuring that adverse effects on cultural, archaeological, and historical resources were either avoided or minimized to the extent practicable. This level of Tribal participation during the preparation of the 100% Documents has reduced the level of cultural impacts associated with the implementation of the groundwater remedy during the planned construction and operation & maintenance (O&M) periods. Continuation of that participation at a similar level is essential. Additionally, the Tribes should have an agreed-upon role and level of involvement in the review of data collected during remedy construction and O&M, after Agency approval of the 100% Documents, because that information may be relevant to changes to the remedy implementation or to remedy O&M that may be made going forward from the time of that Agency approval. It's important to minimize the impacts of accesses needed to conduct this remedy. Therefore, published examples of other areas where precautions have been taken to preserve cultural resources should be considered.	"Access by foot traffic only" routes would require installation of additional infrastructure to facilitate safe sampling and O&M over the long term. For example, "access by foot traffic only" sample collection methods at monitoring wells would require the installation	DTSC disagrees with the Tribes proposal to conduct monitoring and maintenance by foot traffic only. Not only is this proposed method of access inefficient due to necessity of carrying equipment, this practice can be		Comments noted. However this issue is considered unresolved. As this project moves forward, minimization of impacts from vehicular traffic to service and/or monitor wells or equipment should be also be a priority.	DTSC Response: While Agencies will not limit PG&E to access by foot traffic only we agree that work should be conducted in a manner that minimizes impacts from vehicular traffic.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							of additional pipes and conduits (not currently included in the design) for management of purge water, so that it could be collected without requiring a person to carry purge water over a long distance. Without such infrastructure, there is a health and safety concern for workers who have to carry the purge water, especially during the summer months when carrying a heavy load of water in the heat can be dangerous. Currently all monitoring wells have established vehicle access routes. All additional monitoring wells installed with the remedy will also have access routes established as a result of construction. PG&E plans to continue to use these access routes with existing monitoring equipment because it will not add any additional disturbance and will avoid the need for additional disturbance which would be caused by adding sample collection infrastructure (pipes and conduits) that would be required if sample collection was accomplished by "foot traffic only" methods.	seriously dangerous to workers during warm weather days. Foot traffic only also reduces the ability for expeditious egress in the event of emergencies. Although DTSC is committed to minimizing disturbance into areas that Tribes considers sacred, health and safety of potential workers must also be considered.

72	FMIT/TRC	Choose an item.	Choose an item.		Overall Comment	Large amounts of NEW geologic and hydrogeologic data will be generated during drilling, installation and testing of the various elements of the remediation system. These data should be part of an ongoing evaluation for the usefulness of the design elements. The amount of geologic and hydrogeologic data that will be generated during the installation of the system amounts to a very significant portion of ALL geologic data known for the Topock site. The data generated during the installation need to be part of an ongoing evaluation of the design. If unexpected geologic conditions are encountered and there is no flexibility in the design, this could result in wells and construction elements being installed "as planned" that may ultimately not generate any benefit. Significant effort has been made on the part of all parties to minimize such disturbances/number of wells. This effort should continue even as construction of the remedy proceeds.	PG&E is aligned with the Tribes on the goal of minimizing disturbance, overall project footprint, and number of wells. Specifically, PG&E's goal is to avoid unnecessary disturbance and constructing unnecessary infrastructure. To that end, as discussed in RTC #44 FMIT/TRC, #45 Hualapai/TRC, #46 Cocopah/TRC, and #47 Chemehuevi/ TRC, to minimize the potential for uncertainties in the conceptual site model to cause unnecessary disturbance (that is, to avoid constructing unnecessary infrastructure), PG&E had proposed measures such as scheduling data collection at planned Category 1 well locations early in the construction schedule (see Section 3.2.1.3 of C/RAWP) and combining the collection of geotechnical data with the upcoming soil investigation. To this end, PG&E submitted a more detailed construction and start-up sequence in anticipation of construction activity in 2016, during the 90% RTC period (see **Attachment D** of the final RTC table). This sequencing plan provides for start-up of system elements while construction proceeds. This approach will provide more time for data analysis and adaptive design changes while still completing the overall program within the originally			Comments noted. However this issue is considered unresolved. As this project moves forward, minimization of impacts from vehicular traffic to service and/or monitor wells or equipment should be a priority. In addition, responses to the numerous comments regarding groundwater modeling and its application to this remediation as well as the white paper by Prucha and Eggers contain detailed suggestions regarding methods to improve the usefulness and reliability of the model output. Finally, it should always be kept in mind that the Tribe favors early removal of the IM3 facility.	DTSC Response: Tribal comment noted.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							planned schedule. Specifically the sequencing will allow time to assess and accommodate, as appropriate, changes to the remedial system footprint; including the number and location of the Uplands IW, MWs and the associated pipeline alignment, and the Riverbank wells, in coordination with tribal stakeholders and agencies. PG&E will review and consider the Tribes' response (dated Sept 18 and 21, 2015) to PG&E's evaluation of the MW-X/Y White Paper (dated August 14, 2015). PG&E anticipates that additional discussion on a proposed path forward (including model improvements and timing) to occur at a future TWG.

76	FMIT/TRC	Non-design	GW Modeling		Overarching Comment	Modeling tools (microFEM, modflow and MT3D) have been critical to the development of both the proposed remedial system design and operations. Once the system is operating, observed water levels, hydraulic gradients and concentration trends will be compared to simulated values to make critical decisions (decision monitoring frameworks/tables) regarding changes to the currently proposed system design (i.e., new wells) and operation. These models have the ability to incorporate the best available information on the 3-dimensional aquifer geometry, heterogeneous hydraulic property distributions and complex array and timing of the proposed multi-layer injections and extractions. As such, they represent the best available tools for demonstrating to all stakeholders that the remedial system design and operation at any point in time continues to meet RAOs, and that any proposals to change the currently proposed design and operation will do so as well. Despite the clear importance and continued need for these modeling tools, especially during startup and early operations when adjustments to the design and operation will be most frequent, several issues have been identified. These issues are of considerable concern to Tribes because of the potential for poorly thought-out or 'urgent crisis' decisions which lead to increased number of wells/disturbance or unnecessarily impacting sensitive cultural areas. Key issues include: 1) Triggers (i.e., "significant differences") for updating/use of the models are still vague/non-committal as noted comment to the 60% BOD and highlighted in the Prucha, April 3, 2014 summary memo to the Tribes. 2) Details on approach/methodology for updating, re-calibrating, re-optimizing and re-running	The groundwater flow and transport model will be updated during the remedy installation, start-up, and operation phases in an effort to refine the predictive performance of the model. While the model will remain an important tool to predict long term changes, the system performance will be demonstrated and measured with site specific empirical data. 1. Rather than defining specific criteria to trigger model updates, the term "significant differences"			Using site-specific empirical data can certainly be useful in evaluating the CURRENT system performance, but when considering changes to the design and operation of the remedial system, we believe the model will be essential for correctly guiding a) how much to adjust some knob, b) which direction to adjust the knob, c) which knob(s) to adjust. Probably more importantly, we continue to strongly feel that the model	A similar RTC (RTC #78) was discussed at the August 18 TWG meeting. DTSC Response: Tribal comment noted.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						long-term remedial system operations remains vague and limited. Any re-calibration or modification to operations (i.e., rates, TOC dosing) or design (i.e., new wells) should require full re-evaluation of whether the modified system continues to meet RAOs, especially long-term remedial cleanup times. 3) Critical decisions on assessments and potential changes to the operation and design will be made based on various O&M Monitoring Decision Framework diagrams. But detailed narrative on updates to and use of the models is vague and limited.	will be removed from the text and model updates will be conducted according to the timetable described in Section 12 of Appendix B. Due to the large amount of data that will be collected during the various remedy phases, model updates will be beneficial independent of specific “significant difference” thresholds. 2. Additional details will be provided with respect to the approach/ methodology for updating, re-calibrating, re-optimizing, and re-running the model. During each defined model update the following steps will be included: a) the 3D structure of the model will be refined based on new vertical characterization of the alluvial aquifer/bedrock contact. b) hydraulic property distributions will be refined based on updates to the spatial distribution of aquifer test data. c) Actual operational data will be integrated into the groundwater flow model (i.e. pumping rates, pumping schedule, and vertical flow distribution) d) the groundwater flow model will be recalibrated to average observed water levels during each model update interval. e) geochemical modeling parameters will be refined based on observed water quality data and field parameters. f) solute transport modeling parameters will be refined based on			represents the ONLY tool (not empirical site data) that will permit evaluating whether the planned OR modified remedial system design and operation still meet all RAOs, especially over the long term (i.e., decades out). There is no way that empirical site data alone will be sufficient to confirm attainment of long-term RAOs, or long-term performance of the system. The risk to updating on an annual basis rather than for example, after specific sets of data are collected, significantly reduces the potential to learn about actual flow conditions within the natural hydrogeologic environment and how they will change. This in turn limits the ability to 'adaptively manage' the design and operation of the system. We recommend updating/ re-calibrating the model more frequently and immediately after sets of key wells are installed and tested. The model certainly doesn't have to 'drive' all decisions related to design modifications or operational changes BUT stakeholders need to get guarantees that the model will be updated, re-calibrated and future scenarios regenerated whenever new designs/operations are made primarily to ensure for stakeholders that all RAOs are being met, especially the long-term ones that cannot be assessed using “empirical” field data. ONLY the model

							observed water quality data and field parameters as well as geochemical modeling. g) actual remedy operation parameters will be integrated into the solute transport model (i.e. TOC concentration, TOC injection frequency, etc). h) solute transport model will be calibrated against observed movement of Cr(VI), Mn, and As during previous time interval. i) After model calibration, predictive modeling runs will be conducted to evaluate the simulated remedy performance in the future. j) Potential design updates and operations will be considered to further optimize remedy operation (i.e. pumping rates, TOC dosing concentration, dosing and operational frequency) j) Assessment of hydraulic capture zones based on simulated capture delineation and hydraulic gradients. The model will be used to predict future performance and assess the need for infrastructure changes in conjunction with empirical data. The model will not be used for all changes associated with system operation where current empirical data is a more accurate reflection of system performance and the need for operational changes; such as flow rate changes, TOC feed adjustments, and maintenance needs. 3. Text describing the use of models during the remedy installation,			can estimate the changed response in the future - i.e., cleanup times. But to do this, the model must be maintained (i.e., updated, calibrated and long-term future scenarios re-simulated). ALL stresses, and changes to stresses need to be monitored/measured to successfully re-calibrate the model. This will become a serious challenge to do correctly/adequately - and details of how updates and re-calibrations will be performed should be clearly defined for all stakeholders.

							start-up, and operation will be integrated into the model report.				
77	Hualapai/TRC	Non-design	GW Modeling		Overarching Comment	Modeling tools (microFEM, modflow and MT3D) have been critical to the development of both the proposed remedial system design and operations. Once the system is operating, observed water levels, hydraulic gradients and concentration trends will be compared to simulated values to make critical decisions (decision monitoring frameworks/tables) regarding changes to the currently proposed system design (i.e., new wells) and operation. These models have the ability to incorporate the best available information on the 3-dimensional aquifer geometry, heterogeneous hydraulic property distributions and complex array and timing of the proposed multi-layer injections and extractions. As such, they represent the best available tools for demonstrating to all stakeholders that the remedial system design and operation at any point in time continues to meet RAOs, and that any proposals to change the currently proposed design and operation will do so as well. Despite the clear importance and continued need for these modeling tools, especially during startup and early operations when adjustments to the design and operation will be most frequent, several issues have been identified. These issues are of considerable concern to Tribes because of the potential for poorly thought-out or 'urgent crisis' decisions which lead to increased number of wells/disturbance or unnecessarily impacting sensitive cultural areas. Key issues include: 1) Triggers (i.e., "significant differences") for updating/use of the models are still vague/non-committal as noted comment to the 60% BOD and highlighted in the Prucha, April 3, 2014 summary memo to the Tribes. 2) Details on approach/methodology for updating, re-calibrating, re-optimizing and re-running long-term remedial system operations remains vague and limited. Any re-calibration or modification to operations (i.e., rates, TOC dosing) or design (i.e., new wells) should require full re-evaluation of whether the modified system continues to meet RAOs, especially long-term remedial cleanup times. 3) Critical decisions on assessments and potential changes to the operation and design will be made based on various O&M Monitoring Decision Framework diagrams. But detailed narrative on updates to and use of the models is vague and limited.	See above			Using site specific empirical data can certainly be useful in evaluating the CURRENT system performance, but when considering changes to the design and operation of the remedial system, we believe the model will be essential for correctly guiding a) how much to adjust some knob, b) which direction to adjust the knob, c) which knob(s) to adjust. Probably more importantly, we continue to strongly feel that the model represents the ONLY tool (not empirical site data) that will permit evaluating whether the planned OR adjusted/ modified remedial system design and operation still meet all RAOs, especially over the long term (i.e., decades out). There is no way that empirical site data by itself will be able to confirm meeting long-term RAOs, or long-term performance of the system. The risk to updating on an annual basis rather than for example, after specific sets of data are collected, significantly reduces the potential to learn about actual flow conditions within the natural hydrogeologic environment and how they will change. This in turn limits the ability to 'adaptively manage' the design and operation of the system. We recommend updating/re-calibrating	A similar RTC (RTC #78) was discussed at the August 18 TWG meeting. DTSC Response: Tribal comment noted.

Specific Comments – 90% BOD, Executive Summary											
80	FMIT-16	Non-design	Editorial	Executive Summary	Global ES	This ES represents a helpful compilation of information about the 90% BOD. The tabular summaries and provided figures are an excellent summary of information for the reviewers. It might have been nice to have the ES separate from the remainder of the voluminous document.	PG&E appreciates the Tribe's feedback and is glad that the tabular summaries and figures provided in the 90% BOD are useful to the Tribe in your review. It is customary that an executive summary be created for large documents to provide an overview of key contents in the document, and to refer the readers to subsequent chapters for additional details. Separation of the executive summary from the remainder of the document defeats the purpose of an executive summary and introduces yet another document to account for. Therefore, it is not recommended.		Comment noted.		
81	DOI-1	Non-design	Process	ES Introduction/ v	As shown, inputs from Interested Tribes and Stakeholders were solicited and received on the preliminary (30%) and intermediate (60%) Basis of Design Submittals (30% BOD [CH2M HILL	The text inappropriately identifies that comments were solicited only from "interested Tribes and Stakeholders". In accordance with the PA, comments were solicited from all nine federally recognized Tribes. Comments were received from a subset of those Tribes, specifically the Fort Mojave, Hualapai, Cocopah, and Chemehuevi Indian Tribes. Input was received from these Tribes and the Colorado River Indian Tribe throughout the design process. A notation/footnote should be inserted here to note that the term "interested Tribes" will be used to reference the aforementioned Tribes.	Text will be revised to state that comments were solicited from nine federally recognized Tribes, and comments were received throughout the design process from a subset of those Tribes, specifically the Fort Mojave, Hualapai, Cocopah, Chemehuevi, and Colorado River Indian Tribes. A footnote will be inserted to note that the term "Interested				Comment resolved pending DOI review of the final design documents.

					resources will be minimized by implementing the mitigation measures required by the Mitigation Monitoring and Reporting Program (MMRP; DTSC 2011a), adopted by DTSC in 2011 as part of the certified EIR (DTSC 2011b). In addition, mitigation measures have been and will continue to be implemented in accordance with the Programmatic Agreement (PA; BLM 2010); the Cultural and Historic Properties Management Plan (CHPMP; BLM 2012); the Cultural Impact Minimization Program (CIMP; PG&E 2014); and in consultation with the Tribes throughout the construction and startup process. The work will be conducted in a manner that recognizes and respects these resources and the spiritual values of the area.	BOD to require Tribal consultation prior to implementation.					TWG meeting. Tribes and DOI/BLM will discuss what changes during construction invoke Tribal consultation.
90	DTSC-9	Non-design	Editorial	ES.1 Overview/ Page vii	Data collected during the East Ravine Groundwater Investigation indicate that	The cited sentence should be revised. As constructed, the sentence can suggest that all bedrock groundwater occurs simultaneously in irregularly distributed, highly localized, and discontinuous water-bearing zones. The data indicates that bedrock groundwater typically occurs in irregularly distributed fractures. The basis for stating that the bedrock groundwater occurs in discontinuous water-bearing zones should be supported and clarified. As the bedrock formations are generally hydraulically connected to river fluctuations and the more permeable bedrock wells are suggested	The cited sentence will be edited as follows: "Data collected during the East Ravine Groundwater	Resolved.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					groundwater in bedrock occurs in irregularly distributed, highly localized, and discontinuous water-bearing zones, which is characteristic of fractured crystalline rocks.	to be connected with the alluvium, it is currently requested that the sentence be revised to omit "discontinuous water-bearing zones". Identical language and change requested on Section 2.2, Page 2-4.	Investigation indicate that groundwater in bedrock occurs in <u>an</u> irregularly distributed and <u>complex network of fractures</u> ~~discontinuous water-bearing zones~~, which is characteristic of fractured crystalline rocks." The same edits will be made to the sentence in Section 2.2, Page 2-4.				
91	MWD	Non-design	Editorial	ES.2/vii; Sect. 1.2.1/1-8	The Remedial Action Objectives (RAOs) for selected groundwater remedy at the Topock site.	California's MCL of 10 ug/L for hexavalent chromium is cited in Item No. 52 of Table 6.2-1 (Basis of Design Report/Pre-final 90% Design Submittal). California's MCL for hexavalent chromium should also be cited throughout the document whenever the water quality standards that support the designated beneficial uses of the Colorado River are referenced (such as in RAO #2 on page vii of the Executive Summary and in Section 1.2.1).	As mentioned in Item 100 of Table 6.2-1, reducing Cr(VI) concentrations in groundwater by implementation of the remedy will increase the level of certainty that surface water quality will continue to remain below the designated beneficial uses of the Colorado River. To date, surface water sampling in the Colorado River upstream, midstream, and downstream of the Topock site show concentrations of Cr(VI) less than the California Toxics Rule criteria of 11 µg/L (protection of freshwater aquatic life) and the California MCL for Cr(VI) of 10 µg/L. Surface water sampling will be conducted during remedy start-up and operations to confirm and document compliance with RAO #2. If Cr(VI), and manganese concentrations in surface water samples increase and are attributed to the Topock site, operational adjustments will be made according to the decision rules presented in the O&M Manual. If Cr(VI), arsenic, and manganese concentrations do not return to baseline as a result of operational adjustments, the				Comment resolved.

							contingency plan will be implemented.				
92	FMIT-17	Non-design	Other	ES.2, p. vii	RAO #4	It is noted that RAO #4 addresses the *permanent* expansion of the “target remediation area.” Accordingly, this permits at least a temporary expansion. For example, the migration of the plume beyond its initial footprint.	Comment noted. Data will be collected as part of the Compliance Monitoring Program (Section 2.1 of the Sampling and Monitoring Plan, O&M Manual Volume 2) to ensure compliance with this RAO. As the remedy is implemented, data will be collected to determine whether operations or remedy components should be modified to meet the RAO. Groundwater samples will be collected periodically from the Compliance Monitoring Program well network outside the plume. The compliance monitoring wells outside the plume are shown on Figure 2.1-1 and listed in Table 2.1-3. The data collected will be analyzed to ensure that the concentrations of Cr(VI) and remedy by-products, specifically manganese and arsenic, do not permanently increase outside of the baseline Cr(VI) plume. Monitoring for COPCs will also be conducted as described in Section 5.1 and summarized in Table 2.1-6.			How the monitoring data outside the footprint will be used to differentiate whether the plume has temporarily or permanently expanded should be explained further.	DTSC Response: Monitoring data will continue to be reviewed throughout the life of the remedy. DTSC’s position is to maintain the water quality outside of the plume in compliance with the anti-degradation policy. Continuous exceedances or changes to the water chemistry outside of the plume will warrant discussion and careful evaluation. At a minimum, the required 5 year reviews will be a trigger for such an evaluation, if not earlier.
93	DTSC-10	Non-design	Process	ES.2, p vii	Attaining the cleanup criteria of 32 µg/L Cr(VI) in groundwater may be through active	The referenced text is not quite accurate. The use of “Monitored Natural Attenuation” is appropriate only after optimization of the active remedy and as a long term component to address residual hexavalent chromium as stated in the following paragraph on that page and per the January 31, 2010 statement of basis. Recommend changing the last part of the sentence to “…or monitored natural attenuation after active remediation has been employed and optimized.”	As recommended, the bullet will be revised as follows (<u>underline</u> for text addition): “Attaining the cleanup criteria of 32 µg/L Cr(VI)	Resolved.			Comment resolved.

					remediation or through natural attenuation.		in groundwater may be through active remediation or through <u>monitored natural attenuation (MNA) after active remediation has been employed and optimized</u>."				
94	FMIT-18	Design	Contingencies	ES.2, p. vii, beginning at 2nd para. from bottom and continuing onto p. viii.	Discussion of MNA as a long-term component of the groundwater remedy.	This section provides for the contingency of using MNA as a component remedy based on the recalcitrance of certain areas of the aquifer. Such decisions would be made during the 5-year review(s) on the basis of information gathered in the field. The concept of recalcitrance resulting from heterogeneities in the aquifer is understood, however, further insight as to what might be considered acceptable timeframes for such allowable MNA to occur. It is noted that the projected timeframe for the CMS/FS MNA scenario was considered unacceptable by the Regional Board. How might the timeframe(s) for MNA to achieve RAOs be viewed for these (presently unknown) recalcitrant areas? Has PG&E done any simulation to assess this using a reasonable sensitivity range? Is it likely that the MNA timeframes projected for recalcitrant areas be similarly viewed as unacceptable, thereby triggering future expansion of the remedy?	MNA would be applied following active remediation for relative smaller and/or lower concentration areas than the current plume that is to be remediated. The time for concentrations to reduce to less than 32 ppb would depend on the concentration, size and local hydrogeologic conditions of any recalcitrant portion(s) of the plume. Modeling has not been conducted of MNA of potentially recalcitrant areas following active remediation, and modeling results would be highly uncertain before the areas are identified and the factors affecting timeframe are known. It is possible that the timeframe could extend beyond the currently described 10 year MNA timeframe. Given that the aerial extent and potential mass in recalcitrant areas is anticipated to be much smaller relative to the current plume and that the fact that these areas are recalcitrant indicating limited mobility, the agencies may have a different view on the acceptability of timeframes for this portion of the remedy.			The Tribe is interested in hearing how the agencies may view the acceptability of the timeframes for recalcitrant areas differently.	The Agencies will evaluate the extent and mass of contamination of recalcitrant zones during 5-year reviews to determine if the current remedy is still effective. MNA is considered a long-term component of the remedy in addressing residual contamination.
95	DTSC-11	Design	Remedial design	ES.2 Remedial Action Objectives, Completion Criteria/ Performance Standards, and Short-Term	"Based on modeling, the current projection of the remedial timeframe is 30 years of active remediation	Item 1: The section introduces how MNA may be used in the remedy, but the cited sentence doesn't account for the likely effect that MNA would have on the cleanup schedule. Suggest adding the following sentence after the cited sentence, "This timeframe does not account for any additional time for monitoring that may be required if MNA is selected for portions of the plume. Item 2: Text should be revised to clarify why a remedial timeframe of 30 years is stated, yet modeling (see Figures 7.1-1 to 4 of the Appendix B modeling section) illustrates that the plume is not cleaned up after 30 years.	The 30 years of active remediation quoted in this comment refers to the target remedial timeframe. As discussed in Section 7.1 of the groundwater modeling Appendix B, the majority	Resolved.			Comment resolved.

				Goals/ Page viii	followed by up to 10 years of long term monitoring and up to 20 years of arsenic monitoring."		of the alluvial Cr(IV) plume in all for model layers has been remediated by year 30 of the simulated transport run of the nominal case design. The alluvial aquifer Cr(VI) remaining at year 30 for the nominal case is a relatively small footprint located just upgradient of the central portion of the NTH IRZ, as shown on Figures 7.1-1 through 7.1-4. As discussed in this modeling section, optimization of the nominal case over time will be needed to reduce the timeframe toward the target of 30 years. One potential optimization, the addition of intermediate recirculation wells IRL-6 and IRL-7 at year 20 was evaluated in the modeling (Appendix B, Section 10.13). The results shown on Figures 10.13-1 and 10.13-2 indicate this intermediate recirculation well pair can reduce the remaining footprint of the Cr(VI) plume. In practice, routine data evaluations will be conducted to inform the remedy improvements needed to meet the 30 year timeframe target. The following edits will be made to clarify these points in the text (revisions are shown as <u>underline</u> for added text and ~~strikeout~~ as deleted text): "~~Based on modeling, the current projection of t~~ The anticipated remedial timeframe is 30 years of active remediation followed by up to 10 years of long term monitoring and up to 20 years of arsenic

							monitoring. <u>This timeframe does not account for any additional time for monitoring that may be required if MNA is selected for portions of the plume and extends past the 10 years of long term monitoring</u>."				
96	FMIT-19	Design	Remedial Design	ES.2, p. viii	Bullets describing OF & OPS	How do OF and OPS differ? Would it be possible to achieve one without the other? The paragraph above the bullets describes the development of short-term goals and criteria for such evaluations. When will this information be available? The FMIT would like to be involved in discussions during the development of these goals and criteria, as well as in the process of evaluating OF and OPS.	Section 6.2 (Functional Testing, Startup, and Transition to O&M) of the C/RAWP provides expanded discussions of OF and OPS and descriptions of activities involved in making OF and OPS determination. In brief, OPS determination overlaps with OF determination, and the two work in tandem to ensure that the remedy functions and operates properly and successfully. See also DTSC and DOI's responses to this comment.	DOI and DTSC have sole responsibility for the OF and OPS determinations, respectively. Short term goals and criteria are based on agencies' expectations of the design as proposed by the design. The agencies will openly discuss the rationale and approach with stakeholders and Tribes before setting those goals.	The NCP, 40 CFR§300.435(f)(2), states, "A remedy becomes 'operational and functional' either one year after construction is complete, or when the remedy is determined concurrently by EPA and the State to be functioning properly and is performing as designed, whichever is earlier. EPA may grant extensions to the one-year period, as appropriate." DOI, as the lead CERCLA agency, will make the OF determination in coordination with DTSC's OPS determination. DOI and DTSC have sole responsibility for the OF and OPS determinations, respectively, and will conduct a joint inspection at the conclusion of construction of the groundwater remedy to determine that it has been constructed properly. The joint inspection also marks the beginning of the one-year O&F period described above. After the remedy has been	Noted.

							future, including during 5-year reviews to be conducted by DTSC and DOI.		evaluation will occur once the final groundwater remedy boundaries are determined. BLM will take the MWD comment into consideration during the evaluation. The PA also defines the process for revising the boundaries.		
107	FMIT-21	Design	Legal	ES.4	Summary of ICs	This section broadly describes IC categories potentially anticipated in conjunction with the remedy. FMIT believes it may be possible to use ICs to restrict certain categories of land use and access to areas of the site. This is important due to the somewhat unrestricted development and use activities that have occurred recently in adjacent areas.	PG&E will be discussing this comment, and its response to this comment, directly with counsel for DTSC and counsel for the Fort Mojave Indian Tribe.	DTSC will be communicating with FMIT directly regarding this matter.	Land use and access to federal property is addressed through the specific BLM Resource Management Plan and FWS Refuge Comprehensive Management Plan for the property. Institutional Controls are also addressed in the DOI Groundwater Record of Decision. Under the PA, the Tribal Access Plan has been established. BLM has taken measures to reduce potential for incursion by outside parties, e.g., recreational ORVs, and is scheduled to amend the Bullhead Travel Management Plan in FY 2016.	Relative to PG&E's comment, a brief discussion between counsel occur. Please see response to comment FMIT/TRC RTC #44. ed in. Relative to DOI's comments, the Tribe respectfully requests that an ACEC management Plan be developed. It remains unresolved when this plan will be drafted despite the RMP being adopted 8 years ago. The Tribe looks forward to direct discussion with DTSC regarding this matter.	DTSC Response: Tribal comment noted.
108	FMIT/TRC	Non-design	Process	ES.4 Summary of Institutional Controls	With respect to privately-owned lands, PG&E is in the process of obtaining Covenants access agreements from existing landowners or employing other similar mechanisms, as appropriate.	Please discuss the effects on remedial design if Covenants access agreements are not provided by private land owners. Could this cause changes in remedial design?	PG&E is working diligently to secure all necessary access agreements for remedy implementation, consistent with the requirements in the Corrective Action Consent Agreement between PG&E and DTSC and the Remedial Design/Remedial Action Consent Decree between PG&E and the United States, on behalf of DOI. If a needed access agreement cannot be obtained,	See RTCs #82 FMIT/TRC 1s, #83 Hualapai FMIT/TRC 1s, #84 Cocopah/ TRC 1s, and #85 Chemehuevi/TRC 1s above.	DOI agrees with the course of action presented by PG&E.	The Tribes reiterate the desire to be included along with DOI and DTSC as primary parties to whom communication is addressed if material deviation from work plan and design documents, MMRP action specific, and location specific ARARs occur. The current proposed use of monthly progress reports and periodic uploads to SharePoint is not a sufficient level	A similar RTC (RTC #110) was discussed at the August 18 TWG meeting. DTSC Response: Tribal comment noted.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							PG&E will inform the Agencies and propose solutions which may include design modifications.			of involvement when it comes to decisions that could result in permanent disturbance to the Sacred landscape. PG&E should remain mindful of its independent legal obligations under the 2006 Settlement Agreement to consult with FMIT and to provide all non-attorney-client privileged material information, documentary or otherwise, to the Tribe contemporaneously with its receipt or development by PG&E.	
109	Hualapai/TRC	Non-design	Process	ES.4 Summary of Institutional Controls	With respect to privately-owned lands, PG&E is in the process of obtaining Covenants access agreements from existing landowners or employing other similar mechanisms, as appropriate.	Please discuss the effects on remedial design if Covenants access agreements are not provided by private land owners. Could this cause changes in remedial design?	See above			Hualapai reiterates the need to be included (along with DOI and DTSC) as a primary party in communications regarding all project design changes, or work variance requests including material deviations from the design documents and/or C/RAWP due to discovery of changed site conditions as discussed in these earlier comments (at left). Communicating these changes needs to occur as soon as it is known that a change needs to be made. Hualapai needs to be included in those discussions via informing a tribal monitor, or email or telephone calls to designated points of contact. Once the change has been approved then a formal document can be forwarded to Hualapai.	A similar RTC (RTC #110) was discussed at the August 18 TWG meeting. DTSC Response: Tribal comment noted.
110	Cocopah/TRC	Non-design	Process	ES.4 Summary of Institutional Controls	With respect to privately-owned lands, PG&E is in the process of obtaining	Please discuss the effects on remedial design if Covenants access agreements are not provided by private land owners. 											23 TWG meeting.
129	Cocopah/TRC	Design	Infrastructures	Table ES-2B	(same as C/RAWP Exhibit 3.1-2B)	ES-2B/Exhibit 3.1-2b should contain a final row with appropriate column totals, e.g., total number of boreholes, total number of planned boreholes, total number of future provisional boreholes, estimated replacement boreholes, and overall total of estimated boreholes.	See above			Comment noted.	This RTC was discussed at the August 18 TWG meeting.
130	Chemehuevi/ TRC	Design	Infrastructures	Table ES-2B	(same as C/RAWP Exhibit 3.1-2B)	ES-2B/Exhibit 3.1-2b should contain a final row with appropriate column totals, e.g., total number of boreholes, total number of planned boreholes, total number of future provisional boreholes, estimated replacement boreholes, and overall total of estimated boreholes.	See above			Comment noted.	A similar RTC (RTC #129) was discussed at the August 18 TWG meeting. Other RTCs related to well count were also discussed at the July 23 TWG meeting.
131	FMIT-26	Non-design	Process	Figure ES- 1	Site cleanup process	Despite the representation of this figure as "Site Cleanup," it excludes the soils component, which is an important component in addition to the groundwater remedy. While it has been decided that the groundwater and the soils remedies will proceed on different tracks, it remains necessary to disclose that these two components in some way interact with each other. At a minimum, a footnote should be added to emphasize this fact.	As discussed in RTC #27 FMIT-13, much effort were put into integrating the soil information into the remedy design and coordinating with the Soil RFI/RI program to minimize duplication and disturbance. Soil information is prominently discussed and the integration of soil info/program is evident throughout the BOD, the O&M Manual, and the C/RAWP (refer to examples provided in RTC #27). Figure ES-1 is intended to illustrate the cleanup process and various phases for implementation of the groundwater remedy. This figure is not meant to include the soil component and adding a footnote is not necessary.	As the Tribes are aware, the potential need for cleanup of soil at the site can only be determined after the completion of the RFI/RI work plan for soil investigation and the appropriate risk assessment. It is important to note that DTSC has requested PG&E to consider the soil sampling locations relative to the groundwater remedy infrastructures so that soil sampling activities or potential remedy would not be hindered.			
132	FMIT-27	Non-design	Process	Figure ES- 2	Schedule	This schedule represents that "Tribal Communication and Tribal Consultation" is ongoing throughout the project timeframe. While this is appropriate, it would further be helpful to identify junctures where specific consultation with the tribes is intended. For example, prior to startup, prior to construction, etc.	PG&E defers to DOI/BLM for response to this comment. Please see RTCs #44 FMIT/TRC, #45 Hualapai/ TRC, #46 Cocopah/TRC, and #47 Chemehuevi/ TRC, for responses related to tribal communications by PG&E.	See RTCs #44 FMIT/TRC, #45 Hualapai/TRC, #46 Cocopah/TRC, and #47 Chemehuevi/ TRC above.	Consultation will occur in accordance with the Programmatic Agreement (PA) and Appendix B [to the PA] - Consultation Protocol for the Topock Remediation Project.		
133	DTSC-17	Non-design	Editorial	Figure ES-3		Suggest adding FWIP area that was added to project area based on EIR addendum	Addition to Figure ES-3 will be made as requested.	Resolved.			Comment resolved.
134	DTSC-18	Design	Infrastructures	Figure ES-4A	MW-20 Bench	Aside from the additional carbon amendment building and storage tanks, will all other structures	Not all IM features on	See RTC # 1152			Comment resolved.

						and tanks associated with the IM be removed as part of IM3 decommissioning? If not all, what will remain?	the MW-20 Bench will be removed as part of IM3 decommissioning. The brine storage and loading facility (three tanks, the truck lane, and associated pumps and piping) will remain and will be reused by the groundwater remedy in its existing location at the MW-20 Bench (see Section 1.3 of the IM-3 Decommissioning Work Plan for additional details).	regarding retention of addition IM infrastructure.			
135	DTSC-19	Design	Remedial design	ES.3 Summary of Engineering Design Parameters and Features/Key Changes from 60% to 90% Design	Figure ES-4D, Future Provisional/ Contingent Fresh Water Pipe	The document should comment on under what scenarios the Site B well would be used in the future. It would seem more prudent to blend with either wells Topock 2 or 3. A contingent boring/well could evaluate the old Topock 1 water quality and quantity in the future if ever needed as it is ideally located along the planned pipeline and would not require installation of thousands of feet of additional pipeline and trenches. The entire document should be revised to delegate utilization of the Site B well as a last resort. Less impactful alternatives (e.g., see above) should be evaluated and fully vetted prior to proposing selection of the Site B well.	Exhibit 3.3-2 of the 90% BOD and Table 2.3-1 of the Contingency Plan (O&M Manual Volume 3) outline potential scenarios under which water from Site B well could be used in the future. For each scenario, potential operational actions and possible contingency measures were identified. Operational actions (e.g., tie-in HNWR-1, rehabilitate a well) are more readily implementable than the contingency measure (e.g., use water from Site B, implement pre-injection treatment). The use of Site B is identified as a possible contingency measure under each scenario because of the associated added infrastructure (e.g., pipeline, pre-injection treatment system). As for blending with either wells Topock 2 or 3, it should be noted that, in order to separate the freshwater supply for TCS and remedy and ensure that the use of the infrastructure designed and constructed under this project is prioritized for remedy use first, the tie-in of Topock-2 and -3	As the only contingent fresh water supply source located away from the HNWR-1/1A area, the Site B well has water quality concerns as well as significant infrastructure impacts associated with it. Depending on future water supply problems/ needs (e.g., quality and/or quantity), pre-treatment to maintain California water quality (e.g. arsenic, chromium) may be required. Alternatively, PG&E may at some future time elect to investigate the possibility of another new water well in Arizona or California. As PG&E clarified during the August 26, 2015 TWG Meeting, the footprint of the ancestral Colorado River east of the Topock Marina in the general vicinity of Topock 1 is believed to have greater aquifer thickness and			

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							wells was eliminated in the 90% design (see 60% RTC 168 DTSC-63). However, as discussed in RTC #267 DTSC-67, Topock-2 and -3 wells can be tied in with added infrastructure within the Compressor Station footprint. In response to DTSC's request, additional details that describe this tie-in will be provided for review during the 90% RTC period and included in **Attachment E** of the final RTC table. If there is a competing need for Topock-2 and -3 water in the future, the first priority for this water, as noted in 60% RTC 168 DTSC-63, is for fire protection and operational needs at the Station, and that priority cannot be changed. Given the existing infrastructure identified in the design for remedy freshwater supply, and the listed contingency options, it is PG&E's opinion that an additional exploratory borehole/ well at the former Topock-1 location is not necessary. While the former Topock-1 site is located along the planned pipeline route, unlike Site B, it is in close proximity to/within habitat where sensitive biological receptors have been documented (Yuma clapper rail). With respect to EIR mitigation measure WATER-1, the site at Topock 1 is much closer to the bedrock outcrop near the Topock Marina. The proximity of this low permeability bedrock aquifer boundary would tend to focus and increase drawdown of a well pumping at Topock 1	transmissivity than to the west of the marina; therefore, it holds potential for a water well. DTSC does wish to clarify that the exact Topock 1 location was a recommendation and that other locations could also be considered. Finally, one would anticipate drawdown effects at Topock 2 and 3 and private wells associated with a new well in the ancestral Colorado area to be similar to HNWR-1 pumping if aquifer thickness were similar or if hydraulic conductivities were greater in the ancestral Colorado deposits. Regardless, the needed pumping rate for a future contingency pumping well might make this drawdown point moot.			

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							location. Therefore, pumping from a well at Topock 1 is more likely to result in measurable drawdown at Topock 2 and 3 and the domestic wells near the Topock Marina than pumping from HNWR-1A or Site B. It would be necessary to install and test a well at Topock 1 location to determine whether WATER-1 could be met at this location.				
136	DTSC-20	Design	Editorial	Figure ES-5		Since this is a simulation of new remedy building/structures, PG&E should also simulate the Transwestern North Access Road. Also, in ES-7, Trailers were depicted, but did not identify their purpose and ES-5 did not show these trailers. Are the trailers for remediation or station operations?	A simulation of the Transwestern North Access road will be added to Figure ES-5. The trailers depicted in Figure ES-7 are potential trailers used by PG&E and/or its contractors during construction and/or O&M of the groundwater remedy, not for station operations. The need for, the numbers, or types of trailers for remedy use may vary over time. Text will be added to the BOD and Figure ES-7 to reflect above. If helpful, temporary trailers can also be added to Figure ES-5. In addition, after additional evaluation of ways to further minimize remedy footprint/soil disturbance, PG&E proposes to move the carbon amendment facilities (i.e., carbon amendment building and storage tank) at the Transwestern Bench to the MW-20 Bench and consolidate dosing activities. This minimizes cutting into the hillside and resulting in less earthwork at the Transwestern Bench, while keeping the 90% fenced footprint on the MW-20 Bench the same. Further, PG&E proposes	Sheet C-08-03/04, **Attachment BB**, shows both a leach field and reserve leach field. These should be remove as the plan was not to have any leach fields as part of project.			**Attachment BB** was revised to incorporate DTSC's comments.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							to move the Operations Building at the Transwestern Bench slightly to the east, away from the hillside, which again minimizes cutting into the hillside. The revised design was included in **Attachment BB** for review during the 90% comment resolution period.				
137	DTSC-22	Design	Remedial design	ES.3 Summary of Engineering Design Parameters and Features/Key Changes from 60% to 90% Design	Figure ES-6, Approximate Location of New Air Compressor Building (not shown, design in progress)	The Portable Generator Pad and Transformer/Switchgear structure are not show in figure ES-6 as compared to ES-10. The air compressor station building footprint is also not shown. The design of the new compressor building should not be "in progress" as stated. It needs to be developed ASAP. Visualizations should not include the old scrubber banks in the lower yard as they are no longer there. Current lower yard facilities should be used instead.	An updated Figure ES-6 was provided in the Supplemental 90%. In the updated Figure ES-6, the air compressor building is noted as Station facility and not a remedy feature (see RTC #839 DTSC-194). As discussed in RTC# 287, the remedy air compressor is located on the first floor of the Remedy-produced Water Conditioning Plant for remedy-produced water (see 90% drawing M-12-01). Like other elements of the remedy, the remedy air compressor was designed to the 90% level. The Station air compressor building is being designed by the Station on the Station's timeline. PG&E does not anticipate that construction of the Station air compressor building will overlap with construction of the remedy. The portable generator pad is just a reserved flat area behind the Remedy-produced Water Conditioning Plant, so it does not show on Figure ES-6. The transformer/ switchgear does not show on Figure ES-6 due to the angle of the photo. The purpose of Figure ES-6 and similar figures throughout the design reports is to facilitate	Resolved.			Comment resolved.

					up.						
158	DTSC-36	Non-design	CEQA/EIR	Section 1.2.2	EIR Project Area	In addition to the January 2011 certified EIR, DTSC has also completed an EIR addendum to change the project boundary to incorporate the fresh water well locations. Please add language to the design document and update project area maps for accuracy.	Text will be added to Section 1.2.2 to discuss the August 2013 EIR addendum and applicable figures in the design documents will be updated to incorporate the area added pursuant to the 2013 Addendum.	Resolved.			Comment resolved.
Specific Comments – 90% BOD, Section 2: Baseline Site Conditions and Pre-Design Work											
159	DTSC-37	Non-design	Editorial	2.3.3 General Geochemical Indicator Parameters/ Page 2-9	"They are natural compounds that are abundant in the area, as evidenced by their ubiquitous concentrations in the region and across the Colorado River. There are multiple sources of dissolved salts, including geologically older groundwater upwelling across the southern portion of the Mohave basin, evaporite minerals in the aquifer matrix, and evapotranspiration associated with the more vegetated areas of the floodplain, etc. (CH2M HILL 2009a)."	Add the following sentence after the cited sentences to clarify that since the chromium plume is not natural, the TDS associated with the chromium plume would also not be natural within the confines of the plume footprint: "Of course, TDS associated with the chromium plume would have mixed to some degree with the naturally occurring TDS within the aquifer (see last paragraph in this subsection)."	The following statement will be inserted after the cited text in Section 2.3.3. "Of course, TDS associated with the chromium plume could have mixed to some degree with the naturally occurring TDS within the aquifer (see last paragraph in this subsection)."	Resolved.			Comment resolved.
160	DTSC-38	Non-design	Editorial	2.3.3.1 Total Dissolved Solids/ Page 2-10	"Most plume wells are screened close to the bedrock surface."	Delete this sentence as it is not accurate as written (e.g., shallow zone wells are not screened close to the bedrock surface).	This sentence is from the RFI/RI Vol 2 Report (Section 6.5.1, page 6-26, last paragraph), with only the figure reference from that report's sentence deleted. Shallow wells refer to those wells screened near the water table, but if the aquifer is thin in a	Resolved.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							particular location, that screen can also be much closer to the bedrock surface than a shallow well in a thicker part of the aquifer. Figure 5-20 from the RFI/RI Vol 2 Report shows that 17 out of 31 plume wells are screened within 50 feet of the bedrock surface, whereas only seven out of 50 non-plume wells are screened within this same distance of bedrock. The figure shows the same relationship between TDS and screen distance from bedrock for both non-plume and plume wells. This is an artifact of plume characterization concentrated at the up-gradient fringes of the Alluvial Aquifer. The sentence will be deleted as requested.				
161	DTSC-39	Design	Monitoring	2.3.4 Freshwater Injection Area Baseline Concentrations / Page 2-11	"Data from wells listed above are expected to represent the proposed southern injection area as well as the remaining injection areas along the corridor that extends from the northwest boundary of the plume at IRL-1 to the southwest boundary at FW-2."	Delete the cited sentence and replace with the following: "New monitoring and remedy wells to be installed as part of the groundwater remedy will assist in assessing baseline concentrations in the injection areas."	Since existing wells will continue to be used to assess baseline conditions and for consistency with RTC #167 DTSC-41, PG&E propose potential edits (shown in green) to DTSC's edits: "New monitoring and remedy wells to be installed as part of the groundwater remedy will be combined with existing wells described above ~~assist~~ in assessing baseline concentrations in the injection areas. For the reasons noted by DTSC in 90% RTC #161 DTSC-39, certain existing wells, MW-13, MW-14, MW-35, MW-37, MW-40, and OW-5 cluster will be re-evaluated and discussed with the agencies prior to assessing baseline concentrations."	For the purpose of assessing baseline concentrations in freshwater injection areas, DTSC requests the following changes to the list of existing wells: **Remove**: MW-13, MW-37, and MW-40: within plume boundary (not appropriate for baseline) MW-14 and MW-35: both wells contained chromium above 32 ppb in past. **Add**: OW-5 cluster			Comment resolved.
162	DTSC-40	Design	Monitoring	2.3.4	"Constituents	Revise the sentence as follows to allow for additional monitoring, "At a minimum, constituents that	Revision will be made as	Resolved.			Comment resolved.

							into the baseline update. The updates to the injection area baseline may or may not change the range and statistics of baseline concentrations."				
168	DTSC-42	Non-design	Editorial	2.3.4.1 Molybdenum/ Page 2-11	Average molybdenum concentrations in the injection area range from 8.77 to 46.01 µg/L, with a mean around 20 µg/L. The calculated UTL for this injection area dataset is 46.8 µg/L (Table 2.3-2), which exceeds the background UTL of 36.3 µg/L. The wells within the influence of IM-3 injection (i.e., the OW- and CW- well clusters presented in Table 2.3-2) have all shown breakthrough of IM-3 effluent water, which contains much lower molybdenum concentrations than the native groundwater. As a result, the average values for these wells have been skewed downward by the IM-3 injection operations. Pre-breakthrough concentrations in some of these wells ranged between 50 and 90 µg/L	The following portions of the cited paragraphs should be revised to more accurately reflect site conditions: "The calculated UTL for this injection area dataset is 46.8 µg/L (Table 2.3-2), which exceeds the background UTL of 36.3 µg/L. Two of the 27 wells currently exhibit concentrations slightly in excess of the background UTL (Table 2.3-2 and Figure 2.3-2). Most of the wells within the influence of IM-3 injection (i.e., the OW- and CW- well clusters presented in Table 2.3-2) have ~~all~~ shown breakthrough of IM-3 effluent water... These data demonstrate that the deeper zones of the injection area contain~~s~~ moderately elevated natural molybdenum concentrations compared to the dataset used for the regional background study."	The first two suggested changes will be included. The second sentence changes will be modified to read: "~~Most~~ Of the wells within the influence of IM-3 injection (i.e. the OW- and CW- well clusters presented in Table 2.3-2), 16 of the 17 wells have water quality that either approaches or is equivalent to that ~~shown breakthrough~~ of the IM-3 effluent water." The third change will be revised to state: "...the deeper zones of the injection area typically contained moderately elevated natural molybdenum concentrations compared to the dataset used for the regional background."	Resolved.			Comment resolved.

DTSC Response: Tribal comment noted.
184	DTSC-48	Non-design	Other	Section 2.4.7, Special Status Species	Special Status Wildlife	Since the 2011 certified groundwater EIR, DTSC has learned of the potential presence of several special status species at or around the proposed project area. In addition to the Townsend's Big-eared Bat that is now a candidate for protection, DTSC also understands that the Ringtail Cat is also a fully protected species and has been sighted at the Station. The Ring-tail Cat should be listed under this subheading instead of an undescriptive paragraph beneath "Other Avian Species." DTSC also understands that Big Horn Sheep have been sighted near the project area as well. Please include these species in the list.	Special-status wildlife list will be revised to include: Townsend's big-eared bat, ring-tailed cat, Nelson's big horn sheep, and the Western Yellow-billed cuckoo. A subheading for 'Other Mammal Species' will be added and text will be provided to describe the status and occurrence of each at or near the site.				
185	FMIT/TRC	Non-design	CEQA/EIR	2.4.7 p. 2-17	Special-Status Species	Please update this section to include discussion of the Thompson long-eared bat	PG&E is unaware of a species called "Thompson long-eared bat," and believes the commenter may be referring to Townsend's big-eared bats. Please see RTC #184 DTSC-48.			Noted.

209	DTSC-54	Design	GW Modeling	3.1.5 Model Update Procedures/ Page 3-5, and section 3.1.5.1	"If there are significant differences, the groundwater flow model, geochemical model, and/or the solute transport model will be updated and recalibrated."	As described here in the cited sentences, model updates will be performed if there are "significant differences" or if "if the data collected suggest that updates are needed". Please define "significant differences" and "if data collected suggest…" DTSC agrees that annual update of flow and solute transport model is appropriate. It is preferable to calibrate the model periodically with measured data to confirm its accuracy and predictions than a subjective decision that it is needed. Update based on subjective "significant differences" is not appropriate. Currently, the predicted remedy duration, by-product generation and plume capture relies heavily on model predictions. PG&E should provide a table with strategy on timing of model verification and recalibration. The section (or references to other sections) should describe as best as possible what would trigger an actual model update.	See RTC #205 FMIT/TRC, #206 Hualapai/TRC, #207 Cocopah/TRC, and #208 Chemehuevi/ TRC.

210	FMIT/TRC RTC, 60% #359	Non-design	GW Modeling	3.1.1/3-1 and 3.1.5/3-4	Use of PEST to reduce uncertainty	The information provided gave further context to the use of PEST in the model development. However, given the long term, high-quality water level data, associated trends in well CrVI concentrations and operational data associated with the IM3 system, PEST should be used to further calibrate key flow and fate/transport model parameters to reduce uncertainty in a key area of the proposed remedial system (i.e., high concentrations nearest river). Doing so now could provide a) greater credibility in modeling results, and b) greater sense that proposed new wells and associated operations are optimal for system performance to meet RAOs/OPS determination.	It is proposed that the model will be updated and recalibrated as per the schedule described in the model update procedure (Appendix B Section 12). Recent hydraulic data and groundwater quality data have been used to update the groundwater flow model and refine the geochemical and solute transport model parameters. The proposed remedy design is not solely based on modeling and additional calibration prior to remedy design implementation would not likely alter the selected remedy approach. PG&E will review and consider the Tribes' response (dated Sept 18 and 21, 2015) to PG&E's evaluation of the MW-X/Y White Paper (dated August 14, 2015). PG&E anticipates that additional discussion on a proposed path forward (including model improvements and timing) to occur at a future TWG.			We continue to believe it is in the best interest of all Stakeholders, including PG&E, to fix noted deficiencies in the model in a timely manner (i.e., see Prucha and Eggers, July 2015 whitepaper). The model would then be re-calibrated to existing flow and fate/transport data associated with the broader IM-3 area (as opposed to local-scale tests used to calibrate some parameters), as this is a key area of the proposed remediation. At a minimum, the existing model should be validated (standard modeling protocol) against IM-3 flow and fate/transport data now to demonstrate that proposed remediation system design and operation are able to reproduce changes in a key remediation area. This would provide greater transparency and more confidence that the existing model (despite noted flaws) does not need to be updated until after construction of the entire system.	DTSC/DOI Response: See RTC #17

					NATIONAL TRAILS HIGHWAY IN-SITU REACTIVE ZONE (NTH IRZ) ENGINEERING DESIGN ELEMENTS AND FEATURES Groundwater Remedy Basis of Design Report/Pre-Final (90%) Design PG&E Topock Compressor Station, Needles, California"	enough to accommodate all uncertainty in model inputs. To give Tribes a better sense that the 'optimized' system injection/extraction rates/locations etc. are indeed flexible enough to accommodate the significant uncertainty in model inputs/ conceptualization of flow, fate and transport etc. – can a range of maximum/minimum possible injection/extraction rates be provided here for each well rather than the range presented? This is important because additional wells might not be required if additional pumping capacity exists at initial remedial wells, beyond the somewhat loosely defined operational range presented here. This becomes even more relevant given the proposed hydraulic testing which is limited to only a few select wells and not necessarily aimed at determining maximum pumping capacities for each and every injection well.	minimum/ nominal/ maximum injection/ extraction rates on a well-by-well basis are presented in Table 3.2-1 of the BOD document.			However, Table 3.2-1 presents what appears to be prescribed values for minimum/maximum rates that were not fully determined through modeling or other rationale. What are the actual min/max possible ranges at each well rather than the desired ranges. Another way to ask this is, could the min/max ranges provided in Table 3.2-1 actually be extended, thereby potentially limiting the need for new wells? Please describe exactly how min/max ranges were defined for each well. It is our understanding that true evaluation of max/min possible rates at each well were never really assessed via modeling, or any other method. This becomes especially important in wells such as riverbank extraction, which would affect potential movement into Arizona groundwater.	Minimum and maximum well injection and extraction rates were estimates through assessment of available hydrogeologic data, current observed operational rates, and modeling. Actual minimum and maximum rates can only be fully determined after well construction through system operation or field testing. DTSC/DOI Response: Tribal comment and PG&E's response noted.

231	DTSC-56	Design	Infrastructures	Section 3.2.1.3, Uncertainties and Assumptions	"…adjustments to injection or extraction locations…"	Please clarify if this implies PG&E will exchange wells from injection to extraction, or changing well locations altogether? If infrastructure locations are changed, what would be the deciding factors to assist in that determination (i.e. why move a location and why would another location be better)?	There are several ways in which injection and extraction locations may be changed to optimize organic carbon distribution and Cr(VI) treatment. Future provisional well locations may be installed. Locations that are not operating may be turned on, or locations that are operating may be turned off. Extraction wells (e.g., IRZ-23) could be turned into injection wells, although this is not likely. Note it is also unlikely that previously used injection wells will be converted into extraction wells. We have found that injection for a period of time into a given well makes it difficult for that well to be used for extraction, i.e., the well dewaters.	Resolved.			Comment resolved.

							Infrastructure location changes may be triggered if the current locations are not sufficient to achieve carbon distribution as detailed in Appendix L, Volume 2, Section 2.2.				
232	DTSC-57	Design	Editorial	3.2.2 Inner Recirculation Loop/ Page 3-15	"…and (3) provide secondary protection for the Colorado River by controlling the migration of potential byproducts generated by the NTH IRZ."	Revise the cited sentence as follows as to better capture the intent of the loop for protection of both groundwater and surface water: "…and (3) ~~provide secondary protection for the Colorado River by~~ controll~~ling~~ the migration of potential byproducts generated by the NTH IRZ."	The sentence will be revised as suggested. The same language used in other sections of the document will also be revised accordingly.	Resolved.			Comment resolved.
233	DTSC-58	Design	Remedial design	3.2.2 Inner Recirculation Loop/ Page 3-15	"Up to four provisional River Bank Extraction Wells (RB-6 through RB-9, to be located within the approximate area shown in Figure ES-4A)…"	Revise Figure ES-4A to allow, if needed, installation of provisional River Bank Extraction Wells to areas south of the I-40. This is requested to control potential migration of the chromium or byproducts downgradient of the southern IRZ. This concept had been requested during the 60%.	The "Area for River Bank Extraction Wells (RB-6 to RB-9)", as shown on Figure ES-4A, will not be revised per the comment as that portion of this area that can be practicably used to construct a well is severely limited by the actual area of dry land. A portion of this area is wetland with the degree of saturation varying by river stage. As discussed in PG&E's 60% RTC #100 DTSC-27, it is PG&E's opinion that it is unlikely that installing a well to the south of RB-5 would provide significant benefit because the saturated thickness of the unconsolidated aquifer decreases as the bedrock contact is approached in this direction. In addition, it should be noted that there may not be much saturated thickness above the bedrock and below the reducing rind in this southern area of the river bank. Nonetheless, in response to 60% comment, a contingency has been included in Table 2.1-1 of the	To clarify, DTSC is concerned with controlling potential migration of chromium or byproducts downgradient of the southern IRZ south of RB-5. As discussed in the 60% RTC #99 DTSC-26, DTSC is concerned that a contingency may not exist to capture/mitigate potential eastbound byproducts or chromium south of RB-5 towards bedrock (e.g., MW-23). DTSC notes that several roads/ routes currently exist in this specific area and is not mandating that contingency extraction wells would have to necessarily be placed along the river's edge. Resolved.			Comment resolved. DTSC response: Aside from ability to install additional contingency extraction well to control potential migration of chromium or byproducts, PG&E must consider the installation of the River Bank extraction wells during the earlier part of the construction phase. The River Bank extraction wells are important safeguards against unexpected mobilization of contaminants, and should be in place for use shortly after initialization of IRZ injection, if needed.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							Contingency Plan (O&M Manual Volume 3) to install additional wells, including wells south of RB-5, to control potential migration of the chromium or byproducts.				
234	FMIT/TRC	Design	Remedial Design	3.2.2.1 p. 3-16 Description River Bank Extraction Wells	Four of the River Bank Extraction Wells (shown on Figure ES-4A) are planned to be operated initially, although flexibility will be provided to operate any and all River Bank Extraction Wells at any given time based on the need to control potential migration of Cr(VI) located down gradient of the NTH IRZ, control byproduct migration	Specific to the control of potential migration of byproduct migration with the use of river bank extraction wells, please indicate where in the 90% BOD detailed discussions are included pertaining to the method used to remove byproducts from extracted/recirculated water. The information provided on the DMRS is not sufficient to evaluate the efficacy of the design.	The remedy will be operated to control byproduct generation at the NTH IRZ and to control migration across the floodplain that may necessitate extraction at the Riverbank. The process for controlling byproduct generation at the NTH IRZ is discussed in Appendix L, O&M Manual Volume 2, the Sampling and Monitoring Plan, Section 2.2.1 under NTH IRZ DQO-3. Per the comment clarification meeting held on April 23, 2015, the commenter is asking where the detailed information on the DMRS is located. PG&E's response to the clarified comment is the DMRS is a contingency system to address manganese and low pH in remedy-produced water in response to Tribes' comment (60% RTC #341). The system design basis including influent water quality, treatment goals, design flowrate, technology, footprint, and sustainability factors are presented in Appendix A of the Contingency Plan, O&M Manual Vol. 3.			The Dissolved Metal Removal System (DMRS) contingency plan was presented in response to concerns regarding the possible effects of remedy byproducts on groundwater pH, integrity of the organic rind, and the quality of the Colorado River. However, there were few discussions regarding possible scenarios where there could be endangerment to the rind and river. We are uncertain what the DMRS proposes to accomplish, except that a large capacity treatment system to treat high manganese or arsenic concentrations would be no different than a classic pump-and-treat system. If this is the case, then the pump-and-treat system should be employed from the beginning. Otherwise, more discussions are needed regarding the possible scenarios that could endanger the river, and what could be done about it. For example, rather than pump-and-treat, how about chemical stabilization of the byproduct plume using reagents? Response unresolved pending further design scenarios and contingency plans.	DTSC Response: The DMRS is PG&E's proposal to manage pH and other scaling compounds that may be present during system maintenance. DTSC is accepting the contingent design for the purpose of CEQA evaluation. PG&E must decide if the DMRS will need to be installed and operated after remedy is in place. Current proposed throughput is 20-35 gpm and not a high volume treatment. PG&E Response: The purpose of the contingent DMRS is to remove scaling ions (iron, manganese, calcium, and magnesium) from remedy-produced water for well and aquifer protection. Contingencies related to migration of Cr(VI) and in-situ byproducts are presented in Table 2.1-1 of the O&M Contingency Plan (O&M Manual Volume 3).
235	Hualapai/TRC	Design	Remedial Design	3.2.2.1 p. 3-16 Description River Bank Extraction	Four of the River Bank Extraction Wells (shown	Specific to the control of potential migration of byproduct migration with the use of river bank extraction wells, please indicate where in the 90% BOD detailed discussions are included pertaining to the method used to remove byproducts from extracted/recirculated water. The information provided on the DMRS is not sufficient to evaluate the efficacy of the design.	See above			The Dissolved Metal Removal System (DMRS) contingency plan was presented in	DTSC response: See RTC #234

				Wells	on Figure ES-4A) are planned to be operated initially, although flexibility will be provided to operate any and all River Bank Extraction Wells at any given time based on the need to control potential migration of Cr(VI) located down gradient of the NTH IRZ, control byproduct migration					response to concerns regarding the possible effects of remedy byproducts on groundwater pH, integrity of the organic rind, and the quality of the Colorado River. However, there were few discussions regarding possible scenarios where there could be endangerment to the rind and river. We are uncertain what the DMRS proposes to accomplish, except that a large capacity treatment system to treat high manganese or arsenic concentrations would be no different than a classic pump-and-treat system. If this is the case, then the pump-and-treat system should be employed from the beginning. Otherwise, more discussions are needed regarding the possible scenarios that could endanger the river, and what could be done about it. For example, rather than pump-and-treat, how about chemical stabilization of the byproduct plume using reagents? Response unresolved pending further design scenarios and contingency plans.

238	DTSC-59	Non-design	Editorial	3.2.2.1 Description River Bank Extraction Well Details/ Page 3-17	"Note that the lower screen of the River Bank Extraction Wells are proposed to be screened beneath the reducing rind to minimize negative hydraulic impacts to this natural reductive zone, and to minimize the potential for well fouling caused by ~~the high dissolved mineral content of~~ the naturally-reduced groundwater of the rind."	It seems that this sentence should be revised as indicated in the adjacent column to emphasize that fouling due to reduced groundwater being injected into an aerobic aquifer is the key issue. For example, high dissolved mineral content is also being extracted from the lower screen, but is not called out as a concern.	Revision will be made as requested.	Resolved.			Comment resolved.
239	DTSC-60	Design	Remedial design	3.2.2.1 Description Inner Recirculation Loop Injection Well Layout and Flow Rate/ Page 3-18	"The current layout of the Groundwater Flow and Solute Transport Model has the two northern Inner Recirculation Loop Injection Wells (IRL-1 and IRL-2)	DTSC has previously requested that the shallow aquifer be managed for TDS at the IRL injection area. PG&E responded by installing dual screen IRL injection wells so that elevated TDS could be injected into similar TDS zones at depth and not adversely impact the shallow zone that has low TDS. DTSC assumed that freshwater would be injected in the shallow screen at IRL 1 and 2 to assist in managing TDS over time. Table 3.2.-2 indicates that a dual screen well is installed, but the upper screen is not being used. Please discuss anticipated impacts to hydraulic movement if upper third of aquifer is not receiving water. The document should be revised to inject an appropriate amount (e.g., 15 to 20 gpm) of freshwater into the shallow screens at IRL-1 and 2. DTSC is concerned that not injecting water into the shallow screens would not protect the shallow TDS (see results of IM-3 injection monitoring). There is also concern whether the groundwater model flow path and particle track figures have been updated throughout the 90% design document that actually portray not injecting into Layer 1 at both IRL 1 and 2.	Although the proposed injection into IRL-1 and IRL-2 is focused on the deeper portion of the screen, it is anticipated that the resultant mounding and increased pressure head will still enhance flushing in the shallow portion of the alluvial aquifer. TDS mixing may occur within the immediate vicinity of	Increasing TDS concentration trends in the shallow aquifer downgradient of IRL-1 and IRL-2 should trigger fresh water injection at those IRLs if TDS levels depart background levels (e.g., greater than ~1,000 ppm).			

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					receiving water from the River Bank Extraction Wells (without carbon amendment) to the lower two-thirds of the saturated interval, while fresh water is injected at the two southern wells (IRL-3 and IRL-4)."		the well, but it is not anticipated to result in any significant density driven flow. Additionally, freshwater is being injected across the full screen of the upgradient freshwater injection wells (IRL-3, IRL-4, and FW-1) at a total nominal rate of 400 gpm (more than that will help to preserve lower TDS values in the shallow portion of the aquifer throughout the area reducing the need for shallow freshwater injection at IRL-1 and IRL-2. Although the need for shallow freshwater injection into IRL-1 and IRL-2 is not anticipated, flexibility was built into the design if it is deemed necessary. Hydraulic gradients and TDS concentrations in the shallow aquifer will be monitored in the vicinity of IRL-1 and IRL-2 to gauge the impact of deep injection into these two wells. If there are steady increasing TDS concentration trends in the shallow aquifer downgradient of IRL-1 and IRL-2, freshwater injection into the shallow screen of IRL-1 and IRL-2 will be considered. Groundwater flow modeling and particle pathlines indicate that without shallow injection in IRL-1 and IRL-2, the resultant gradient magnitudes are similar. The greatest impact is the radial distribution of particles around IRL-1 and IRL-2 shallow is narrowed and at depth is widened, but there is not a significant impact on the remedy performance. Figures will be adjusted	Comparison to approaching deep TDS concentrations that can exceed 10,000 ppm is not appropriate.

					O&M Manual, Volume 2, Section 2.2.2.						
248	DTSC-61	Design	Remedial design	3.2.3 TCS Recirculation Loop/ Page 3-22	Exhibit 3.2-3 “…maximum flow includes up to 75 gpm of freshwater”	The basis and triggers for adding up to 75 gpm freshwater to the TCS loop needs to be discussed as it is lacking in the document. Discussion is also lacking in Section 3.3.3 and Exhibit 3.3-4.	Freshwater would be used in the TCS Recirculation Loop should yields from the Transwestern Bench Extraction Wells and East Ravine Extraction Wells be insufficient to promote treatment in this area,. The maximum of 75 gpm is specified to match the design maximum injection flow rate. However, this scenario is not likely. We recommend moving this potential scenario of injecting freshwater into the TCS injection loop to Appendix L, Volume 3, the Contingency Plan, Table 2.1-1 in the TCS Recirculation loop section. This section will acknowledge that a plan for arsenic monitoring wells and establishing baseline arsenic conditions including prior carbon injections in the area would be required prior to changing operations to injection of freshwater at the TCS injection wells. The quoted design detail on use of freshwater at the TCS injection loop in Exhibit 3.2-3 in the main BOD will be deleted. The following text will be edited in Section 3.2.3.3 Uncertainties and Assumptions, “Modifications to operations and design may include adjustments to injection rates, extraction rates, <u>augmentation of injection rates with freshwater</u>, and/or organic carbon loading.”	Resolved.			Comment resolved.
249	DTSC-62	Design	Remedial design	3.2.3.1 Description/East Ravine Extraction Well Details/	“Up to 6-inch nominal diameter carrier casing would be set to	Is there any advantage to drilling the East Ravine extraction wells with larger diameters (e.g., 12-inches as previously proposed) to better accommodate anticipated well cycling due to low yield?	Based on the hydraulic testing of the bedrock wells previously constructed in the East Ravine area, PG&E	Resolved.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
				Page 3-23	the top of competent bedrock, or a minimum of 20 feet bgs."		anticipates that the East Ravine extraction wells will be low yielding relative to wells installed within the unconsolidated aquifer. Therefore, it is anticipated that the current design, which utilizes 5-inch diameter wells/boreholes, will be sufficient to operate submersible pumps up to 4-inches in diameter. A 4-inch diameter pump is capable of providing flows in the tens to hundreds of gallons per minute (gpm), which is significantly greater than the less than 10 gpm yield that is current estimated for these wells. Therefore, there is not a significant advantage to constructing the East Ravine extraction wells with a larger diameter at this time; however, as discussed in the response to comment 950 (DTSC-171), the diameter of the carrier casing will be increased to 12-inch to allow for reaming the bedrock borehole to a larger diameter at a future date if well performance were to decline significantly or if actual well yield warrants a larger pump.				
250	DOI-4	Non-design	Other	3.2.3.1/3-23	Up to 6-inch nominal diameter carrier casing would be set to the top of competent bedrock, or a minimum of 20 feet bgs.	The latter part of this statement is confusing. It indicates carrier casing would not be set at the top of bedrock if bedrock were greater than 20 feet bgs, and if bedrock were near the ground surface, it indicates the casing would be set 20 feet into bedrock. Neither scenario seems logical. Suggest deleting "or a minimum of 20 feet bgs".	The carrier casing diameter is now 12-inch per RTC #950. The sentence will be clarified as follows: "Up to 12-inch nominal diameter carrier casing would be set to the top of competent bedrock, or a minimum of 20 feet bgs. A minimum of 20 feet of carrier casing is required to comply with State well regulations for a sanitary seal."		Resolved		Comment resolved.

264	DTSC-64	Design	Request for Information	Section 3.2.4.1, CIP description, page 3-28, 2nd paragraph	"… and clean water will be used to flush the lines."	Is this water from Arizona? Where is the source of the clean water for line flushing?	The clean water referenced in the specified text is anticipated to be freshwater from Arizona, although conditioned water from the Remedy Produced Water Conditioning Plant may also be considered. The text will be revised to read "freshwater or conditioned water" in place of "clean water".	Resolved.			Comment resolved.
265	DTSC-65	Design	Editorial	3-31	Below-grade piping will be constructed with HDPE pipe in a standard construction trench.	Additional text describing above-grade piping construction, similar to the description for below-grade, should be added for clarity.	The IRZ system design does not include above-grade piping outside of the MW-20 Bench; thus, text describing above-grade piping construction is not considered applicable to this section (Section 3.2.5.2 of the BOD).	Resolved.			Comment resolved.
266	DTSC-66	Non-design	Editorial	3.3.1 Freshwater Supply Sources/ Page 3-32	"However, the groundwater in the shallow zone beneath the river contains water that is geochemically reduced and contains elevated concentrations of iron and manganese, which could foul the injection wells. It is likely that a conditioning system would be needed to remove iron and manganese before the water pumped from beneath the river bottom could be used in the injection wells. Therefore, no matter whether water was extracted	As part of TDS groundwater management discussions, PG&E has recently cited data from deep extraction well PE-1 and how it indicates that initial deep water conditions (e.g., high TDS) have changed over time due to capture of groundwater from the shallow zone. PG&E indicates that high TDS concentrations indicative of the deep zone will be a transient condition and lower in concentration as Riverbank wells operate over the years. It is noteworthy that the PE-1 data also indicate that iron and manganese in the deep portion of the aquifer actually decrease over time along with the TDS. This suggests that the shallow zone in the vicinity of PE-1 might have minimal effect with regards to injection well fouling should a shallow infiltration gallery beneath the river be ever be installed. Therefore, revision of the cited text is requested.	PE-1 is completed in a zone of coarse sand and gravel that lies at a depth between 90 and 100 feet just above bedrock. Unlike the shallow sediments near the river, this zone is sufficiently oxic to contain Cr(VI). Thus PE-1 is not representative of the geologic materials or the geochemical reducing conditions in shallow floodplain where an infiltration gallery would be installed. The concentrations of iron and manganese typically found in the shallow floodplain wells (at depths typical of an infiltration trench) would quickly foul an injection well. While it is true that after extended pumping the water quality from an infiltration gallery might improve, PG&E does not agree that one could assume no treatment would be needed for	Resolved. This issue should be studied during remedy operation of extraction wells along the floodplain.			Comment resolved.

					directly from the river or from beneath the river bed, some type of conditioning system would be needed to make river water usable for injection."		water sourced from an infiltration gallery. We propose to revise the text be revised as follows: "It is likely that a conditioning system would be needed, <u>at least during the first few years</u>, to remove iron and manganese <u>from groundwater that is extracted from more reduced portions of the aquifer beneath the river such that the potential for fouling of the associated injection wells is minimized</u>."				
267	DTSC-67	Design	Contingencies	3.3.2 Evaluation of Freshwater Supply Sources/Selection of Preferred Source/ Page 3-34	EXHIBIT 3.3-1 "Because of this separation of freshwater storage, the tie-in of Topock-2 and -3 wells has been eliminated in the 90% design."	It is requested that the tie-in be retained as DTSC believes that the Topock-2 and -3 wells could easily act as an immediate contingency measure to supplement the remedy that would not require delay or added infrastructure.	Topock-2 and -3 wells currently supply freshwater for TCS use for fire protection and operational needs, via the existing 6-inch pipeline. At the 60% design stage, it was decided to separate the freshwater supply for TCS and remedy to ensure that the use of the infrastructure designed and constructed under this project is prioritized for remedy use first (see 60% RTC 168 DTSC-63). Hence the tie-in of Topock-2 and -3 wells was eliminated in the 90% design. To tie in Topock-2 and -3 wells for remedy use, additional infrastructure will be needed within the Compressor Station footprint. In response to DTSC's request, additional details that describe this tie-in were provided for review during the 90% RTC period and included in **Attachment E** of the final RTC table. Please note that if there is competing need for Topock-2 and -3 water, the first priority for this	**Attachment E** should also include the design of the piping from the gate valves to the remedy fresh water tank in both map and section view. Note that DTSC would consider the Topock 2/3 water as an immediate			**Attachment E** was revised to address DTSC's comment.

274	DTSC-70	Design	Contingencies	3.3.2.1 Uncertainties and Assumptions/ Page 3-38	EXHIBIT 3.3-2 "Bring Site B well online." Multiple occurrences.	First occurrence: Revise text as follows: "Supplement flow with water from Topock 2/3 or bring Site B well online potentially with a FWPTS for both arsenic and chromium." Second occurrence: Revise text as follows: "Bring on Topock 2/3 to supplement flow or bring Site B well online potentially with a FWPTS for both arsenic and chromium." Last occurrence: Revise text as follows: "Bring Site B well online along with a FWPTS for both arsenic and chromium."	In the event Site B well is needed to be brought on line (after the identified operational actions have been exhausted), PG&E will first collect sample(s) to confirm the Cr(VI) and As concentrations in the well. Site B water will be blended with water from other wells (e.g., HNWR-1, Topock-2 and -3). With the low levels of Cr(VI) (34 ppb) detected in Site B well in 2014, PG&E does not anticipate needing Cr treatment. PG&E will discuss with the Agencies before implementing any contingency measure. PG&E suggests additions edits (shown in green) to DTSC's edits: First occurrence: Revise text as follows: "Supplement flow with water from Topock 2/3 or bring Site B well online. Blend Site B water with water from Topock-2/3 and/or HNWR-1. Potentially implement ~~with~~ a ~~FWPTS~~ contingent ~~for both~~ arsenic ~~and chromium.~~ treatment system per State Water Resources Board letter (SWRCB 2013)[1]" Second occurrence:	See RTC # 135 on potential water quality issues associated with Site B well. Additionally, fresh water chromium concentrations in HNWR-1A/HNWR-1 could trend up over time during the life of the remedy. PG&E should not adversely impact the quality of the aquifer outside of the chromium plume from injection in California. The use of Site B contingency may not be needed, its use, however, may necessitate pre-treatment of the water prior to injection to maintain the water quality at the point of injection. Since chromium in the water from the Site B well has always been higher than the current MCL (10 ppb) and the current receiving water quality (shallow aquifer averages around 16 ppb), pre-treatment of chromium may also be required, not only arsenic.

					brought online to supplement any shortage in flow if needed.”		with added infrastructure within the Compressor Station footprint. In response to DTSC’s request, additional details that describe this tie-in was provided for review during the 90% RTC period and included in **Attachment E** of the final RTC table. If there is a competing need for Topock-2 and -3 water in the future, the first priority for this water, as noted in 60% RTC 168 DTSC-63, is for fire protection and operational needs at the Station, and that priority cannot be changed.				
286	DTSC-74	Design	Remedial design	3-42	Exhibit 3.3-4, Water Pipe Based upon this design approach, no cathodic protection is required.	Conflicting statement issue: App C 5.1 Corrosion Control states above and below ground steel pipe will be coated. Any steel pipe near the point where it emerges from the ground will be coated. Air-to-soil transition piping is any steel piping located 18" below ground or 6" above ground. Cathodic protection equipment will be applied as follows: 1) steel piping and structures will be cathodically protected underground; 2) plastic pipe will be preferentially used when appropriate for corrosion resistance; and 3) steel pipe will be cement mortar-lined to prevent internal corrosion. The text above seems to contradict this revision in Exhibit 3.3-4 from RTC #173. Either change BOD 3.3.3.1 (and other similar sections dealing with corrosion protection for steel pipe) to conform to the requirements for cathodic protection in Appendix C or change the requirements and explain/justify why cathodic protection is not necessary in Appendix C.	The text in section C.5.1 will be revised to clarify where cathodic protection is necessary as opposed to other listed corrosion control needs.	Resolved.			Comment resolved.
287	DTSC-75	Design	Remedial design	3.3.3 Design Basis for Freshwater Supply System/ Page 3-43	“As a result of its evaluation, PG&E recommended modifications to select structural members of the Arched Bridge (see Appendix G). PG&E Gas Transmission, as the entity responsible for the pipe bridge within the PG&E organization, is leading the discussion with Kinder Morgan regarding modifications to the Arched Bridge.”	There is some concern with the lack of progress on the recommended structural modifications as this item has lingered for some time. What are the issues and is there a problem? What is the schedule for completing discussions? Modification of the Arched Bridge will need to be considered in the upcoming CEQA evaluation. Although PG&E does not believe the bridge modification to be remedy related, the bridge will carry remedy components and should be considered, at a minimum, a cumulative impact evaluation.	PG&E and Kinder Morgan are working through the details regarding bridge modification. It is anticipated that the bridge modification will commence in late 2015; completion is scheduled for April 2016. PG&E will keep the agencies updated on the progress. The Arched Bridge modification is a PG&E Gas Transmission project and has independent utility from the Project. The project is being completed to add lateral support to the bridge. PG&E defers to DTSC on how it may consider the modifications in future cumulative impact	Okay.			Comment resolved.

300	DTSC-77	Design	Contingencies	3-51	Sub-section 3.3.3.2 and 3.3.3.3 As discussed in RTC #168 DTSC-63, to ensure first priority for remedy use and after further evaluation of the additional controls, instrumentation, and tank upgrades that would need to be installed in the existing tanks in order to harmonize various demand for freshwater, PG&E now proposes to separate the freshwater supply storage for the remedy and the Compressor Station in the 90% design. A separate and smaller tank (10,000 gallons) will be installed inside the Compressor	The new storage tank for remedy only use of freshwater is 10,000 gallons. At the maximum total injection rate of 900 gpm the tank will empty in 11 minutes. Even at the nominal injection rate the reserve is severely limited. The issue of reserve capacity was brought up in the 60% RTC. The 60% RTC states 7-27 hours of reserve for injection wells is available based on the then 420,000 gallons of storage (TCS supply tanks for operations). The BOD states injection of freshwater is needed to provide hydraulic control to prevent migration of the chromium plume beyond the identified boundaries. Given the reduction in storage capacity with the modified design, a contingency should be included in the BOD (App L, vol. 3 seems appropriate) to ensure adequate supply to the injection wells in the event the freshwater supply is interrupted.	The provision to tie-in ~~of~~ Topock-2 and 3 wells, via the existing 6-inch supply line~~, TCS freshwater storage tanks, to the Remedy freshwater storage tank~~ will essentially supplement the remedy freshwater flow by an amount that equals to the supply flow rate from the wells minus any usage by the Compressor Station at that time ~~of increase the total storage capacity of freshwater up to 430,000 gallons (maximum)~~. If there is a short term loss of the freshwater source (on the order of days or weeks) it is not likely hydraulic control of the plume will be lost as the average groundwater velocities are still relatively slow and the natural ambient gradient is still from west to east, which would limit the potential for plume migration beyond the plume boundaries. As this is a long term remedial approach, short term down periods of the freshwater injection wells will not have a significant impact on the longer term	Resolved.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					Station for remedy use only and will be supplied by well HNWR-1A from Arizona.		regional hydraulic gradients. In the case of FW-2, the operational rate of the TCS Injection Loop can also potentially be adjusted to minimize the potential for westward expansion of the plume due to TCS injection. Additional details regarding this tie-in were provided for review during the 90% RTC period and included in **Attachment E** of the final RTC table.				
301	FMIT/TRC	Non-design	Request for Information	3.3.3.2 Page 3-44 Freshwater Supply Storage	An analysis of the fire protection water system hydraulic performed at the 60% design stage suggested that there is adequate storage capacity to meet the fire flow storage requirement that can be shared with the remedy, as long as there is sufficient supply	Please state exactly the quantity needed for fire flow storage, how is this quantity affected if more injection wells are added? What is considered sufficient supply?	The maximum fire water demand is 642 gallons per minute for remedy facilities on the MW-20 Bench and TW Bench (see “MW-20 Bench and TW Bench Carbon Amendment Buildings Fire Suppression Calculations” in Attachment B of Appendix C). Typically, volumetric demand is based on one hour flow, so this would result in 38,520 gallons. This demand is much smaller than the combined storage capacity of 420,000 gallons of the existing TCS freshwater storage tanks, therefore, supply of fire protection water for remedy facilities is adequate. As mentioned in 60% RTC #168 DTSC-163, to ensure first priority for remedy use and after further evaluation of the additional controls, instrumentation, and tank upgrades needed to be installed in the existing TCS tanks in order to harmonize various demand for freshwater, PG&E had proposed to separate the freshwater supply storage for the operation of the remedy and the Compressor		Response noted. 							Station in the 90% design. As a result, PG&E designed a separate and smaller tank (10,000 gallons) inside the Compressor Station for remedy use only and the tank will be supplied by well HNWR-1A from Arizona. Fire protection water for the remedy facilities will continue to be supplied by the existing TCS freshwater storage tanks. Therefore, the fire protection water storage volume will not be affected if more injection wells are added.

309	FMIT/TRC	Design	CEQA/EIR	3.3.3.3 p. 3-45 Freshwater Injection Wells	Consideration will be given to installation of an additional well to ensure that sufficient injection capacity is available for the life of the remedy. If the low capacity of the well appears to be due to low permeability in the aquifer, the new well should be located some distance away	If numerous wells are installed in one location how will this be reflected in the total EIR well count? Will this be considered one well or numerous wells?	The design for the freshwater injection wells only includes one well per location (FW-1 and FW-2), but acknowledges that if sufficient injectivity cannot be achieved at a given location with one well then additional wells may be required. The injection wells will be constructed and operated according to industry best practices to maximize well effectiveness (i.e., injectivity) and lifetime. That said, the geologic conditions at a given location might limit the		DOI defers to DTSC regarding well count.	The Tribe disagrees with the agency rational that replacement wells installed in the vicinity of an abandoned, once operable well do not increase the total remedy well count: It is the additional environmental impact that is potentially significant, not just an abstract numerical increase. The Tribe would like to reiterate that the groundwater remedial infrastructure is being installed in a Sacred landscape and any additional borehole	RTCs related to well count were discussed at the July 23 and August 18 TWG meetings. DTSC response: DTSC has clarified for years that the well count considered in the 2011 FEIR was provide by PG&E during the conceptual stage of the remedy. DTSC has since the 2011 FEIR (as early as August 2013 as comment to the 60% design), clarified in CTF meetings, CWG

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					from the existing well in hopes of finding better aquifer materials. Any additional wells needed to achieve this capacity would be installed in the same area as the primary well. Well drilling at any one area would only continue until this target of three times the design capacity was reached. There is also a possibility that the design flow rates for individual well locations could be adjusted to allow for somewhat more injection in the higher permeability locations and somewhat less injection in the lower permeability locations. In sum, there may be more than one well installed at the FW or IRL well locations initially to ensure sufficient capacity		effectiveness of an injection well, and it might be determined that additional injection wells are required for proper remedy operation. In this scenario, it is expected that these additional wells, which would be identified in the construction or early O&M phase of the project, would be counted as new boreholes. Alternatively, if the initial injection well(s) are determined sufficient for proper remedy operation but become inoperable over time during the O&M period, such as through clogging or damage, then replacement wells might be required. The FEIR defines the process for establishing a replacement well in that the existing well would be abandoned and replaced with an entirely new well. The new well would be located close to the existing well, within the areas currently designated in the EIR (see Exhibit 3-4 of the FEIR). Unless the new well encountered different geologic conditions and/or has significantly smaller capacity than the well it replaced, there would be no net change in the total number of existing wells. If the new well has significantly smaller capacity, it might be necessary to replace an existing well with two new wells under certain conditions. Replacement wells put in the same location as original wells were not counted as additions to the estimated number of wells disclosed in the			placed in the ground is considered a significant impact to cultural resources. All wells regardless of use, name, or placement should be included in the overall well count. In addition, any increased number of allowable wells that may occur in the future SEIR is a continuation of project scope creep that has occurred throughout the groundwater remedy design process without apparent significant concern for the effect on a unique archeological and historically significant resource.	meetings, TWG meetings and in 60% RTCs (see RTC #228 and #632 from 60% design) that the design must be based on identified purpose and need, and not the borehole constraints stated in the FEIR. DTSC has committed to conducting an SEIR for additional wells identified.

320	FMIT/TRC	Design	Infrastructures	3.5.1 p.3-58	Electrical Power Supply First paragraph	While it is possible that the new air compressor building will generate relatively low sound power levels in comparison to the other noise sources at the TCS, and that the new air compressors will generate less noise than the old compressors, the design documentation should inform all of the sound power levels of these new sources in the context of the sound power levels of existing sources at the TCS. These new noise sources should be included and quantified in Table D1-13 of Appendix D. Going forward in time, the TCS should implement a meaningful noise mitigation program to reduce TCS noise impacts on cultural and religious use of adjoining properties and parcels.	The TCS, including its new air compressor building, is not part of the project. Thus, it is not appropriate to include in the table of aboveground non-emergency remedy equipment (Table D1-13 in Appendix D). Although the TCS equipment may increase ambient noise levels, the project's contribution to cumulative noise impacts would remain as disclosed in the EIR. Additional mitigation measures, such as a noise mitigation program, to control noise from the TCS would lack a nexus to the proposed project.		Comment and response noted.	Just because TCS improvements, necessitated by and integral to the remedy project, may have some additional, future utility for TCS operations, it does not follow that the improvements are not included within the remedy project. It is the position of the Tribe that these improvements are indeed part of the remedy project. Therefore, this comment is considered unresolved. See also RTC 48 FMIT/TRC.	DTSC response: DTSC has deliberated on this matter with legal representatives of PG&E and determined that the TCS improvements are not specifically part of remedy infrastructures but must be considered in the cumulative impacts of the SEIR.
321	Hualapai/TRC	Design	Infrastructures	3.5.1 p.3-58	Electrical Power Supply First paragraph	While it is possible that the new air compressor building will generate relatively low sound power levels in comparison to the other noise sources at the TCS, and that the new air compressors will generate less noise than the old compressors, the design documentation should inform all of the sound power levels of these new sources in the context of the sound power levels of existing sources at the TCS. These new noise sources should be included and quantified in Table D1-13 of Appendix D. 							documented in Tables ES-2A and ES-2B, and redundant discussion of the number of boreholes/well locations will be removed from the text in Section 3.6.				
334	DTSC-82	Design	Monitoring	3.6 Monitoring Well Design/ Page 3-65	"Preliminary screen interval estimates for each of the proposed supplemental monitoring locations are provided in Table 3.6-1. However, the details included in this table are estimated and will likely change as additional data are collected during construction.	The preliminary screen interval estimates for each of the proposed monitoring locations were <u>not</u> provided in Table 3.6-1 of the September 2014 90% submittal. An updated Table 3.6-1 for all new monitoring wells was provided in the February 2015 supplemental submittal. See separate comment below regarding screen interval lengths. Some initial concerns with screen intervals for those intervals provided in Table 3.6-1 are identified below and should be addressed: MW-HH/II: Revise the document to have two screened intervals (from 20 to 40' long) at each well location to maximize coverage of the aquifer thickness (also to assess if TDS stratification affects injected water flow). MW-FF/GG: Table 3.6-1 indicates two intervals monitored, yet cross-section D-D' (Figure 3.1-5) illustrates four. Revision is required based on this discrepancy. Obviously, DTSC would prefer four zones to monitor the entire aquifer thickness as depicted in Figure 3.1-5, but recognizes that Tribes would want only one borehole and PG&E would probably propose two boreholes to monitor four zones in this area. Discussion is needed. A number of alternatives/options exist including: utilizing Westbay/Solinist-type wells to screen multiple zones while using one borehole; Utilizing packers to separate two screened intervals; Installing three monitoring zones in one borehole; and Alternating/offsetting dual screened zones in wells MW-GG/MW-FF. Of course, hydrogeological information obtained from nearby/associated wells MW-Q and IRL-4 could assist in the final well design. Aquifer testing at IRL-4 with MW-Q and possibly MW-J and MW-R as observation well clusters (all proposed to be screened with four intervals) is currently requested to assist in assessing more permeable zones in the area which may help guide the number of monitoring intervals in MW-GG/MW-FF. The exact same issues exist for the other Arsenic Monitoring wells (MW-AA to MW-EE) except as the aquifer should thicken to the north, the need for additional screened intervals is further supported towards the north.	See RTC #336 DTSC-84 regarding MW-HH and II. Regarding MW-FF and GG, the cross section that indicates four monitoring intervals pre-dates the finalization of Table 3.6-1 for the 90% design submittal. The cross-section will be revised to show two monitoring intervals in accordance with Table 3.6-1; however, it should be noted that Table 3.6-1 includes estimated design details based on hydrogeologic information collected to date. As indicated in footnote 1, the actual design details are subject to change based on observations in the field. Alternative monitoring well designs are evaluated in Section 3.6 of the design (see also the comment and response to comment 336 [DTSC-84]). Rationale for the collection and use of field data is provided in Section 3.2.1 of the C/RAWP. Also see the response to comment 346 (DTSC-86) regarding the number of screen intervals required at each location.	Resolved.			Comment resolved.
335	DTSC-83	Design	Monitoring	3.6.1 Key Variables and Well Design Considerations Borehole Quantity Constraints/ Page 3-66	"However, the number of available boreholes is limited (DTSC 2011d). No more than 60 boreholes can be installed for the construction of monitoring wells. To date,	This paragraph should be revised to be consistent with DTSC's position on well counts. DTSC has repeatedly clarified that although the total number of wells should be minimized to address tribal concerns, but should be sufficient for proper operation and monitoring of the remedy. The cited monitoring well count was based on an estimate generated by PG&E circa 2009 when the CMS was being developed and when the proposed remedy was highly conceptual. The estimated well count was also established prior to the East Ravine and compressor station evaluations which, at the time, were thought to be uncontaminated by PG&E. However, for clarity of the design, the total number of boreholes planned for the remedy should be documented. According to an August 2, 2014 email from CH2MHill, PG&E is planning to install 53 monitoring well locations and 4 provisional locations that totals to 73 monitoring well boreholes when including the existing 16 wells). Please verify the current count and clearly indicate in the design document.	The "Borehole Quantity Constraints" portion of Section 3.6.1 will be re-written to speak to the design requirement of minimizing the total number of boreholes drilled for construction of the remedy monitoring network and not include discussion of the specific quantity of wells/boreholes. The	Resolved.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					16 of the allotted 60 boreholes have been installed as part of the investigation activities in the East Ravine area. As a result, 43 boreholes remain available for monitoring well construction associated with the final groundwater remedy.”		total number of boreholes planned for the remedy is documented in Tables ES-2A and ES-2B, and these tables supersede the information provided in the August 2, 2014 email referenced by DTSC in this comment. As stated in Tables ES-2A and ES-2B, the estimated borehole count is 100 for planned monitoring and remediation wells and 70 for future provisional monitoring and remediation wells, which when added to the existing 18 boreholes, totals 188 boreholes. A reference to these tables will be added to the revised text, as indicated below: “**Borehole Quantity Constraints:** Multiple monitoring depths will ~~likely~~ be needed at ~~each~~ the majority of new monitoring locations. Using conventional well design ~~most commonly used at Topock,~~ each monitoring interval would require a separate borehole. However, the number of ~~available~~ boreholes ~~is limited~~ drilled to construct the remedy well network will be minimized to address tribal concerns, yet must be sufficient for proper operation and monitoring of the remedy. ~~No more than 60 boreholes can be installed for the construction of monitoring wells. To date, 16 of the allotted 60 boreholes have been installed as part of the investigation activities in the East Ravine area. As a result, 43 boreholes remain available for monitoring well~~

							~~construction associated with the final groundwater remedy.~~ ~~If~~ Therefore, utilizing an alternate well design ~~were used~~ that could monitor multiple zones within a single borehole and meet groundwater monitoring objectives (thereby minimizing the total number of boreholes required)~~, the 19 proposed locations would require 19 total boreholes and 24 boreholes would remain available for future groundwater monitoring requirements. However, if multiple boreholes are required at some or all of the 19 locations, the flexibility to install wells later on to meet future monitoring requirements may be limited. Therefore, monitoring well designs that require fewer boreholes to meet the monitoring objectives are~~ is strongly preferred at the Topock site. Tables ES-2A and ES-2B (Executive Summary of this document) provide a detailed accounting of the planned and future provisional boreholes included in the design of the groundwater remedy for both monitoring wells and remediation wells."				
336	DTSC-84	Design	Monitoring	3.6.3 Well Design Selection/ Page 3-70	"The new monitoring wells are also designed to monitor remedial activities and will generally have longer screen lengths. The exception to this may be the wells designed to monitor the distribution of carbon along	New contaminant plume monitoring wells should be designed just like the hundreds of existing monitoring wells that were used to discretely characterize the plume. These existing monitoring wells are also proposed to be part of the monitoring network. Having two differing designs may lead to additional interpretation problems, diminish the value of the historical data base, and potentially lead to more wells in the future. As a general rule, contaminant plume monitoring wells should be constructed with screen lengths of 10 to 20 feet. Request screen interval changes to 20 feet in the following Table 3.6-1 wells: MW-O, U, V, X, Y, and slant wells. Additionally, two intervals should be monitored at well MW-V. Monitoring wells used to monitor gross changes in water quality (e.g., effects of groundwater injection) can use larger screen lengths similar to that already used at the OW and CW series wells (20 to 50 foot screen intervals). Revision of the section is required. Additionally, low flow purging is currently not proposed for longer screened wells (such as CW	PG&E agrees that plume monitoring wells should be designed for compatibility with the existing monitoring wells since they will be integrated as part of the remedy monitoring program. The screen lengths provided in Section 3.6 of the design were estimated to balance the anticipated data needs (based on estimated aquifer thickness) and the goal of minimizing the total	Resolved. 							(previous bullets). The exception to this will be for MW-HH and II, where the "Estimated Number of Intervals to be Monitored" will be increased to two (in response to comment 334 [DTSC-82]) and the estimated interval will be decreased to a depth range of 40 feet since the estimated saturated thickness is only 90-93 feet. • The following text will be added to the end of footnote 1: "<u>As requested by DTSC, at least three monitoring intervals (shallow-middle-deep) will be utilized to monitor portions of the aquifer that are 250 feet in thickness or greater.</u>" • In response to comment 346 (DTSC-86) the "Estimated Number of Intervals to be Monitored" for MW-AA, BB, and CC will be changed from "2" to "3". Per the fourth bullet in this response, the number of intervals for the slant wells will have a reference to new footnote 3. PG&E agrees that the use of multiple groundwater sampling techniques at monitoring wells across the same site is not ideal. At the time of the design, and in				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							coordination with DTSC, PG&E is methodically integrating the low flow sampling technique as a replacement for the three volume purge technique, and intends to utilize only the low-flow technique provided the trial data is supportive. Regarding the consideration of the appropriate number of monitoring intervals to assist with hydraulic interpretations, the estimated screen lengths and vertical arrangement within the aquifer will be adequate to assess hydraulic conditions in the shallow, middle, and deep intervals, as is current practice at the site.				
337	FMIT/TRC	Non-design	Editorial	3.6.3 Page 3-70 Well Design Selection	In addition, these well types can generally be decommissioned in place, which is the preferred decommissioning method as it represents the field procedures that are least intrusive and create the least amount of disturbance.	This statement appears not to support the well decommissioning protocol which specifies that wells will be decommissioned on a well by well basis. Please ensure that the language included in the BOD report supports the commitment to address decommissioning on a well by well basis with Tribal stakeholder involvement	The referenced language is consistent with Well-SOP-1 in that decommissioning a well in place is the preferred decommissioning method because over-drilling is not necessary. That said, the 4th paragraph of Section 3.6.2 will be modified as follows: "Key design details associated with conventional, nested, and multi-level well types as they relate to the design constraints are provided below. <u>Well decommissioning considerations for each of the designs are also presented in this section; however, the actual decommissioning methods used will be determined for each well at the time of decommissioning.</u> Monitoring well designs are included in drawings C-16-01 through 03 of Appendix D, Plans			As the Tribe has stated many times throughout the design process Tribal preference is for all remedial infrastructure to be removed from the Sacred Landscape. This includes wells and well casings.	DTSC Response: Revised language provided for a well by well decision on decommissioning. However, in DTSC and DOI's joint direction letter to PG&E on 4/4/2014, the Agencies required PG&E to remove subsurface infrastructures to the extent possible. DTSC is also directing PG&E to consult with landowners for their ultimate preference. For well decommissioning, which is the original comment, PG&E will follow the Standard Operating Procedure in O&M manual Volume 1, Appendix B.

356	FMIT/TRC	Design	Remedial Design	Section 4	Entire section	This section is incomplete therefore it is difficult to make any meaningful assessment of this section. Is there a timeline regarding when the various elements of this Sustainability assessment will be completed? What will be the review process for the future elements of this part of the design documents?	This section discusses the framework for and presents the results of the integration of sustainability principles and practices into the design. Ten sustainability factors were identified as applicable for the Topock remedy design and implementation as well as IM decommissioning; these factors are listed on page 4-2 of the 90% BOD. For each sustainability factor, several BMPs were identified and tabulated in the Green Remediation Evaluation Matrix (GREM) (see Table 4.0-1). The BMPs listed in the GREM were incorporated into each design stage (30%, 60%, 90%); the design documents were reviewed and comments on by agencies, Tribes, and stakeholders. The GREM will be scored when implemented during remedy construction, IM decommissioning, and when the system is in operation.

							caused disturbance to project facilities or significant cultural resources. *See* Sections 2.2 (Inspection) and 2.3 (Notification and Reporting) of the Site Security Plan, Appendix Q to the Construction/ Remedial Action Work Plan. In the course of performing its obligations under the Site Security Plan, if PG&E observes groundwater well installation unrelated to the remedy on private lands in the vicinity of the plume or remedy infrastructure, PG&E will notify DTSC and DOI. PG&E notes that there is limited private land ownership (PG&E, FMIT and BNSF property) within the footprint of the chromium plume and the areas outside the plume where control of groundwater flow directions and gradients is necessary to contain and remediate the chromium plume (see Figure 5.1-1 of the BOD). For the parcel owned by the FMIT, there is a Covenant and Environmental Restriction recorded, which prohibits the construction of water wells unrelated to the remedy until and unless DTSC and all other applicable governmental agencies approve such construction of wells. Additionally, PG&E and DTSC are discussing relevant institutional controls, including potential restrictions on water extraction unrelated to the remedy, at the Topock Compressor Station parcel. PG&E defers to DOI		by the Selected Remedy for the Site are specified in the BLM Lake Havasu Field Office Resource Management Plan issued in May 2007 and in the 1994 Lower Colorado River National Wildlife Refuges Comprehensive Management Plan. These plans restrict surface uses and use of the groundwater. Institutional controls will remain in place for the duration of the remedy until RAOs are achieved.”		

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							regarding groundwater well installation on federal lands.				
361	DTSC-97	Non-design	Legal	Section 5, page 5-1, 3rd Paragraph	"It is PG&E's understanding, after discussion with DTSC and DOI, that with respect to the majority of privately-owned lands, access agreements from existing landowners are appropriate IC mechanisms."	Although DTSC agrees that access agreements may provide some protection over the remedy (especially if infrastructure is located within the private parcel or access is needed for further site investigations). Access agreement alone, however, may not be sufficient to meet the objective of preventing interference or degradation of the hydraulic influence from the remedy. Access agreements also will not prevent the installation of new groundwater wells on private properties. PG&E should carefully consider the type of IC or agreement needed for the protection of the remedy at each privately held parcel that may have effect on the remedy and negotiate the appropriate agreements needed.	See RTC #361 DTSC-97. Additionally, the need for and effectiveness of institutional controls for the remedy will continue to be evaluated in the future, including during 5-year reviews to be conducted by DTSC and DOI.	Resolved.			Comment resolved.
362	FMIT/TRC	Design	Remedial Design	Sect. 5.1.1, p. 5-1	Arsenic monitoring wells	The Tribes are aware of the California State Water Board's position related to arsenic in groundwater near the freshwater injection wells. However, the Tribes had no input on the Water Board's decision to construct sentinel wells at proscribed radii to monitor arsenic. The Tribes reiterate their need for consultation in the careful placement of these wells to avoid areas of cultural sensitivity.		Since DTSC is the lead agency for the cleanup project, Tribal concerns regarding the sensitivity of the areas for monitoring wells have been discussed throughout the design process. Also, the Tribes always had the option of providing specific comments on the State Water Board's decision in writing. DTSC recalls that the Tribes were not in favor of pretreating the Arizona water due to footprint of treatment plant, therefore DTSC must balance the need to monitor the effects of the injected water with the desire to not have treatment system on site.		Officials from DTSC assured the Interested Tribes and stakeholders that a waiver would be granted for the slight exceedance of arsenic concentrations in injection water. However, meetings and hearings were held outside of the Topock process, and well sites were selected outside of the stakeholder process that had endeavored for many years for transparency and cooperation. The Water Board apparently was not interested in transparency and cooperation, and did not include input from those that would be injured the most—the Native American Tribes.	DTSC response: DTSC disagrees with the statement that we assured Tribes that a waiver would be granted for the arsenic exceedance as the State Board evaluated PG&E's proposal for arsenic injection in California. DTSC also disagrees with the generalization that the process excluded Tribal input. In particular selection and siting of monitoring wells. Agencies fully discussed each well location and conducted several site walks with Tribal representatives to gather input and preferences on its locations.
363	Hualapai/TRC	Design	Remedial Design	Sect. 5.1.1, p. 5-1	Arsenic monitoring wells	The Tribes are aware of the California State Water Board's position related to arsenic in groundwater near the freshwater injection wells. However, the Tribes had no input on the Water Board's decision to construct sentinel wells at proscribed radii to monitor arsenic. The Tribes reiterate their need for consultation in the careful placement of these wells to avoid areas of cultural sensitivity.		See above		Comment noted. Once the remedy is operational, the issue of pretreating the Arizona water may arise again due to data gaps, and or changes in water components. Hualapai consider this TRC#363 to be un-resolved.	DTSC response: Tribal comment noted.

							Bernardino County, California, and Mohave County, Arizona. October. ______. 2012. Cultural and Historic Properties Management Plan, PG&E Topock Compressor Station, Needles, California. January 20. CH2M HILL. 2014. Programmatic Biological Assessment, Pacific Gas and Electric Company, Topock Compressor Station, Final Groundwater Remedy. April, 28.				
401	DOI-227	Non-design	Cost estimates	Attachment D		The estimate for regulatory oversight during construction appears inadequate. Please provide further detail regarding the estimate assumptions to the agencies to account for this cost.	Based on an analysis of recent regulatory oversight (DTSC and DOI) costs for the Topock remediation program, PG&E estimates that DTSC and DOI oversight will cost approximately $2.4M annually ($1.5M for DTSC, and $0.9M for DOI) for the overall Topock program during the years where GW remedy construction is occurring. This total includes all regulatory oversight, not just oversight associated with the groundwater remedy. PG&E estimates that during GW remedy construction, approximately one third of this total regulatory oversight spend will be associated with specific DTSC and DOI oversight of the GW remedy construction project, or $0.5M for DTSC and $0.3M for DOI, (total $0.8M annually). PG&E will revise this line item of the remedy cost estimate with the updated values. The revised estimate will be based on $800K annual		DOI concurs with the response.		Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							spent over four years. Spend period assumes a 3 year construction period (as described in C/RAWP), plus 6 months before and after construction to account for oversight activities before mobilization and after completion of construction field activities. This will add approximately $2.9M in costs to the 90%/Supplemental design costs.				
402	DTSC-114	Non-design	Cost estimates	General	Contingency %	The contingency was reduced from the 15% used in the 60% design to 5% in the 90% design. The contingency should be returned to 15%. DTSC guidance is to use a contingency of 10-20%. There is enough uncertainty and the level of effort required for this site justifies the upper portion of this range. We also note the CE does not include costs for provisional wells or contingent actions (FWPTS).	The cost estimate will be revised with an across-the-board contingency factor of 15%. This will add approximately $14.9M in contingency costs to the 90%/Supplemental design costs. The text of Appendix H, Estimate Contingencies and Markups, will also be revised to address this comment.	Resolved.			Comment resolved.
403	DTSC-115	Non-design	Cost estimates	Task 1.3	# of wells	The number of wells included in the back-up documentation provided does not match the number of wells included in the 90% BOD, several IRZ injection wells appear to be missing. Also, the cost estimate should include installation of all contingent wells as that would constitute the worst case scenario, which is required for determining financial assurance.	All new wells are accounted for in the cost estimate. The difference in well counts between Drawing Sheet C-00-03 and the cost estimate is due to the counting method used for Dual-Screen Injection Well Clusters at the IRZ. These are counted as 2 wells on the drawing sheet, but were counted them as single well in the cost estimate. Contingent wells (referred to as future provisional wells in the design) were not included in the original cost estimate. The cost estimate has been revised to include this cost. If counted as a single unit (following the counting method for new intermediate wells	Resolved.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							previously used in the cost estimate), there would be 22 future provisional injection wells and 5 future provisional extraction wells. The total additional cost for these 27 future provisional wells is approximately $18.8M prior to markup/ overhead/profit. The text of Appendix H, Section 1.3 will also be revised to address this comment.				
404	DTSC-116	Non-design	Cost estimates	General	Regulatory oversight	Cost for regulatory oversight included in the MMRP of $300,000 appears inadequate for DTSC oversight over the construction phase of the project. We note oversight costs for O&M activities are included separately.	See RTC #401 DOI-227. This will add approximately $2.9M in costs to the 90%/ Supplemental design costs.				
405	DTSC-117	Non-design	Cost estimates	Discount rate	Discount factor of 3.17% used	This is not consistent with DTSC's method of calculating Present Value using the Real Interest Rate listed in the Office of Management and Budgets (OMB) Circular A-94, Appendix C, currently listed as 1.4%, for all present worth calculations.	Section 8, Exhibit 8.1 will be revised using an interest rate of 1.4% for the 90%/Supplemental design cost estimate. The additional costs discussed in the other comments (i.e.: 4, 5, 6, 7, 9) will be included prior to applying the 1.4% interest rate. This will result in adding $32M to the calculated present value.				
406	DTSC-118	Non-design	Cost estimates	Post-Remedy Closeout		The cost does not include submission of reports to DTSC for review and approval which are necessary to complete close-out.	A line item with a value of $250,000 will be included in the post-remedy closeout estimate to account for close-out reporting preparation, submittal, and review. This task cannot be estimated precisely, as these costs would be incurred up to 50 years after remedy implementation, and reporting requirements, level of effort, and associated labor/materials costs cannot be accurately estimated. The post-remedy closeout estimate also includes a 25% contingency to

Specific Comments – 90% BOD Appendix B: Development of Groundwater Flow, Geochemical, and Solute Transport Models											
411	DTSC-119	Design	Editorial – GW Modeling	General		DTSC is concerned with the numerous groundwater modeling comments prepared by agencies and Tribes that touch on both the flow model as well as the fate and transport component. It is imperative that the model be improved to assist with future project decisions and ensure past ones were appropriate. DTSC concerns with the fate and transport modeling (e.g., byproduct mobility and persistence) have been documented as far back as the 30% and CMS stages of the remedy. Recent comments raise some of the same DTSC concerns from the past. These recent 90% comments coupled with the underestimation of byproduct migration (e.g., manganese) at PG&E Hinkley Compressor Station solidifies agency concerns. It would be a serious detriment to the project, including the schedule, should current conclusions made with the existing model change significantly. PG&E should make resolution of groundwater modeling comments a high priority.	Comment noted. For clarification byproduct Manganese was not discretely modeled at the PGE Hinkley Compressor Station, however the observed Mn at Hinkley was one of the key reasons Mn modeling was incorporated into the PGE Topock modeling.				
412	DOI-9	Non-design	GW Modeling	2.3/7	The groundwater at the Site is a sodium chloride-dominated type with a highly variable total dissolved solid (TDS), varying from about 1,000 milligrams per liter (mg/L) to greater than 10,000 mg/L, with the most frequent values ranging between about 4,000 (33rd percentile) to 7,000 mg/L (66th percentile) and a median value of about 5,000 mg/L based on the most recent site-wide TDS data collected through 12/31/2013In general, higher TDS levels are	A common problem with predicting density dependent flow is that the very high TDS concentrations can lead to errors in the calculations of equivalent freshwater heads due to the density (and even temperature) gradients within the monitoring wells. When the inward gradients created by the capture wells are so low (.001 to .003) please explain how the uncertainties associated with the density corrections are being addressed in the capture zone assessment?	PG&E has been monitoring water levels in the floodplain and applying density corrections (on the basis of salinity as well as temperature) to the data throughout the operation of IM-3. Though it is acknowledged that there are uncertainties associated with any form of density correction, the current method has been accepted by other technical reviewers over the course of the project and the calculated freshwater heads over time were used to calibrate the groundwater model. The inward gradient targets were assigned on the basis of the distribution of these calculated heads, and therefore the modeling and monitoring are internally consistent. Any alteration in freshwater head calculation would simply shift model, monitoring,		Accepted.		Comment resolved pending DOI review of the final design documents.

413	FMIT/TRC	Non-design	GW Modeling	Append B 3.3/ Page 15.	"The currently proposed design includes continuous operation of injection wells along the IRZ, which will allow for significantly higher injection volumes and greater radii of influence than could be achieved with the point injection method that was applied during the floodplain ISPT."	Was the seasonal variation in river stage (and associated fluctuations of groundwater in wells near the river) considered in maintaining hydraulic control for the final proposed 6/18 month on/off IRZ cycle (which will likely adjust based on "adaptive" decisions in the OM monitoring decision framework diagrams)? For example, during spring/summer - high river stage will cause heads to rise notably at extraction wells – which will reduce the gradient across the IRZ (even reversing it?). Did any of the optimization or sensitivity simulations consider benefits of maintaining a constant gradient across the IRZ year-round by adjustments to IRL and/or River extraction wells? Could the time to complete remediation be reduced in this way?	As described in Appendix B Section 7.4 the seasonal variation in river stage was considered with respect to the transport modeling and hydraulic control. Despite the seasonal stage fluctuations there was not a significant difference between the transient and the steady state flow and transport modeling. River stage and water levels will still be monitored to gauge relative impacts of local gradient fluctuations. Despite fluctuations in river stage, the groundwater flux through the NTH IRZ is primarily controlled through upgradient injection in IRL and FW injection wells, and to a lesser extent the riverbank extraction wells located downgradient. It is not anticipated that the river stage variation will have a significant impact on the flux through the NTH IRZ during both the on and off cycles of the NTH IRZ. Additionally, the overall remedial timeframe is controlled by the alluvial aquifer upgradient of the NTH IRZ, therefore local gradient fluctuations near the river will not likely have a significant impact on the remedial timeframe. PG&E will review and consider the Tribes' response (dated Sept 18 and 21, 2015) to PG&E's evaluation of the MW-X/Y White Paper (dated			It is still unclear whether fate/transport was simulated with time-varying river stage for the final proposed remediation design and operation. Time-varying stage only appears to have been simulated in one former (pre-final) design/operation - not similar to 6 month on/18 month off NTH IRZ injection/extraction system. Given the noted errors and issues with the model as outlined in Prucha and Eggers July 15, 2015 mw-x/mw-y whitepaper, we suggest re-assessing the importance/need to include fluctuating river stage, especially related to monitoring (done at specific times of the year, which are influenced by the stage at that time of year) compared to steady state simulated (constant) levels. The model should have been calibrated for all intended uses (i.e., assessing hydraulic gradients as specified in frameworks in OM Vol2, flow directions, capture zones etc.). Calibration results were never shown in an industry standard way (i.e., ASTM), so it's unclear what sort of spatial bias might exist in the current model. Therefore, this comment is considered unresolved.	DTSC response: In deference to Tribal cultural concerns, DTSC will consider various proposal made by the TRC on behalf of the Tribes to further evaluate the hydro- geological understanding , including additional work on the model. The agencies will provide direction to PG&E. It is important to note that DTSC does not completely agree with the technical basis or statements made by the TRC in their white paper and their rebuttal to PG&E's response. However, for the purpose of promoting progress on this project, DTSC will not debate those disagreements here.

417	DOI-10	Design	Remedial Design	3.4.1/16	Although the maximum concentrations of TOC utilized in the ISPTs were high, the test results indicate that effective Cr(VI) treatment can be achieved with relatively low TOC concentrations. For example, Cr(VI)	It’s not clear how this conclusion is being drawn. Figure 3.4-1 shows that the drop in Cr(VI) concentrations follows a large spike in TOC concentrations. Furthermore, the authors’ of the of the floodplain ISPT study conclude that a sustained concentration of 100 mg/L is required for successful remediation of the Cr(VI) as noted in Section 5.2.1.3 (p. 14) of the ISPT report: *“Delivery of a sufficient amount of TOC was important for achieving complete Cr(VI) reduction to below the reporting limit of 0.2 mg/L. Reductions of this magnitude occurred only in locations where sufficient TOC was delivered, as indicated by sustained TOC concentrations above 100 mg/L for at least a few weeks. The delivery of sufficient TOC was limited to the injection well during the first three injections. Cr(VI) concentrations following these injections dropped below the reporting limit only in PTI-1D, where TOC concentrations of up to 204 mg/L were observed. In contrast, the decrease in Cr(VI) levels in downgradient wells as a result of the first three injections was notable but not as extensive. Cr(VI) concentrations remained above 450 mg/L in PT-1D and PT-2D, where less TOC was delivered and maximum TOC concentrations reached less than 100 mg/L (the maximum TOC concentrations were 58.4 and 26.9 mg/L, respectively).”* Presumably higher sustained TOC concentrations would be required in the upland areas where the	The "spike" TOC concentrations associated with the first three injections as shown on Figure 3.4-1 are in the 50 mg/L range (please note that the TOC concentrations are shown on the right hand vertical axis). The comment author is correct that the floodplain in situ pilot test (ISPT) concluded that sustained TOC		Accepted		Resolved.

					concentrations decreased to below 5 ug/L in the floodplain ISPT (monitoring well PT-1D) within the first three of six injection events with observed TOC concentrations between 10 and 50 mg/L (Figure 3.4-1).	prevailing conditions are not as reducing and background TOC concentrations not as high. Since the TOC dosing in the IRL will be a maximum of 50 mg/L please provide additional justification that this dosing rate will be effective.	concentrations over 100 mg/L were needed to stimulate reduction. An amount of electrons/organic carbon equivalent to the 100 mg/L TOC that was sustained for several weeks can be delivered at a lower concentration for a longer period of time with a continuously operating system such as the in situ reactive zone (IRZ) systems for the final remedy. These IRZ systems will be operated continuously for months at a time. Lower dosing amounts are required for the Inner Recirculation Loop (IRL), versus the NTH IRZ, because the primary objective is to treat Cr(VI) that may be present in the extracted groundwater that is being re-injected in the upland areas. This differs from the primary objective of the NTH IRZ—i.e., to distribute enough organic carbon between injection wells to stimulate Cr(VI) reduction. As was discussed in the response to Comment #110 (DTSC-36) on the 30% Design, approximately 3.4 mg/L of TOC from ethanol would be required to reduce 8 mg/L of oxygen, 2 mg/L nitrate as nitrogen, and 13 ppb Cr(VI). The 50 mg/L upper end of the TOC dosing range for the IRL was established above this concentration to allow for additional consumption of TOC for cell growth, promotion of reducing conditions in the subsurface, and to accommodate for uncertainties in field implementation.

					transport model (described below; see Section 6) assumes Cr(VI) reduction in the presence of organic carbon above 0.1 mg/L.	CR(VI) (100 mg/L) it is difficult to see why this assumption is made particularly since the reporting limits for the TOC are 1 mg/L. Please provide justification for the 0.1 mg/L TOC assumption.	TOC needed to establish chromium-reducing conditions given a continuous injection system will be different than that needed to establish chromium-reducing conditions during the discrete injection pilot test. The 0.1 mg/L TOC threshold was established as the minimum carbon concentration to support microbial growth and Cr(VI) reduction through a series of sensitivity analyses for other Cr(VI) impacted sites where Cr(VI) reduction using a large-scale recirculation system had been observed (i.e., PG&E Hinkley Compressor Station site). During continuous injections at Hinkley, the 0.1 mg/L threshold was well-correlated to the zone of Cr(VI) reduction. This analysis was done by fitting the chromium reduction data and available TOC data above the reporting limit, which allowed for the determination of the threshold below the reporting limit. The lower 0.1 mg/L also allows the model to account for potential lysis effects where carbon from previous microbial communities is essentially recycled to support further microbial growth. A sensitivity analysis was also performed on the trigger TOC level for Cr(VI) reduction to evaluate potential effects. As discussed in Section 10.15 of Appendix B, the TOC threshold concentration was increased an order of magnitude to 1 mg/L. At this higher TOC

							threshold, sufficient Cr(VI) reduction was achieved. The model predicted potential Cr(VI) breakthrough along the NTH IRZ line at the 10-year mark during the IRZ OFF cycle. However, much of this Cr(VI) is treated during the subsequent IRZ ON cycle, and the model results are comparable for the 0.1 and 1 mg/L TOC triggers at 30 years. Potential operational adjustments to address a higher TOC threshold concentration are described in Table 6.6-1 of Appendix B and include the following (primarily applicable to the NTH IRZ): adjust TOC dosing concentration, frequency, and/or duration; and activation of provisional wells to bolster lateral coverage. A memo which provides supporting information regarding the development of the simulated threshold TOC concentration for reduction of Cr(VI) is provided in **Attachment L** of the final RTC table as requested by DOI.				
419	DOI-12	Design	GW Modeling	3.4.3/19	Given this observation, it was possible to derive an arsenic attenuation rate from the ISPT data for use in the solute transport model. Based on these results, an	The tracer test data provides additional insight that suggests a better conceptualization of the arsenic mobility would be similar to that used for chromium in which a certain TOC concentration is assumed to mobilize the arsenic. A concern with using the tracer test data to calculate arsenic attenuation rates is that; as noted on page 11 of the study: "*In contrast, tracer data at PT-2D (Figure 9) indicate breakthrough occurred a period of time after the injection period for all six injections.*" The cause for this apparent anomalous result is never discussed. Furthermore, iodide was injected in May and September of 2006 and in July 2007. The largest iodide peak arrived in PT-2D around May 20, 2007 (Figure 9- main report). Since the last iodide injection before this arrival was in September 2006 apparently it took 8 months for the iodide (a conservative tracer) to arrive. Something does not seem right and it leads some doubt to the interpretation of arsenic attenuation using assumed travel times. Furthermore, the iodide spike was accompanied by a spike in TOC, a sharp increase in dissolved iron, arsenic and hex chrome. It seems pretty clear that the arsenic solubility (as indicated throughout the text in Appendix B) is controlled by how reducing the aquifer conditions are. Please explain why the arsenic is not being modeled in a similar fashion to the manganese and linked to TOC concentrations through proportionality constant. Attenuation rates for the arsenic that are independent of the prevailing geochemistry of the aquifer do not appear to be well supported by the data. As noted in Section 3.4.3 (p. 18); "*The ISPT results demonstrated that the amount of byproducts (manganese, arsenic, iron, and barium) liberated within the IRZ are proportional to the strength of the reducing environment created by TOC injection, which, in turn, is proportional to the concentrations of TOC used.*" Furthermore, the use of a half-life to model potentially reversible reactions also does not fit the geochemical conceptual	The comment author is correct—there was an error in Table 2 of the floodplain ISPT report identifying which tracers were used for the May 2007 and July 2007 injection events. As the analytical data in Table 9 show for injection solution #3, the May 7-8, 2007 injection event did in fact use iodide, which was detected downgradient at PT-2D later in May 2007. The data from the first four volume injection events are still valid for evaluating arsenic attenuation rates.		Accepted.		Resolved.

					arsenic attenuation half-life of between 20 and 40 days was calculated (base-case half-life assigned as 30 days), assuming a PT-2D arsenic concentration between 2.5 and 5 µg/L.	model. The application of a half-life will permanently remove the arsenic from both the sorbed and mobile phase. In reality, the arsenic is partitioning to the sorbed phase but could be remobilized if the TOC concentrations increase and the conditions become more reducing.	It is important to distinguish between the conceptual models for byproduct generation and byproduct attenuation, which are treated as decoupled processes in the geochemical and solute transport models. Specifically, Section 3.4.3 describes the basis for arsenic generated within the IRZ—it is in fact treated the same way as manganese. Manganese and arsenic are both generated within the IRZ at levels proportional to the TOC concentration, with generation coefficients of 0.016 mg manganese per mg TOC and 0.000108 mg arsenic per mg TOC. Downgradient of the IRZ, within the floodplain, the attenuation of manganese and arsenic are treated differently based on the anticipated geochemical mechanisms controlling uptake. However, manganese and arsenic attenuation processes are not activated within the maximum simulated 1 mg/L TOC footprint; i.e., manganese and arsenic do not attenuate in the model within the IRZ footprint, but only downgradient of it. In this way, arsenic and manganese attenuation are still dependent on the redox conditions within the aquifer. This is consistent with the co-occurrence of elevated TOC, dissolved iron, and arsenic observed at PT-2D during the pilot test. The rate-limited coprecipitation reaction of arsenic with iron oxides, with associated adsorption, is

							documented in the literature (Waychunas et al., 1993; Fuller et al., 1993). However, as described in Section 5.4.2, is an attenuation mechanism that cannot be described by a simple adsorption isotherm such as that of manganese. Observed arsenic data from the pilot study support this, yet for simplicity a simpler time-dependent relationship is included in the model to empirically mimic the more complex process that takes place. Although it is true that the half-life relationship is not reversable, this is what would be observed in the aquifer in the absence of a switch to more reducing conditions in the Alluvial Aquifer downgradient of injection (which is not predicted by the conceptual model or geochemical modeling). In summary, arsenic and manganese are modeled in the same way with respect to TOC content (both in terms of generation and lack of attenuation within the IRZ). Because it may not have been explicitly clear that manganese and arsenic attenuation only occur outside of the IRZ, the following text will be added to Section 6.2.7 between the third and fourth paragraphs: "Downgradient of the IRZ within the floodplain, manganese attenuation is modeled via adsorption, whereas arsenic attenuation is modeled via rate-limited co-precipitation according to a given half-life. These processes are assumed

420	DOI-13	Design	GW Modeling	3.4.4/19	Aquifer mobile porosity estimates were obtained from the floodplain ISPT during tracer injection. These results, which are described in detail and presented in Table 6 of the Floodplain ISPT Final Completion Report (ARCADIS 2008), indicate a mobile porosity of 12%.	ARCADIS (2008) presents two methods for calculating the effective porosity from the tracer test data; the method that they term "Ratio of Velocity" as well as a second method they refer to as a "Radius of Influence" (ROI) method. The ratio of velocity method basically uses the peak arrival time of the tracer in conjunction with the hydraulic gradients and hydraulic conductivities to back out the mobile porosity. The Ratio of Velocity results from the ARCADIS tracer test indicate an effective porosity of 0.02 and 0.005 percent. ARCADIS presents another method "Radius of Influence" which they describe as *"During tracer injection, transport occurred primarily by displacement of the tracer solution away from the injection well screen. As an approximation, radial transport away from the injection well over the length of the screened interval was assumed. As a result, tracer observed in nearby monitoring wells during an injection period can be used to estimate the mobile-phase effective porosity of the aquifer."* The results from this analysis are shown in Table 6 of the report to be 12% for all three wells. The ROI method is based on measuring the injected volume and tracking the tracer concentrations in the dose-response wells. For this method to provide representative results, however, the tracer concentrations at the dose-response wells should be near the injected concentrations. For the wells where mobile porosities were calculated with the ROI method; PT-1D, PT-3D and PT-4D the relative concentrations of the injected tracer was approximately 0.4, 0.4 and less than 0.02, respectively. These relative tracer concentrations suggest that there may be significant issues with the calculated mobile porosities. ARCADIS (2008), however, does not present any of supporting calculations for how the 12% effective porosity was derived. Please provide the actual calculations, and discuss the uncertainty in the results and potential impacts on the predicted range of remediation times.	The Radius of Influence calculations are consistent with methods discussed in Remediation Hydraulics (Payne et al., 2008). The method provides a more measure of mobile porosity and is more accurate as compared to the Ratio of Velocity method. For the first small volume (6000 gallon injection) the ROI was approximately 15 ft, as indicated by strong arrival at PT-3D versus PT-1D. The mobile porosity is computed by dividing the injected volume by the volume of impacted aquifer ($\pi * r^2 * h$) (where r = radius of influence in the aquifer and h = screen		Accepted.		Comment resolved pending DOI review of the final design documents.

							length). For PT-3D the resultant mobile porosity = 12%. Particle tracking with the groundwater flow model was also indicative of a 12% mobile porosity for the pilot testing in this area (CH2M HILL 2009, CMS/FS Report, Appendix F). For the six large volume injection of 18,000 gallons, the ROI was approximately 25 ft based on the arrival of tracer at PT-4D which yields 12% mobile porosity as well. Arrival concentrations were less than the injected concentrations likely due to heterogeneous advection in the aquifer that may influence the distribution of tracer in the aquifer. Although aspects of the tracer test were not ideal (monitoring frequency, breakthrough concentration), the results of the tracer test are still supportive of a 12% effective porosity which is consistent with effective porosities for similar lithologies. In addition to the ROI calculations from the pilot test, a mobile porosity of 12% was also calculated through the evaluation of the breakthrough of TDS and specific conductivity in deep monitoring wells in the vicinity of the IM-3 wells (CH2M HILL 2009, CMS/FS Report, Appendix F). This analysis showed good correlation between observed and simulated TDS arrival times and the range in effective porosity calculated from three different wells was between 11% and 14%. The observation

							wells ranged from approximately 40 ft to 200 ft away from the injection well and the monitoring duration extended up to 200 days yielding a comprehensive data set. This additional support of the 12% mobile porosity will be added to the 100% Design text. As there is uncertainty associated with these mobile porosity calculations, an additional porosity sensitivity analysis will be added to Appendix B Section 10 as described in comment # 441.				
421	FMIT/TRC	Non-design	GW Modeling	Append B 4.0/ Page 21	"Additional modifications to the groundwater flow model include the incorporation of additional hydrogeologic data developed during the installation of the HNWR-1A well, about 75 feet from HNWR-1, and the Site B well located about 3,300 feet to the north of HNWR-1."	A new USGS model "*Fred D Tillman, Bradley D. Garner, and Margot Truini, 2013. Preliminary Groundwater-Flow Model of the Basin-Fill Aquifers in Detrital, Hualapai, and Sacramento Valleys, Mohave County, Northwestern Arizona. Scientific Investigations Report 2013–5122*" includes Sacramento wash and these two wells. Do the modifications (hydraulic property distributions, aquifer thickness etc.) to the MicroFEM model in this area (HNWR-1 and Site B) compare well to the USGS model inputs/results? If not, will the MicroFEM model be updated?	The USGS 2013 Model will be considered in future model updates, but unfortunately due to the scale of the regional USGS model, it has limited utility for providing data on the refined scale needed for our model. The Colorado River forms the western boundary of the USGS model, so the bulk of our area of concern is outside the USGS model domain. Additionally the regional USGS model is only a 1 layer flow model with 1,000 m x 1,000 m grid cells so resolution is limited. The USGS model also uses a single arbitrary bottom elevation for the entire model domain. The USGS model area that contains HNWR-1, HNWR-1A, and Site B well has comparable K values to the Topock model and similar water level patterns. However, reported USGS water level residuals in this area range from -25 ft to 100 ft. Due to the size of the USGS model, the calibration isn't refined in our area of interest.			The USGS model overlaps the regional MicroFEM model domain. Prucha and Eggers (July 15, 2015 whitepaper) point out a number of issues with the model setup & boundary conditions. In particular, simulated ET losses are very likely at least an order of magnitude too low, and the 100 ac-ft/yr inflow prescribed from Sacramento Wash into the MicroFEM model appears at least an order of magnitude too low based on this publication (i.e., this is only ~62 gpm from a watershed that exceeds 1300 square miles) and river-aquifer exchange is incorrectly simulated within Arizona. Instead of focusing on comparing simulated water balances, PG&E consultants focus on modeled residuals, which have not been shown in standard ASTM format for either the MicroFEM or Modlow models (i.e., simulated vs. observed graphs, or residuals plotted spatially by	DTSC response: Agencies will provide direction to PG&E in separate letter.

425	FMIT/TRC	Non-design	GW Modeling	Append B 4.3/ P. 22	"The model contains 232 rows, 256 columns, and five layers for a total of 296,960 active cells (Figure 4.2-1). A uniform cell size of 25 feet by 25 feet occurs throughout the entire sub model domain. The boundaries of the model grid are defined as constant flux cells that reflect the flux of the original groundwater flow model under the same flow conditions."	This suggests constant (steady state) fluxes from the regional MicroFEM model were assigned to the local Modflow model boundaries. If so, simulated mounding from IRL-5 injection clearly shows heads/flow paths change along the boundary. This implies that internal calculations are affected by this western constant flux boundary. What are the implications on model predictions if the time-varying IRL-5 injection influence on the western boundary weren't considered here?	Pumping well locations and rates were incorporated into the regional model to generate the boundary conditions for the submodel in order to account for the influence of pumping. The most sensitive wells in influencing the boundary conditions are FW-1 and HNWR-1 (outside submodel domain) due to the proximity to the submodel extents. However, the effects from the other remedial wells (i.e. IRL wells, FW-2) were considered as well as they influence boundary conditions to a lesser extent. In order to account for potential time variant flow in the steady state model, long term average flow rates were utilized to represent the long term hydraulic impact of pumping wells on the			Regional well production external to the regional model is not likely considered, but could easily affect internal 'regional' flows calculated by microFEM model, which translate to local model. Review of 60% local model files suggests that translation of regional model flows to local model (modflow) is not done through constant flux cells, but rather constant head cells. These are two different types of boundary conditions. Specifying constant head boundary conditions, instead of constant flux, will result in differences in water balance/ inflows/ outflows between the two models. This should be re-evaluated/ restated.	DTSC response: Agencies will provide direction to PG&E in separate letter.

429	DOI-14	Design	GW Modeling	4.4/23	In order to properly translate groundwater flow conditions from the regional model to the extracted submodel, constant flux	Apparently, the regional model is being used to establish the flux boundary conditions for both the steady-state and pumping scenarios of the local model. This step is important because of the head changes that are observed at the local grid boundaries due to the pumping/injecting. Flux boundaries calculated from the non-pumping regional model would not adequately simulate the water moving across the boundary under pumping/injection conditions. This process of how the regional model output is being used (for the pumping scenarios) as input to the local model needs to be better described in Appendix B. Please be sure to specify if this handoff of fluxes from the regional model to the local model is <u>not</u> done for any of the pumping simulations or sensitivity analyses.	The regional MicroFEM model was used to generate flux boundaries for the submodel under both ambient (non-pumping) and active pumping scenarios. All of the pumping in the submodel was in the regional model, so the effects of that pumping		Accepted.

					boundaries were simulated around the edges of the extracted submodel.		are reflected in the boundary conditions. Text will be clarified to reflect this process.				
430	DOI-15	Design	GW Modeling	4.4/23	In order to properly translate groundwater flow conditions from the regional model to the extracted submodel, constant flux boundaries were simulated around the edges of the extracted submodel.	As described in CH2M HILL 2005 the regional model was calibrated to transient flow data and qualitatively to chromium plume development. Since there is not a good way to directly check that the fluxes from the regional model are being properly integrated into the local model or whether the changes made to the local model have affected the overall calibration there needs to be some quantitative check between the two models. On February 11, 2015 Martin Barackman (CH2MHill) emailed a comparison of the groundwater contours of the local and regional models to David Back (DOI consultant) (attached). Mr. Barackman states "The attached figures show that water level match between the two models is generally within a foot in the area north of the freeway, where most of the plume is present. The match is less good in the southwest corner of the model. In this area of the model, where the alluvium pinches out against bedrock, the MicroFEM grid cells are large and the layer thicknesses are small. Both of these factors add to the imprecision of the interpolation process. In summary, PG&E believes the process of translation between the MicroFEM and MODFLOW models produces two models with hydraulic properties and gradients similar enough to be used for the purposes of remedial design." Although there is a general agreement between the contours, according to Appendix L, the gradients necessary to maintain capture are on the order of 0.003 which is incredibly flat and small differences in the water-level elevations can have a significant impact. Furthermore it is unknown what the impacts of the differences in gradients will have on remediation times and flow directions. Based on the CH2M HILL 2005 report the calibrated regional model provides an excellent match to the monthly water levels in the flood plain wells (Figure B-2). Based on the potentiometric map comparison provided by Mr. Barackman, it does not look like the local model is calibrated nearly as well. Some type of quantitative check needs to be presented on how well the local model is calibrated. The potentiometric maps provided by Mr. Barackman should be included in Appendix B to provide a visual comparison of the regional and local model predictions.	A figure will be provided in Appendix B that compares the regional model simulated water levels to the submodel simulated water levels. Specific calibration targets from future model calibrations will also be evaluated in both the regional and submodel for a more quantitative evaluation, in accordance with the schedule identified in Appendix B Section 12. An additional paragraph will be added to Appendix B Section 12 to discuss the intended future use of the model including updating remediation time frame estimates, supporting capture zone analyses, and analyzing potential remedy design operation changes.		Accepted.		Comment resolved pending DOI review of the final design documents.
431	DOI-16	Design	GW Modeling	4.4/23	In order to properly translate groundwater flow conditions from the regional model to the extracted submodel, constant flux boundaries were simulated around the edges of the extracted submodel.	Moving forward this approach of only calibrating the regional model and using the results to parameterize and set the boundaries on the local model will become more and more problematic as additional data become available. Once the remedial system is up and running additional transient and steady state data sets will become available to fine tune the calibration, optimize the injection/pumping and predict capture zones. A significant degree of the regional model calibration is being lost in translation to the local model. The local model is uniformly spaced at 25 feet with the total number of active cells at less than 300,000. It seems that if a variably spaced grid was employed with additional nodes the local model boundaries could be extended to where the boundary effects would be minimal. This would allow the more traditional approach of using the regional model to set the boundaries on the local model but continue to calibrate only the local model. The boundary conditions could also be changed from the constant flux to General Head Boundaries to further minimize potential boundary effects.	The process for extracting model parameters and boundary conditions from the regional MicroFEM model to the MODFLOW model has been streamlined to allow for a relatively quick conversion between the two models. Further consideration will be given to either expand the submodel domain to minimize boundary effects (be able to change pumping rates in just the submodel, rather the both the regional model and submodel) or possibly convert the full MicroFEM model to MODFLOW to negate the need for future model conversions, at				DTSC response: Agencies will provide direction to PG&E in separate letter.

							the time of the next model update. There would not be a significant difference with the use of general head boundaries verses constant flux boundaries as the constant flux boundaries were adjusted to account for the hydraulic impacts along the submodel boundary. Both GHBs and constant flux boundaries would represent equivalent fluxes into and out of the submodel domain.				
432	FMIT/TRC	Design	Remedial Design	Append B, Sect. 5.1, p. 24, and Append B Att. 1	Batch simulations were performed with the geochemical modeling software PHREEQC using the default PHREEQC Thermodynamic database.	Chromium species are not available in the PHREEQC data base, and thermodynamic properties for chromium species were not shown in Appendix B Attachment 1. What data base was used for the geochemical modeling? Chromium behavior is difficult to predict through geochemical modeling (D.K. Nordstrom, USGS, verbal commun, 2012); therefore, wouldn't selection of the chromium data base be important in order to run the geochemical model after remedy start up, insert new data collected during construction and monitoring, and use the model for rapid geochemical assessment?	Thermodynamic constants for aqueous Cr(III) and Cr(VI) species, which were not available in the default PHREEQC database, were obtained from Morel and Hering (1993); this reference is cited in Section 5.1 of the text. Solubility products for Cr(III) mineral phases were obtained from Sass and Rai (1987); also cited in the text. It is true that chromium behavior is difficult to predict using geochemical modeling alone; accordingly, it is important to validate model predictions with performance data. In this case, historical plume evolution and the results of pilot tests were used to develop the geochemical and solute transport models, as described in the text. These models will continue to be refined after remedy startup as new information is obtained. This may include review and updating of thermodynamic constants as warranted.			It doesn't appear as though chromium was included in the geochemical model at all. The Sass and Rai (1987) and Morel and Hering (1993) citations are outdated and do not provide adequate information (e.g., enthalpy values) to fully conduct geochemical modeling of chromium species. An important project such as Topock should be using the best available chromium thermodynamic data, and these data can be found in Ball and Nordstrom (1998). Suggest that the geochemical modeling should be conducted without fixing pH at 7. Suggest that geochemical modeling should not restrict arsenic to only reduced arsenic-3 species, but should include all of the possible arsenic complexes. Suggest that the geochemical modeling should be re-done with conditions representative of the upland and floodplain. Solid-phase constraints	PG&E Response: One of the references for chromium thermodynamic constants was inadvertently left out of the references list. Specifically, equilibrium constants for aqueous Cr(III) species and the amorphous chromium hydroxide Cr(OH)3 were taken from Rai et al., Journal of Solution Chemistry, 2004. This reference will be added to Appendix B. Other chromium thermodynamic values taken from Morel and Hering, including the Cr(VI) hydrolysis species and the Cr(III) – Cr(VI) redox couple, were compared against those provided in Ball and Nordstrom (1998). Differences in values between the two sources are sufficiently minor as to not affect the overall results. DTSC/DOI response:

										groundwater remedy.	
436	DOI-17	Design	GW Modeling	5.2/25	All geochemical speciation and redox calculations were based on published thermodynamic constants	Please indicate if there was a need to correct the constants (e.g, Pitzer) for the high ionic strengths?	PHREEQC uses the Davies equation to make ionic strength corrections, with Davies equation constants included in the thermodynamic database. This approach is largely recognized as valid for ionic strengths as high as 0.7 M, much higher than the ionic strengths of the groundwater modeled at Topock, which exhibits an ionic strength closer to 0.1 M (e.g., Morel and Hering, 1993; reference cited in Appendix B). Accordingly, use of a database with Pitzer model parameters was not necessary. The following text will be added to Section 5.2: "Activity coefficients for charged aqueous species were calculated using the Davies equation, as described in the PHREEQC manual (Parkhurst and Appelo, 1999)."		Accepted.		Resolved.
437	DOI-18	Design	GW Modeling	5.3.3/31	Oxidation of Mn(II) was incorporated in the Topock solute transport model assuming a half-life of 29 days. This value was obtained by starting with a first-order rate coefficient of 0.083 h^{-1}, representing the slowest rate observed by Harvey and Fuller (1998) at the Pinal Creek, Arizona site, and scaling it back by two orders of magnitude to conservatively account for	Please clarify where in the Harvey and Fuller paper the first-order rate coefficient of 0.083 h^{-1} was obtained and why a rate constant of 0.69 h^{-1} was not used. The Harvey and Fulley text on the bottom of page 632 states "considering the fast timescale of laboratory uptake (<6 hours) for all experiments, the range in rescaled rate constants for unpoisoned sediments from Pinal Creek was 0.28-0.69 h^{-1}." A rate constant of 0.69 h^{-1} is more than 8 times slower than 0.083 h^{-1} . A rate constant of 0.083 h^{-1} is a half-life of 8.4 hours, so a half live scaled back by two orders of magnitude would be 840 hours or 35 days; was something else factored in that resulted in the assignment of a half-life of 29 days (rather than 35)? If the rate constant of 0.083 h^{-1} was increased by two orders of magnitude it would be 8.3 h^{-1} and would result in a half-life of 0.34 days. Harvey and Fuller explain that the manganese precipitation is due to the gas exchange of oxygen within the hyporheic zone at the interface between the sediments and surface water as well as biological processes. This oxygenated area is typically thin and the O_2 gas exchange component needs to be integrated into the current conceptual model because it appears to be inconsistent with the reducing rind concept. This could involve a simple explanation that a well oxygenated zone within the streambed separates the reducing rind from the surface water. The manganese rate constants will also be strongly affected by the reduction of dissolved oxygen caused by the injection of the TOC and resulting increase in biological activity. There needs to be additional justification for the assumption that two orders of magnitude adjustment adequately represents the system. The potential impacts of the uncertainty on the model predictions should be discussed in an uncertainty section.	The objective was to use the most conservative (longest half-life) manganese oxidation rate observed in the study. The range on the bottom of page 632 in the Harvey and Fuller reference was based on the laboratory scale results only. Table 3 in Harvey and Fuller cites the averages and ranges in results applicable to the different scales studied. The 0.083 h^-1 rate constant was based on the observed range in hyporheic flow path-based observations, which exhibited a range in the time constant (inverse of the rate constant) of 1 to 12 hours. Thus the rate of 0.083 h^-1 was obtained as the inverse of 12 hours. Note that a rate		Accepted.		Resolved.

					potential differences in nutrient status and microbial population.		constant of 0.69 h^-1 (half-life = 1 hour) is more than 8 times faster, not slower, than a rate constant of 0.083 h^-1 (half-life = 8.3 hours), and would therefore be a less conservative assumption on oxidation rate. The following text will be added to Section 5.3.3: "This value was obtained by starting with a first-order rate coefficient of 0.083 h^-1, representing the slowest rate observed by Harvey and Fuller (1998) at the Pinal Creek, Arizona site (time constant range of 1 to 12 hours, Table 3 in Harvey and Fuller [1998]), and scaling it back…" The half-life of 29 days appears to have been a typographical error in the text, possibly due to a round-off error (noting that a rate coefficient of 0.1 h^-1 would yield a half-life of 29 days). The text and model will be corrected. The two order of magnitude increase in half life precludes the need for a sensitivity analysis, as it is not a data-based estimate but rather is a deliberate conservative assumption that reaches far beyond estimates in a similar environment. It is correct that manganese oxidation would not occur in the reducing rind, due to the absence of oxygen in this zone. It would also not occur in zones where TOC is being injected – accordingly, manganese oxidation does not occur (and is not modeled) in the IRZ. The text will be modified as follows: "Oxidation of Mn(II) was incorporated in the Topock solute transport model

							assuming a half-life of 35 days in zones where sufficient oxygen is present to yield manganese oxidation."				
438	DOI-19	Design	GW Modeling	5.3.3/32	This rate was used to simulate Mn(II) oxidation in the upland, where Mn(II) oxidation was assumed to be active outside of the TOC footprint (TOC less than 0.1 mg/L) of the remedy.	Since the Mn oxidation rate will be very sensitive to the prevailing geochemical conditions and microbial populations please provide some justification (e.g., DO and/or ORP values) for this assumption.	Historical field measurements of dissolved oxygen in groundwater monitoring wells located in the upland OW wells typically range between approximately 5 and 14 mg/L (which includes field probe measurement variability/uncertainty). This range of measured values will be included as justification in Section 5.3.3.		Accepted.		Comment resolved pending DOI review of the final design documents.
439	DOI-20	Design	GW Modeling	5.3.3/33	Therefore, the hyporheic zone PHT3D results demonstrate that the immobilization reaction used in the site-wide solute transport model adequately accounts for the chemical reactions that take place.	The hyporheic zone provides a geochemical environment that is unique to that area of the site where oxygen from the stream is exchanged with the groundwater leading to the precipitation of manganese minerals. Please provide additional explanation of how these modeling results obtained with PHT3D under these conditions now demonstrate that the same conditions are applicable to the entire site. Obviously, if there are areas within the site that are naturally reducing the same assumptions would not apply and manganese may not be oxidized and immobilized.	The text in this section is intended to make the point that oxidation of manganese (when and where it occurs, which is not everywhere) results in a thermodynamically stable and low-solubility mineral phase which is resistant to re-dissolution; therefore, although the site-wide solute transport model does not include any reactions for the precipitated phase, this is not necessary because the geochemical model demonstrates that these phases are stable. This does not preclude the possibility that manganese oxides can be reductively dissolved in some circumstances (this process is included in the model within the IRZ), and it does not suggest that manganese will oxidize and precipitate in the absence of oxygen (it is made clear in other portions of the text that manganese oxidation is only modeled in zones where oxygen is present, including the upland). The text in Section 5.3.3 will be modified as follows: "Therefore, the		Accepted.		Resolved.

							hyporheic zone PHT3D results demonstrate that the immobilization reaction used in the site-wide solute transport model adequately accounts for the chemical reactions that take place where oxygen is available for manganese oxidation."				
440	DOI-21	Design	GW Modeling	6.2.1/37	Solute mass is exchanged between mobile and immobile portions of the aquifer by diffusion. This conceptualization of solute transport is the dual-domain formulation, and is often referred to as advection-diffusion. There is extensive literature on the dual-domain model (Gillham et al. 1984; Molz et al. 2006; Flach et al. 2004; Harvey and Gorelick 2000; Feehley et al. 2000; Julian et al. 2001; Zheng and Bennet 2002) and it is generally considered the most accurate approach for simulating solute transport.	Please explain why the dual domain model was assumed when as noted in ARCADIS (2009, p. 18) the tracer test data did not indicate dual porosity behavior: *Note that the dual-domain mass transfer model of Zheng and Wang (Zheng and Wang, 1999) was not used in the solute transport model because minimal tailing was observed in the actual tracer breakthrough curves and that a dual-domain approach to solute transport was not necessary to closely simulate tracer behavior.* If there is significant dual phase behavior the tracer profile should be more log-normal as opposed to Gaussian. ARCADIS, 2009. Upland Reductive Zone In-Situ Pilot Test Final Completion Report.	The dual-domain model was utilized as a conservative measure to account for the likely interaction of the mobile and immobile fractions in the simulation of this heterogeneous aquifer. While the dual porosity was not clearly indicated by the tracer testing, for the simulation of the full aquifer it was deemed appropriate to utilize the more conservative dual-domain approach. The mass transfer coefficient and mobile/immobile porosities utilized in the final dual domain model did not result in a significant dual phase behavior.		Accepted.		Resolved.
441	DOI-22	Design	GW Modeling	6.2.1/37	The mechanics of deposition and consolidation of unconsolidated materials result in aquifer soils at the Site exhibiting a total porosity of	There really needs to be a basis for the estimate of 35% percent total porosity. Since the mobile porosity is 12% the immobile porosity is 23% (which checks out with the *.btn file). Most of the contaminant mass will be in the immobile porosity and remediation times are typically very sensitive to the immobile porosity. Furthermore, it's difficult to see how the local variability would not have an impact on overall results. As stated above the assumptions regarding immobile porosity and the transfer coefficient will have a significant impact on predicted remediation times. It also seems unusual that the mobile and immobile porosities were not included in the sensitivity analysis since they are both fairly uncertain and the model results will be very sensitive to the values assumed. Please provide a basis for the value of 23% for the immobile porosity. Please provide the rationale for not including the porosities in the sensitivity analysis.	The mobile, immobile, and total porosity values used in the solute transport modeling are consistent with the range of values presented in Attachment A of CH2M Hill 2010 - Methods of Estimating Pore Volume Flushing Efficiency Used in Calculating Mass		Accepted.		Comment resolved pending DOI review of the final design documents and the sensitivity analysis.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					approximately 35%. Local variability will not have an impact on overall results, and 35% is a reliable estimate for the total porosity of modeled layers 1 through 4.		Removal Rates for CMS/FS Alternatives. This Attachment indicates a range in immobile porosities of 22% to 28%, and a range in total porosities of 29% to 40%. The total porosity range is supported by porosity measurements made on 20 site samples as part of the original draft RFI (E&E, 2004), which ranged between 26.8% and 42.7%, with an average of 35.5%. As the computed mobile porosity from ARCADIS, 2008 support a 12% mobile porosity, an immobile porosity of 23% and a total porosity of 35% were selected as average values for the solute transport modeling exercise. The total porosity of 35% is also consistent with porosity values recorded for similar alluvial and fluvial aquifer materials (Fetter, 2001; Payne et al., 2008). The preceding text and references will be added to Section 6.2.1 to further justify porosity values used in the solute transport modeling. Local variations in porosity due to aquifer heterogeneity are not expected to have a significant impact on remedy performance as the average values are more representative of the entire Site in evaluating remedy performance. In order to evaluate the potential impact of immobile and mobile porosity values on the simulation of the remedy, a sensitivity analysis will be conducted on a representative range of porosities.

442	FMIT/TRC	Non-design	GW Modeling	Append B Sect. 6.2 P. 37	"6.2 Solute Transport Parameters"	Why weren't more realistic values developed for transport parameters by calibrating the flow and solute transport model against Quarterly IM3 water level and concentration changes (i.e., instead of from publications)? Is there any reason this couldn't be done now, prior to finalization of design/operation/installation/testing etc.? These data seem to be the best available information on how the model (flow/fate/transport) performs in a critical area.	Solute transport parameters were developed using a combination of geochemical modeling based on Site data, observations made during in-situ pilot testing (ISPT), historical plume movement, and literature. The ISPT data are comparable to the proposed remedial strategy, and recent IM-3 data, with respect to overall groundwater flow and Cr(VI) plume movement, were considered and appear to be consistent with the simulated groundwater flow and solute transport parameters utilized. Flow and transport model calibrations will also be conducted during the future model updates.			The last statement of PG&Es comment misses the point . Conducting this analysis BEFORE completion of the 90%BOD is so that all stakeholders can be guaranteed, to the extent possible, that all data have been used to calibrate the model in a key area. The IM-3 data represent years of good quality data in the most contaminated part of the site (vs. the ISPT location). The IM-3 data cover a much larger geographic area and are available for much longer (i.e., 10 years), which might require different assumptions about fate/transport parameters (i.e., floodplain vs. upland etc.), both of which are influenced by IM-3 data. We strongly recommend that IM-3 data are used at a minimum to validate current assumptions used in the fate/ transport model, where relevant (i.e., obviously one can't evaluate Mn and As w/out TOC, which IM-3 doesn't include.	DTSC response: Agencies will provide direction to PG&E in separate letter.

446	DOI-23	Design	GW Modeling	6.2.3/38	The text states "A Kd value of 0.05 L/kg in the aquifer results in a retardation factor of approximately 1.25 for the Cr(VI) plume in the solute transport model."	Please revise the Retardation Factor (RF) calculation and discussion. A kd of 0.05, bulk density of 1.73 (p.30) and a mobile porosity of 12 percent will result in a RF of 1.72 (as opposed to 1.25). It appears that the total porosity (35%) was used for the RF calculation; however, based on a review of the model input files it appears that RF's were calculated for both the mobile and immobile domains. Since the mobile porosity is used to calculate advective transport rates rather than the total porosity. Since MT3D allows a number of options with respect to the treatment of sorption it would be worthwhile to present how it was actually assigned in the model.	In a dual-domain model, MT3DMS automatically fractionates the bulk density into mobile and immobile portions based on the mobile and immobile porosities to ensure a consistent retardation factor in both domains. In order to maintain the same retardation factor in		Accepted.		Resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							mobile and immobile domains, the basis for the retardation factor should be total porosity. Using total porosity in the calculation results in a retardation factor of 1.25. To check the MT3DMS calculation print flag (IFMTRF flag) located in the Basic Transport file (BTN) was enabled. This flags prints the model computed retardation factor in the MT3DMS output file and a value of 1.25 was reported, which indicates that the retardation factor will be applied consistently in both domains.				
447	DOI-24	Design	GW Modeling	6.2.3/38	The text states "The presence of background Cr(VI) concentrations associated with the naturally occurring mineralogy suggests nominal adsorption (low Kd value) is representative of the aquifer. This assessment is consistent with the literature, which identifies a wide range of Kd values (USEPA 1999) for naturally occurring Cr(VI) in aquifer soils with a normal pH range."	The amount of chromium mass that is initialized in the model as well as the transport velocities and remediation times will be very sensitive to the Kd value. The text indicates that the Kd values are thought to be low due to the background concentrations but goes on to conclude that this is consistent with a wide range of values. Please explain how low Kd values are consistent with a wide range? It is also unclear how high background concentrations by themselves indicate low Kd values. Since the Kd is simply proportionality constant, high background concentrations could also result from high Kd values if the sorbed concentrations of chromium are high enough. Please clarify the text. Although the actual Kd value is not predicted by the solubility modeling described in Section 5 the approach should integrate the information gained from the solubility modeling into the selection of the Kd values.	The text will be clarified to state that the low K_d value falls within the range of reported K_d values. A laboratory study on aerobic core samples from the Site (CH2M Hill, 2005, *Summary of Results—Aerobic Zone Hexavalent Chromium Core Testing*) indicated the range in Kd values from two aerobic core samples collected from the flood plain varied between 0.01 and 0.09 L/kg. This study therefore supports the value of 0.05 L/kg utilized in the baseline hexavalent chromium modeling. A reference to this technical memo will be added to the text. Additionally, the current Cr(VI) plume distribution and the relatively low groundwater flow velocities support the assumption that minimal sorption of Cr(VI) is occurring at the Site. If K_d values for Cr(VI) were high, the current plume footprint would be much more limited in spatial extent. For comparative purposes, an elevated K_d value was assessed in a sensitivity analysis to		Accepted.		Comment resolved pending DOI review of the final design documents.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							demonstrate potential impact on remedial timeframe and plume distribution. To the extent possible, the Cr(VI) K_d value used will be checked for consistency against other geochemical model parameters developed in Section 5.				
448	DOI-25	Design	GW Modeling	6.2.3/38	The text states "The Cr(VI) Kd value was further adjusted in the bedrock to better simulate the movement of Cr(VI) in the fractured bedrock.	The text indicates that the Kd was fixed to obtain a Rf of 1.25 rather than adjusted to better simulate the movement of Cr(VI). So was it the porosity (rather than the Kd) that was adjusted to better simulate the movement in the fractured bedrock? Since the RF's are calculated separately in MT3D for the mobile and immobile porosity—there really is not a RF of 1.25. So please describe how the matrix and mobile porosities in conjunction with the Kd's are assigned in the fractured bedrock and overlying aquifers.	Porosity was reduced in the bedrock first to better represent the fracture flow. If the K_d value utilized in the alluvial aquifer were held constant in the bedrock, a significantly higher retardation factor would result in the bedrock as the bulk density increased and the total porosity decreased in the computation. This would be inconsistent with respect to the current spatial extent of Cr(VI) in the bedrock. Therefore, the K_d value in bedrock was reduced to yield an equivalent R_f of 1.25 as simulated in the aquifer. This lower K_d value is also supported by the limited fraction of organic carbon in bedrock fractures. As stated in the RTC #446 DOI-23, MT3DMS utilizes total porosity in the calculation of the R_f.		Accepted.		Resolved.
449	DOI-26	Design	GW Modeling	6.2.3/38	The bedrock was simulated with a total porosity of 2% so the Kd value in bedrock was reduced to 0.0029 L/kg to yield an equivalent Rf as calculated in the aquifer to establish a uniform Rf value of 1.25 throughout the entire submodel	For this Kd assumption to be valid the bedrock should have similar geochemical conditions (e.g., ionic strengths, cations, anions, pH, Eh and total organic carbon) to the overlying units. Please provide justification for this Kd assumption.	By reducing the K_d in the bedrock, the assumption is made that geochemical conditions are not similar in the bedrock; however, a similar resultant nominal R_f value of 1.25 was utilized to represent the current Cr(VI) plume distribution in bedrock.		Accepted.		Resolved.

461	FMIT/TRC	Design	GW Modeling	Figs. 6.5-13 to 6.5-20	Injections at FW-1 and IRL wells	Previous model presentations (e.g. Groundwater EIR) showed that the water-table would rise about 28 feet near injection well FW-1, and the current model shows lower water table rises. Cobble layers within the lithology have been noted in drilling logs from the FW-1 injection area (RFI-RI v. 2 App). Do these cobble layers outcrop in the arroyos to the north? If the water table rises due to FW and IRL injections, these cobble layers could transmit injected water to the surface, appearing as unnatural springs in the arroyos. Have threshold water levels been established for monitoring wells? Has a monitoring program been considered for induced seeps and springs?	In the area of FW-1, the vadose zone is approximately 100 ft thick Mounding will be greatest in the immediate vicinity of the injection well and then reduce rapidly as distance from the injection point increases due to the overall thickness of the alluvial aquifer in this area (>350 ft). Even with mounding up to 28 ft, the extent of the hydraulic mound would be limited and there is still substantial vadose zone above the water table. For these reasons it is highly unlikely that water will transmit along potential continuous cobble layers and appear as springs in the arroyos. Therefore threshold water levels for monitoring wells and a monitoring program for induced seeps and springs is not needed.			Reviewer did not answer the question: “Do these cobble layers outcrop in arroyos to the north of FW and IRL wells?” Maintaining the integrity of the maze area is of the utmost importance. For example, when the remedy is operating and nobody is monitoring, a seep appears unnoticed, and the seep grows like a leaking dam, which could cause great destruction to the cultural resources of the area, especially if such a seep goes unnoticed for long periods of time. Volunteers have offered to monitor for unnatural springs in the project area; however, reliance on volunteers for a 30-50 year project does not provide security that a potential disaster could be averted. Comment unresolved.	DTSC/DOI response: Agencies will provide direction to PG&E in a separate letter.

465	FMIT/TRC	Non-design	GW Modeling	Append B 6.6 p. 54	"While the model will be updated with new data where applicable as described in Section 12, general initial design considerations can be made relative to design operation if significant deviations in parameters occur."	This is confusing. The meaning of "significant deviations" needs to be made much clearer and based on very specific quantitative performance metrics to avoid ambiguity and confusion. This can only be done with an updated/re-calibrated model. Whether parameter deviations are significant can ONLY be determined using an updated/re-calibrated model and considered 'significant' ONLY if they change system performance to RAOs/OPS by some threshold, yet to be specified. Greater details of how/when all models are updated and re-calibrated should be presented here, given the importance to future decisions on changes to the design/operation that will have to rely heavily on the models.	See response to comment #76. The term "significant differences" will be removed and the model update schedule will be followed as described in Appendix B Section 12. Material changes to the model including update and recalibrations will be noted in the corresponding quarterly report, and presented in detail in the annual report.			The Tribe requests that PG&E consultants keep track of not only all 'Material changes' made to the model(s), which should be defined better here, but should also track adjustments to all 'knobs' that are changed to the currently planned design (i.e., new wells) and operations (TOC injection rates, durations, volumes injected, increases and decreases in injection and extraction flow rates, timing and duration of all stoppages of injection/ extraction of all wells etc.) so that when different models (,i.e., MicroFEM, Modflow, MT3D, Phreeqc, PEST etc.) are updated and re-calibrated to available time-varying heads, 3-d gradients and concentrations, the models can actually be	DTSC/DOI response: Agencies will provide direction to PG&E in a separate letter.

477	DOI-30	Design	GW Modeling	8.1.2/63	[Mn(II) half-life = 8.3 hours for dissolved oxygen greater than 2.5 mg/L], corresponding to the lowest hyporheic zone rate observed by Harvey and Fuller (1998).	Please clarify where in the Harvey and Fuller paper the first-order rate coefficient of 0.083 h^{-1} was obtained. The Harvey and Fulley text on the bottom of page 632 states "considering the fast timescale of laboratory uptake (<6 hours) for all experiments, the range in rescaled rate constants for unpoisoned sediments from Pinal Creek was 0.28-0.69 h^{-1}."	See RTC #437. The text in Section 8.1.2 will be modified as follows: "…corresponding to the lowest hyporheic zone rate observed by Harvey and Fuller (1998), who reported a range of hyporheic zone time constants (inverse of the rate constant) between 1 and 12 hours (see table 3, Harvey and Fuller 1998)."		Resolved.		Resolved.
478	DOI-31	Non-design	GW Modeling	8.1.2/63	Based on the literature observations discussed in Section 5.3, the oxidation rate was assumed first order with respect to Mn(II) concentration above 2.5 mg/L (i.e., independent of dissolved oxygen content above 30% dissolved oxygen saturation) and second order with respect to Mn(II) and dissolved oxygen (first order with	Please explain the origin of the 2.5 mg/L dissolved oxygen and oxidation rate assumptions. Marble et. al. (1999) state "DO concentrations in the hyporheic zone at Pinal Creek typically decrease with depth from about 60 µM at the interface with surface water to the merging groundwater value of about 3 µM." A conversion of 60 µM of DO results in a concentration of 1.92 mg/L [60 µM x32 g/M) = 1920 µg = 1.9 mg/L]. Therefore, the highest DO concentrations and resulting Mn oxidation appear to have been calculated at DO values less than 2 mg/L. Mn oxidation rates as a function of DO concentrations could not be readily identified in the other reference cited for the Mn oxidation assumptions (Harvey and Fuller, 1998).	Marble et al. (1999) state on Page 7 of the text (section entitled Dissolved-O2 Dependence) and on Figure 6 that the net rate of Mn(II) removal is independent of DO above 30% air saturation and first-order with respect to the dissolved oxygen concentration below 30% air saturation. The value of 2.5 mg/L DO was calculated as 30% of 8 mg/L (the approximate concentration of dissolved oxygen at 100% air saturation). The text in Section 5.3.3 (which is cited in Section 8.1.2) will be modified as follows: "Further work (Marble et al. 1999) demonstrated that these				Comment resolved pending DOI review of the final design documents.

					respect to each) below 2.5 mg/L (Marble et al. 1999).		rates were independent of dissolved oxygen concentration above 30% saturation (approximately 2.5 mg/L assuming an air-saturated dissolved oxygen concentration of 8 mg/L) and first-order with respect to dissolved oxygen concentration below 30%."				
479	DOI-32	Design	GW Modeling	8.1.2/63	Very limited information is available on the actual hyporheic zone thickness for the Colorado River at the Site.	The degree of Mn oxidization will be very sensitive to the thickness of the hyporheic zone. The current assumption of 2 feet appears fairly arbitrary and non-conservative (e.g., redox and mixing conditions indicate that it is less than 6 feet). Harvey and Fuller (1998) use tracers and mathematical equations to provide a means to estimate the hyporheic zone thickness that they consider a good assumption for streams that are much wider than they are deep. It looks like the thickest hyporheic zone depth they predicted or measured was 17 cm. Please explain whether there is any other supporting rationale for assuming a thickness for the hyporheic zone of about 60 cm.	The thickness of the hyporheic zone will be highly specific to the stream or river system, depending on a number of factors related to groundwater discharge and stream dynamics. Although Harvey and Fuller achieved a detailed quantification of the hyporheic zone thickness, their hyporheic zone thickness can only be applied to their particular stream system. For example, other studies have indicated hyporheic zone depths from 50 cm to as high as 10 meters, based upon a publically-available document by the Environment Agency, U.K. (Groundwater-surface water interactions in the hyporheic zone, Science Report SC030155/SR1, 2005; see Hendricks and White, 1991 and Triska et al., 1989 as cited in this document). Justification for the hyporheic zone depth in the final design will also consider the results of sediment porewater temperature measurements collected at Topock during the Porewater and Seepage Study performed by CH2M-Hill in 2006. These and other available literature references will be compiled and provided		Accepted.		Comment resolved pending DOI review of the final design documents.

481	DOI-34	Design	GW Modeling	8.1.2/63	The assigned dissolved oxygen profile consisted of river water dissolved oxygen concentrations persisting to 1-foot, and then dropping linearly to zero between 1-foot and 2-feet, for a total hyporheic or mixing zone depth of 2 feet (see Figure 8.2-1).	If there is some assumption regarding the oxygen profile with respect to any other parameters or Mn interface calculations it needs to be described. The Mn interface calculation appears to be performed simply by taking the thickness of the hyporheic zone and adjusting the initial concentrations by the half-life and travel time.	It is true that in the ultimate realization of the hyporheic zone model, the Mn interface concentration could have been approximated simply by adjustment of the influent boundary concentration based on the oxidation half-life and travel time (or residence time) within the hyporheic zone. However, the geochemical reactive transport model serves to validate this point; in particular, that other geochemical factors (including thermodynamic stability of the precipitated phase and Mn(II) adsorption) do not impact the result. In addition, the model accounts for the second-order attenuation of manganese for dissolved oxygen concentrations below 30% air-saturation, although this effect is minor. This point will be described in Section 8.1 of Appendix B. There are no other assumptions regarding the oxygen profile with		Resolved.		Resolved.

							respect to any other parameters, other than what is already described in the text.				
482	DOI-35	Non-design	GW Modeling	8.2 Table 8.2-1/65	2. IRZ Active Conditions 10x half-life: 83 hours	The hyporheic zone is assumed to be 2 feet thick (8.1.2, p. 63), and the groundwater velocity through the hyporheic zone is 0.12 ft/day (8.1.1 p. 64). Therefore, Mn takes approximately 16 days (384 hours) to travel this distance. At a half-life of 83 hours approximately 4.626 half-lives will pass. Since the initial concentration is 2000 ug/L the following equation can be used to estimate river interface concentrations. $2000 \times 0.5^{4.626} = 81$ or 4% Since the calculated value of 81 is also the model prediction (see Table 8.2-1) it appears that the approach outlined above captures the fundamental processes that are simulated by the model. So a key question that strongly controls the predicted Mn concentrations entering the river is; will the Mn residence times in the hyporheic zone really be as long as those assumed in the modeling? Conceptually, the hyporheic zone is supposed to be a relatively thin region where groundwater and surface water are easily exchanged leading to elevated oxygen content that stimulates enhanced biological activity. In fact, the Harvey and Fuller paper cited in Appendix B describes this interchange as also being responsible for removal of the Mn already in the stream. Essentially, the hyporheic zone scrubs the stream of Mn as the Mn and surface water enters the hyporheic zone this exchange may happen multiple times over a basin scale. As further noted in Harvey and Fuller (p. 624) "The cumulative effect of enhanced manganese oxidation in the hyporheic zone was a 20% decrease in the load of manganese flowing out of the drainage basin**."** While the assumptions with the current modeling approach would lead to a 95+% reduction in the Mn loading rates. This may be the case, but the apparent discrepancy between the length of time the Mn is allowed to reside in the hyporheic zone in the model with the high permeabilities that would be required to form the hyporheic zone need to be resolved. Please provide additional justification for the long residence Mn residence times assumed in hyporheic zone in the model.	It is true that in the ultimate realization of the hyporheic zone model, the Mn interface concentration could have been approximated simply by adjustment of the influent boundary concentration based on the oxidation half-life and travel time (or residence time) within the hyporheic zone. However, the geochemical reactive transport model serves to validate this point; in particular, that other geochemical factors (including thermodynamic stability of the precipitated phase and Mn(II) adsorption) do not impact the result. In addition, the model accounts for the second-order attenuation of manganese for dissolved oxygen concentrations below 30% air-saturation, although this effect is minor. This point will be described in Section 8.1 of Appendix B. It is true that the reduction in manganese loading rate described by Harvey and Fuller was smaller (20%) than what is predicted at Topock (95+%). However, as the reviewer points out, it is important to note that Harvey and Fuller were describing oxidative attenuation of manganese that was already in the creek (as well as groundwater manganese), which relies on transfer of creek water dissolved manganese into the hyporheic zone for attenuation. In contrast,				Comment resolved pending DOI review of the final design documents and sensitivity analysis.

							the Topock hyporheic zone model considers attenuation of manganese that must pass through the hyporheic zone before getting to the river. Accordingly, it may be anticipated that a greater level of attenuation may be achieved. While the depth of the hyporheic zone will be controlled by such factors as river dynamics, streambed geometry, and river sediment permeability, the velocity of the groundwater discharging to the river will more strongly be controlled by the groundwater gradient and aquifer properties within the floodplain upgradient of the hyporheic zone. Groundwater velocities were assigned based on the site-wide solute transport model. Accordingly, because the groundwater flux and the hyporheic zone depth are controlled by different factors, the assumed groundwater velocity which controls the residence time and the 2-ft hyporheic zone depth are not believed to be inconsistent. Literature references that provide a justification for hyporheic zone depths greater than that observed by Harvey and Fuller, as described in Comment #479, will be included in the 100% design. In addition, the 100% design will include a sensitivity analysis on the hyporheic zone depth.				
483	DOI-36	Design	GW Modeling	9.2/p.70	As discussed in Section 3, these parameters [pH] are not	A common issue with organic substrates is the production of H^+ which lowers the pH and in turn has a detrimental effect on the microbial populations which are largely responsible for creating the reducing conditions. Does the aquifer have enough buffering capacity for neutralizing the free hydrogen for many years in the future?	Organic matter consumption will proceed via numerous pathways, including aerobic (coupled to		Resolved.		Resolved.

					expected to have a significant impact on organic matter biodegradation or Cr(VI) reductive precipitation given the ranges observed within the floodplain.		dissolved oxygen) and anaerobic pathways (coupled to Cr(VI), sulfate, nitrate, iron, etc.). Although it is common for acidity to be produced for fermentation reactions, the same is not the case for aerobic and anaerobic oxidation. In particular, anaerobic oxidation of ethanol and lactate (used in pilot testing) consume rather than generate H+. Complete aerobic oxidation of ethanol (the substrate currently chosen for the final remedy design) yields carbon dioxide (3 moles per mole of ethanol), with no additional H+ generation. Although the aerobic reaction will add dissolved CO2 (carbonic acid) to the solution, it is anticipated that this will be balanced by anaerobic reactions. Example reactions for ethanol are as follows: Aerobic: C2H6O + 3O2(g) = 2 CO2(g) + H2O Anaerobic (all alkalinity generating/H+ consuming): C2H6O + 2.4 NO3- + 0.4 H+ = 1.2 N2(g) + 2 HCO3- + 2.2 H2O C2H6O + 1.5 SO4-2 = HS- + 0.5 H2S + 2 HCO3- + H2O The anaerobic processes and alkalinity production will be the dominant processes and it is anticipated that minimal buffering capacity by the aquifer solids will be required to maintain circumneutral pH. This has thus far been demonstrated at

							Hinkley, where remedy operation over a time span exceeding 7 years has not resulted in consumption of aquifer buffering capacity. Likewise, it is anticipated that the aquifer solids at Topock have sufficient buffering capacity.				
484	DOI-37	Non-design	GW Modeling	10.4/p.79	The decreased and increased stoichiometric generation ratios are 0.005 and 0.05, respectively.	Please provide a basis for assigning this range. In particular, could the generation ratios get much higher than 0.05?	The ranges assigned for each model parameter in the sensitivity analysis were based on a best assessment of appropriate levels of uncertainty. Although many of these ranges were difficult to quantify with limited information, the ranges that were chosen fully bracket the actual anticipated level of parameter uncertainty. The manganese generation ratio of 0.016 was estimated based on site-specific pilot testing information that is anticipated to be highly representative of field-scale implementation conditions. The value of 0.05 represents a factor of 3 increase in this ratio, which is believed to be more than sufficient to capture the anticipated level of variability		Resolved.		Resolved.
485	DOI-38	Design	GW Modeling	10.4/p.80	Similar to manganese, arsenic sorption was simulated using the non-linear Freundlich isotherm ($C^* = KC^N$), where K and N are constants that were calibrated to site-specific conditions as described in Section 5.4. In all three sorption scenarios, the N exponent was held	For both manganese and arsenic, if both K and N were calibrated to site data why was the range on K tested in the sensitivity analysis rather than that of N which could have led to a much larger increase in dissolved phase concentrations?	The purpose of the sensitivity analysis was to vary model parameters to capture the reasonable anticipated range in uncertainty and variability of the processes being modeled. Specifically, the model sorption parameter sensitivity ranges were chosen to capture the actual anticipated range in sorption behavior. In the case of manganese and arsenic sorption, these ranges were further constrained by considering known		Resolved.		Resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					constant at 0.465, while the K multiplier was varied.		variability in aqueous geochemistry (see Section 9.2). Although variability in sorption behavior also could have been captured by varying N, this was not necessary; varying K alone was sufficient to capture the effects of variability in sorption behavior. It is true that, depending on the range applied to N, varying this parameter could have resulted in a larger increase in dissolved phase concentrations; however, that would not represent a realistic scenario given the anticipated extent of variability in sorption behavior.				
486	DOI-39	Non-design	GW Modeling	10.6/p.81	While this increase in Cr(VI) retardation would suggest significantly longer remediation timeframes, this is not a likely scenario as the understanding of groundwater flow and plume development suggests a Cr(VI) Kd of 0.5 L/kg would be excessive. This sensitivity analysis was done for comparative purposes to gauge the relative impact of Cr(VI) sorption.	The remediation times are almost always extremely sensitive to the Kd of the contaminant. Therefore, it is unclear why Kd values would be tested outside of the expected range when a major outcome of the sensitivity analysis should be evaluating the range of potential remediation times. What Kd value is the expected upper range based on the understanding of the plume development?	A laboratory study on aerobic core samples from the Site (CH2M Hill, 2005, *Summary of Results—Aerobic Zone Hexavalent Chromium Core Testing*) indicated the range in Kd values from two aerobic core samples collected from the flood plain varied between 0.01 and 0.09 L/kg. This study therefore supports the value of 0.05 L/kg utilized in the baseline hexavalent chromium modeling. A reference to this technical memo will be added to the text.		Accepted.		Comment resolved pending DOI review of the final design documents.
487	DOI-40	Design	GW Modeling	10.6/p.81	While this increase in Cr(VI) retardation would suggest significantly longer remediation timeframes,	Since the Kds tend to have the greatest uncertainty and most sensitivity to the remediation times, this assumption is one of the most important in the entire modeling analysis. Please provide additional information as to where the plume development was investigated and Kds estimated.	The original regional groundwater flow model was calibrated to 4 data sets: 1. Recovery period after shutdown of TW-2D in November 2004;		Accepted.		Comment resolved pending DOI review of the final design documents.

					this is not a likely scenario as the understanding of groundwater flow and plume development suggests a Cr(VI) Kd of 0.5 L/kg would be excessive.		2. Average monthly groundwater elevations between 2003 and March 2005; 3. Injection well testing at IW-2 and IW-3 in January 2005; and 4. Evolution of the Cr(VI) plume footprint from 1951 to 1999 (CH2M Hill, 2005). The final calibration period that focused on the plume evolution from 1951 to 1999 was divided into 3 stages to reflect different hydraulic stresses in the system over time. Even though this calibration was only performed with respect to groundwater flow and minimal historical Cr(VI) data were available throughout the Site, the analysis was consistent with the observed evolution and final footprint of the Cr(VI) plume. This result supports the conclusion that Cr(VI) in groundwater not a strongly sorbed compound that travels freely through the general oxidizing conditions of the alluvial area between Bat Cave Wash and the MW-20 cluster. This transport behavior that is similar to advective groundwater flow supports the use of a relatively low Kd value that would translate to a low retardation factor. A retardation factor was integrated into the model as a conservative assumption with respect to remedial timeframe, and a higher Kd value was evaluated in the solute transport model sensitivity analysis. A laboratory study on

488	DOI-41	Non-design	GW Modeling	12/p. 91	Model Update Procedure	The linkage between the regional model and local model through the flux boundaries will continue to add a complexity to the analysis that may not be necessary. Furthermore, if refinements to the transmissivities are made through model calibration or manually in the local scale model and not in the regional model, the boundary fluxes predicted with the regional model will begin to diverge from the more accurate flow conditions predicted by the local model. It is recommended that PG&E determine how far out boundary effects may be experienced under the most stress-induced conditions and moving the boundaries in the local model to those locations. It is further recommended that only the local model be used in the future.	See RTC #431 DOI-16				
489	DOI-42	Design	GW Modeling	12/p. 91	Model Update Procedure	As the model update text is currently written the decision as to what actually triggers whether the model will every require updating is ambiguous (p. 91) If there are significant differences, the groundwater flow model, geochemical model, and/or the solute transport model will be updated and recalibrated. (p. 91) During the well construction period the groundwater flow and solute transport model will be updated annually, if the data collected suggests that updates are needed. Quantitative criteria need to be developed to determine whether the model needs to be updated and recalibrated. It is currently very unclear of what the model will be used for. It seems that, at a minimum, it should be used to support the capture zone analysis, optimize the remediation system pumping/injection/dosing rates; assist in determining whether the system is performing as designed; and updating remediation time estimates. There should be a section after Section 12 that provides a detailed discussion how the model will be actually be used (including performance metrics) to support these activities.	See RTCs #76 FMIT/TRC, #77 Hualapai/TRC, #78 Cocopah/TRC, and #79 Chemehuevi/TRC The language "if there are significant differences" and "if the data collected suggests that updates are needed" will be removed and the model update schedule discussed in Appendix B Section 12 will be used. An additional paragraph will be added to Appendix B Section 12 to discuss the intended future use of the model including updating remediation time frame estimates, supporting capture zone analyses, and analyzing potential remedy design operation changes.				Comment resolved pending DOI review of the final design documents.

526	DOI-50	Non-design	Editorial	Attachment A p. 6(of 7)	Dosing Design	This section makes a number of references to Appendix B of the 60% design report which should be updated to the Appendix B of the 90% design. Please also indicate where the dosing calculations are found in the 90% design report. Recommend including the dosing design calculations in Appendix B.	References will be updated and dosing calculations will be included in the final design.		Accepted.		Comment resolved pending DOI review of the final design documents..
527	DOI-51	Design	Editorial	Attachment A p. 7(of 7)	However, the amount of EVO required to achieve sufficient distribution can be up to an order of magnitude greater than the amount of oil retention reported in the literature, based on field implementation at a number of sites (Schnobrich et al., 2011). In practice, the required EVO loading must be evaluated on a case by-case basis to confirm the site-specific degree of droplet retention and to ensure sufficient organic carbon distribution for treatment within the targeted area.	Please provide a reference in the 90% design to where the site specific loading rates are calculated that factor in the droplet retention. Recommend including the loading rate calculations in Appendix B.	See also RTC #526 DOI-50. The following references that discuss the retention of oil droplets for EVO distribution will be included in the final design: Solutions-IES, 2006. Protocol for Enhanced In Situ Bioremediation Using Emulsified Edible Oils. Environmental Security Technology Certification Program, Arlington, Virginia. (www.estcp.org) Soo H. and C.J. Radke, 1984. The flow mechanism of dilute stable emulsions in porous media. Ind. Eng. Chem. Fundam., 23: 342-347. Soo H. and C.J. Radke, 1986. A filtration model for the flow of dilute stable emulsions in porous media – I. Theory. Chem. Eng. Sci., 41: 263:272. It should be noted that, in ARCADIS's experience, the EVO requirement calculated based on oil retention typically underestimates the amount of oil needed for adequate distribution/to overcome the electron acceptors present. The final design will include the method to calculate the amount of EVO needed for distribution based on oil retention while acknowledging the potential need for injection of higher amounts of EVO based		Resolved. 							on past experience.				
528	DOI-52	Design	Editorial	Attachment B p. 71	Calculation Cover Sheet	According to the QA Cover Sheet the calculations for the caustic feed usage that were revised on 4/4/2013 have not been independently checked.	Calculations included in Appendix C have been updated where required. In many cases the calculations serve to size vessels and quantify approximate anticipated quantities of reagent use and as such do not require independent verification. Calculations are revised when needed based on engineering judgment. The actual use of chemicals may vary during operations and is difficult to fully predict during the design stage.		Resolved.		Comment resolved.
529	DOI-53	Design	Editorial	Attachment C/Section C.1 p.C-1	The purpose of this geotechnical summary is to provide information on existing site geology and geotechnical data in support of the groundwater remedy design and to propose areas where supplemental geotechnical investigation is needed to verify design parameters.	Since this is the 90% design, please indicate when this work will be completed.	Coordination with the Soil RFI/RI investigation program was conducted in planning of the supplemental geotechnical investigation to minimize the number of boreholes, thereby minimizing ground disturbance. Specific areas are proposed in Section C.2 of Attachment C (Geotechnical Analysis) to Appendix C (Design Criteria). Due to the limited amount of geotechnical data available at the time of this design, assumptions made during the design will be reviewed after receipt of supplemental geotechnical data, currently planned to be collected as part of the forthcoming Soil RFI/RI sampling effort (anticipated in Fall 2015). Any material changes to the design required by this supplemental information will be discussed with the agencies. It is important to note that as PG&E continues to engage in discussions with transportation agencies,		Resolved.		Comment resolved.

538	FMIT/TRC	Design	Infrastructures	Append D Table D1-13	Table Heading / Explanation	The table heading/explanation should identify whether these are the items in the new infrastructure that are expected to be the major potential sources of environmental noise, or whether this a subset of such major sources, and how the subset was defined or otherwise determined.	This clarification was obtained from the commenter on April 22, 2015: "What I am looking for is some statement/narrative from the preparers of Table D1-13 that the equipment itemized in the table are those items felt, by the preparers/designers, to be the significant above-ground sources of sound power levels (SPLs) generated by the project during its operation." Response to clarified comment: The levels stated in Table D1-13 are the Sound Pressure Levels (SPLs) that would be expected when measured at the specified distance. They are different from Sound Power Levels (PWL or Lw) which are calculated quantities that are not directly measured. While the preparers/ designers do not find these sound levels to be either substantial or significant, this list summarizes the primary aboveground, non-emergency, remedy equipment that is likely to be a source of audible sound during operation.		Response noted.	Noted.

D	C-07-100,101, 102,103	There appears to be an inconsistent application of the pipe and conduit spacing in the pipe cross sections from the engineering specification. This inconsistent spacing typically results in a wider trench than appears to be necessary. Trench width may be reduced if minimum design spacing of 3-inches between water pipes or sum of half the diameters for pipelines or electrical conduit are used, in some cases up to 1 foot may be eliminated. Optimizing the trenches may result in significant reduction in the volume of excavated materials. Details A2 and A5 have concrete encasement width of 2-feet, while A6 has a 1'-6" encasement. Concrete encasement for 12 kV line varies from 1'-6" to 2'-9". Varying red concrete cap widths, some details cover all electrical conduits, while others do not.	See above				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
						Detail A3 has electrical conduits within the 12 inch min. spacing, not protected by a concrete cap, or detection tape. Why is there a 12" min between concrete trench and electrical conduit? Multiple details show a 12" minimum spacing between water pipes, concrete, and various objects (i.e. concrete, electrical pipes, concrete trench for example). Spacing between water lines inconsistent, for example Section H1 depicts 9-inches of spacing between water lines, while Section A10 spacing ranges between 4 and 6 inches between water lines. Narrower trenches are preferred by FMIT. Spacing between conduits should be reexamined for example in Section A8 the space between 2-inch conduits is 6 inches, while in other sections the spacing is 3 inches. A final example is the width of Section H2 is narrower than Section H1. These trenches should contain the same water lines and conduits but vary in width. It should be noted that Section H1, a lateral to one IRL well is only 5-inches narrower than Section A10 the trunk line to Pipeline Segment A. Please refer to the attached markup of the figure titled "Pipeline Sections" as an example.

554	FMIT	Design	Infrastructures	Appendix D; C-07-105, C-07-106	CH2MHILL 90% Design Plans	Why is there 12" spacing between electric conduit and water pipelines in underground trenches on previous sheets, but less than 12" spacing in the open air concrete trench? If power and water are so close together in the concrete trench, why is there so much spacing for water lines in concrete trenches and direct bury electrical conduits?	The 12" horizontal/ vertical spacing between conduits and water lines is an engineering approach selected with consideration for future operations and maintenance. By separating the lines, we can excavate and repair/inspect the water lines without needing to move the electrical lines that are installed closer to the surface out of the way. The spacing is reduced in the concrete trenches where the lines can be accessed without excavating around each.			Noted.

560	FMIT/TRC	Design	Remedial Design	Append D AND Supplemental Section 3	Design group "09" Compressor Station Ponds	There appears to have been no effort made to estimate the CUMULATIVE noise impacts resulting from this, or other major segments (e.g., TCS improvements) of this project. This is important considering both the duration of the build-out, and the long-term operation of the remedy. The approach appears to be to design and construct, and then see if complaints arise, and if there are complaints, to then attempt to deal with the issues. Instead, the designers should quantify in advance the projected cumulative noise level impacts resulting from planned improvements at such locations. As an illustration, for the TCS evaporation ponds segment of the project, partial sound level information is provided in Appendix D, Equipment List D1-12 for the natural gas generator that will power the facility.	Certain TCS improvements, such as the new air compressor building, are not part of the project. Improvements to the ponds, however, are part of the project. The cumulative noise analysis for the project can be found on page 6-38 of Volume 2 of the EIR. The analysis accounts for the possibility that the project may be constructed at the same time as unrelated projects at the compressor station, as well as noise from I-40, the railroad, and other existing noise sources in the area. According to this analysis, the project will not make a cumulatively considerable contribution to cumulative noise impacts if the project complies with Mitigation Measures NOISE-1, NOISE-2, and NOISE-3. The approach for this project is to comply with the applicable regulatory standards that are set to protect certain resources and/or receptors and implement the mitigation measures specified in the EIR. The County's noise standards	DTSC has considered cumulative impacts of all known projects in the Certified EIR. Noise impacts are evaluated against regulatory thresholds. DTSC understands that culturally, Tribes may consider noise differently than regulatory thresholds, thus DTSC evaluated the potential cultural impacts of the project and considers it significant and unavoidable.		Now that the design is close to 100% complete, the Subsequent Groundwater EIR should include a comprehensive cumulative noise impact evaluation that considers the project as it now exists, because the project has changed in important ways. Therefore, this comment is considered unresolved.	DTSC Response: Comment noted. Noise impact and cumulative impact are subject areas that DTSC will consider in the upcoming SEIR.

						However, NO sound level data are provided for the two 3-HP pontoon-mounted pumps that will be installed and operational in each of two lagoons to provide aeration of pond waters. Further there is no analysis or evaluation of noise levels from the aeration/emitter sub-system installed along the top edges of the ponds. This approach to individual equipment items provides no analysis or evaluation of the potential cumulative noise impact that can be anticipated at various locations from the planned facility improvements. The cumulative impacts under consideration here get at the impacts to the larger cultural landscape. It is important not only to quantify the noise impacts, but to provide mitigation of those impacts, especially at this remote location. In the interest of further noise attenuation at the remote pond location, the designers should consider a Cummins Quiet Connect Series RS 30 generator (or equivalent), which offers improved noise attenuation (as compared to the Cummins GGMC R.I.C.E. model) – when specified to include the available sound-attenuating enclosure. This approach, in conjunction with planned placement in the structure, may offer significantly reduced sound levels at the site.	and the EIR mitigation measures limit the amount of noise allowed to be produced. These thresholds are numerical and quantifiable (see Section C.11 of Appendix C). These numerical standards are supplemented by protocols specified in the CIMP to further reduce auditory impacts. These design criteria avoid the need to have to quantify the project's contribution to cumulative noise impacts by ensuring that the project's contribution to cumulative noise will be the same as disclosed in the EIR. Further, the type of equipment proposed is consistent with that assumed in the EIR, indicating that additional mitigation above and beyond what has already been specified is not required. The noise emitted by the two 3-HP pontoon mounted pumps (one pump per pond) satisfy the noise design criteria. Details are provided below. The pontoon pumps utilize totally enclosed fan-cooled (TEFC) 3 Hp motors. The sound pressure level for a standard 3 Hp motor at loaded conditions is predicted to be 60 dB at a distance of 9 meters. The minimum distance from the proposed location of the pontoon mounted pumps to the fence line is approximately 20 meters, therefore a standard motor will be expected to be 54 dB at the fence line. This complies with the applicable noise requirements for the

							TCS Evaporation Ponds. In addition, the above calculations are based on standard motors. Higher efficiency motors are being utilized which are quieter than standard motors. In the unlikely event that actual noise levels exceed the criterion of 60 dB at the fence line, additional engineering controls will be installed to achieve compliance. The commenter noted that RICE generator sets may be specified with sound attenuating enclosure. These enclosures provide additional insulation and sound suppression to attenuate sound. Several manufacturers (Cummins, Kohler, Generac) produce natural gas fueled RICE generator sets that meet the noise design criteria at the ponds. PG&E recently learned that Cummins no longer produces the GGMC model. Therefore, we evaluated other models from Cummins and other manufacturers; Cummins RS30, Kohler 30REZG and Generac SGO35. All models, when specified with sound enclosures, will meet the noise design criteria at TCS ponds. In addition to the enclosure, the generator will be housed in a utility building which further attenuate sound levels. The Kohler Model 30REZG was selected because of its certified Prime rating. A Prime rating allows the operational flexibility (in terms of allowed operating hours in a year) needed for the

607	DOI-82	Non-design	O&M	2.7.1.1: p. 2-19	Components	Since the water in the TCS Evaporation Ponds may have a high TDS there should be a leak detection system. Please provide a description of the construction of the ponds within this section.	PG&E proposes to include the following text after the first paragraph at the beginning of Section 2.7: "<u>By design, discharge to the TCS ponds is and will continue to be fully</u>		Resolved.		Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							contained, thereby designed to prevent any leaks. In layers (from top to bottom), each pond has a new 60-mil high-density polyethylene (HDPE) top liner; the original 60-mil HDPE primary liner (with repairs); a leachate collection and removal system (LCRS); and a secondary 40-mil HDPE liner underlain by 2 feet of low-permeability clay. The LCRS functions as an early warning system to prevent leaks by enabling a determination of whether the top liner system has been compromised, prior to a potential release of pond water to the environment. In addition, the area immediately adjacent to the TCS ponds lysimeters were installed underneath the clay base, and seven groundwater monitoring wells were installed to detect leaks. The groundwater and vadose zone monitoring systems are sufficient to allow detection of any potential before any discharge reaches groundwater (groundwater is between approximately 160 and 190 feet below the bottoms of the ponds, as noted earlier)."				
608	DTSC-143	Design	Remedial Design	Section 3.1.1.2 p3-2	At the injection well valve vaults, the Inner Recirculation Loop and freshwater forcemains connect to the smaller diameter injection well piping	Consideration should be given to installing check valves near this connection to prevent inadvertent transfer between the freshwater and IRL forcemains should manual valves be left open.	Check valves will be added to the injection well vaults in the final design.	Resolved.			Comment resolved.

						the mechanical and P&ID drawings as appropriate.	details become available from the manufacturer during the project construction phase, they will be incorporated into the as-builts, O&M Manual, and SOPs, as appropriate. As mentioned in RTC #600 DTSC-142, the vapor recovery system is an integral component of the carbon substrate storage tank and is not detailed separately. The vapor recovery system design and O&M requirements will be specified by the manufacturer to match the tank size and flow rates required, and will comply with applicable codes and requirements including San Bernardino Fire Marshall and MDAQMD requirements. System maintenance requirements will be further detailed in the tank ATC permit and inspections are anticipated to be performed, at minimum, during annual certification and testing processes. As additional details become available from the manufacturer during the construction phase, this information will be incorporated into the as-builts, O&M Manual, and SOPs, etc. Material changes to the SOPs and O&M Manual such as incorporation of the above vapor recovery system will be reported in the progress reports and posted on the SharePoint site for access by agencies, Tribes, and stakeholders.				
610	DOI-83	Design	O&M	3.1.1 p. 3-3	As detailed in the Sampling and Monitoring Plan in Volume 2 of this O&M Manual, carbon substrate	As noted in the text, the carbon substrate amendment concentrations will be determined from monitoring data but the rationale behind the actual dosing rates, frequency and duration needs to be presented somewhere in the O&M manual.	The injected concentration is the main dosing control that will be adjusted, i.e. if not enough carbon is distributed; a higher concentration will be		Resolved.		Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					amendment concentrations, frequency, and duration will be adjusted based on analytical groundwater data and injection well performance data.		added such that a higher concentration will remain after substrate degrades during distribution in the subsurface. The dosing parameter of frequency may also need to be adjusted to maintain injection capacity. For example, water levels tend to increase during ethanol dosing and decrease following injections. As injected concentration changes, a different frequency of injection may be needed to accommodate the water level changes associated with ethanol injection and maintain injection capacity. The duration of the injection will be adjusted to control the total amount of ethanol being injected. For example, it may be advantageous to store more reducing equivalents within the aquifer, while not changing how far the ethanol is distributed by changing the injection concentration. In this example, the footprint of byproduct generation could be held constant while increasing the stored Cr(VI) reducing capacity while the IRZ is ON. The following text explaining the interplay between concentration, frequency, and duration of injections will be added to the text in the O&M Manual, Volume 2 on page 2-1 to add further detail to this section where adjustments of dosing are discussed: "The injected concentration is the main dosing control that will be adjusted to improve distribution. Frequency may also need to be adjusted to

							maintain injection capacity. The duration of the injection will be adjusted to control the total amount of ethanol being injected."				
611	DOI-84	Design	O&M	3.1.3.1 p. 3-6	Continuous or intermittent injection or dosing of the selected carbon substrate, carbon substrate target total organic carbon (TOC) concentrations, and injection frequency and duration will be adjusted based on groundwater analytical data and injection well performance, as summarized in Section 2.1.1.4 and presented in the Sampling and monitoring Plan in Volume 2 of this O&M Manual.	The discussion pertaining to using the monitoring data to establish and optimize dosing rates really does not fit in the "Sampling and Monitoring Plan". The dosing uses the data from the monitoring but has more to do with the operation of the system. Recommend moving the discussion about the dosing to Vol 1.	The most appropriate location for the explanation of how groundwater monitoring data will be used to guide dosing parameters is somewhat subjective. For the 60% Design, the data quality objectives used to guide design of the monitoring program were presented in the Sampling and Monitoring Plan. These data quality objectives, which were requested by the agencies, include decision rules that, in the case of this program, provide the framework for how data will be used to make operational decisions. As such, the operational decision framework based on groundwater monitoring data was presented in the Sampling and Monitoring Plan. For consistency, we would like to retain the operational decision framework for dosing in the Sampling and Monitoring Plan along with the rest of the operational decision frameworks that are part of the data quality objectives.		DOI concurs with the response.		Comment resolved.
612	DOI-85	Non-design	Editorial	3.2.1.2/3-15	Fresh water stored in the Remedy Freshwater Storage Tank (TNK-103) will flow by gravity to the freshwater injection well FW-02 (P&IDs I-02-01 and I-02-02). 					level set point (LSL-155) A given injection well must have water level greater than the low-level set point (LT-052)		A given injection well must have water level less than the high-level set point (LT-052).				
614	DOI-87	Non-design	Editorial	3.2.1.2/3-15	Backwash pump (PMP-001) is not in RUN mode Well head pressure is below the high-pressure set point (PI/PIT-062)	These conditions should be prefaced with "A given injection well vault…"	The referenced bullets will be revised as follows: • Backwash pump in a given injection well (PMP-001) is not in RUN mode • Well head pressure is below the high-pressure set point in a given injection well (PI/PIT-062)		Resolved.		Comment resolved.
615	DOI-88	Design	O&M	3.2.1.2/3-16	TNK-103 outlet valve (V-103C) – Open	This valve could be closed if FW-02 was being backwashed. This would allow flow to the other injection wells and the filling of T-103.	Under normal operating conditions V-FWST-103C will always remain open. Actuated valve FV-FW-02-011 at FW-02 will close during the automated backwash sequence.		Resolved.		Comment resolved.
616	DTSC-145	Design	Infrastructures	Section 3.5 3-71		The SCADA system should include offsite backup of the information stored in Historian.	The Historian database, SCADA/HMI programs and PLC logic programs will be backed up off-site to support system continuity and access to data.				
617	DOI-89	Design	O&M	4.1.1.1 p. 4-2 Notes in Table 4.1.1	water level data will be collected from each well and will be used to calculate the specific capacity and specific injectivity once the well is in service	It can often be difficult collecting accurate water levels from pumping and injection wells due to the interference from the pump wires and water spray. Recommend completing the wells with a 1-inch stilling well inside the casing – basically the way water levels were collected before transducers were common.	Stilling wells are part of the existing remediation well design. Please see the well design drawings in Appendix D of the BOD for further details (M-02-02, M-03-01 to M-03-02, M-04-01 to M-04-02, and M-05-01 to M-05-03). Transducers will be installed in the stilling wells to allow for automated water level data collection. The stilling wells will also allow for manual measurement of water levels in the remediation wells.		Accepted.		Comment resolved.
618	DOI-90	Design	O&M	4.1.1.4 p. 4-3	The two baseline samples will be collected	It would seem that the best baseline data would come a week or two after pumping is initiated. Otherwise the water in the vicinity of the well may not have recovered to ambient geochemical conditions due to the introduction of water during drilling etc.	Agreed. We will confirm that we are close to steady state conditions prior to sampling.		Resolved.		Comment resolved.

							specific nature of the various wastes in addition to quantity will be further refined through operational experience once the remedy is implemented.”				
624	MWD	Non-design	Request for Information	Vol. 1, Sect.6.1.5/6-6		Provide an estimate of generated waste material (RCRA and Non-RCRA hazardous) that is to be stored onsite and/or disposed of offsite.	It is anticipated that the quantity of hazardous wastes generated from remedy operations to be small. This will be confirmed after start of operations.				Comment resolved.
625	DTSC-123	Design	SOPs	Remedy-SOP-03, O&M Volume 1, Appendix B, Page 10	“4.4.6. Reinstall the low level switch.”	Typo. Revise to “high” level switch.	Text will be revised as requested.	Resolved.			Comment resolved.
626	DTSC-124	Design	SOPs	Remedy-SOP-03, O&M Volume 1, Appendix B	Sheet I-02-01	The figure shows drywell pits being constructed in association with sand separators for wells HNWR-1A and Site B. Ensure that design text (not an SOP) describes the function and dimensions of these units and what will be discharged into these pits. Design drawings (C-01-01, C-01-02, S-01-07) indicate the drywell pits are quite large and, therefore, may be objectionable to Tribes. As these units were hard to find in the design document, it is suggested that they be brought to the attention of the Tribes. As indicated above, DTSC would like to understand the basic operation of these units. How necessary are these pits? Are there alternative methods to knocking out the sand? Why are these type of pits not utilized with most production wells (e.g., Topock 2 and 3). If constructed, will the pit at HNWR-1A be used for HNWR-1 or Site B should they come online?	The sand separator is located at the wellhead to minimize the amount of sand in the water and thereby minimize solids settle-out at the bottom of the downstream conveyance pipe. Accumulated sands from the sand separator will be contained in the purge water. The purge water from the separator will be allowed to percolate into the ground via the dry well filled with rock located near the well. Sands in the dry well will be periodically removed. Dry well is simple to operate and is located within a sub-grade vault. If HNWR-1 were to be brought online, it will share the dry pit with HNWR-1A. If Site B were to be brought online, it will require a separate dry well near the well head. Other options evaluated to remove sands from the freshwater supply well include: 1) using blow-offs to flush solids from low points in the freshwater conveyance piping, 2) installing filters (large) to remove the solids at the well				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							head, 3) installing a large tank at the well site to allow the solids to settle. These options were rejected for various reasons including the need for multiple blow-offs needed along the freshwater conveyance piping (Pipeline B)/adjacent to County Road 10, large visible equipment near the well head on the Refuge, or inefficient removal of sands. A brief description of the dry well and associated O&M was included in Section 5.4 of the O&M Plan (O&M Manual Volume 1). The following text will be added to Exhibit 3.3-4 of the BOD in response to this comment: "<u>Item: Solids Removal Design Parameter: Install a sand separator at the well head to minimize the amount of sand in the water and thereby minimize solids settle-out at the bottom of the downstream conveyance pipe. Accumulated sands from the sand separator will be contained in the purge water. The purge water from the separator will be allowed to percolate into the ground via the dry well filled with rock located near the well. Periodic removal of the solids accumulating in the dry well is needed.</u>"

							• <u>If the leaked transformer oil is a hazardous waste, remove using absorbent.</u>				
Specific Comments – 90% BOD, Appendix L: O&M Manual -- Volume 2: Sampling and Monitoring Plan											
667	DOI-94	Design	O&M	Appendix L, Vol.2; 2.1 p. 2-2	The Tables 2.1 4 and 2.1 5 include anticipated Cr(VI) concentration trends toward treatment to less than 32 g/L for wells located within the plume boundary. As the remedy progresses, if the observed concentration trends are not consistent with anticipated Cr(VI) attenuation timeframes (i.e., if the monitoring results indicate that Cr[VI] attenuation is actually taking substantially longer than anticipated), then operational changes to the …	The information in Tables 2.1.4 and 2.1.5 simply indicates whether the trend should be increasing or decreasing at each well based on the model results. An important aspect of this approach that is lost is that it's not just whether the trend is decreasing but the rate that the concentrations are decreasing. This approach really makes it difficult, particularly for a third party review, to evaluate the monitoring data against the model predicted attenuation rates. Since the modeling results are being used to establish whether the attenuation is occurring at the anticipate rate the actual model predicted concentration vs. time data at each of the wells should be provided. The means by which the trends will be established should also be mentioned.	The intent of Tables 2.1.4 and 2.1.5 is to provide a basis for looking at well-specific data to see if areas of the site are following the general trends that are anticipated. If the trends are not behaving as anticipated, the implications for the remedy will be evaluated by recalibrating the model to incorporate the observed data and re-predict the remedial timeframe. The changes in predicted timeframe, rather than any individual well trend, will be used to make decisions about whether additional infrastructure is needed. More quantitative descriptions of anticipated trends at individual wells are not recommended, because it would imply greater certainty in the model and imply greater importance in decision making for individual well trends than intended.		Resolved.		Comment resolved.
668	FMIT/TRC	Non-design	GW Modeling	Append L Vol. 2 2.1/p 2.3	"If operational adjustments are implemented, the effects will be assessed in the context of the overall plume remediation using the field data and re-calibrated groundwater modeling projections."	This is unclear: 1) Does it just refer to re-calibration of the GW flow model, or also recalibration of the fate/transport model? What are calibration data and targets? 2) Would this include re-calibration of the regional MicroFEM model 1st, followed by local scale Modflow model updates (i.e. new BC and new parameters)? Using PEST? Optimization runs? 3) This statement suggests the model will be used first to assess changes (i.e. alternatives), and then second to assess effects AFTER operational adjustments have been implemented, but WON'T be used to guide operational adjustments?	1. The groundwater flow model, geochemical model, and solute transport model will all be recalibrated to data collected prior to scheduled model update interval. 2. The regional MicroFEM model recalibration will need to be conducted first and then directly converted to the MODFLOW submodel. The flow model will be calibrated to observed			This PG&E response is still very vague and doesn't appear adequately thought-out. To avoid future confusion to all stakeholders, Hualapai request that PG&E consultants revise such text (throughout the documents) to further clarify a) exactly which models will be updated (i.e., 4 different models described in Appendix B (90%BOD) -	PG&E Response: Additional details on potential model update components will be included consistent with RTC #76. What are calibration data and targets? 2) Would this include re-calibration of the regional MicroFEM model 1st, followed by local scale Modflow model updates (i.e. new BC and new parameters)? Using PEST? Optimization runs? 3) This statement suggests the model will be used first to assess changes (i.e. alternatives), and then second to assess effects AFTER operational adjustments have been implemented, but WON'T be used to guide operational adjustments?	See above			This PG&E response is still very vague and doesn't appear adequately thought-out. To avoid future confusion to all stakeholders, Tribes request that PG&E consultants revise such text (throughout the documents) to further clarify a) exactly which models will be updated (i.e., 4 different models described in Appendix B (90%BOD) - MicroFEM, Modflow, MT3D, and Phreeqc), b) what will be updated (i.e., inputs changed, and basis), c) what is involved in re-calibration, d) what will be used as new calibration targets, e) what the calibration tolerances will be - to meet continued use of the model (i.e., Tables 2.1-4 and 2.1-5 and Figures 2.2-2 thru 2.2-9 in O&M Vol2 document) to meet RAO performance evaluations. With respect to the substantial amount of hydrogeologic/chemical data that will be collected during installation/testing/startup - Tribes also request that PG&E consultants make it very clear how these data will be a) interpreted or characterized with existing datasets, b) how the conceptual site model (CSM) will be updated, c) how these data will be incorporated into the existing model (i.e., will model layers be adjusted to match new well screens instead of stratigraphic	See response 668

677	FMIT/TRC	Design	Monitoring	Append L Vol. 2 IRL DQO-5 p. 2-7	Six-month baseline and 25% Action Levels	There are significant natural variations of byproduct concentrations exhibited in water from wells in the study area. The 25% Action Levels could be violated due to natural variation, which could trigger regulatory enforcement measures, which in turn could delay the timely completion of the remedy. Rather than setting hard baseline values (numerical standards), the geochemistry that contributes to the exceedance event should be described through modeling and visualization in order to describe impacts on the remedy. Geochemical modeling could then be used to simulate ways to reverse or correct the byproduct exceedances.	The purpose of establishing these action levels is to ensure awareness about what concentrations are being injected into the Uplands, rather than to directly trigger changes to remedy implementation. Note that as stated in this section, these action levels do not apply to byproducts arsenic and manganese which have action levels established elsewhere that are based on geochemical modeling and that are part of a process of understanding geochemical changes that are resulting from the remedy (for example, see the discussion of action levels on page 2-2).			How will you know whether arsenic or manganese in water from IRL monitoring wells comes from the freshwater source or from geochemical reactions within the aquifer near injection zones (especially IRL wells that inject carbon)? Arsenic and other water-quality constituents should be monitored in water from the freshwater source well(s). The wording of the section appears as though regulatory actions could be taken that might affect the operations or outcome of the groundwater remedy. If such actions were to occur, Hualapai would appreciate involvement in the data analysis and discussion of the proposed actions. Comment unresolved pending development of a plan to distinguish between different sources of arsenic and manganese at IRL monitoring wells.

685	FMIT/TRC	Non-design	GW Modeling	Append L Vol. 2 2.2.3/p. 2-9	"The decision statement for this DQO is: should extraction system operations or configuration be changed to optimize Cr(VI) migration control?"	This seems different than the actual TCS DQO-2 problem statement above. The question is now posed as an optimization problem and not just removing CrVI mass. If it is truly meant to be an optimization problem - then optimization criteria, constraints, and objectives should be clearly stated and discussed here. One key optimization criteria would be to maximize removal of CrVI in shortest possible time - so a following question is...how serious is the 30 year remedial time constraint in driving any 'optimization' of the TCS operations/configuration? How does the modeling fit into the optimization?	The text for this section was not intended to imply that operation of the TW bench extraction wells is a strong control on overall remedial timeframe, which is not anticipated. To clarify, the decision statement will be modified to match the problem statement: "The decision statement for this DQO is: should extraction system operations or configuration be changed to optimize improve Cr(VI) removal and migration control?"			This response remains unclear. Will all/some model(s) be used to run simulations aimed at optimizing extraction system to maximize removal of CrVI and to minimize plume migration/expansion? This sounds like a modeling optimization problem, which should be further clarified and restated.	PG&E Response: Assessment and optimizations of the performance of the TCS components will be driven by observed hydraulic and groundwater quality data in the field. The model can then be utilized to assess the potential long-term effects of the proposed adjustments or modifications.

693	Chemehuevi/ TRC	Non-design	GW Modeling	Append L Vol. 2 Table 2.1-1	"If hexavalent chromium concentrations are not decreasing within expected timeframes, operational changes (potentially including the addition of provisional IRZ wells) will be implemented per the process control decision rules (Figures 2.2-2 through 2.2-9)."	What are the "*expected timeframes*" and what is the basis? If models are updated during installation, startup, initial operation and for any 'operational' adjustments post- startup - will these "*expected timeframes*" also be updated and provided to stakeholders?	See above			Comment noted.	
694	FMIT/TRC	Non-design	GW Modeling	Append L Vol. 2 Table 2.1-4	Model Predicted Cr(VI) Concentration Trend	Based on review of the 3rd quarter 2014 GW monitoring report data trends - several monitoring IM-3 monitoring wells showed increasing CrVI trends for several years (i.e. MW-40D, MW-47-115, MW-62-110, MW-66- 230, MW-69-195 etc.), probably due to redistribution from an imperfectly known plume distribution. Were such changes considered in the predicted trends provided in Table 2.1- 4 here? It seems likely similar redistribution effects will occur for years after starting remedial system operations, which aren't attributed to TOC effects? This table is referred to often and triggers important decisions on operations (and provisional wells) – how will these effects be considered? At a minimum, wouldn't this require updating and re-calibrating all 3 models (MicroFEM, Modflow, mt3d) and re-simulating the baseline 30 year + remediation scenario with new concentration distributions from all of the new data collection obtained during installation/monitoring? Could actual numerical values be indicated by year with some level of uncertainty instead of indicating "increasing/decreasing" to avoid premature and potentially incorrect operational/design changes? Shouldn't this table be updated after installation, when new monitoring data in many new locations/depths will become available? Model updates seem vague throughout 90% documents, occurring only if 'significant deviations' - but it seems essential to plan now to update all models so key decisions are made with the best possible predictions.	Table 2.1-4 was based on the baseline Cr(VI) distribution described in Section 2.2 of the BOD and did not assume any additional mass in areas noted based on recent concentration trends. Yes, there could be changes in Cr(VI) concentrations in the early data set as wells are installed and equilibrate. Yes, the Cr(VI) distribution data is a key part of the data that will go into the model updates during remedy construction and those model updates may change the expectations provided in Table 2.1-4. See comment # 667 for a discussion of numerical refinements of the expectations. More details on model update timing are provided in response to comment # 205.			The Tribes recommends that PG&E consultants quantify the duration of time they will wait to take actions (i.e., new wells, adjustment to extraction/injection rates etc.) and what their basis is. Again, Tribal concerns are that PG&E consultants may conclude that additional injection/ extraction and/or monitoring wells are required after limited and inadequate trend analysis (i.e., 1 to 3 years based on IM-3 data), where concentrations may deviate from currently modeled trends (i.e., increasing vs. decreasing, or changing at a rate much faster than expected) that are based on a flow model that has a number of flaws (i.e., see Prucha and Eggers, July 15, 2015 whitepaper) and are highly uncertain. In	DTSC response: Tribal comment noted. DTSC agrees that careful evaluation of data and trend would be priority.

698	DOI-107	Non-design	Process	Section 2.2	Figure 2.2-2 through Figure 2.2-9	The text of Section 2.2 and the referenced flow charts imply that data evaluation per the flow charts and operational changes (if needed) occur whenever data is collected. However, most of the flow charts call for model recalibration or adjustment which seems onerous considering some data is collected on a monthly basis. Please clarify the frequency of data evaluation/operational adjustments including updating of the model.	The flow charts will be updated to clarify the timing of model updates as discussed in modeling Appendix B Section 12 and clarified in response to Comment #205. An additional paragraph will be added to Appendix B Section 12 to discuss the intended future use of the model including updating remediation time frame estimates, supporting capture zone analyses, and analyzing potential remedy design operation changes.		Accepted.		Comment resolved pending DOI review of the final design documents.
699	DTSC-147	Design	Monitoring	Operation and Maintenance Manual Volume 2 Sampling and Monitoring Plan / Appendix I, Page I-15		DTSC requests that the flow chart figures such as Fig 2.2-2, 2.2-4 and 2.2-9 where multiple monitoring aspects are presented on one interrelated figure be blocked out in some similar fashion as was done on the figures during the February 18, 2015 TWG meeting. DTSC had done this independently during the 60% and believes it will make the charts easier to understand, especially for those new or peripherally involved with this aspect of the project. Although the flow charts as presented are a frame work for O&M, these should be considered living documents that would potentially change based on operations. Note: Agencies are still in discussion regarding 60% design RTC 38 – short term goals which may lead to revisions of the Operation and Maintenance Manual Volume 2 Sampling and Monitoring Plan including longer term goals.	Comment noted. Similar blocking will be incorporated into the flow chart figures to provide additional clarity and will be included in the final design document. It is also recognized that the flow charts should be considered living documents.	Resolved.			Comment resolved.
700	FMIT/TRC	Non-design	GW Modeling	Append L Vol. 2 Figures 2.2-2 to 2.2-9		These monitoring decision framework diagrams point to many key decisions which are based on model-derived expected concentration ranges or trends (i.e., Tables 2.1-4, 2.1-5 and 2.2-1), but don't discuss when, how or which models need to be updated, nor whether these tables would then be updated and how long all of these decisions (short-term or long-term) will actually take. Based on Table 2.2-1, some decisions might take up to 30 years. It is recommended that decision time-frames be included in the framework diagrams, and more detail on when, how and which models will be updated. Use of models should be more frequent and iterative with any potential	The timing of model updates is provided in modeling Appendix B Section 12 and is clarified in response to comment 205. In our experience, decreases in sulfate concentration are sufficient to determine whether sulfate reduction is occurring.				
705	FMIT/TRC	Design	Monitoring	Append L Vol.2 Sect. 4.2 and Table 2.2-1 Process Control Monitoring Program	Analytes	A full suite of cations, anions, and redox sensitive parameters are necessary for rapid geochemical assessment of groundwater remedy progress. For example, upconing of higher density water from the Mohave Basin could occur at the riverbank extraction wells, and chloride analyses could detect this occurrence. However, major ions (including chloride) would only be collected “as needed.”	The key redox sensitive parameters (e.g. nitrate, dissolved iron, dissolved arsenic) have been included in the sampling plan for evaluating the establishment of conditions for Cr(VI) treatment in the IRZ. With regards to cations and anions, previous analysis of density considerations due to salt concentrations for the remedy have not indicated that this is an important consideration for the project. Regardless, specific conductivity data will be collected during groundwater sampling that will be able to detect significant changes in salt concentrations. If this occurs, chloride or other cation/anion analysis can certainly be conducted under the "as needed" frequency designation.			Hexavalent chromium contamination at Topock is a chemistry problem, and the proposed remedy is a chemistry solution. But the chemistry solution is not being fully implemented. As the remedy is implemented, chemistry changes will occur to the aquifer over time that will require detailed analyses, modeling, and interpretation of geochemical changes. For example, ethanol may not be the carbon used for the entire remedy (the aquifer will become weary of ethanol), and there will be subtle changes in aquifer geochemistry that could only be described through persistent sampling and geochemical modeling. However, there seems to be a “seat-of-the-pants” approach being applied here. Such a large and important project should not be operated by seat-of-the-pants methods that can exacerbate significant impacts. Comment unresolved pending development of a plan to analyze major ions on a routine basis.	DTSC/DOI Response: Tribal comment noted.

					MW H /MW 46 175: 0.0026 ft/ft MW D /MW 46 175: 0.0034 ft/ft	due to the cyclic nature of the water levels that are impacted by the river stage. Please describe how this temporal nature of the water levels will be factored into the capture zone analysis. There should also be some discussion of how often these gradients will be checked and how the operation of the injection/pumping operations will be altered if these gradients are not maintained.	flow model runs as described in Section 4.3.3.1, p. 4-11. Regarding potential system operation changes as a result of observed gradients, the gradient thresholds for the identified monitoring well pairs are only a single line of evidence. As explained in Section 4.3.3, "a single line of evidence is not considered sufficient to demonstrate plume control because the uncertainties inherent to any single method are likely too great. Therefore, plume control is best demonstrated through multiple lines of evidence." Accordingly, injection/pumping operations will not necessarily be altered if the single-line-of-evidence threshold gradients for the identified well pairs are not maintained, which is consistent with DTSC comments during teleconferences discussing potential well pair analysis. Instead, the multiple lines of evidence approach will be employed to determine the potential need for operational changes. Therefore, these well pair gradients will be checked as part of hydraulic control assessments which will incorporate all of the lines of evidence discussed in Section 4.3.3. The method for addressing water level fluctuations due to river stage effects for the purpose of selecting representative water level elevations for hydraulic assessments is described in Section

713	DOI-106	Design	O&M	Appendix L, Vol.2; 4.3.3.1 p. 4-11.	Second, in lieu of having piezometers immediately adjacent to extraction wells, piezometers will be installed within the filter	This approach of trying to estimate water levels in the pumping wells with piezometers in the sand pack seems really difficult to justify. The actual well loss at a number of pumping rates and at different times would have to be established and even then the uncertainty would be high, particularly at these flat gradients. The EPA guidance cited in O&M Vol. 2 as the basis for the overall approach states: *"If a piezometer is not available near a pumping well, a possible approach (<u>until an appropriately located piezometer is available)</u> is to estimate aquifer water levels at the extraction well by correcting the measured water level for well losses. Bierschenk (1964) and Hantush (1964) presented a graphical method (see Exhibit 4) for determining head loss coefficients for well losses caused by turbulent flow across*	The proposal of having piezometers within the filter pack (outside of the well casing) is a technical solution to minimize the number of boreholes drilled at the site with consideration of the FEIR. If PG&E is directed to install		Resolved.		Comment resolved.

					pack (outside of the extraction well casing) in some wells, and the difference between the water levels in the piezometer and in the extraction well casing during pumping will also aid in proper correction for well efficiency effects.	*the well screen, based on a plot of specific capacity versus pumping rate developed from a step-drawdown test. However, this approach incorporates the assumption that all well inefficiency results from turbulent flow near the well and in the well screen. Driscoll (1986) points out that other causes of well inefficiency are not accounted for in this approach. Dougherty (2003) presents another well loss estimation technique based on a recovery test in a pumping well. Note that well losses can change over time due to well fouling, further complicating the issue. <u>Again, locating piezometers near extraction wells is much preferred to correcting water levels in extraction wells based on calculated well losses.”</u>* It is DOI’s opinion that only piezometer data should be used to establish the water levels in order to predict capture zones.	piezometers in separate boreholes, this will add to the total borehole count for the project. Additionally, even though the filter pack would have associated head loss compared with the aquifer directly adjacent to the borehole, the water level in a piezometer within the filter pack will be more reliable than the operational water level within the well casing, and well testing can still be conducted to assess head loss occurring in the filter pack in order to estimate actual water level within the aquifer material. Also, piezometers located outside of well borings are not going to add any significant reliability to the model which will be used in conjunction with other lines of evidence to assess plume control.				
714	FMIT/TRC	Non-design	O&M	Append L Vol. 2 Section 5		The O&M manual ought to include monitoring of water levels in the Topock #2 & #3 and possibly other wells monitored as part of the 90% BOD Water Supply evaluation, to verify that long-term pumping at HNWR-1a does not cause long-term drawdowns at those wells. This is an issue regarding impacts, rather than an issue regarding protecting water quantity. Volume 2, Section 5, of the O&M plan does identify monitoring of water at wells #2 & #3, however, this is only for water quality. Therein, it stated that there exist co-operative agreements between PG&E and the well owners. The existence of such agreements ought to facilitate water level monitoring.	Topock Wells #2 and #3 are active water supply wells operated by Southwest Water Inc. Appendix N contains a technical memorandum titled *Addendum to the Summary of Findings Associated with the Evaluation of Alternative Freshwater Sources in the Topock Remediation Project Area* dated September 8, 2014. The fourth bullet on page 2 concludes that “72-hour constant-rate-extraction tests conducted during Phase I at both HNWR-1 and the Site B well suggest that neither will substantially adversely affect the production rates of existing nearby wells (see EIR Mitigation Measure WATER-1, Addendum No. 1)…” and “…pumping at HNWR-1A also will not			While the interpretation of test pumping may indicate no substantial future adverse impacts, all should recognize that, due to the various production wells in Arizona, local aquifer depletion is likely occurring and will occur, even if it not monitored or forecast from short-term test pumping. Therefore, This comment is considered unresolved.	DTSC response: Tribal comment noted. That is the reason for having a contingency source for fresh water.

724	DOI-108	Non-design	O&M	Appendix L, Vol.2; Appendix A, SOP -1A, p. 3 (of 7).	Install the pump with the intake 15 feet below the surface of the static water level.	Typically the wells are set at the midpoint of the well screen. The approach described in the SOP assumes that if there is greater than 15 feet of drawdown recovery rates will be relatively rapid. Please clarify if this is the expected case.	The cited text refers to sampling using the three-volume purge method and a temporary (non-dedicated) pump, at a well that does not have a dedicated pump or dedicated sampling tubing (which would already be set at an appropriate pump depth), or has not been previously sampled. In this case, the pump is set at a depth of 15 feet below the static water level (water surface in the well), *or* at a depth prescribed by the project manager or field team manager based on review of available data (e.g., previous sampling records, development log, well completion diagram, drilling log, etc.). If there is drawdown approaching 15 feet, the pumping rate would be adjusted. If necessary due to continued drawdown, the procedures given for "Low Yield and Poor Recovery Wells" on page 5 of this SOP would be followed instead.		Resolved.		Comment resolved.
725	DOI-109	Non-design	O&M	Appendix L, Vol.2; Appendix A, SOP -1A, p. 4(of 7).	Stabilization Criteria +/1 10% NTU units.	It's not just the stability of the parameters that is important for collecting representative samples, turbidity should be below 50 NTUs (as a rule of thumb) not to adversely affect the dissolved metals concentrations. Please address.	The SOP will be revised to include a turbidity stabilization target of 10 NTU or less before collecting samples, unless other parameters have already stabilized during extended purge, and turbidity, while trending flat, is still above 10 NTU.		Accepted.		Comment resolved pending DOI review of the final design documents.
726	DOI-110	Non-design	O&M	Appendix L, Vol.2; Appendix A, SOP -1A, p. 5(of 7).	Install the pump as previously described and start the purge.	For low recovery wells the pump should be set within the well screen. Please consider this option. 733	DOI-116	Non-design	O&M	Appendix L, Vol.2; Appendix A, SOP –A22, p. 1(of5).	Procedures for Calculation of Freshwater Equivalent Heads	From a mathematical standpoint the calculations in the SOP are correct. However, using single point values for temperature and specific conductance fails to recognize the influence of density/temperature stratifications within the well. The errors caused by using a single point measurement may not be significant where the hydraulic gradients are relatively steep. In the floodplain, however, it appears even small errors could lead to misinterpretations of groundwater flow since the hydraulic gradients are so flat. Frequently, temperature and salinity profiling is done within the well if density variations are thought to be significant. Please address this concern.	PG&E uses salinity profile data to calculate freshwater equivalent heads for the key gradient control wells (MW-27-85, MW-31-135, MW-33-150, MW-34-100, and MW-45-95a) that are used to establish the landward gradient in the floodplain. There are	DTSC requests that PG&E provides in the next GMP report a technical memorandum/ analysis regarding the salinity correction procedures currently used at the site and describe the			Comment resolved pending DOI review of the final design documents.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							three well pairs that are used to evaluate the landward gradients. One well (MW-45-95a) is common to two of the pairs, so there are a total of 5 wells where profiling rather than point measurements of SC is used in head calculations. The data for the key gradient wells provides a basis for evaluating the differences between heads calculated using single point measurements and head calculated using the salinity profile data from the same wells. These are all deep zone wells. The magnitude of the salinity adjustment is greater in deeper wells with a longer water column than in shallower wells. Based on recent data from 4th quarter 2014, the differences in freshwater equivalent heads calculated using the conductivity profiling data vs single-point conductivity measurements from samples collected after pumping range from 0.02 feet to 0.14 feet with an average of 0.07 feet. Note that well MW-45-95a is not routinely sampled so there are no recent single-point conductivity measurements available from this well. The differences quoted are from the other four wells, MW-27-85, MW-31-135, MW-33-150, and MW-34-100. Based on data from these four deep wells, it appears that single-point conductivity measurements provide freshwater equivalent head values that are comparable to those	comparison of profiling data vs single-point conductivity measurements at select wells.			

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							calculated using conductivity profiling. The conductivity profiles in the floodplain wells typically show a relatively uniform conductivity within the casing above the screen and a zone of significantly higher conductivity within the well screen or in the lower section of the wells screen (generally 20 foot screens). The single-point samples tend to have an intermediate value between the higher conductivity observed in the deeper screened interval and the lower conductivity within the blank well casing. This results in single-point conductivity measurements from samples collected after pumping being comparable to the average well profile conductivity that is calculated from conductivity profiling. During the past decade while these methods for salinity adjustments have been in use, detailed groundwater contour plots have been produced showing freshwater equivalent heads at three different depths in the floodplain. On these plots, the heads in the key gradient control wells are calculated based on profiling while the heads in the other wells are based on single point measurements. The gradient control wells contour in with the other wells nicely and the overall groundwater gradients have been stable and consistent over this time. The interpreted landward				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							groundwater flow directions are supported by chromium trends and other geochemical data such the stable isotopes of oxygen and deuterium (See Performance Monitoring Reports from 2004 through 2009 [CH2M HILL] and Interim Measures Performance Monitoring and Site-Wide Groundwater and Surface Water Monitoring Report Reports, [CH2M HILL, 2009 through 2015]). In summary, hydraulic assessments, such as calculating horizontal hydraulic gradients between well pairs, or preparing potentiometric contour maps is always based on data from discretely screened monitoring wells (i.e., a mid-depth well is not compared to a deep well). Based on comparison of recent data for the key gradient control well pairs, the head differences associated with using conductivity profiles vs single-point conductivity measurements are small, averaging less than 0.1 ft. Therefore, using single point values provides a reasonable basis for freshwater equivalent head calculation in most wells.				
734	DTSC-129	Design	SOPs	SOP-A22, O&M Volume 2, Appendix A, Page 5	"It is assumed that: • The salinity of the water column in wells is constant throughout the water column."	Groundwater wells at the Topock site often exhibit salinity stratification. Groundwater well sampling is switching from three volume purge to low flow micropurge. TDS/SC data obtained from the micropurge technique may be less representative of the actual TDS/SC value for the water column as compared to three volume data. Therefore, the water level adjustment/correction may be less accurate and adversely affect groundwater interpretations. PG&E should evaluate this matter in detail and determine if a change in procedure is needed.	As described in response to RTC #733 DOI-116 above, the single-point conductivity measurements from micropurge samples are comparable to the average conductance from the conductivity profiles in the key gradient well pairs. Since the sampling method was switched from the three casing volume	See DTSC response to RTC #733 above. DTSC will continue to evaluate this item.			Comment resolved.

							current depth to groundwater, but no more than 15 feet below the current depth to groundwater, unless the monitoring well is located near a pumping well. If the monitoring well is located near a pumping well, install the transducer at least 5 feet below the maximum expected pumping depth to water see step 4 below.”				
742	DTSC-131	Non-design	SOPs	SOP-C1, O&M Volume 2, Appendix A, Page 8	POINTS OF CONTACT FOR QUESTIONS CONCERNING THESE PROCEDURES:	Will the point of contact information remain the same for the 90% design? If there is a change, what will the procedures be to ensure the SOPs stay current at all times through remedy? This applies to other SOPs as well (e.g., SOP-C2).	The POC information is current. It is the responsibility of the PG&E Construction Manager (or designee) and the PG&E Topock Site Operations Manager (or designee) to maintain the SOPs. PG&E staff will have the latest Standard Operating Procedures (SOPs) on file at the site. As stated in Section 1 of the O&M Manual Volume 1, material changes to the SOPs will be reported in the quarterly progress reports and updates will be made in a timely manner for proper implementation. It is anticipated that for administrative changes such as changes in POC information, a log of changes will be maintained by PG&E. For efficiency, administrative changes will be bundled and/or opportunistically combined with updates to incorporate material changes.	DTSC requests that all current SOPs and change logs be made available in the Topock SharePoint for agencies, stakeholders and Tribal information. It is critical for health and safety, as well as project communication that all participants have advance knowledge of the most current SOPs prior to field visits/monitoring events.			Comment resolved.
743	DOI-118	Non-design	O&M	Appendix L, Vol.2; Appendix A, SOP –L02, p. 1(of 2).	Ferrous Iron Analysis	In areas where the TOC has made a significant impact the ferrous iron concentrations can be very high and require several dilutions with the Hach method. Performing multiple dilutions can lead to significant errors. Recommend that after the proper dilution rate (e.g., 1:5, 1:10) is determined that the process be repeated to ensure accuracy.	Agree, this is consistent with current practice at Topock. This step will be emphasized by adding the following text to the SOP (shown in underline): “Common dilutions <u>(once a dilution has</u>		DOI concurs with the response.		Comment resolved.

							been determined, a duplicate will be analyzed at the dilution determined):				
744	DTSC-132	Design	SOPs	SOP-L02, O&M Volume 2, Appendix A.		The SOPs for chemical methods, including this one, should touch on and document the analytical capabilities of the instrument to ensure that they are appropriate for the task at hand. For example, what are the typical detection limits and optimum analytical concentration range for the instrument? Suggest a section titled “Analytical Capabilities” between the Scope and Equipment sections. Could also add this information to Scope section as done for TDS (SOP-L19).	Agree, a discussion of the practical analytical range of the instrument will be added. However, to be complete, the discussion will also need to include dilutions and sample volume as factors that affect the analytical range.	Resolved.			Comment resolved.
745	DTSC-133	Design	SOPs	SOP-L04, O&M Volume 2, Appendix A, Page 2	“Confirm the calibration by checking the conductivity of the 1000 uS/cm standard at the beginning of each shift.”	The SOP for conductivity should be revised to also include calibration standards that approximate the fluid that will be measured. For example, some saline groundwater will yield much higher conductivities than the 1000 uS/cm standard currently proposed.	Agree. The manufacturer’s manual says the Conductivity probe is shipped with a 1000 µS/cm (at 25 °C) NaCl standard solution. For typical applications with conductivity of 0–10,000 µS (10 mS/cm), calibration will be done with this standard to achieve the accuracy specified for the meter. Outside this range, calibration will be done using a standard that lies closer to the measurement range. Additional steps will be added to the SOP to include a standard of 12,000 – 18,000 us/cm to calibrate for samples that exceed the 10,000 us/cm concentration. In addition, a standard in the general range of 25,000 – 45,000 us/cm will be used as a verification checked whenever a sample with greater than 20,000 us/cm is to be analyzed.	Resolved.			Comment resolved.

If the sample is suspected to have a TDS concentration greater than 100,000 mg/L, the site analyst will consult with the Project Chemist.</u>”	Resolved.			Comment resolved.
Specific Comments – 90% BOD, Appendix L: O&M Manual -- Volume 3: Contingency Plan											
751	DOI-119	Non-design	O&M	1.0, p. 1-1	The following types of unacceptable conditions have been identified: **Category B: Schedule** — Failures that cause the schedule to achieving the groundwater remedy RAOs to be extended by more than 5 to 15 years.	Although some of the categories listed are fairly straightforward in assessing whether the conditions are met others are not. For instance, at what interim points in the process are evaluations made to assess whether remediation will be extended by more than 5 years and what are the triggering events? Please explain the overall approach.	In general, this type of evaluation is typically done during the technical assessment of the five-year reviews to be conducted by the agencies, to answer questions such as is the remedy functioning as intended by the decision documents, has any other information come to light that could call into question the protectiveness of the remedy, etc. Based on current projected construction and start-up schedule (Figure ES-2 of the BOD), the first five year review will occur approximately one year after the end of construction and start of

							O&M, therefore, in PG&E's opinion, the earliest timeframe for a meaningful evaluation would be during the second five year review. Outside of the five-year reviews, PG&E is obligated under the CD and CACA to report to DOI and DTSC, respectively, discovery of changes or events that might cause a delay to the schedule described in the progress reports. Depends on the nature and extent of the changes/events, such discovery could trigger an evaluation of potential effects to remediation timeframe. PG&E propose to discuss with the agencies on the merit/need for any follow-on evaluation.				
752	DTSC-148	Design	Contingencies	Operation and Maintenance Manual Volume 3 Contingency Plan 2.3 Freshwater Supply Page 2-2		Table 2.3-1 should be revised to include wells Topock 2 and 3 as contingent supply wells as well as potential installation of a new well along the planned HNWR-1A pipeline route. As discussed in other DTSC comments, the priority for Site B as a contingent well should be lowered. Use of Site B could also require chromium treatment as a contingency measure.	Table 2.3-1 is identical to Exhibit 3.3-2 of the 90% BOD. Revision to Exhibit 3.3.2 (RTC #274 DTSC-70) will be carried over to Table 2.3-1.	See response to RTC #274 regarding potential chromium treatment. See RTC #135 regarding possible well locations along the pipeline route.			Comment resolved.
753	DOI-120	Non-design	O&M	Table 2.1-1/9	Rising water levels in Colorado River	Potential flooding causes could include extreme rain events as well and should be considered when identifying mitigation.	Extreme rain events will be added as a potential cause for flooding. Mitigations for flooding caused by extreme rain events would be similar to those identified for flooding caused by rising water levels in Colorado River.		Accepted.		Comment resolved pending DOI review of the final design documents.
754	FMIT/TRC	Non-design	O&M	Append L Vol. 3 Sect. 5		The contingency plan in the O&M manual appears to not include planning for water quantity protection, other than for inadequate well yield at a single well - HNWR-1a in Table 2.3-1. That is, the contingency planning should be more encompassing to consider long-term climatic variations (that we are in the midst of) and water supply vulnerability to climate change. Given the 30-yr (+/-) operational timeline, contingency planning should explicitly consider larger impacts to water quantity, e.g., due to long-term regional drought.	PG&E has recently provided a response to a question regarding the potential effects of a prolonged drought on AZ water supply and the remedy process via an email from Yvonne Meeks/PG&E to Doug Bonamici/CRIT, titled Re; February TWG Action Item and dated March 24, 2015. The questions and responses are stated			Please add the provided note to Table 2.3-1. With that addition, this comment is considered resolved.	Comment resolved.

							as follows: "1.) Are you saying severe drought will not adversely affect remedy flow characteristics as it operates, and, *PG&E Response:* That's correct, PG&E professional judgment is that potential future drought conditions would not be expected to significantly impact the remedy flow characteristics as it operates, and therefore the remedy performance or simulated timeframes. The remedy doesn't depend on local precipitation for its function. 2) That a prolonged drought is unlikely to reduce/impair the availability of Arizona freshwater supply so much that it would jeopardize the remedy process? *PG&E Response*: Again correct, as long as there is flow in the Colorado River, then the remedy is expected function as designed (including the availability of freshwater from Arizona). The aquifer on both sides of the river Topock is fed by the Colorado River and the river is highly controlled by the dams upstream. So as long as there is some water flowing in the Colorado River, there would be adequate water in the aquifer to support the pumping associated with the remedy. Although it has never happened, in an extreme drought there could possibly be curtailments on water usage in the Colorado River basin. That could cause PG&E,

772	FMIT/TRC	Design	Remedial Design	Append L Vol. 4 Sect 2.4 p. 2-4		In this section, the definition of a "bed" needs to be specified so that all understand what is meant by a clay bed. For example, the minimum thickness needs to be agreed upon, so that equipment operators and Tribal monitors have a clear understanding of what will trigger the prescribed clay material handling protocol for a clay layer or stratum.	PG&E agrees that additional clarification would be beneficial; however, defining a "bed" based on a			Noted.	

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							specific minimum or maximum thickness is not practicable for the construction project given the various types of excavation that will occur. It is appropriate to define encountering a clay bed, and therefore the application of the clay handling protocol, in terms of being able to physically identify and separate the clay material from the rest of the cuttings or excavation soil. For example, when trenching with a backhoe it will be possible to identify relatively thin beds of clay material (e.g., less than a foot) and separate it from the rest of the excavated soil, but when drilling with a method that doesn't retrieve core that can be closely observed and precisely separated (e.g., hollow-stem auger) a relatively thin clay bed might not be identified or the clay material might become mixed with the rest of the cuttings to the point where it cannot be practicably separated. The text will be modified as follows: "Consistent with the special handling procedures requested by the Hualapai Department of Cultural Resources for displaced material generated from clay beds (this does not include clay-containing sediment mixtures, only clay beds), if clay bed(s) are encountered during construction, the clay material will be set aside on 100% cotton muslin (dye free) for future disposition following discussions with the Tribes. <u>For the purpose</u>

							of this project the identification of a "clay bed", and therefore the application of this special handling procedure, will be based on the practicability for the clay material to be separated from other excavated soils or drill cuttings. For example, when trenching with a backhoe it will be possible to identify relatively thin beds of clay material (e.g., less than a foot) and separate it from the rest of the excavated soil, but when drilling with a method that doesn't retrieve core that can be closely observed and precisely separated (e.g., hollow-stem auger) a relatively thin clay bed might not be identified or the clay material might become mixed with the rest of the cuttings to the point where it cannot be practicably separated. PG&E will notify the Agencies and Tribes in the event clay material is encountered and separated for storage.				
773	Hualapai/TRC	Design	Remedial Design	Append L Vol. 4 Sect 2.4 p. 2-4		In this section, the definition of a "bed" needs to be specified so that all understand what is meant by a clay bed. For example, the minimum thickness needs to be agreed upon, so that equipment operators and Tribal monitors have a clear understanding of what will trigger the prescribed clay material handling protocol for a clay layer or stratum.	See above

777	DTSC-149	Design	O&M	Operation and Maintenance Manual Volume 4 Soil Management Plan 3.1.2 Stockpiles Page 3-2	**"RCRA and non-RCRA Hazardous Soil.** Stockpiling of RCRA and non-RCRA hazardous waste/soil is not planned. It is anticipated that all soil that is above soil screening levels will be placed in roll-off bins or similar containers. If it is necessary to temporarily stockpile soil classified as RCRA or non-RCRA hazardous waste for up to 90 days to facilitate characterization or staging for offsite transportation … **Non-Hazardous Soil Above Interim Screening Levels.** It is anticipated that all soil that is above soil screening levels will be placed in roll-off bins or similar containers."	DTSC agrees with PG&E's preference to contain all contaminated soil (including hazardous waste) in roll-off bins. However, the third sentence referenced on the adjacent column (highlighted for emphasis) to "temporarily stockpile" hazardous waste is not allowed pursuant to hazardous waste management law. The only authorized methods for accumulating hazardous waste on-site for less than 90 days under generator status are specified in Title 22, Section 66262.34(a)(1). The referenced sentence must be removed from the design. In addition, PG&E should notify and receive agencies approval prior to stockpiling soil above screening levels at other locations than those pre-specified for soil storage and staging areas. Furthermore, proper records must be maintained so that the locations and quantities of soil piles can be tracked.	Under California Health and Safety Code Section 25123.3 (b)(4)(B), a generator is permitted to temporarily stockpile hazardous waste soil for up to 90 days for the purposes of offsite transportation if certain requirements are met. In response to DTSC's comment, Section 3.1.2 (Stockpiles) of the O&M Volume 4, Soil Management Plan, will be revised as follows. After the sentence "Hazardous waste stockpiles shall use a minimum 20-mil liner if constructed on a foundation (e.g., pavement or compacted soil) or a 60-mil liner if constructed in a location without a foundation (e.g., unpaved, un-compacted soil)", the following sentence will be added. "Stockpiled soil will not contain free liquids." The following sentence will be added to the end of Section 3.1.2. "After the final volume of stockpiled soil has been removed, the area will be inspected for visual contamination due to stockpiling activities, and any remaining residual contaminated material will be removed." The following text will be added to Appendix C, Construction and Operations Best Management Practices (BMPs) Plan for Soil Storage, Section 1.3, Stockpile Management Control BMPs: **Non-RCRA Hazardous Soil.** It is anticipated that non-RCRA hazardous soil will be placed in roll-off	DTSC agrees with PG&E's citation of the provision in the California Health and Safety Code for temporary stockpiling (less than 90 days) of non-RCRA hazardous waste. However, the cited requirements for compliance with temporary stockpiling of non-RCRA hazardous waste provision are not fully specified in Section 3.1.2. In particular, 25123.3(b)(4)(B)(ii) and (vi). Furthermore, discussion regarding stockpiling of hazardous waste (RCRA or non-RCRA) is absent from Appendix C, BMP for soil storage, section 1.3, Stockpile Management. Finally, PG&E must comply with H&SC 25123.3 for the purpose of the remedy if carried forward.			Comment resolved.

Specific Comments – SUPPLEMENTAL 90% Design Documents - Basis of Design Report/C/RAWP											
798	DTSC-178	Non-design	Editorial	Figure ES-14.		Details in Figure ES-14 are inconsistent with details of other figures (e.g. Figure 4.2-2 of the C/RAWP). Please explain the differences. If the differences are duration driven with Figure ES-14, this should be clarified so that it is easily understood that additional structures will be present.	DTSC is correct in that the differences in layout between BOD Figure ES-14 and C/RAWP Figure 4.2-2 are driven by duration—i.e., only long-term remedy support area structures/features are shown on Figure ES-14. This will be clarified on Figure ES-14.	Resolved.			Comment resolved.
799	DTSC-180	Non-design	CEQA/EIR: Cultural	Section 2/p 21 AND Appendix A11/p 124	Because the proposed soil storage and processing facilities are located outside the . . . APE . . .and the . . . (EIR, DTSC 2011) Project Area, additional surveys were completed to support the design. ---- "To comply with these requirements" [referencing EIR Mitigation Measures CUL-1b/c-1 and 1-b/c-2 and CUL-2; also PA and CHPMP].	Section 2 Page 21 correctly states that the proposed Park Moabi facilities are located outside the APE and the 2011 EIR Project Area and that is the reason additional surveys were required. However, Page 124 of supplemental 90% BOD states that archaeological surveys were conducted at Park Moabi in response to mitigation measures in the Groundwater EIR, and the PA and CHPMP. It is incorrect to cite the CEQA mitigation measure or the PA and CHPMP, which reference an APE that does not include the survey area, as the reason this additional survey was undertaken. Survey of potential additional project area is called for by non-project-specific regulations (e.g. PRC 5024 and 36 CFR 800). The wording of the rationale for the necessary survey should be revised.	PG&E undertook the additional surveys outside the current APE to support the design of the groundwater remedy in compliance with the PA, CHPMP, and the Project mitigation measures in the MMRP. To comply with various requirements of the PA and CHPMP, such as the requirement to avoid and/or minimize adverse effects, see PA Section III(B)(3)(b), PG&E needed to conduct the additional surveys in the area of the proposed soil storage and processing facilities. Because of this, it is appropriate to refer to the PA and CHPMP and not the Section 106 regulations (36 C.F.R. Part 800). See PA Recitals at 5:222-224 ("[A]ll Signatories and Invited Signatories agree that BLM, on behalf of the Federal Agencies, shall administer the Undertaking in accordance with the following stipulations to satisfy the Federal Agencies' Section 106 responsibilities for this Undertaking."). Similarly, the additional surveys outside the	Resolved.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							current Project Area were completed to support the design in compliance with the Project mitigation measures. These mitigation measures require PG&E to assess the potential for construction to result in significant impacts on historically significant resources (CUL 1b/c 2) and to create a design that would avoid historical and archaeological resources to the maximum extent feasible (CUL 1b/c 1, CUL-2). PG&E could not make the required assessment or create a compliant design without the information provided by the additional surveys. DTSC's comment indicates the text on page 124 of Appendix A11 is ambiguous and needs clarification. PG&E will revise the text as follows: "To <u>support the design of the Project in compliance</u> with these requirements, PG&E retained Applied EarthWorks, Inc. (AE) as its Qualified Cultural Resources Consultant to conduct archaeological and historical field surveys of the additional locations considered for Project features in Moabi Regional Park."				
800	DTSC-181	Design	CEQA/EIR	Section 2.1.1.3/ Page 24	Sewage generated from the CHQ will be collected in two 10,000-gallon buried fiberglass-reinforced plastic tanks...The tanks will be emptied and removed sewage hauled offsite as	At Park Moabi, the proposed treatment for sewage and wastewater is to contain and remove it (water, sewer, fire protection are designed as stand-alone systems). PG&E also noted there may be some opportunity to connect with existing potable water and wastewater systems at Moabi Regional Park (if the County were to approve). Can PG&E provide more information on these potential alternatives to be included in the CEQA analysis?	In response to RTC #803 DOI-333, PG&E will provide a revised design for Park Moabi facilities which will include utility corridor information adequate for CEQA analysis.	Resolved.			Comment resolved.

					needed, approximately monthly…						
801	DOI-331	Design	Remedial design	2.1.1.3/2-5	A booster pump and 15,000-gallon water storage tank located on the utility pad in the northwest portion of the CHQ yard will provide fire suppression water for the sprinkler system as well as to a fire hydrant located near the vehicle entrance to the long-term remedy support area.	Please indicate whether the electrical source for the booster pump will be outside of the area for potential fires.	While it is unlikely that a fire would occur near the booster pump electrical feeds, it is not possible to say that any area of the CHQ yard is outside of the area for potential fires. The booster pump is served by the main electrical feed provided by the City of Needles. A backup diesel-fueled electric generator located on the utility pad is also available to power the booster pump in the event of a failure of service on the City of Needles power line.		Noted.		Comment resolved.
802	DOI-332	Non-design	Process	2.1.2/2-6	Water will be transported to the soil processing area in portable tanks as needed…	Please discuss whether any additives, such as brine solutions (sodium and/or magnesium chloride), will be used for dust control and if so, potential impacts on revegetation efforts and groundwater quality.	While fugitive dust control will be conducted using mainly water, PG&E may also apply approved commercial dust control or soil stabilizing agents such as SoilTac (approved for use during and after the AOC 4 Time Critical Removal Action), PM10-50 (used at Hinkley Compressor Station), Gorilla-Snot, etc. Future commercially available products with comparable functionality may also be used, as appropriate.		Resolved.		Comment resolved.
803	DOI-333	Design	Infrastructures	2.1.3/2-6	The soil storage area, also comprising approximately 1.55 acres, will serve as the primary storage area for excavated soils…	Based on discussions with San Bernardino County, the adjacent leasee of Park Moabi Regional Park, and internal discussions between the Bureau of Land Management and the Department of the Interior, PG&E must find an alternate location for storage of waste soil above screening levels.	Based on further clarifications from DOI and BLM, PG&E understands that storage of waste soil above screening levels will not be allowed on federal lands. The remaining potential storage locations are private properties owned by FMIT and PG&E. Given the remedy facilities already planned to be located on the TCS and the Station's own operational needs for		Resolved.		This RTC was discussed at the July 23, August 19, and August 26 TWG meetings. Comment resolved.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							the property for its natural gas compressor operations, there is only space on PG&E property to temporarily store soil bins while awaiting analysis prior to final disposition. There is not adequate space on PG&E property to store waste soil on a long term basis. PG&E also contacted local TSDFs and was told that the TSDFs would accept the waste soil for disposal, not for storage. Given the above, at this time, PG&E has not been able to identify an alternate location for storing the waste soil. PG&E defers to the FMIT regarding its views on potential use of the Tribe's property within the project area for this purpose. In the meantime, in response to this comment, PG&E will eliminate the proposed soil storage area at Moabi Regional Park and move the proposed CHQ into that area. Note that displaced soils that are below screening levels may still be stored at the currently proposed soil processing area and the CHQ (subject to space availability). The management protocol for handling and disposition of displaced site materials (Appendix C to the CIMP, Appendix B to the Soil Management Plan) was revised to reflect that the materials above screening levels will be disposed of offsite. The revised protocol was provided in this 90% RTC period and included in **Attachment Q** of the final RTC table.

					orientation, size, and density of the noise barrier will be determined by a qualified acoustical consultant in accordance with the requirements of EIR Mitigation Measure NOISE-2 (DTSC 2011).		construction noise criteria will conform to San Bernardino Development Code and Mojave County standards, as well as the EIR mitigation measures NOISE-1, -2, and -3. Per San Bernardino County Code Division 3 Chapter 83.01.080, temporary construction, maintenance, repair, or demolition activities between 7:00 a.m. and 7:00 p.m., except Sundays and federal holidays, are exempt from noise limits." Regarding construction, NOISE-2 requires a sound barrier under the following conditions: "When construction activities are conducted within . . . 1,850 feet and 5,830 feet from California receptors and 330 feet and 735 feet from Arizona receptors for daytime and nighttime noise, respectively[,] relative to noise-sensitive uses in the project area, noise measurements shall be conducted by a qualified acoustical consultant at the nearest noise-sensitive land use relative to the construction activities with a sound level meter that meets the standards of the American National Standards Institute (ANSI Section S14 1979, Type 1 of Type 2) to ensure that construction noise associated with the project component complies with applicable daytime and nighttime noise standards. If noise levels are still determined to exceed noise standards, temporary barriers shall be erected as close to the construction		text and note the establishment of the disturbance coordinator Okay.		documents.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							activities as feasible, breaking the line of sight between the source and receptor where noise levels exceed applicable standards.” The Moabi Regional Park mobile home area is considered a noise-sensitive use. The applicable daytime and nighttime noise standards are found in the San Bernardino Development Code. The Code states that the noise standard for residential uses is 55 dB(A) from 7:00 am to 10:00 pm and 45 dB(A) from 10:00 pm to 7:00 am. The noise standard for residential uses from adjacent mobile noise sources is 60 dB(A) on the exterior and 45 dB(A) on the interior. If ambient noise exceeds the noise standards, the noise standards are increased to reflect ambient noise levels. In addition, under the Code, certain sources of noise are exempt from regulation, including noise from temporary construction, maintenance, repair, and demolition activities that occur between 7:00 am and 7:00 pm, except Sundays and federal holidays. In compliance with Mitigation Measure NOISE-2, the evaluation and installation of sound barriers near construction activities is triggered by the distance between the activity and noise sensitive receptors, the applicable noise standard depending on the time of day of the activity, and the sound level attributable to the activity. In addition,

825	DOI-336	Design	Infrastructure	4.1/4-2 & 4.2/4-2	…the riprap and metal guard rails will also be stained to more closely match the surrounding natural colors. New riprap would be stained to match adjacent riprap.	It is unclear why stained riprap would be necessary if local materials are used.	Staining may be needed because the use of locally-sourced materials may not guarantee identical coloring. The colors may differ if the (locally-available) riprap source rock has a different color(s) than the existing soil and rock at the site. Even if they are from the same source material, the colors may differ because the newly-excavated riprap will have fresh cut faces, while the soil and rock exposed at the site has been subject to erosion and other weathering processes that affect color. PG&E recognizes that it is the preference of the land owner and/or manager as to whether the riprap is stained. PG&E will coordinate with land owner and/or manager on this item.		Resolved.		Comment resolved. This will be addressed by the individual landowner(s)/land manager.

					compliance with the CFDW AMMs implemented …		as requested.				
827	DTSC-184	Design	Infrastructures	4.4 Evaluation of the TRC's Proposed Concept for BCW Crossing. Page 4-4.	• The proposed unvented ford would drastically alter the road profile which would violate PG&E's design criterion to keep the elevation and profile of the road surface at or near existing. - The design criterion was developed so that the features of the new crossing (such as elevation, width, slopes, etc.) would be similar to those of the existing service/access road to allow continued use by PG&E and other entities. Drastically altering the road parameters could negatively affect all users.	The cited bullet should be deleted or significantly revised. The bullet discusses the ford altering existing road profile, yet the section states, "*Both options of the ford concept, a vented ford and an unvented ford, would be similar to existing or past conditions at the Topock site.*" and "*the end result would look much like the unimproved ford that was used to cross the wash before the existing culverts were installed.*" Both statements indicate that little change would be expected from the ford design in direct contrast to the cited bullet. The RCB design seems to yield the greatest profile change.	As stated in RTC #19 FMIT-5, after further deliberation and consideration of all 90% comments received on this topic, PG&E changed the design of the northern BCW crossing to involve a) keeping the existing access road and b) burying the piping/ conduits within BCW and up-gradient of the existing access road. Similarly and concurrently, PG&E also changed the design of the southern BCW crossing to remove the aerial crossing and bury piping/conduit within BCW. Therefore, this comment is considered moot given this proposed design change.	Resolved.			Comment resolved.
828	DTSC-185	Design	Infrastructures	4.4 Evaluation of the TRC's Proposed Concept for BCW Crossing. Page 4-4.	"The fords would be overtopped by the 25-year 24-hr design storm event, which would violate PG&E's hydraulic design criterion. In other words, the fords	Regarding the latter highlighted sentence: As storm events are of short duration at the site, the cited bullet does not appear significant, especially since alternative access roads exist and could suffice for short durations. Are there any other design or operational justification that should be considered?	As stated in RTC #19 FMIT-5, after further deliberation and consideration of all 90% comments received on this topic, PG&E changed the design of the northern BCW crossing to involve a) keeping the existing access road and b) burying the piping/ conduits within BCW	Resolved. 							plume (if the well is constructed within the plume, a replacement well might be required).”				
839	DTSC-194	Design	CEQA/EIR	Section 5.3 Page 40	The new air compressor building is for the Topock Compressor Station and is not part of the remedy project.	Moving of the air compressors are necessitated by the need to create space for new generators, which are part of the remedy. Therefore the moving of the air compressors into a new structure at a different location must be considered as part of the remedy even though the ultimate use of the air compressors would not be for the remedy.	For reasons unrelated to the remedy, the Compressor Station needs to upgrade its air compressors and decided to relocate them into a new building as part of the upgrade. The new air compressor building gives the Compressor Station better access to the upgraded compressors for maintenance and other purposes and makes operation easier than it is in the existing building. Accordingly, moving the air compressors is desired by the Compressor Station for its own independent purposes. Under CEQA case law, proposals (such as the moving of the air compressors) that have independent utility from the project being analyzed (here, the remedy) do not have to be included as part of the CEQA analysis for a project, although to the extent possible based on known and reasonably foreseeable information, would be considered in a cumulative analysis as was done in the 2011 EIR (see page 6-4). 855	DTSC-200	Design	Other	C/RAWP Appendix V Technical Memorandum: Preliminary Assessment of Proposed Mitigation Planting Areas for Final Groundwater Remedy Impacts. Page 2.	"Further, it is intended that mitigation plantings would mimic the natural spacing and patterns of the surrounding vegetation, therefore, mitigation plantings are located within the sparsely vegetated areas between existing perennial vegetation."	The technical memorandum discusses revegetation and restoration and details how plantings would mimic natural spacing and patterns. However, Table 1 indicates one area (i.e., RHR-1) has not been previously disturbed. If so, why would one "revegetate" a pristine area, especially if revegetation has some level of impact/disturbance. Clarification and revision is requested.	In the case of RHR-1, there was no readily apparent ground surface evidence of previous disturbance. The intent of planting in this area would be to enrich the sparsely vegetation cover of native perennial shrubs beyond what is currently present. This site will be withdrawn from future consideration and still leave enough riparian mitigation area for projected plantings. We identified more riparian mitigation planting areas than needed in case a proposed site was disqualified during review. The terms 'revegetation' and 'restoration' as they apply to the proposed plantings are described in the 4th paragraph of the Introduction section of this appendix.	Assuming that planting would have some associated impacts, DTSC is not in favor of using area RHR-1.			Comment resolved.
856	DTSC-201	Non-design	Editorial	C/RAWP Appendix V Technical Memorandum: Preliminary Assessment of Proposed Mitigation Planting Areas for Final Groundwater Remedy Impacts. Page 3. 				Proposed Mitigation Planting Areas for Final Groundwater Remedy Impacts. Page 4.	plume (areas where the groundwater contains hexavalent chromium above background levels) is shown with a blue line in Figure 1. Based on that mapping, every proposed planting area, except UHR-3, is located well outside the known hexavalent chromium plume. For this reason, the potential for increased plant uptake of chromium from the groundwater would not be an issue at these locations."	entire floodplain after the remedy is implemented. Additional discussion and revision are requested.	the remedy is designed to reduce Cr(VI) along the NTH IRZ to prevent the migration of Cr(VI) into the floodplain, and there is a shallow naturally occurring reducing rind present in the shallow floodplain, it is unlikely that elevated Cr(VI) concentrations in the shallow floodplain groundwater will occur. Geochemical and solute transport modeling of the proposed remedial strategy indicate that the simulated arsenic and manganese byproducts already present in the shallow floodplain groundwater will remain within the range of the naturally occurring average observed manganese and arsenic concentrations in the shallow floodplain groundwater. Therefore it is anticipated the proposed remedy will not result in an increase in the average manganese or arsenic concentrations in the shallow floodplain groundwater. During remedy implementation manganese and arsenic concentrations will be monitored in the floodplain to confirm the magnitude and extent of byproduct concentrations. If byproduct concentrations increase beyond maximum observed concentrations, further evaluation of plant uptake of IRZ byproducts will be considered as part of the upcoming risk assessment activities.	more will be generated as byproducts of the remedy. It is likely that the average manganese and arsenic concentrations in the shallow floodplain groundwater will increase. DTSC is concerned with soluble constituents, such as arsenic, that may become bio-available for uptake by plants. DTSC wants to make sure that contaminants in the groundwater do not become available to receptors. If they are available to receptors via plant uptake, then the associated risk should be understood. This section should discuss the potential for plant uptake of IRZ byproducts, such as arsenic and manganese, expected along the entire floodplain after the remedy is implemented, and provide consideration for its impacts.			
858	DTSC-203	Design	Other	C/RAWP Appendix V Technical	"The sole proposed planting area	Other than being located near highly contaminated groundwater (e.g., well MW-20), location UHR-3 is located adjacent to the main IRZ line – the heart of the remedy. Earlier in the Introduction section (page 2) it was indicated that the planting areas were to be located away from infrastructure. Discussion is requested to see if UHR-3 area is appropriate or whether it should be dropped or replaced. Any changes would need to be reflected in the Conclusions section.	would not be needed for future remedy operations. A slightly larger amount of mitigation planting areas were identified in case a proposed site was disqualified during the 90% review. The proposed mitigation planting area UHR-3 will be dropped from further assessment of mitigation planting areas from the 90% Design.				
859	DTSC-204	Design	Other	C/RAWP Appendix W 3.3 Evaluation of Alternative Approaches to Staging Areas Pages 6-8.		PG&E has recently indicated that bin storage in Area 4 is no longer desired by them. Therefore, Area 4 space would now be available for alternative uses, and, at a minimum, could reduce use at other areas where the Tribes desire less impact. The Tribes (12/1/14) have noted a potential staging location around MW-25, yet PG&E has not responded to the potential to use that specific location. PG&E should provide a discussion based on Tribes recommendation as a response.	As discussed in RTC #803 DOI 333, in response to that comment, PG&E will eliminate the proposed soil storage area (Area 4) at Moabi Regional Park and move the proposed CHQ into Area 4. Therefore, Area 4 is no longer available for other use. The potential use of the area around MW-25 was brought up by Tribes in the March 2014 letters (see attachments to Appendix I of the 90% BOD). PG&E responded to the Tribes' question in an email dated March 11, 2014 as follows: "For Area #19, the Tribes also had the following question: There is a better place to the west (down the slope) where there already exists a large level place with a well (MW25). Why not go there instead? Proposed IRL-7 nearby. Also N (?). **Response:** The level place to the west of Area #19 serves as an access road used by BNSF, Southwest Gas Company, and PG&E gas transmission department. The access to their facilities cannot be impeded by PG&E's remediation work. Although a small portion	Resolved.			Comment resolved.

							of this area may be periodically useful and available for PG&E remediation work, these other utility constraints and limited access using a steep driveway and tight turning radius led PG&E to conclude that this potential staging area has little value to the project." To date, PG&E has not received feedback from the Tribes on this response or an explanation as to why Tribes think this area is useful as a potential staging area.				
860	FMIT/TRC	Design	Infrastructures	Append W Table 1	C/RAWP Supplemental	Tribes have specifically expressed objections to the use of areas 6, 7, 12 and 13. Supplemental BOD information contains alternatives to these areas. The Tribes would like these alternatives to be utilized and assurance that areas 6,7,12, and 13 will be avoided. In addition, there should be a process to track and verify that the soil staging and construction work and temp storage areas AS IMPLEMENTED DURING CONSTRUCTION are actually consistent with Tribal input and the final lists extent of each area and its designated appropriate use of as ultimately determined.	Section 3.4 of the technical memorandum presents the following conclusion of the alternatives analysis: "All of the alternative approaches evaluated to avoid the use of the proposed Upland areas would have adverse effects on worker safety, public safety and nuisance, environmental impacts, and construction schedule duration that in PG&E's view would outweigh the benefits of eliminating those areas. Location of support zones for staging of construction-related equipment in close proximity to the actual construction activities is critical to PG&E's proposed approach for construction at the Topock site, and specifically in the Upland. This will allow for the safe and effective installation of all remedial facilities, as well as the subsequent decommissioning of IM-3, while protecting the surrounding sensitive resources, minimizing the overall construction footprint and use of			Comment noted. The Tribe continues to emphasize the unsuitability of these areas for use as work/storage areas during construction. If such use is allowed to occur, every effort should be made to limit the actual area used, and to minimize impacts on these areas and their surroundings. Comment is considered unresolved.	DTSC response: Tribal comment noted. Agencies will provide direction to PG&E regarding use of these areas.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							undisturbed areas to the extent practicable, and minimizing the overall environmental impacts associated with the work activities." PG&E reiterates that the current proposed use of the Upland areas (Areas #6, 7, 12, and 13), which are in close proximity to the remedial infrastructure in the Upland, is required for efficient, successful and safe implementation of construction activities as they will result in the following benefits: • Providing the minimum number of practical locations to temporarily stage the required quantity of equipment and materials necessary to safely construct Pipelines A and H, the Upland monitoring and remediation wells, Bat Cave Wash crossing, and supporting infrastructure. • Increasing worker safety (e.g., reduces onsite construction traffic, vehicle congestion at primary work zones, and the overall mileage required to complete the work). • Increasing public safety and reducing nuisance to the public by decreasing the density of construction vehicle traffic on public roads (e.g., between Moabi Regional Park and				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							the staging areas in the Upland), and reducing both the trip frequency and trip duration for construction vehicles (typically have relatively poor visibility) traveling between primary work zones and distant staging areas. • Reducing environmental impacts associated with execution of the work, including dust, noise, and GHG emissions. • Reducing the total construction schedule by allowing for the most efficient construction approach. In general, increasing the distance between an active primary work zone and its supporting staging area has several adverse impacts. Travel time increases significantly due to the greater distance between these locations, especially given the generally slow rate of travel of construction vehicles. To adequately supply a primary work zone from distant staging areas also requires use of either more frequent or larger, higher-capacity support vehicles to deliver required construction materials. Primary work zones then become more congested due to either the larger quantity of smaller vehicles or having larger vehicles unloading their materials at the already tightly-constrained primary work zones. The support vehicles will thus be more likely to				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							become backed up at the primary work zone, impacting traffic at and near the work area and potentially traffic on nearby public roads (such as National Trails Highway). Congestion in primary work zones will also result in increased safety hazards associated with construction vehicles, which typically have relatively poor visibility, in close proximity to equipment and construction personnel. Increased traffic will increase dust, noise, and GHG emissions. Regarding the process for tracking and verification of the use of soil staging areas during remedy construction, PG&E refers the commenter to CIMP section 2.16 (Protocols for the inspection of remediation facilities and/or staging areas throughout the construction phase), CIMP section 2.12 (Protocols for Tribal Monitors to observe ground disturbing activities), and PA Appendix C – Monitoring Protocol/CHPMP §§ 6.6.4 (Protocols for Tribal Monitors to observe ground disturbing activities).

884	FMIT/TRC	Design	Process	C/RAWP, Sect. 2.6, p. 2-10	The data will be maintained in a database and will be reviewed by experienced field staff or chemist. Historic trends, water quality data, and well construction details will also be made available.	In order to ensure transparency throughout the remedy installation and operation, the Tribes request that field data and subsequent data analyses be audited by tribal representatives as the data are generated. For example, Tribes would like to be provided with all data that might result in installation of more wells, and data related to progress and success of the groundwater remedy. This process will ensure project transparency and allow the Tribes continued participation in the protection of the Cultural Spiritual Landscape.	PG&E will describe the data collected (generated or received) in the monthly progress reports to be prepared during construction (see C/RAWP Exhibit 2.6-2 (Monthly Progress Report Template) under "Description of Activities and Work Completed"). A summary of the lithologic and water quality data collected during well installation will be provided in the monthly progress reports (see C/RAWP Section 3.2.1.3, Approach to Finalizing Well Design and/or Siting). PG&E will submit the reports to DTSC and DOI, and will also post them on a SharePoint site (see C/RAWP Section 2.6.2.4). Information posted on the SharePoint site can be viewed or downloaded by Tribes and stakeholders for		DOI concurs with the response.	It is understood that agencies, especially federal, have a trust responsibility to the Tribes to implement a rigorous quality assurance review program in order the assure that the data are collected and analyzed with the utmost of care and professionalism. Comment resolved pending development of plans for outside quality assurance reviews of information and data related to laboratory analyses, water levels, surveys, operations, maintenance, safety, and mitigation.	DTSC and DOI response: The Agencies agree that careful review and evaluation of data is necessary throughout the life of the project. That is part of our role as the lead agencies to provide oversight of this project. The Agencies will ensure that PG&E follows the QA/QC programs currently in place for construction, remedy operation and groundwater monitoring. Regulatory oversight will continue throughout remedy implementation. No independent (outside) plans are necessary .However, DTSC does not agree that there is a need to develop plans for outside quality assurance review.

928	DTSC-162	Design	Remedial design	3.2.1.1 Borehole Drilling and Decommissioning, Hollow-stem Auger. Page 3-12	"…however, it is possible that the method might prove useful for the installation of some wells such as the shallower wells near the southern end of the NTH IRZ, where the thickness of the unconsolidated material above bedrock is relatively thin and the depth	Revise the text to further indicate that HSA is not recommended at the site as it can lead to misinterpretation of the bedrock contact. The presence of a boulder can halt drilling with HSA. DTSC does not recommend HSA in most situations at the Topock site.	PG&E agrees that hollow-stem auger (HSA) is not a preferred method of borehole drilling at the site when the determination of the depth to bedrock is included as an objective for the borehole. It is anticipated that the majority of borehole drilling will be conducted using the rotary drilling with casing advance and rotosonic methods. However, HSA may be appropriate for constructing infrastructure that is not	Resolved.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					to water is shallow."		designed based on the depth to bedrock, such as a conductor casing (i.e., carrier casing) or a relatively shallow, small diameter well. The first sentence of the second paragraph in the "Hollow-stem Auger" portion of Section 3.2.1.1 will be revised as follows: "This method is typically not used at Topock because of the rocky lithology throughout the site, which can lead to misinterpretation of the bedrock contact,.".				
929	DTSC-163	Design	Remedial design	3.2.1.1 Borehole Drilling and Decommissioning, Drilling Fluid. Page 3-12	"Examples of potential additives include foaming agents (Baroid Quik Foam), bentonite-based products, and fluid control additives (soda ash, Baroid Quik Gel, Quik-Trol, EZ-Mud, Penetrol, and N-Seal). The function of some example drilling additives and the example ingredients are included in Exhibit 3.2-1."	Exhibit 3.2-1 indicates that a variety of drilling additives are organic based (e.g., ethanol, light petroleum distillate, polysaccharide). Add a discussion to the section addressing what the affects the fluids could have on the representativeness of groundwater sampling results. DTSC is concerned that the mud additives could become entrained via the filter cake/skin along the borehole wall and become lodged in the formation for some time. Adding such organics as ethanol additives to a monitoring well environment at the site could alter the redox and geochemistry and provide misleading laboratory results. The discussion should conclude that additives should be avoided and that if utilized, they should be well documented in logs, yet also discussed in the text of reports so as to alert a reviewer.	The following text will be added to the end of the referenced section: "The use of some drilling fluid additives (e.g., organic based additives), if not completely removed during the drilling and well development process, could alter the redox and geochemical environment in the aquifer proximate to the given borehole. This could lead to misleading laboratory results for groundwater samples collected during the time these additives persist in the aquifer. For this reason, in addition to the general objective of trying to minimize the amount of foreign material introduced to the subsurface during drilling, well construction and development, additives should be avoided to the extent possible. If additives are utilized the types and volumes used as well as the volumes of drilling fluid returned during drilling and the volume of groundwater removed during well	Resolved.			Comment resolved.

							development will be documented in field logs and associated reports, and the potential effects of the additives on groundwater sample laboratory results will be presented along with the data."				
930	DTSC-164	Design	Remedial design	3.2.1.1 Borehole Drilling and Decommissioning, Borehole Decommissioning. Page 3-13 and 3-14.	"PG&E will propose to temporarily backfill the boreholes by allowing it to either naturally collapse or with the placement of clean granular material (sand)." "It is assumed that temporarily backfilled boreholes will be overdrilled within 3 to 4 months for well construction."	DTSC does not support collapse of boreholes as a planned backfill procedure as a collapse does not meet decommissioning standards for protecting aquifers. Returning to a collapsed hole, potentially 3 to 4 months later, offers no guarantee that an overdrill will stay plumb and on target and chase the collapse to total depth so that it can be completed as a well or be properly decommissioned. Of course, collapses in areas that are contaminated can exacerbate environmental conditions. Further discussion is requested to see if alternatives exist and what can be done to eliminate or minimize this practice.	The proposed practice of temporarily decommissioning a borehole as proposed in the reference section is seen by PG&E as an approach to remedy construction that is critical to both the performance of the remedy and the minimization of the total number of boreholes drilled during the project. If these boreholes are not permitted to naturally collapse, then the borehole must either be sealed using sealing material, or backfilled with clean (i.e., imported) granular material. As discussed in this section, if sealing material is used to backfill these boreholes, there is risk that a new borehole would be needed for the planned well to function properly. PG&E prefers to avoid backfilling with imported material to the extent possible because upon over-drilling it will not be practicable to separate the imported material from the formation material. If this material is ultimately reused on site (determined to be clean) then the practice will result in an increased volume of imported material being disposed onsite. The second paragraph of the referenced text will be modified as follows	DTSC is directing PG&E to eliminate or minimize the proposed practice of temporarily backfilling boreholes that will be overdrilled at a later date. The practice could lead to creating aquifer interconnections and potentially allow for mixing of contaminated or geochemically dissimilar waters. After discussion with PG&E consultants, it is understood that this practice is only being proposed along the IRZ line where select, large diameter, IRZ wells will be installed after a smaller diameter pilot boring has first been completed. DTSC is not allowing this practice to be used at any monitoring well installations. DTSC believes the proposed practice can be overcome by carefully planned drill rig scheduling and quick turnaround times for any critical laboratory data. For example, after a smaller diameter sonic rig completes the pilot boring and			DTSC response: comment resolved pending revision of document in final design.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							to more clearly indicate that PG&E will only implement this approach if a permit variance is approved by the appropriate permitting agency prior to construction: "…however, prior to drilling, PG&E will seek a variance to this approach with the appropriate permitting agency (San Bernardino County or Arizona Department of Water Resources) when a borehole is only to be temporarily backfilled.	rush lab data are obtained, IRZ well design could then be finalized At that point the sonic rig would pull off the hole (without encouraging borehole collapse) and the large diameter drill rig could move over and complete the large diameter borehole and well. In the event that the proposed borehole collapse/temporary backfill method is desired by PG&E (e.g., due to unforeseen events such as drill rig failure), PG&E must first notify DTSC and obtain approval to proceed. This way DTSC will be more informed regarding site specific details and understand the entire scope of the proposal at the time it is proposed to be implemented. It is recommended that the document be revised to capture the salient points above.			
931	DOI-150	Non-design	Remedial Design	3.2.1.1/3-13	Borehole Stabilization.	A discussion should be provided within this section regarding the potential use of cement bentonite grout in the event of a surface slumping event, such as the event that occurred during FW HNWR-B construction.	The referenced text will be modified as follows: "During drilling, as was experienced during the installation of the freshwater supply well at Site B in Arizona, field conditions might require that a borehole be stabilized to prevent an unsafe working condition or limit the amount of formation material that is removed during drilling. This is typically addressed by using the drill rig to		Resolved.		Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							install a temporary or permanent conductor casing in the shallower portion of the borehole, or by filling the borehole with drilling fluid (as described in the previous section) to control borehole pressure. Temporary conductor casings, which could simply be larger-diameter sections of drilling pipe, are removed when drilling is complete, whereas permanent casings are incorporated into the design of a given well construction. <u>As was the case at Site B, if void space around the borehole which can lead to slumping of the ground surface must be stabilized, then an appropriate material like cement bentonite grout must be used to fill the void created by the unstable borehole.</u>				
932	DTSC-165	Design	Remedial design	3.2.1.2 Borehole Groundwater Sample Collection. Page 3-15 and 3-16.	"Borehole groundwater samples will be collected from specific intervals of select boreholes drilled within the unconsolidated aquifer. When the water table is reached, samples will be collected from the borehole approximately every 30 to 50 feet…One exception to this frequency is when borehole groundwater samples are being collected to support the design of a well	PG&E needs to define "select boreholes". The document should be revised to clearly list the boreholes currently planned for sampling. DTSC assumes most monitoring, IRZ and FW-2 area boreholes would be included in this sampling. It will probably be easier to list those wells to be excluded. DTSC requests that samples also be collected at potentially repetitive horizons, but at lesser frequencies (e.g., every 75 feet). These samples could assess aquifer heterogeneity and assist in plume delineation and the development of the CSM.	A table will be added to the referenced section that defines which planned boreholes will be used for groundwater sample collection during drilling. This table will include a note that the plan is subject to change based on observations in the field. The table was developed during the 90% RTC process ad included in **Attachment T** of the final RTC table. In all likelihood, field observation will lead to more boreholes being utilized for groundwater sample collection as opposed to less. In addition, the text in Section 3.2.1.2 (Data Collection During Well Construction), Borehole Groundwater Sample Collection subsection, 2nd paragraph, 3rd sentence, will be modified to explicitly	DTSC requests that the following wells be added to Attachment T: H, L, M, N, and Y. These wells are generally located in areas with sparse well density and larger aquifer thicknesses. Finally, it is recommended that MW-U be identified as a Category 1 well as results from the well might alter the location of IRL-4 and associated wells.			**Attachment T** was revised to incorporate DTSC's request.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					that will supplement an existing well. For example, if a well is being installed to evaluate deeper water quality where a water table well already exists, samples will typically only be collected from depths deeper than the existing well screen interval(s)."		indicate the referenced sample collection frequency will only be modified at existing MW locations: ~~One~~ The only exception to this frequency is when borehole groundwater samples are being collected to support the design of a well that will supplement an existing well (i.e. "twinned" wells at the same location). It is PG&E's opinion that collecting borehole groundwater samples at the same depths as existing monitoring well screens with the intent of comparing the results of the borehole samples with that from the monitoring wells will not provide particularly useful information. The primary reason for this is that samples from the borehole might not be representative of the same depth interval or the same flow condition that is effectively sampled from an established monitoring well screen. Different sampling purge methods are also used for the two sample types. It is understood that DTSC would like to use this information to try and determine if borehole samples are biasing higher or lower than the well samples, but this comparison could be misleading for the reason mentioned in the previous sentence. PG&E appreciates DTSC's consideration to increase the distance between borehole groundwater samples to offset the additional samples collected at existing screened depths, but would prefer

							to maintain the frequency currently included in the C/RAWP (approximately every 30-50 feet) without collecting samples at existing screened depths, or with the addition of specific existing screened depths directed by DTSC.				
933	DTSC-166	Design	Remedial design	3.2.1.2 Borehole Geophysical Logging. Page 3-16.	"The determination to conduct borehole geophysical logging will be made in the field when drilling conditions are appropriate and as needed to finalize design details for the remedy well network."	Plans to conduct geophysical logging should also be planned as part of this document. Revision requested. Additionally, for all bedrock wells, the document should be revised to indicate that a standard suite of geophysical logs (e.g., caliper, acoustic televiewer, video, borehole flow tests) will be used.	While this section identifies the types of geophysical logging that might be conducted during the construction of the remedy well network, geophysical logging is not anticipated to be conducted regularly. It is estimated that the majority if not all of the boreholes drilled for pilot data collection or well construction in the unconsolidated aquifer will be installed using casing advance methods (e.g., rotosonic and rotary drilling with casing advance), which will result in a steel-cased borehole to total depth. The steel casing precludes the use of the majority of the listed geophysical logging techniques with the exception of natural gamma ray logging, which is primary used to log clay units (clays have only been very sparsely logged in the unconsolidated aquifer based on review of existing boring logs). Further, continuous core will be collected from many of the boreholes drilled for remedy well construction, which will provide better lithologic data than geophysical logging. Based on lithologic logging of bedrock core, geophysical logging, and borehole flow testing conducted during	Okay.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							investigation of the bedrock aquifer in the East Ravine area, the geophysical logging data was only of marginal value. Although geophysical logging data was collected early in the investigation it was later discontinued when it was determined that observation of the bedrock core in combination with borehole flow testing provided the best data set to determine which intervals of fractured rock were responsible for groundwater flow. The only planned bedrock boreholes that will be installed for the groundwater remedy includes the line of East Ravine extraction wells and MW-70BR-D. As discussed in Sections 3.2.1.1 and 3.2.1.4, MW-70BR-D will be used to provide vertical characterization of Cr(VI) in bedrock and will be installed like other boreholes used for East Ravine characterization with the collection of bedrock core and the use of borehole flow testing, as determined necessary (if depth-specific concentration data is determined necessary based on groundwater sample results collected from the open borehole). As discussed in Section 3.2.1.4, the line of East Ravine injection wells will be constructed to provide hydraulic capture of Cr(VI)-impacted groundwater in bedrock. It is PG&E's opinion that geophysical logging and borehole flow testing is not necessary to meet this objective; however, should questions arise

					reduction potential), and the temporary screen will be considered developed (ready for sample collection) once measurements are indicative of estimated aquifer conditions as compared to the water used for drilling (for example, elevated specific conductance when compared to lower specific conductance drilling water).						
937	Chemehuevi/ TRC	Non-design	Monitoring	C/RAWP Page 3-16 3.2.1.2 Data Collection during Well Construction - Borehole Ground-water Sample Collection	Water quality measurements will be monitored on the pump effluent at the surface (for example, specific conductance, pH, and oxidation-reduction potential), and the temporary screen will be considered developed (ready for sample collection) once measurements are indicative of estimated aquifer conditions as compared to the water used for drilling (for example, elevated specific conductance when	Please indicate if water temperature will be evaluated and if not provide an explanation why this measurement is not important.	See above			Noted.	

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					compared to lower specific conductance drilling water).						
938	DTSC-167	Design	Remedial design	3.2.1.2 Well Sampling. Page 3-17.	"Groundwater samples will be collected from select wells to guide decisions during construction of the well network. For example, as detailed in Section 3.2.1.3, water quality samples will be collected and analyzed from key wells (referred to as Category 1) to determine proper siting of key extraction, injection, and monitoring wells."	The document should also discuss sampling new wells to develop baseline data for each well. This should consist of a wide suite of constituents (e.g., general mineral, metals scan). These data will be needed as the remedy progresses and will assist in understanding plume movement. The baseline data should be collected before the remedy becomes operational and should be conducted for several quarters as it may take certain wells extended periods of time to equilibrate with the aquifer.	A new Section 3.2.1.6, Baseline Well Sampling, will be added to the C/RAWP. This section will detail the plans and methods to collect initial baseline samples from all new extraction, injection, and monitoring wells constructed as part of the groundwater remedy. The analytical suite for baseline groundwater samples collected from injection and extraction wells will be consistent with the analytes listed in Exhibit 4.1-1 (Biological and Geochemical Analytical Monitoring Parameters) of the O&M Manual (Volume 1). The analytical suite for baseline groundwater samples collected from monitoring wells will include: total organic carbon, total dissolved solids, title 22 metals (total and dissolved), Cr(VI), iron and manganese (total and dissolved), cations (total calcium, potassium, magnesium, and sodium), and anions (chloride, fluoride, bromide, nitrate, nitrite, and sulfate). The new Section 3.2.1.6 was developed during the 90% RTC period and included in **Attachment U** of the final RTC table.	Resolved.			Comment resolved.
939	DTSC-168	Design	Remedial design	3.2.1.2 Data Collection during Well Construction. Page 3-17.		The document should also discuss conducting aquifer tests (either injection or pumping) to assist in selecting monitoring well screen locations in hydraulically connected portions of the aquifer. See the DTSC comment above regarding citing well screens for wells MW-FF and GG based on an aquifer test conducted at IRL-4. Hydraulic parameters obtained from aquifer tests would also be used to update the groundwater model and make future modeled estimates more reliable.	PG&E agrees that the hydraulic parameters obtained from aquifer tests will be useful for updating the groundwater model. The approach to aquifer testing is presented in Section 3.2.1.5 of the C/RAWP.				DTSC Response: Resolved. Agencies will provide direction to PG&E regarding aquifer testing.

Appendix I – Response to Comments on the 90% Design Documents (Basis of Design Report, O&M Manual, Construction/Remedial Action Work Plan)
Groundwater Remedy Basis of Design Report/Final (100%) Design

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							It is PG&E's technical opinion that aquifer testing is not necessary or appropriate for designing monitoring wells as specified in the comment. The unconsolidated aquifer at Topock is one continuous water bearing unit with no confining units, and given the depositional environment of the sediments (as confirmed by existing boring logs), is heterogeneous. The drawdown observed in monitoring wells screens at one location during an aquifer test will not conclusively identify preferential groundwater flow pathways that will correlate to another monitoring location, especially one that is a greater distance from the given pumping well. It is PG&E's understanding the DSTC is most interested in using aquifer testing to design monitoring wells for the arsenic monitoring wells; however, these wells, like other wells with the objective to monitor gross changes in water quality within the aquifer, will be designed with relatively long screened intervals (20-50 feet in length). This will result in the monitoring of a relatively large percentage of the overall aquifer saturated thickness and minimize the potential for "missing" key portions of the aquifer. The screen intervals chosen for arsenic monitoring wells, and all other monitoring wells, will be based on lithologic core and depth-specific borehole groundwater				

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							samples from the same or nearby boreholes. This process for using borehole data to select monitoring well screen intervals has been successfully utilized for years at the Topock site to construct the majority of the existing monitoring well network and will be effective for the expansion of the monitoring network as part of groundwater remedy construction.				
940	DTSC-169	Design	Remedial design	3.2.1.3 Approach to Finalizing Well Design and/or Siting Page 3-17.		The intent of the well categories is not clear in the introduction. It appears the intent is to sequence Category 1 wells first and so on as mentioned on page 3-18. The rationale for designating the wells as Category 1 should be made more explicit. (e.g., install wells in IRL area to confirm chromium plume location –see Table 3.2-6). Not quite certain why MW-70BR-D is included as Category 1. It was assumed NTH IRZ wells would be Category 1 to confirm bedrock depths and plume distribution via borehole grab samples. Associated IRZ monitoring wells and downgradient monitoring wells could then be adjusted based on that data. MW-A might be replaced by IRZ-1 pilot boring. Could adjust River Bank extractors as well if needed. DTSC wants the arsenic monitoring wells to go in last (Category 3) to ensure they are properly screened using all other sources of data because the proposed plan has limited the number of screened intervals. Wells MW-10D and 11D should be Category 1 of 2 as they are a trigger for Well V which needs to be added to Figure 3.2-1.	Given the additional data that will be collected and considered in the process of finalizing well designs, the intent of the well categories is to group well locations as defined by the types of decisions that will be made related to well design (all categories) and in some cases well siting (Category 1). Please note that the well category (1, 2, or 3) is not necessarily indicative of when in the schedule a well will be constructed. For example, while Category 1 wells will be sequenced early in the project, the pilot boreholes for select Category 3 locations will also be installed early in the schedule (ahead of data collection at some Category 2 well locations). As defined in Exhibit 3.2-2 data that will be collected at Category 1 well locations will be used to finalize the locations and/or design of other remedy wells. In the case of MW-70BR-D, as presented on Table 3.2-6, data collected at this location will be used to determine if East Ravine extraction wells will function properly at	Okay.			Comment resolved.

							the designed total depth; this will not affect East Ravine extraction well siting but could affect design (i.e., depth). In the case of the NTH IRZ well locations, they have been largely designated as Category 3 locations because while data collected from these locations will be used to finalize the design of these and other nearby wells, the location of these and other wells is not dependent on the data. PG&E agrees that bedrock depth and plume distribution data (collected from borehole groundwater samples) is important to finalize the design of these wells, and this data will be collected from an initial group of pilot boreholes (see RTC #945, DTSC-170). Planned monitoring well locations on the flood plain, including MW-A are located with specific objectives given the planned location of remediation wells and would not be expected to move. Regarding the adjustment of planned River Bank extraction well locations, it is PG&E's opinion that the wells are currently located in the appropriate locations to achieve their objectives. While data collected from these and nearby boreholes will be used to finalize extraction well design, the data is not anticipated to require changes in well location. If operational data suggest that additional River Bank extraction wells are required to achieve the stated objectives then

							future provisional wells will be sited and constructed as informed by data collected during system operation. See RTC #939 (DTSC-168) for additional discussion related to the design of arsenic monitoring wells. Given the planned proximity to planned injection wells, in some cases the arsenic monitoring well locations provide an opportunity to confirm key assumptions prior to construction of the larger footprint remediation wells and associated pipelines (MW-BB, MW-DD, and MW-FF; see Table 3.2-6); therefore, they are considered for installation early in construction. In light of discussion with DTSC and proximity to sensitive cultural resources, MW-DD will be sequenced as late as possible in the Category 1 well locations. Arsenic monitoring wells that aren't as well located to confirm these assumptions would be sequenced later in the construction once the associated injection well location is finalized (e.g., MW-AA, CC, GG, HH, and II). As requested by DTSC, monitoring wells MW-Z, MW-10D, and MW-11D will be reclassified as Category 1 well locations given the results of data collected from these wells will be used to determine if monitoring well location MW-V should be constructed.

				during Well Construction - Well Sampling.	guide decisions during construction of the well network.	The Tribes request continued involvement at the level that has currently existed through the design stage during and post the construction phase of the groundwater remedy system. Please discuss in detail PG&E's and DTSC's intent on Tribal involvement post the design phase of the project.	"Description of Activities and Work Completed", data collected (generated or received) will be described in the monthly progress reports during construction. A summary of the lithologic and water quality data collected during well installation will be provided in the monthly progress reports (see C/RAWP Section 3.2.1.3, Approach to Finalizing Well Design and/or Siting). The monthly progress reports will be submitted to DTSC and DOI, and also posted on a SharePoint site for access by Tribes and stakeholders (see C/RAWP Section 2.6.2.4). PG&E also currently holds monthly meetings with Tribes to address current issues and provide a forecast of upcoming activities. Other communications may take place depending on purpose of the communication and type of information to be exchanged. Tribes are welcome to request discussions of specific topics or information that are of interest to the Tribes during these information exchanges. The nature and pace of activities during the construction phase will be very different from those experienced during the design, and will be more field focused. Table 2.3-1 presents the proposed communication framework for construction and startup, including communication of data collected during construction of the groundwater remedy			to which communication is addressed if material deviation from work plan and design documents, MMRP action specific, and location specific ARARs occur. The current proposed use of monthly progress reports and periodic uploads to SharePoint is not a sufficient level of involvement when it comes to decisions that could result in permanent disturbance to the Sacred landscape. PG&E should remain mindful of its independent legal obligations under the 2006 Settlement Agreement to consult with FMIT and to provide all non-attorney-client privileged material information, documentary or otherwise, to the Tribe contemporaneously with its receipt or development by PG&E.

					and as appropriate based on the borehole data collected. A summary of the lithologic and water quality data collected will be communicated to the agencies via monthly progress reports as defined in Section 2 of this C/RAWP.						
950	DTSC-171	Design	Remedial design	3.2.1.4 Well Construction and Development East Ravine (ER) Extraction Wells. Page 3-23.	"Each of the wells will be constructed using up to a 6-inch-nominal-diameter conductor casing to the top of competent bedrock or a minimum of 20 feet bgs."	Large diameter conductor casings (e.g., 10 to 14 inches) should be considered to allow overdrilling in the future (to remedy fouling or increase yield/storage reservoir). This could negate drilling a new well. References of "up to" should be replaced with planned diameters. This also applies to similar uses throughout the document including the sentence following the cited sentence. The sentence also needs to be revised as, currently written, it can lead to improperly constructed conductors.	The primary reasons to implement this change would be if the actual well yield warrants a pump diameter larger than 4-inches in diameter, or if an alternative well design (e.g., nest well casings) was determined appropriate. While neither of these scenarios is included in the current design, implementing this change would decrease the likelihood that a well would need to be replaced should they ever be warranted. In accordance with the comment, the diameter of the conductor casing will be increased to 12-inch to allow for the potential to ream the bedrock borehole to a larger diameter at a future date, but the primary borehole/well casing will remain as currently designed. The referenced text will be revised as follows: "Each of the wells will be constructed using ~~up to~~ a ~~6~~12-inch-nominal-diameter conductor casing to the top of competent bedrock ~~or a minimum of 20 feet bgs~~."	Okay.			Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							The initial borehole diameters will be added to the final design document. However, it is PG&E's opinion that the use of "up to" is appropriate elsewhere in this section as it preserves the flexibility to utilize smaller diameter boreholes and well casings as determined appropriate based on actual field conditions. In accordance with the EIR, PG&E will continuously work to identify opportunities to decrease the size and footprint of the remedy infrastructure, including wells. For example, If it is determined that the saturated thickness at a given southern IRZ well location only warrants one well screen as opposed to two, or a smaller well casing due to smaller in-well equipment, then the decision to down-size will be appropriate.				
951	DTSC-172	Design	Remedial design	3.2.1.4 Well Construction and Development East Ravine (ER) Extraction Wells. Well performance. Page 3-23.	"Following the development of a given well, the specific capacity will be compared to assumptions used in the design. Lower-than-predicted flow will not necessarily indicate that additional wells are required. Sustainable flow rates will be considered in the context of the conceptual site model, which will be continually updated as needed during remedy	The section should be rewritten to explain what will be done if lower-than-predicted flow is obtained from any given well. Tangible examples are requested. This comment applies to all other occurrences throughout the document.	The "Well Performance" bullet for this section will be revised as follows: "**Well performance.** Following the development of a given well, the specific capacity will be compared to assumptions used in the design. <u>Specifically, the combined extraction rates from each of the East Ravine extraction wells will be compared to total nominal flow rate of 5 gpm that was used in the design.</u> Lower-than-predicted flow <u>from a specific well</u> will not necessarily indicate that additional wells are required. Sustainable <u>average</u> flow rates <u>for the line of</u>	Okay.			Comment resolved.

968	DOI-151	Non-design	Process	3.2.1.4/3-26	A gyroscope survey will be conducted to verify that the well casing is plumb and straight, as determined necessary.	Since there are not too many options besides redrilling the borehole, if the well casing is not plumb – consider running the gyroscope down the sonic casing prior to setting the well.	Plumbness data collected from within the drill casing would be of very limited use since it would not directly correlate to the plumbness of the well casing itself. In general, a benefit of the casing advance methods that will be used for the majority of borehole drilling for well construction, including rotosonic, is that the boreholes are typically very straight compared to other methods (e.g., direct rotary, hollow-stem auger, etc.). In addition, the estimated maximum drilling depths for this project are relatively shallow (approximately 400 feet) and would not be expected to deviate significantly. More significant factors that could lead to well plumbness problems include defective well casing sections, uneven welded joints, or improper vertical		Resolved.		Comment resolved.

							loading of the well casing during construction.				
969	DTSC-173	Design	Remedial design	3.2.1.4 Well Construction and Development Annular Seals. Page 3-27.	"Concrete. … and is typically reserved for large volume/diameter borehole or well decommissioning."	Concrete is not typically used as an annular seal in well construction and should be removed.	The following clarifying statement will be added to the end of the "Concrete" bullet: Concrete is typically only used in the shallowest portion of the borehole as a construction component of the wellhead protection.	Resolved.			Comment resolved.
970	DTSC-174	Design	Remedial design	3.2.1.4 Well Construction and Development Well Development. Page 3-28.	"The well will be considered developed (that is, ready for subsequent hydraulic testing and/or sample collection) when turbidity measurements are low and stable (typically 50 nephelometric turbidity units or less), specific capacity is stable, and the well is yielding groundwater that exhibits water quality measurements indicative of aquifer conditions as compared to the water used for drilling."	Revise to indicate that 5 to 10 NTUs is the goal for monitoring wells. Also add that a well will be considered developed after water has been removed during development that is greater in volume than any imported water added during well installation. Also add that all development activities will be documented and reported to agencies.	A target turbidity goal of 5 to 10 NTU is typically not practical for well development, but will be added to the groundwater sampling SOPs (for monitoring wells) as a target (O&M Manual Volume 2, SOP-A1, A2, A18); however, it is understood that this is not a hard criterion that must be met prior to sample collection. The referenced text will be modified as follows: "The well will be considered developed (that is, ready for subsequent hydraulic testing and/or sample collection) when turbidity measurements are low and stable (typically 50 nephelometric turbidity units or less), specific capacity is stable, <u>a minimum volume greater than the volume of any water introduced during drilling and well construction has been removed,</u> and the well is yielding groundwater that exhibits water quality measurements indicative of aquifer conditions as compared to the water used for drilling. The following text will be added to the end of Section 3.2.1.4 (well development subsection) of the	Okay.			Comment resolved.

975	DOI-155	Design	Remedial Design	3.2.2.1/3-31	The contractor(s) will select and implement the method used to prevent trench cave-ins and that selection will meet regulatory construction safety requirements.	DOI recognizes that the methodology for trench stabilization is based on site/soil conditions and engineering factors and that the contractor will have the ultimate decision on steps implemented to prevent collapse. However, given the sensitivity regarding excavation within the Topock cultural area, it is recommended that the preference for shoring over increased excavation be discussed within the design documents.	As presented in the 90% design, the majority of the trenches are shallow trenches (about 3 feet deep). With the exception of the floodplain, PG&E does not anticipate cave-ins to be an issue and most trenches will probably have near vertical walls based on soil type. Sloping or shoring may be required on the flood plain. PG&E will require and incentivize the construction contractors via contracting mechanism to limit excavation and not over-excavating. We found this method to be fairly effective without prescribing or restricting the means and methods for construction. The following text will be added (shown as <u>underline</u>): "The contractor(s) will select and implement the method used to prevent trench cave-ins and that selection will meet regulatory		Resolved. 976	FMIT/TRC	Non-design	Request for Information	C/RAWP p. 3-31 3.2.2.1 Direct Burial	Hand work, as well as soft dig methods, may also be required when trenching near existing underground utilities. Soft dig techniques include hydrovacuum excavation, and air lancing. With hydrovacuuming the soil is loosened by spraying the ground with high-pressure water. The loose soil and water is then vacuumed into a truck for transport and disposal.	The Tribes request that handwork as well as soft dig methods, be required when trenching near existing cultural resources. In addition please provide a detailed explanation of how protection will be ensured of unearthed cultural resources when soil loosening techniques such as spraying the ground with high-pressure water are used.	PG&E intends to use "soft dig" methodologies (primarily hydrovac) when the presence of underground utilities warrant the technique (mostly within the Topock Compressor Station and occasionally outside the station). Because the hydrovac system has a large footprint, it would not be suitable for use near identified cultural resources that need protection. For such resources, hand work or backhoe may be used. CIMP CUL-1a-8n protocols were developed for locations requiring specific protective devices, such as temporary fencing, flagging, or other type of demarcation during construction. According to the CIMP, protective measures may include, but are not limited to, protective coverings of soil or riprap, onsite personnel to prevent access to sensitive areas, use of flagging, blaze orange mesh fencing secured to steel posts, bollards, natural barriers of rocks or piled brush, cables suspended between secure posts, and/or signage (e.g., "This Area Closed" or "Exclusion Zone: Keep Out"). Any such measures will be temporary (only as needed during construction), and will, to the extent practicable, not call undue attention to the nature of the resource being protected. In the event that previously unidentified potentially			Noted.

1000	DOI-163	Non-design	Legal	Exhibit 3.3.1/3-50	Preliminary Construction Schedule	In accordance with the Consent Decree, the projects schedule should identify the anticipated date for submittal of the Construction Completion Report.	Exhibit 3.3.1 will be revised to note that the line item TC.CC shown in the schedule graphic includes preparation and submittal of the Construction Completion Report, and the Construction Completion Report will be explicitly mentioned in Section 3.2.6 and Section 3.3.6.		Accepted.		Comment resolved pending DOI review of the final design documents.
1001	DOI-164	Non-design	Editorial	3.3.3.3/3-51	Some wells require installation of the respective pipeline to provide access to the well and for management of water generated during well development	Do you mean the road to install the pipeline must be installed to access the well location? Please clarify. Also, according to Exhibit 3.3-1, most of the wells are installed before completion of the remedy produced water conditioning plant. Please clarify how the existence of the pipeline allows management of generated water.	Yes, in some cases the road needed to install the pipeline will also be needed for well drilling equipment to access the well location. As a result, the road and associated pipeline will be constructed before drilling the well in select locations (for example, Pipeline H and Well IRL-4).		Resolved.		Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
					and testing.		In some cases (e.g., wells on the flood plain), the pipeline installed prior to well drilling may be used to convey water associated with well drilling, development, and testing. This could reduce the need to transport water to/from the well site with a water truck.				
1002	DOI-165	Non-design	Process	3.3.3/3-52	Exhibit 3.3-2. Further, advance construction of the pipelines will provide for the ability to convey water generated during well construction, development, and testing; thus limiting the associated equipment footprint.	It seems the logistics of transporting drill cuttings and well development water to a remote location is impractical. Finding a suitable remote location may also be difficult. Please provide an example of this scenario.	Pipeline H may be used to convey water associated with the construction, development, and testing of well IRL-4. Similarly, wells on the flood plain, which can be difficult to access, could be constructed with less footprint (i.e., traffic to the work areas) if pre-constructed pipelines were utilized. Also refer to response to comment DOI-164.		Resolved.		Comment resolved.
1003	DOI-166	Design	Infrastructures	3.3.3/3-52	Exhibit 3.3-2. Temporary IM-3 injection piping may be constructed before IRL-3 and FW-1 so the drilling work does not interfere with IM-3 injection activities.	This statement implies that the current IM-3 injection piping will be removed to access IRL-3 and FW-1. Please provide additional clarifying text as to how this piping interferes with access and what the anticipated configuration is for temporary piping. For example, is the underground piping in the vicinity of IW-2 and IW-3 to be removed and replace with temporary above ground piping?	The existing IM-3 injection piping will be in proximity to Pipeline B and likely interfere with construction. The existing piping lies on the ground surface on the north side of the IM-3 access road (DWGs C-07-20 and -21) and the edge of the Pipeline B trench will be very close to the IM-3 piping. The existing pipeline also runs directly through the planned work areas for multiple planned well locations including FW-1, IRL-3, MW-BB, and MW-CC. It is possible that the injection piping may fall into the trench or be struck by construction equipment. This piping must remain in service to allow continued operation of IM-3. The construction contractor is required to protect the piping in-place but they may also install temporary		Resolved.		Comment resolved.

							Exhibit 3.3-3). In addition, Pipeline C may be used to convey water used for leak testing Pipeline G and nearby wells.				
1008	DOI-171	Non-design	Infrastructures	3.3.4/3-53	Exhibit 3.3-3. Construction of Pipeline C in the IRZ North/River Bank area may begin after completion of monitoring well MW-A.	Please provide additional explanation of how installation of monitoring well MW-A constrains the timing of installing Pipeline C. What are you expecting to learn from installation of MW-A that influences the installation of Pipeline C. Would IRZ-1 and IRZ-2 not be installed?	As indicated on Table 3.2-6 of the C/RAWP, the construction of MW-A is intended to confirm the assumption that the northern margin of the groundwater plume is defined and the northern extent of the NTH IRZ and River Bank extraction wells are adequate. Planned well IRZ-1 and future provisional well IRZ-2 are sited based on this assumption holding true, but data collected from MW-A (primarily in the deeper portion of the unconsolidated aquifer) might indicate that additional IRZ wells are needed to the north; therefore, it would be prudent to construct Pipeline C after it is confirmed that the northern margin of the groundwater plume is defined.		Resolved.		Comment resolved.
1009	DOI-172	Non-design	Infrastructures	3.3.4/3-53	Exhibit 3.3-3. Construction of Pipeline C in the East Ravine area may begin after completion of monitoring well MW-70BR-D.	It appears this statement refers to pipeline C-18. Please revise. Also, please provide additional explanation of how installation of well MW-70BR-D constrains the timing of installing Pipeline C-18. What are you expecting to learn from installation of MW-70BR-D that influences the installation of Pipeline C-18. Please clarify.	The statement refers primarily to the portion of Pipeline C along the river bank that will serve the East Ravine extraction wells. As indicated on Table 3.2-6 of the C/RAWP, the construction of MW-70BR-D is intended to confirm the assumption that the East Ravine extraction wells will function properly at the designed total depth (i.e., confirm that concentrations decrease with depth at this location). While this information is not expected to change the siting of the wells, it could affect the well design (i.e., depth). Therefore, the extraction wells would		Resolved.		Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							not be drilled and constructed until the designed depth is confirmed, and it would follow that that pipeline may not be constructed until the wells were constructed. Pipeline C-18 will be plumbed to existing well MW-70BR-200 and this pipeline might also be useful for conveying water associated with the construction of MW-70BR-D into/out of the East Ravine without the use of a water truck (see also responses to comments DOI-164 and DOI-165).				
1010	DOI-173	Non-design	Infrastructures	3.3.5/3-55	Exhibit 3.3-4. Cannot start until TWB-02 well installed….	It is not clear why construction cannot start on the TW Bench until well TWB-02 is installed. The well is not within the TW bench footprint. Please clarify.	TWB-02 is located within the TW bench footprint (see C/RAWP Figures 3.1-1 and 3.2-1, and BOD Appendix D Drawing C-08-04). Construction of the TW Bench facilities before drilling TWB-02 would likely limit access to and constrain space at the drilling site. With the TW Bench being a heavily trafficked and constrained work area even before the addition of remedy facilities, the TW Bench facilities well construction will be made easier, safer, and less expensive to install by sequencing the construction of other constraining facilities them after drilling well TWB-02. 					on, and investigation-derived waste management.		waste management."				
1012	DOI-175	Non-design	Infrastructures	4.2.3/4-7	The location of access routes and staging areas are depicted on Figure 4.2-3.	On Figure 4.2-3, please demark new remedy access routes that require construction of a road (e.g., grading, adding bedding, etc.). Also, please identify the location of County Highway 10 on the figure. Please identify the purpose of the road to the north of the NTH. Lastly, why is there a new remedy access road down to the Topock Marina? The access to the well should be an existing road.	Additional details will be added to Figure 4.2-3 as requested (A revised Figure 4.2-3 will be prepared for review during the 90% RTC period and included in **Attachment W** of the final RTC table). The spur road north of the NTH is not currently used nor planned for remedy use. It will be removed from Figure 4.2-3. The same change will apply to Figure 3.5-9A in the BOD. The access road to the well in Topock Marina is an existing road. Color will be changed from green to purple.		accepted		Comment resolved pending DOI review of the final design documents.
1013	DTSC-176	Design	Remedial Design	4.2.5 Construction Water Supply Page 4-8.	"Treated water from IM-3. Excess treated water from IM-3 will be accessed by the existing IM-3 storage and distribution system, or utilizing a temporary storage and supply system."	It is not certain if utilizing treated IM-3 water for construction water supply is appropriate. The text should discuss limitation associated with the elevated TDS of the treated water (approximately 4,500 mg/L). Can it adversely impact plants or threaten the shallow aquifer? Concurrence from the Water Board is also suggested.	Excess treated water from IM-3 is one of several options identified for construction supply water (see Section 4.2.5 of C/RAWP). PG&E will obtain concurrence from the Water Board and DOI prior to using IM-3 treated water for dust suppression during remedy construction in areas within the Uplands. Having access to a local source of water would reduce construction truck traffic and congestion to/from the Uplands. Most construction areas in the Uplands are limited to the access road and previously disturbed areas, with very minimal vegetation. Biological clearance (including vegetation) will be obtained prior to the start of construction. It is anticipated that protective measures for sensitive plants that may occur near construction	Text in the design document should discuss potential limitations associated with the elevated TDS of the treated water. In addition to potential impact of TDS to the shallow aquifer, repeated applications when used as construction water supply could raise total salt build up in soil. This could limit potential restoration and reuse of the soil in the future (e.g., affect future vegetation planting) Best management practice may be to inject the saltier waters to the deeper, saltier, portions of the aquifer. Again, the text should discuss limitations and any needed action(s).			Without further evaluation by PG&E of impacts from TDS, this use should be removed from the remedy as an option for disposing treated IM-3 water. PG&E Response: PG&E understands the agency's concern, and will conduct further evaluation of potential TDS impacts associated with the use of IM 3 treated water for dust suppression during remedy construction. The evaluation will be submitted to DTSC for CEQA evaluation. If useful, this language can be added to the CRAWP.

				Dust Control	nonessential earth moving activity under high-wind conditions (greater than 25 miles per hour), or develop a plan to control dust during high-wind conditions.	hour) to disrupt the surface. It is suggested that the limit be reduced to 15 mph or rationale be provided on why 25 mph is appropriate and will not result in localized increases in suspended particles.	measure AIR-1e which states: "e) Curtail nonessential earth-moving activity under high wind conditions (greater than 25 miles per hour) or develop a plan to control dust during high wind conditions. For purposes of this rule, a reduction in earth-moving activity when visible dusting occurs from moist and dry surfaces due to wind erosion shall be considered sufficient to maintain compliance." Mojave County Air Quality Management District (MAQMD) guidance for "Fugitive Dust Control for the Mojave Desert Planning Area" included in the FEIR (page 4.2-15), defines "High Winds" as "When wind gusts exceed 40 kilometers (25 miles) per hour or, on an hourly average, when wind speeds exceed 24 kilometers (15 miles) per hour. The average wind speed determination shall be on a 15 minute average at the nearest meteorological station or by wind instrument on site." Therefore, while the EIR mitigation measure AIR-1e correctly references <u>the maximum wind speed of 25 mph</u>, the MAQMD definition of high winds further clarifies the applicability of <u>the hourly average wind speed of 15 mph</u>. From an implementation standpoint, PG&E's practice has been to conduct dust suppression to minimize the generation of visible dust during high wind conditions in compliance with the EIR mitigation measure. PG&E defers	EIR mitigation measure AIR-1e condition for which dust control is necessary (i.e. when visible dusting occurs from moist and dry surfaces due to wind erosion) is less onerous than a continuously measured wind speed as proposed by the MAQMD. However, this does not limit PG&E from conducting air monitoring by following MAQMD's guidance to determine "high wind" conditions.		support a curtailment or reduction in nonessential earthmoving activity when visible dusting occurs from moist and dry surfaces due to wind erosion) rather than a dependence on a measured wind speed value of 25 mph.	noted. PG&E Response: PG&E reiterates that our practice at the Topock site has been to conduct dust suppression to minimize the generation of visible dust generated by PG&E activities during high wind conditions (greater than 25 miles per hour) in compliance with the EIR mitigation measure AIR-1e.

							impacts, including the impacts to the Topock Cultural Area, which the EIR defines as the Topock Maze and "the area surrounding the Topock Maze" (EIR; DTSC 2011d). One of the mitigation measures addressing potential impacts to the Topock Cultural Area requires PG&E to submit a Cultural Impact Mitigation Program (CIMP) as part of the final design of the Project. PG&E completed the CIMP and submitted it to DTSC in May 2014 for DTSC's review and approval. DTSC is undertaking additional environmental review pursuant to CEQA to inform its decision on additional Project approvals. The Area of Potential Effects (APE) for the Topock site is contained within what the Fort Mojave Indian Tribe and other Native American Tribes have identified as a larger area of traditional and cultural importance. The Tribes believe that the environmental, cultural, and spiritual resources may not be physically perceptible. DTSC has concluded within the January 2011 certified Environmental Impact Report (EIR; DTSC 2011d) that the 779.2-acre project site "appears to qualify as a historic resource under CEQA [California Environmental Quality Act] as an area that is significant in the social and cultural annals of California," and the BLM also has determined that a traditional cultural property or property of

Specific Comments – Construction/Remedial Action Work Plan, Appendix B: Standard Operating Procedures											
1076	FMIT/TRC	Non-design	SOPs	C/RAWP Append B SOP-A7	Water Level Measurements	Because of the importance of water-level measurements for determination of OPS and OF, it is not specified in the 90% BOD whether transit/level surveys would be conducted to determine altitude of water-level measuring points at wells. Altitude of wells determined by GPS is not accurate enough when measuring water levels to 0.01 ft.	All monitoring wells are surveyed to 0.01-foot for water level measuring point (typically ‘top of casing’) and to 0.1 foot for ground surface at wellhead (and for stick-up wells, the top of protective monument). This work has been done by PG&E land survey crews, not determined by GPS. This information will be included in the design criteria in Appendix C (Section C.2.1).			There appears to be an anomaly in the PG&E topographic map when comparing the California and Arizona sides of the Colorado River. If you stand on the western river bank on contour 475 ft and look perpendicular to the flow across the river, you should be looking at contour 475 on the other side because it is a man-made trapezoidal channel with engineered banks. However, the corresponding topographic contours on the Arizona side do not match up. Causes of the anomaly are uncertain, but could be related to differences in elevation of benchmarks on the California and Arizona sides that were used for the photogrammetric survey. As these possible benchmark elevation differences could be causing confusion over water levels in MW- 54 and MW-55, it would be most helpful to have the surveys checked and verified. Checking with differential GPS (within +1 to 3 cm) would be a good starting point. Comment unresolved pending development of a plan to resurvey the altitudes of wells located on the Arizona side.	PG&E Response: The mapping on both sides of the river was based on the same High Precision Geodetic Network (HPGN) benchmark. The well elevations are also tied to this same single benchmark. It’s not clear from the comment exactly what is thought to be an anomaly, but if there is a discrepancy in a topo map it is likely due to some slight imprecision in the positioning of features on the figure and not due to the use of different benchmarks on different sides of the river.

1080	FMIT/TRC	Non-design	SOPs	C/RAWP Append B SOP-A8, p. 2	pH measurement using flow-through chamber	Because of the importance of pH to protect the organic rind, pH measurement in flow-through chambers can be affected by the streaming potential, and can be avoided by pH measurement in quiescent water (Wilde and others, 2006, USGS TWRI Book 9, Chapter A6).	If a pH measurement is measured under static conditions, the pH meter will continuously drift, that is caused by a state of equilibrium forming across surface of the glass sensing electrode. By deploying a flow-thru-cell and a flow of about 0.2 gallons/min the water in contact with the pH probe is constantly refreshed. The pH will stabilize very quickly and maintain a constant pH far longer than if measured under static conditions. In the case of multi-parameter probes used during sampling, the probes are calibrated everyday they are used. Calibration is performed to compensate for changes in potential within the measuring and reference electrodes, as well as any change of potential between them. The			pH values by electrometric methods are determined by an iterative and asymptotic approach to the actual pH value. Therefore, the pH probe must be allowed to stabilize, and the final pH value determined when the measured pH shows change of 0.01 unit over a minute. By expecting the asymptotic approach, 95% of the final value can be captured within a shorter time period; however, pH measurement takes time. The pH probe will drift in response to temperature changes and the streaming potential of water flowing past the glass membrane. If pH is measured in quiescent water, probe drift due to the streaming potential is eliminated.	DTSC Response: Tribal comment noted. DTSC will accept pH “flow through” measurements that are consistent with standard industry practice and follow manufacturer instructions (e.g., properly calibrated). Should pH data become critical and suspect at the Topock site, this method can be re-evaluated.

							calibration also involves checking the slope of the measuring electrode. Slope defines the ability of the measuring electrode to change its output by 59.16 mV per pH unit at 25°C. Virtually all pH instruments use a slope adjustment to compensate for the inability of the measuring electrode to accurately produce its output signal. If the slope falls outside the manufactures' recommended range, the probe is replaced. This information will be included in SOP-A8.			Please consider that accurate and precise measurement of pH in the field is just as great a priority as accurate laboratory measurements of contaminants of concern (e.g. hexavalent chromium); therefore, the time it takes to accurately measure pH in the field should not be compromised. Comment unresolved pending development of a plan to compare pH measurements in flowing and quiescent water.	
1081	Hualapai/TRC						See above			pH values by electrometric methods are determined by an iterative and asymptotic approach to the actual pH value. 1100	FMIT/TRC	Non-design	SOPs	C/RAWP Append B SOP-A22, p. 2	Fresh water equivalent head calculated using Salinity (%) = TDS/10,051.1	Because of the importance of freshwater equivalent heads for the determination of Operating Properly and Successfully (OPS) and Operational and Functional (OF), this fixed relation does not account for variable densities at the site.	The criteria for measuring OPS are currently under development by the agencies. However, it should be noted that laboratory certified data for analytical parameters, rather than field data, will be used as needed for OPS determinations. This equation does account for variable densities site-wide. The equation uses well-specific SC or TDS value obtained from field parameter at the end of well purging and/or laboratory data collected from discretely screened well to estimate a single salinity value for each monitoring well. The salinity measurement for each well is then used to calculate freshwater equivalent head. See also RTCs #733 and 734.			The response is unclear. Will freshwater equivalent heads be used to determine OPS and OF? If the freshwater equivalent heads do not represent the natural system, but represent an average condition. The Tribe believes that using data representative of the natural system is a better technical approach to making the OPS/OF determination. Comment unresolved pending development of a procedure to accurately represent freshwater equivalent heads.	DTSC response: Tribal comment noted.
1101	Hualapai/TRC	Non-design	SOPs	C/RAWP Append B SOP-A22, p. 2	Fresh water equivalent head calculated using Salinity (%) = TDS/10,051.1	Because of the importance of freshwater equivalent heads for the determination of Operating Properly and Successfully (OPS) and Operational and Functional (OF), this fixed relation does not account for variable densities at the site.	See above			The response is unclear. Will freshwater equivalent heads be used to determine OPS and OF? If the freshwater equivalent heads do	DTSC response: Tribal comment noted.

				p. 3	using TDS = SC * 0.65	freshwater equivalent head by reference density.	development by the agencies. However, it should be noted that laboratory certified data for analytical parameters, rather than field data, will be used as needed for OPS determinations. As presented in Hem, J.D. (1985) Study and Interpretation of the Chemical Characteristics of Natural Waters, USGS Water-Supply Paper 2254, the use of the fixed 0.65 value for the conversion factor provides a reasonable estimate of TDS, with most natural waters having factors that fall between 0.55 - 0.75. Use of the mid-point of the range noted for natural waters as an approximation for the Topock site has not yielded any noticeable issues with the hydraulic gradients calculated from freshwater equivalent heads (see RTC #733). However, where sufficient laboratory TDS data currently exists, a conversion factor will be calculated for each well and the SOP will be modified to reflect this change. In PG&E's opinion, adding the suggested additional step of measuring specific gravity by field or laboratory methods would not likely result in a significant improvement of density estimates for the calculation of freshwater equivalent heads. It is not common practice to measure specific gravity in the field, so the potential measurement error of field measured specific gravity could			due to injection of foreign water. There may be outliers in the data (see examples below), and statistical correlations will shift, causing uncertainty and rendering historical data less useful. Below are examples of conversion factor slopes that might be affected by outlier data (in red circles).   Determination of TDS by residual on evaporation (ROE) would be the most representative method because other methods (i.e. lab sum of major ions) does not include metals and carbon. It is anticipated that samples from the groundwater remedy will have elevated concentrations of metals (Fe, Mn) and carbon.

							MW-20 Bench and along the extraction pipelines as needed to facilitate decommissioning activities and protect worker and public safety. The following sentence will be added to Figures 3-2 to 3-6 as new notes: Contaminant reduction zones will be established as needed in the field by the project manager in accordance with the approved Work Plan.				
1150	JDS-2	Design	Remedial Design	Appendix F; Figure 3-5	Notes 4, 5, 6	The pipe down the slope and under the wash should be removed. IM-3 restoration should address post removal restoration of wash and slope.	There are four water pipes and several conduits in a shared trench under Bat Cave Wash. PG&E intends to abandon these pipes and conduits in place (after cleaning) to avoid disturbance to sensitive habitats in the wash. PG&E recognizes that FMIT as a landowner may have a preference to remove the pipes/conduits. PG&E will discuss this issue with FMIT prior to decommissioning, as part of its development of the final, detailed restoration plan.	PG&E has committed to removing all subsurface infrastructures for remedy to the extent practicable. IM3 should not differ. See PG&E response to comment 8.		Tribe agrees that IM3 should not differ.	DTSC response: Tribal comment noted. PG&E will discuss infrastructure removal with the landowner prior to decommissioning and during the development of the restoration plan.
1151	JDS-3	Design	Remedial Design	Appendix F; Figure 3-6	Notes 2 and 3	The pipe down the slope should be removed. IM-3 restoration should address post removal restoration of slope.	There are 4 conduits and 1 water pipe buried in the steep slope. PG&E intends to abandon the pipe/conduits in place (after cleaning) to minimize soil disturbance, control erosion, and improve safety for workers on the slope. Removing the pipe would increase the volume of earthwork on the project by approximately 30 cubic yards. In addition, pipe removal would disturb the ground surface and nearby biological resources, and potentially create a preferential flow paths that would increase erosion. Finally, working	PG&E has committed to removing all subsurface infrastructures for remedy to the extent practicable. IM3 should not differ. See PG&E response to comment 8.		Tribe agrees that IM3 should not differ.	DTSC/DOI response: The Agencies will provide direction to PG&E. Tribal comment noted.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							on steep slopes is inherently risky to construction workers. PG&E recognizes that BLM as a land manager and is committed to discussing decommissioning practicality at the time of decommissioning.				
1152	DOI-235	Non-design	Other	4.1.1.2/4-3	In accordance with the California Well Standards, filler material will not be used to decommission IM-3 system wells because they are located in an area of contaminated soil and groundwater; however, this assumption will be confirmed with DTSC, DOI, responsible agency (San Bernardino County), affected land owner, Tribes, and other stakeholders before backfilling the wells.	The discussions should occur now and the decision should be made regarding filler material during comment resolution and included in the final design package for approval.	PG&E assumes that the decision as to whether filler material can be used to decommission all or a subset of the listed wells (TW-2S, TW-2D, TW-3D, PE-1, IW-2, and IW-3) cannot be made until the time of permitting (with San Bernardino County) and decommissioning since it will depend on whether or not the wells are located in an area of contaminated soil and groundwater. Currently the listed wells with the exception of IW-2 and IW-3 are located within the contaminated groundwater plume and on the flood plain of the Colorado River, which represents an area of increased potential for surface water infiltration relative to nearby uplands. It is also understood that IW-2 and IW-3 could be considered in the area of the groundwater plume. Based on this PG&E would anticipate that filler material would not be used to decommission these wells, and that sealing material would be used to seal the well casing from total depth. PG&E will revise the document accordingly unless otherwise directed by the agencies.	Although decommissioning of these wells can be planned for the future and included in the IM3 Decommissioning plan, DTSC is concerned that the wells identified may have potential to be utilized as part of the remedy. For example, the TW wells are located in a contaminated portion of the plume near the IRZ line in close vicinity to a provisional IRZ well. The decision to decommission these wells should be evaluated on a case by case basis when understanding of the subsurface hydraulics is gained after the operational capabilities of the remedy are defined. If decommissioned prematurely, PG&E may have to drill new wells in the same vicinity if deemed technically necessary for the remedy.	Resolved.		Comment resolved.

							confidence limit of the mean, using ProUCL Version 4.0 software (USEPA, 2007)."				
1163	DOI-246	Non-design	Editorial	9.2/9-2	A biological evaluation will be performed to outline the IM-3 decommissioning, removal, and restoration activities as they relate to federally listed species in the area. The USFWS issued a concurrence letter on July 7, 2014 for the Final Remedy Programmatic Biological Assessment (PBA) which addressed a variety of activities, including activities identified in this Work Plan. The intent of the PBA is to provide programmatic coverage of these actions and avoid the need for individual project-specific consultations under the federal ESA.	Revise text as follows: PG&E will outline how the IM-3 decommissioning, removal, and restoration activities will affect federally listed species in the area. Since the USFWS issued a concurrence letter on July 7, 2014 for the Final Remedy Programmatic Biological Assessment (PBA) which addressed a variety of activities, including activities identified in this Work Plan, a new, separate consultation may not be necessary. The intent of the PBA was to provide programmatic coverage of all groundwater remedial actions and avoid the need for individual project-specific consultations under the federal ESA. However, if PG&E determines that the PBA needs to be updated or that a separate, individual consultation on the IM-3 decommissioning is necessary, they will work with the BLM and the USFWS to address additional impacts to federally listed species.	PG&E believes that the 2014 PBA adequately addresses the IM-3 Decommissioning and Restoration activities. For that reason, minor text changes for the proposed rewrite are suggested, as follows: "~~A biological evaluation will be performed to outline~~ PG&E will outline how the IM-3 decommissioning, removal, and restoration activities [will affect] ~~as they relate to~~ federally listed species in the area. Since the USFWS issued a concurrence letter on July 7, 2014 for the Final Remedy Programmatic Biological Assessment (PBA) which addressed a variety of activities, including activities identified in this Work Plan, a new, separate consultation is not anticipated]. The intent of the PBA ~~is~~ was to provide programmatic coverage of ~~these actions~~ all groundwater remedial actions and avoid the need for individual project-specific consultations under the federal ESA. However, should PG&E determine that the PBA needs to be updated or that a separate, individual consultation on the IM-3 decommissioning is necessary, then they will work with the BLM and the USFWS to address additional impacts to federally listed species." It would be beneficial for the reader to define "solid waste" either directly or by reference to Section 261.2 of RCRA.	The term "solid waste" used in this section refers to solid materials, as opposed to liquid materials, and does not refer to the RCRA definition of solid waste. Waste generated by construction activities will be classified as hazardous or non-hazardous based on the requirements of the California Hazardous		Resolved.		Comment resolved.

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
							Waste Control Law (California Health and Safety Code, Division 20, Chapter 6.5) and regulations (Title 22, California Code of Regulations, Division 4.5). Because EPA authorized California to implement RCRA based on enforcement of California's laws and regulation, the definition of solid waste in 40 CFR 261.2 is not relevant. California' waste classification system does not include a definition of solid waste. The corresponding definition in California regulations is the definition of "waste" in 22 CCR 66261.2. All of the materials being managed under this waste management plan are considered waste under this definition.				
1185	DOI-265	Non-design	Other	3.1.3/3-2	Empty, used 55-gallon drums that formerly contained hazardous materials will be labeled with the word "empty" and the date emptied and will be returned to the original chemical supplier or turned over to a drum reconditioner.	PG&E must ensure that drums containing hazardous materials are emptied in accordance with appropriate regulations prior to storage and shipment. DTSC has developed regulations that set forth a definition of "empty container." The regulations are found in Title 22, California Code of Regulations, Section 66261.7.	This section will be revised to read: "Empty, used 55-gallon drums that formerly contained hazardous materials will be labeled with the word "empty" and the date emptied and will be returned to the original chemical supplier or turned over to a drum re-conditioner. <u>Containers managed as empty will meet the requirements of 22 CCR 66261.7</u>."		Accepted.		Comment resolved.
1186	DOI-266	Non-design	Other	3.2.3/3-2	Concrete and asphalt rubble that exhibits visual evidence of contamination (staining, residue, etc.) will be sampled by chipping or coring.	All concrete/asphalt sampling, including in situ sampling, shall be biased toward visible staining.	The following sentence will be added. "<u>Samples will be collected from the stained areas to identify the nature of the contaminants. For waste disposal purposes samples will be collected, in accordance with procedures that are acceptable to the disposal site</u>."		Accepted.		Comment resolved.

New Decommissioning Section of the Executive Summary

ES.6 Remedy Decommissioning Process

As directed by DTSC in comments on the 90% BOD (90% RTCs #8 DTSC-4, #12 DTSC-8 [Appendix I]), this section describes the decommissioning process envisioned for the proposed remedy even though it is understood that ~~a~~ the detailed decommissioning plan will be prepared much later in the remedial process.

In compliance with the Agencies' April 4, 2014 directive letter (DTSC and DOI 2014), PG&E has and will continue to reiterate its commitment to remove all underground utilities and infrastructures to the extent practicable at the time of remedy decommissioning. Per DTSC's request, below is a conceptual list of remedy components that PG&E believes cannot or should not be removed at the end of the remedy (note that this list is based on current information and may be subject to change):

- Freshwater pipeline (and casing) under I-40;
- Piping/conduits located in (e.g., direct buried or in trenches) or under (e.g., jack and bore) paved, public roadways; and
- Subsurface infrastructure that property owner(s) or land manager(s) request not to be removed, and such request is approved by DTSC and DOI.

ES.6.1 Requirements Related to Remedy Decommissioning

Several documents require PG&E to prepare a plan for remedy decommissioning and/or impose requirements that apply to decommissioning activities of the remedy. This section presents the exact language in each of the documents that ~~requiring~~ require a remedy decommissioning work plan/~~,~~ decommissioning activities or that are otherwise applicable to decommissioning activities.

Programmatic Agreement (BLM 2010). Stipulation V of the PA includes the following applicable measures:

> *All facilities and appurtenances related to the Topock Remediation Project are to be removed as soon as practicable upon attainment of cleanup standards and a determination by DOI that removal of such facilities is protective of human health and the environment. PA, § V(A).*
>
> *All such removal will be planned in consultation with the Signatories, Tribes, and Invited Signatories following the guidelines in [PA] Appendix B [the consultation protocol]. PA, § V(A).*
>
> *The removal of such facilities shall be monitored following the monitoring guidelines in [PA] Appendix C [the tribal and archeological monitoring protocol]. PA, § V(B).*
>
> *The removal of such facilities shall take place along existing graded roads to the maximum extent practicable. PA, § V(C).*
>
> *Prior to decommissioning of any remediation facility, the Federal Agencies will consult with all Signatories, Tribes, and Invited Signatories during the development of the closure plan to determine how to best restore the areas affected by the Topock Remediation Project, including, but not limited to, the site of the existing treatment plant and related facilities, but excluding the Topock Compressor Station and related facilities, to ensure that environmental restoration of conditions existing prior to the construction of the Project is achieved to the extent practicable. PA, § V(D).*

Cultural and Historic Properties Management Plan (BLM 2012). The CHPMP also includes provisions applicable to remedy decommissioning:

> *PG&E will remove all other remediation facilities and appurtenances related to the Topock Remediation Project as soon as practicable following the attainment of cleanup standards and a determination by DOI that the removal of these facilities is protective of human health and the environment (BLM et al. 2010:13). CHPMP, § 6.2.3.*
>
> *A Remedy Decommissioning Plan will be drafted that will describe procedures for the removal and decommissioning of the groundwater remedy treatment system and associated infrastructure. The*

Plan will also describe the post-remedy restoration of the site to the conditions existing prior to the implementation of the remedial investigation and remedy construction, including related appurtenances and facilities, to the extent practicable. This Plan will be submitted by PG&E to DOI within 120 days of DOI's certification of completion of the CERCLA Remedial Action and determination by DOI that removal of such facilities is protective of human health and the environment. CHPMP, § 6.3.

PG&E will retain a qualified professional archaeologist to inspect and evaluate any previously unidentified or suspected archaeological or historical remains, including human remains and/or associated funerary objects or graves, uncovered during construction, operation, or decommissioning of the Project. Should any such remains, objects, or features be found, all Project activities will cease immediately within an area extending not less than 5 meters and not more than 50 meters (to be determined in the field on a case-by-case basis) from the potential find. The BLM, and Tribal representatives if the resource is Native American in nature, will be notified immediately of the discovery. No further work will be undertaken until the BLM, in consultation with Tribes and PG&E, has determined the nature of the discovery and developed appropriate measures for its evaluation and/or treatment, consistent with the PA. CHPMP, § 8.1.

The CHPMP also refers to Stipulation V of the PA, as previously outlined.

Consent Decree and Appendix C, Scope of Work to Consent Decree (DOI 2013). Section 9 of the CD states the following:

The Remedy Decommissioning Plan describes procedures for the removal and decommissioning of the groundwater remedy treatment system and associated infrastructure. The Plan will also describe the post-remedy restoration of the site to the conditions existing prior to the implementation of the remedial investigation and remedy construction, including related appurtenances and facilities, to the extent practicable. This Plan will be submitted by PG&E to DOI within 120 days of DOI's certification of completion of the RA and a determination by DOI that removal of such facilities is protective of human health and the environment. Removal of remediation facilities will be consistent with the PA.

Environmental Impact Report and Mitigation Monitoring and Reporting Program (DTSC 2011d). The EIR and the MMRP contain information relevant to decommissioning.

The EIR makes the following statements about decommissioning:

Following completion of the remedial action, when it is determined through monitoring cleanup of contaminated groundwater plume to background levels or 32 µg/l of Cr(VI), and/or following the determination that the remedial structures are no longer needed, the remedial facilities (e.g., in situ reductant storage and delivery systems, foundation material, process controls/instrumentation systems) would be decommissioned. EIR at 3-28.

Standard well decommissioning procedures required by San Bernardino County and the California Water Resources Department would be followed for the decommissioning of all wells (including remediation and monitoring). This would generally include either perforating the well casing and filling the well with cement grout or overdrilling the well. EIR at 3-28.

Decommissioning reductant storage facilities would include removing above grade treatment facilities from the site. Removed materials would be reused, transported to an off-site disposal facility, or sold as scrap material. EIR at 3-29.

While most facilities would be expected to be decommissioned following the completion of the remedial action, it is possible that water supply wells or the surface water intake structure may not be decommissioned and that it could be transferred to another use. EIR at 3-29.

Pipelines would be decontaminated as appropriate. Aboveground piping would be removed and either reused or disposed off-site as scrap material. Subsurface pipelines would likely be abandoned in place following decontamination. EIR at 3-30.

As wells and other infrastructure are removed and it is determined that access roads are no longer necessary, roads would be decommissioned from further use. The efforts involved in decommissioning would be dependent on the type of road (could be paved with asphalt, covered in gravel, or left unpaved) and the location of road (such as in previously disturbed areas or areas that were in a more natural state prior to the proposed project). EIR at 3-30.

The MMRP also contains several mitigation measures pertaining to decommissioning of the remedy.[1]

ES.6.2 Trigger for Remedy Decommissioning

As stated in response to 90% comment #28 FMIT-14, once the completion criteria/performance standards for the groundwater remedy are met to the satisfaction of the agencies, PG&E will submit a plan to decommission the remedy in accordance with the CD and CACA. The completion criteria/ performance standards for the remedy are presented in detail in both the 90% BOD (Sections ES-2 and 1.2.1) and the O&M Manual (Section L.4).

Due to heterogeneity in the aquifer at the Topock site, it is expected that during the decades-long O&M period there will be portions of the site that attain the completion criteria/performance standards at different times. During future evaluations, such as 5-year reviews, distinct geographical areas of the site, where criteria/standards have been attained and/or where it has been determined that Monitored Natural Attenuation (MNA) is appropriate to address residual chromium, could be designated (as appropriate) for Corrective Measure (CM)/Remedial Action (RA) Completion. At that time, PG&E can submit a request for certification of RA completion (CD Appendix C Section 8) and a CM completion report (CACA Attachment 6, Item G) to DOI and DTSC, respectively. Once DTSC and DOI are satisfied and determine that remedy facilities in those geographical areas are no longer needed, PG&E will proceed with decommissioning in accordance with the decommissioning plan.

ES.6.3 Conceptual Narrative of Key Remedy Decommissioning Steps

At this time in the design process and before the remedy is constructed, steps to decommission any remedy components, which will occur decades into the future, will have to be general and conceptual. Descriptions of the conceptual decommissioning steps (below and in the 60% RTC #6) reflects this fact. Any additional details provided herein should be considered speculative best estimates, and are subject to change based on information and conditions that become available prior to and at the time of remedy decommissioning.

- **Site preparation and demarcation** – typical activities include mobilization of resources (personnel, equipment, materials), delineate access/haul routes, demarcate work and support zones including staging areas, and set up temporary facilities. Temporary facilities may include trailers, restroom facilities, safety and security lighting, equipment storage area, and parking area.
- **Utility survey and isolation** – typical activities include locating and marking underground utilities prior to intrusive work, and isolation of identified utilities. Utilities may include water, sewer, gas, phone, and power lines. Underground Service Alert or “Dig Alert” will be contacted to identify public utilities that

---

1 Mitigation measures included in the MMRP that apply during decommissioning include, but are not limited to, Mitigation Measure BIO-2c, which requires the preparation of a Bird Impact Avoidance and Minimization Plan based on surveys conducted prior to decommissioning and during the breeding season (as defined in the EIR for each species or suite of species), and CUL-1a-8e, which requires protocols for the appropriate methods to be used to restore the environment to its preconstruction condition upon decommissioning.

operate within the work areas. Identified utilities will be isolated and disconnected by the utility provider prior to decommissioning and removing portions of a utility.

- **System components decommissioning** – decommissioning renders the components permanently out of service. Typical activities include decontamination and removal~~ or abandonment in place~~. Decontamination will involve cleaning and removing waste materials, and render the components appropriate for reuse, recycle, or disposal. After decontamination, the components will generally be removed~~ or abandoned in place~~.

  PG&E has and will continue to reiterate its commitment to remove ~~of~~ all underground utilities and infrastructures to the extent practicable at the time of remedy decommissioning. Per DTSC's request, below is a conceptual list of remedy components that PG&E believes cannot or should not be removed at the end of the remedy (note that this list is based on current information and may be subject to change):

  - Freshwater pipeline (and casing) under I-40;
  - Piping/conduits located in (e.g., direct buried or in trenches) or under (e.g., via jack and bore) paved, public roadways; and
  - Subsurface infrastructure that property owner(s) or land manager(s) request not to be removed, and such request is approved by DTSC and DOI.

- **Waste characterization and management** – waste generated from decommissioning may include liquid wastes, solid wastes, and sludge. Waste will be characterized and managed appropriately.
- **Soil confirmation sampling, as needed** – subsequent to decommissioning and removal, soil confirmation sampling may be conducted to assess soil conditions as needed.
- **Post-decommissioning restoration** – after decommissioning and confirmation sampling are complete, site restoration will commence. Restoration activities will start with returning the land to a safe condition, backfilling of excavated infrastructure, and compacting uneven areas. Light grading and contouring may be required to provide proper drainage and to control erosion. Revegetation will occur after final grading and contouring.

The above conceptual steps apply to pipelines and vertical infrastructure. Decommissioning of wells will be in accordance with the approach outlined in the project Well Decommissioning SOP (Well-SOP-01) presented in the O&M Manual Volume 1, Appendix B.

Re: Pacific Gas and Electric Company (PG&E) Topock Compressor Station Remedial Investigation; SHPO-2007-0694(35381); DOI-BLM; FWS; ADEQ

Dear Mr. Politsch:

Thank you for consulting with us on the above-proposed undertaking and on your finding of effect. We have reviewed the summary documentation included and concur with the Agency's finding of "no historic properties affected" based upon the level of information obtained in your tribal consultation efforts.

We appreciate your continued cooperation with this office in complying with the historic preservation requirements for federal undertakings. If you have any questions or concerns, please feel free to contact me at 602/542-7138, or e-mail me at ahoward@azstateparks.gov.

Sincerely,

Ann V. Howard

Subject:
Response to 90% BOD Comment #418 with Supporting Data from Hinkley

---

Introduction

This technical memorandum serves as a document to provide supporting information in response to Comment #418 (DOI-11) regarding the development of the simulated threshold total organic carbon (TOC) concentration for reduction of hexavalent chromium (Cr(VI)).

Comment #418 (DOI-11)

Referenced Text: (90% BOD Appendix B Section 3.4.1) "The solute transport model (described below; see Section 6) assumes Cr(VI) reduction in the presence of organic carbon above 0.1 mg/L."

Comment: "In light of the discussion pertaining to the apparent TOC concentrations required for reduction of Cr(VI) (100 mg/L) it is difficult to see why this assumption is made particularly since the reporting limits for the TOC are 1 mg/L. Please provide justification for the 0.1 mg/L TOC assumption."

PG&E Response: The concentration of TOC needed to establish chromium-reducing conditions given a continuous injection system will be different than that needed to establish chromium-reducing conditions during the discrete injection pilot test. The 0.1 mg/L TOC threshold was established as the minimum carbon concentration to support microbial growth and Cr(VI) reduction through a series of sensitivity analyses for other Cr(VI) impacted sites where Cr(VI) reduction using a large-scale recirculation system had been observed (i.e., PG&E Hinkley Compressor Station site). During continuous injections at Hinkley, the 0.1 mg/L threshold was well-correlated to the zone of Cr(VI) reduction. This analysis was done by fitting the chromium reduction data and available TOC data above the reporting limit, which allowed for the determination of the threshold below the reporting limit. The lower 0.1 mg/L also allows the model to account for potential lysis effects where carbon from previous microbial communities is essentially recycled to support further microbial growth.

A sensitivity analysis was also performed on the trigger TOC level for Cr(VI) reduction to evaluate potential effects. As discussed in Section 10.15 of Appendix B, the TOC threshold concentration was increased an order of magnitude to 1 mg/L. At this higher TOC threshold, sufficient Cr(VI) reduction was achieved. The model predicted potential Cr(VI) breakthrough along the NTH IRZ line at the 10-year mark during the IRZ OFF cycle. However, much of this Cr(VI) is treated during the subsequent IRZ ON cycle, and the model results are comparable for the 0.1 and 1 mg/L TOC triggers at 30 years. Potential operational adjustments to address a higher TOC threshold concentration are described in Table 6.6-1 of Appendix B and include the following (primarily applicable to the NTH IRZ): adjust TOC dosing concentration, frequency, and/or duration; and activation of provisional wells to bolster lateral coverage.

DOI Response: "Hinkley data which was not provided"

Addendum: Supporting Analysis from Hinkley Site

In order to further support the response to #418, below is a summary of the modeling used for the Hinkley site and the TOC threshold used in the solute transport modeling for that site. Large scale IRZ operations, similar in design to the continuous recirculation systems planned for the Topock site, began at Hinkley in late 2007. A solute transport model was first developed for the Hinkley site in 2008 in support of the feasibility study for the site. In 2014, the solute transport model parameters were further examined in comparison with data collected through 2014 as part of an assessment of remedial timeframes (ARCADIS 2014). The results of these modeling evaluations indicate that the TOC threshold is between 0.1 and 1 mg/L, consistent with the range of values considered in the Topock solute transport modeling (ARCADIS 2014).

The attached figure shows the results of model runs conducted with actual Hinkley site IRZ operations (i.e. actual injection and extraction locations, flowrates over time, and TOC injection concentrations) using 0.1 and 1 mg/L TOC threshold concentrations in comparison to actual groundwater data over the period of large scale IRZ operations from Fourth Quarter 2007 to First Quarter 2014. A comparison of the results for the IRZ areas south of Highway 58 shows that the 0.1 mg/L TOC threshold concentration replicates the downgradient flush of the clean water from IRZ injection points well (Location 3 on **Figure 1**), while the 1 mg/L TOC threshold results in a better agreement with the lateral distribution than the 0.1 mg/L TOC threshold run (see Locations 1 and 2 on **Figure 1**).

Given that the higher TOC threshold value improved prediction of some aspects of actual performance, while underpredicting other aspects of actual performance, remedial timeframe assessment modeling for the Hinkley site was conducted with both TOC thresholds to provide a range of remedial timeframe estimates. These TOC threshold values are consistent with those utilized in the 90% BOD Appendix B and associated sensitivity analyses. The performance of the proposed Topock remedy will be evaluated against the model in future model updates to further support solute transport parameters.

Revised REMEDY-SOP-08: Inspection of Frac Tanks

Standard Operating Procedure
PG&E Topock Groundwater Remedy Operation and Maintenance Plan

Title: Inspection of Frac Tanks

Number: Remedy-SOP-08_Rev1~~0~~

~~Creation~~ Revision Date: 5/19/2015~~8/26/2013~~

1 Background and Scope

Pacific Gas and Electric Company (PG&E) is implementing a groundwater remedy near the intersection of Park Moabi Road and Interstate 40, approximately 12 miles southeast of Needles, California at the PG&E Topock Compressor Station (TCS).

The objective of this Standard Operating Procedure (SOP) is to describe the procedure for inspection and maintenance of frac tanks at the MW-20 Bench and Remedy-produced Water Conditioning Plant.

The operator should not break the plane of the tank openings with body parts at any time during this procedure, as it would be considered confined space entry. If confined space entry is necessary for a special procedure, the Health and Safety Plan should be referenced.

2 Drawing Numbers

- IRZ Carbon Amendment Building: I-06-02
- Remedy-Produced Water Conditioining Plant Influent Tank Farm: I-11-01 through I-11-04
- Remedy-Produced Water A-Side Conditioned Water Storage Tanks: I-14-01

3 Equipment/Supplies

- Appropriate personal protective equipment (PPE), including fall protection
- Health and Safety Plan
- Lockout/tagout tags and lockout/tagout manual for frac tank maintenance (if tank shutdown is performed)
- Portable/submersible pump or vac truck (if tank draining is performed)

4 Procedure

~~1.~~ Inspect tanks and associated equipment with reference to the following instructions (steps 2 through 12). ~~.~~

~~2.~~ 1. If unsuitable tank conditions are observed at any time throughout the procedure:

1.1. Reference the Hazardous Materials Business Plan (HMBP) if the tank contains hazardous materials (acid or caustic) to determine how the materials should be handled if the chemicals are discharged from the tank.

1.2. Shut down and/or drain the tank if it is warranted (e.g. the tank is in danger of a blow out or failure). Steps a through f below are procedures to shutdown and drain an individual frac tank (If more than one frac tank is to be shutdown and/or drained at the same time, special procedures are required):

a. Influent Tank Farm (TNK-201 through TNK-204), Shutdown Frac Tank

i. Lockout/tagout the frac tank by following instructions in the lockout/tagout manual.
ii. Use the HMI to turn OFF the tank's recirculation pump (PMP-201 for Influent Tank 1, PMP-202 for Influent Tank 2, PMP-203 for Influent Tank 3, PMP-204 for Influent Tank 4).
iii. Close the following manual valves upstream, downstream, and on the chemical recirculation line of the frac tank:
   1. Influent Tank 1: V-201A, V-201F, V-201G, V-201I, V-201K
   2. Influent Tank 2: V-202A, V-202F, V-202G, V-202I, V-202K
   3. Influent Tank 3: V-203A, V-203F, V-203G, V-203I, V-203K
   4. Influent Tank 4: V-204A, V-204F, V-204G, V-204I, V-204K

b. Influent Tank Farm (TNK-201 through TNK-204), Drain Frac Tank

i. Use the HMI to verify that there is sufficient volume in the other influent tanks for the discharge from the influent tank being drained.
   - Proceed to next steps only if there is sufficient volume in the other influent tanks.
ii. Inspect the secondary containment per Remedy-SOP-07 (Secondary Containment Inspection and Maintenance at Buildings).
iii. Proceed to next steps only if the secondary containment is in acceptable condition.Plug in the Influent Tank Farm sump pump (PMP-205).
iv. If the frac tank is not already shutdown, shutdown the frac tank by completing all steps listed for shutting down an Influent Tank Farm Frac Tank (see step a. above).
v. Slowly open the manual drain valve on the frac tank (V-201M for Influent Tank 1, V-202M for Influent Tank 2, V-203M for Influent Tank 3, V-204M for Influent Tank 4):
vi. Ensure that the tank discharge properly drains in the secondary containment to the sump pump.
   - If there is any malfunctioning of the secondary containment and/or sump pump, immediately close the manual drain valve that was opened in Step v.
vii. If the frac tank does not drain completely by gravity, pump out the remaining water using a portable pump or vac truck.
   a. Drain the discharge into the influent tank farm sump (with the portable pump) OR haul to the influent tanks or liquid phase separator (with the vac truck).
viii. After the frac tank has completely drained, close the manual drain valve that was opened in step v.
ix. After all discharge has been pumped from the sump, unplug the Influent Tank Farm Sump Pump (PMP-205).
x. If frac tank is to be cleaned after draining, see RTP-SOP-07 (Manual Cleaning of Frac Tanks).

c. Conditioned Water Tank Farm (TNK-401 and TNK-402), Shutdown Frac Tank

i. Lockout/tagout the frac tank by following instructions in the lockout/tagout manual.
ii. Close the manual valves upstream/downstream of the frac tank:
   1. Conditioned Water Storage Tank 1: V-401A, V-401B
   2. Conditioned Water Storage Tank 2: V-402A, V-402B

d. Conditioned Water Tank Farm (TNK-401 and TNK-402), Drain Frac Tank

i. Use the HMI to verify that there is sufficient volume in the other influent tanks for the discharge from the influent tank being drained.

ii. Proceed to next steps only if there is sufficient volume in the other influent tanks.

iii. Inspect the secondary containment per Remedy-SOP-07 (Secondary Containment Inspection and Maintenance at Buildings).

iv. Proceed to next steps only if the secondary containment is in acceptable condition.Plug in the Conditioned Water Tank Farm sump pump (PMP-407).

v. If the frac tank is not already shutdown, shutdown the frac tank by completing all steps listed for shutting down the Conditioned Water Tank Farm Frac Tanks (see step c. above).

vi. Slowly open the manual drain valve on the frac tank (V-401C for Conditioned Water Storage Tank 1, V-402C for Conditioned Water Storage Tank 2):

vii. Ensure that the tank drainage properly drains in the secondary containment to the sump pump.

- If there is any malfunctioning of the secondary containment and/or sump pump, immediately close the manual drain valve that was opened in step v.

ii. If the frac tank does not drain completely by gravity, pump out the remaining water using a portable pump or vac truck.

- Drain the discharge into the conditioned water tank farm sump (with the portable pump) OR haul to the influent tanks or liquid phase separator (with the vac truck).

viii. After the frac tank has completely drained, close the manual drain valve that was opened in step ~~i~~v.

ix. After all discharge has been pumped from the sump, unplug the Conditioned Water Tank Farm sump pump (PMP-407).

x. If frac tank is to be cleaned after draining, see RTP-SOP-07 (Manual Cleaning of Frac Tanks).

e. MW-20 Bench (T-IRZ00-720, T-IRZ00-721, T-IRZ00-723), Shutdown Frac Tank

i. Lockout/tagout the frac tank by following instructions in the lockout/tagout manual.

ii. Close the manual valves upstream of the frac tank as applicable:

- Backwash Frac Tank (T-IRZ00-721): V-IRZ00-728C, V-IRZ00-728I, V-IRZ00-728K, V-IRZ00-728S
- Clean-in-Place Frac Tank (T-IRZ00-723): V-IRZ00-728A, V-IRZ00-728E, V-IRZ00-728G

f. MW-20 Bench (T-IRZ00-721, T-IRZ00-723), Drain Frac Tank

i. Use the HMI to verify that there is sufficient volume in the Remedy-produced Water Conditioning Plant Influent Tank Farm (TNK-RTP-201 through TNK-RTP-204) for the discharge from the frac tank being drained.

ii. Proceed to next steps only if there is sufficient volume in the Influent Tank Farm.

iii. Close/open valves on discharge line to direct flow to Remedy-produced Water Conditioning Plant.

- V-IRZ00-726B (open, manual), V-IRZ00-726D (open, manual), V-IRZ00-727D (open, manual), V-IRZ00-727E (open, manual)
- Backwash Frac Tank (T-IRZ00-721): V-IRZ00-726O (closed, manual)
- Clean-in-Place Frac Tank (T-IRZ00-723): V-IRZ00-726O (open, manual), V-IRZ00-726F (closed, manual), V-IRZ00-726B (closed, manual), FV-IRZ00-732 (closed, via HMI)

iv. Follow Step 4 of IRZ-SOP-13 to transfer water to the Remedy-produced Water Conditioning Plant.
v. Close the manual valves downstream of the frac tank:
- Backwash Frac Tank (T-IRZ00-721): V-IRZ00-726B
- Clean-in-Place Frac Tank (T-IRZ00-723): V-IRZ00-726C

iii. If the frac tank is not sufficiently drained, pump out the excess water using a vac truck or submersible pump placed in frac tank.
vi. If frac tank is to be cleaned after draining, see RTP-SOP-07 (Manual Cleaning of Frac Tanks).

g. MW-20 Bench (T-IRZ00-720), Drain Conditioned Water Frac Tank

i. Use the HMI to verify that the National Trails Highway (NTH) In-Situ Reactive Zone (IRZ) injection well system is active.
ii. Proceed to next steps only if NTH IRZ injection wells are able to receive water.
iii. Open manual valves on discharge line to direct flow to the NTH IRZ: V-IRZ00-726A, V-IRZ00-727B, V-IRZ00-727H, V-IRZ00-710H
iv. Place FV-IRZ00-728S into the “OPEN” position via the HMI
v. Place PMP-IRZ00-748 (Conditioned Water Injection Pump) into “AUTO”
vi. Visually inspect the lines for signs of leaks
vii. Once T-IRZ00-720 is empty, LT-IRZ00-756 will initiate the programmable logic controller to do the following:
- FV-IRZ00-728S will close
- PMP-IRZ00-748 will automatically shut off

viii. Use HMI to place PMP-IRZ00-748 into “OFF”
ix. Close manual valve V-IRZ00-726A downstream of the frac tank
iv. If the frac tank is not sufficiently drained, pump out the excess water using a vac truck or submersible pump placed in frac tank.
x. If frac tank is to be cleaned after draining, see RTP-SOP-07 (Manual Cleaning of Frac Tanks).

~~1.2. .~~

1.3. Attempt to fix the tank conditions with reference to the manufacturer’s instructions, if feasible.

1.4. If the tank conditions cannot be fixed, the operator should contact the Maintenance Supervisor so parts can be procured and work can be scheduled.

~~3.~~2. Inspect the outside of the process tank (including tank walls, anchors, supports, stairs and platforms) for the following:

- No signs of distortion, buckling, denting, or bulging on tank
- No signs of cracks, leakage, or corrosion on tank
- No severe corrosion or damage on staircase

~~4.~~3. Inspect the nozzles, piping and actuated and manual valves for the following:

- No signs of leakage or damage along piping
- No evidence of vibration along piping
- Piping is adequately supported
- No signs of leakage or damage at valves
- Nozzles are adequately sealed and there are no signs of leakage or damage
- Flanged connection bolts are tight and fully engaged with no sign of wear or corrosion

~~5.~~4. Carefully climb the staircase to the top of the tank to inspect the lid of the tank.

~~6.~~5. Fall protection must also be used when inspecting the lid of the tanks. Set up and connect to fall protection and ascend onto the roof of the tank.

~~7.~~6. Do not break the plane of the tank lid with body parts at any time during this procedure, as it would be considered confined space entry. If confined space entry is necessary for a special procedure, the Health and Safety Plan should be referenced

~~8.~~7. Inspect the roof for the following:

- No signs of distortion, buckling, denting, or bulging on roof
- No signs of cracks, leakage, or corrosion on roof

~~9.~~8. Descend from the roof of the tank

~~10.~~9. When it is safe to do so, disconnect from fall protection.

~~11.~~10. Carefully descend the staircase.

~~12.~~11. If applicable, move to next tank for inspection and repeat steps 1 through 10.

~~13.~~12. Contact the Maintenance Supervisor if there are any notes that require further maintenance so parts can be procured and work can be scheduled.

OSHA Suggested Spotting Signals for Vehicles

Preventing Backovers

Backing Safety Solutions

Spotter

Spotters are a proven method of protecting employees on foot behind vehicles with an obstructed view, but spotters themselves can be at risk for injury or even death. Employers can implement the following actions to help keep spotters safe:

- Ensure that spotters and drivers agree on hand signals before backing up.
- Instruct spotters to always maintain visual contact with the driver while the vehicle is backing.
- Instruct drivers to stop backing immediately if they lose sight of the spotter.
- Not give spotters additional duties while they are acting as spotters.
- Instruct spotters not to use personal mobile phones, personal headphones, or other items which could pose a distraction during spotting activities.
- Provide spotters with high-visibility clothing, especially during night operations.

Vehicles Causing the Most Backover Fatalities 2005-2010+

Dump Truck	**67**
Semi/Tractor Trailer	**40**
Truck	**30**
Forklift	**21**
Garbage Truck	**20**
Pick-up Truck	**16**

+OSHA Integrated Management Information System data

Suggested Spotting Signals

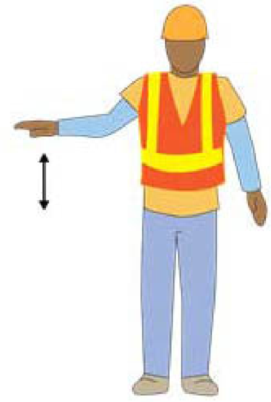
Back up

Back, turn left

Back, turn right

Move forward

Distance left to back



Slow down

Stop

Note: The following list of solutions is not required by any OSHA standard. It is provided for informational purposes only.

Cameras

Most vehicles (and some types of mobile equipment) can accommodate a camera that provides operators with a view to the rear. Some vehicles come equipped with cameras or may be offered with them as optional equipment. Camera systems can also be purchased as after-market equipment for vehicles. Viewing screens may be dash-mounted but must not block the driver's view out the windshield. Harsh environments, such as some construction sites or mines, may require more rugged cameras. Determining where to mount a camera for maximum effectiveness may be difficult, especially on large vehicles. For example, dump trucks may require two or three cameras to monitor the blind spots on the front, rear, and side of the vehicle.

Proximity Detection Systems

Radar and ultrasonic technology both are used in backing safety systems. A radar system transmits a signal, which is bounced off an object. The signal is then received by a receiver. These systems alert the driver with a visual and/or audio warning. These systems must be positioned so that they won't detect harmless objects, such as the concrete slab of a driveway, which can interfere with the detection of an object or person behind the vehicle or mobile equipment. Also, the composition of an object can affect detection, with some materials being virtually invisible to radar. Like cameras, this equipment can be mounted on most vehicles and may be an option from some manufacturers.

Ultrasonic systems, such as sonar, emit bursts of ultrasonic waves in a frequency above the hearing threshold of humans. When the waves strike an object, they generate echoes used to determine the distance to the object. These systems alert the driver with a visual and/or audio warning.

Tag-based Systems

Another type of proximity detection system is an electromagnetic field-based system, which is a type of tag-based system. This system consists of electromagnetic field generators and field detecting devices. One electromagnetic field-based system uses electromagnetic field generators installed on a vehicle and electronic sensing devices (a tag) worn by persons working near the vehicle. Another electromagnetic field-based system uses field generators worn by persons working near the vehicle, with the sensing devices installed on the vehicle. These electromagnetic field-based systems can be programmed to warn affected workers, stop the vehicle, or both, when workers get within the predefined danger zone of the vehicle.

Internal Traffic Control Plans

An internal traffic control plan (ITCP) is another method used to address backover hazards. These are plans that project managers can use to coordinate the flow of moving equipment, workers, and vehicles at a worksite to minimize or eliminate vehicles and employees from crossing paths. These plans can significantly reduce, or possibly eliminate, the need for vehicles to back up on a site.

- Freshwater B-Side Conditioned Water Storage Tank (TNK-510): I-14-02
- Conditioned Water Storage Tank Mechanical Plans and Details: S-14-01 through S-14-05

3 Equipment/Supplies

- Appropriate personal protective equipment (PPE), including fall protection
- Health and Safety Plan
- Lockout/tagout tags and lockout/tagout manual for B-Side Conditioned Water Storage Tank maintenance (if tank shutdown is performed)
- Portable pump and water hauling truck OR vac truck (if tank draining is conducted)

4 Procedure

~~14.~~ Inspect tank and associated equipment with reference to the following instructions (steps 2 through 11).

1. If unsuitable tank conditions are observed at any time throughout the procedure:

    1.1 Shut down and/or drain the tank if it is warranted (e.g. the tank is in danger of a blow out or failure).

    1.1.1 Shutdown Tank

    i. Lockout/tagout the tank by following instructions in the lockout/tagout manual for B-Side Conditioned Water Storage Tank maintenance.

ii. Use the HMI to turn OFF the B-Side Filter Feed Pumps (PMP-330 and PMP-340).

iii. Close the manual valve upstream (V-510A) and downstream (V-510B) of the Conditioned Water Storage Tank.

~~1.1.1~~1.1.2 Drain Tank

i. Use the HMI to verify that there is sufficient volume in the influent tanks for the discharge from the B-Side Conditioned Water Storage Tank.

a. Proceed to next steps only if there is sufficient volume in the influent tanks.

ii. If the tank is not already shutdown, shutdown the tank by completing all steps listed for shutting down the tank (see step a. above).

iii. Slowly open the manual drain valve on the tank (V-510G).

iv. Ensure that the tank discharge properly drains into the influent tanks.

a. If there is any malfunctioning of the tank discharge draining to the influent tanks, immediately close the manual drain valve that was opened in step iii.

v. If the tank does not drain completely by gravity, pump out the remaining water using a portable pump and water hauling truck OR ~~,~~vac truck.

a. Close V-510G.

b. Connect the portable pump or vac truck to the connection downstream of V-501D.

c. If using a portable pump, ensure the water flows to the water hauling truck.

d. Initiate pumping using the portable pump or vac truck.

e. After TNK-510 is completely drained, terminate pumping from the portable pump or vac truck.

f. Close V-501D.

g. Disconnect the portable pump or vac truck.

h. The discharge in the water hauling truck or vac truck may be drained in the influent tanks or liquid phase separator.

vi. After the tank has completely drained, verify V-510G is closed.

1.2 Attempt to fix the tank conditions, if feasible.

1.3 If the tank conditions cannot be fixed, the operator should contact the Maintenance Supervisor so parts can be procured and work can be scheduled.

2. Inspect the outside of the tank (including tank walls, anchors, supports, stairs and platforms) for the following:

- No signs of distortion, buckling, denting, or bulging on tank
- No signs of cracks, leakage, or corrosion on tank
- No severe corrosion or damage on staircase
- Grating at flush cleanout catch basin is intact
- Flush cleanout catch basin is free of standing water

3. Inspect the nozzles, piping and actuated and manual valves for the following:

- No signs of leakage or damage along piping
- No evidence of vibration along piping
- Piping is adequately supported
- No signs of leakage or damage at valves
- Nozzles are adequately sealed and there are no signs of leakage or damage
- Flanged connection bolts are tight and fully engaged with no sign of wear or corrosion
- Bird screen on overflow line is intact

4. Carefully climb the staircase to the top of the tank to inspect the lid of the tank.
5. Fall protection must also be used when inspecting the lid of the tanks. Set up and connect to fall protection and ascend onto the roof of the tank.
6. Do not break the plane of the tank lid with body parts at any time during this procedure, as it would be considered confined space entry. If confined space entry is necessary for a special procedure, the Health and Safety Plan should be referenced
7. Inspect the roof for the following:
   - No signs of distortion, buckling, denting, or bulging on roof
   - No signs of cracks, leakage, or corrosion on roof
8. Descend from the roof of the tank
9. When it is safe to do so, disconnect from fall protection.
10. Carefully descend the staircase.
11. Contact the Maintenance Supervisor if there are any notes that require further maintenance so parts can be procured and work can be scheduled.

Revised Management Protocol for Handling and Disposition of Displaced Site Material and Park Moabi Design

Management Protocol for Handling and Disposition of Displaced Site Material, Topock Remediation Project, Needles, California

PREPARED FOR: Topock Remediation Project Files

PREPARED BY: Pacific Gas and Electric Company

DATE: October 3, 2012, rev. July 2015

This document presents the general approach and management protocol required for the handling and disposition of soil and/or rock (referred to as "material" throughout the document) that is displaced as a result of past (as practical), present, and future activities associated with the Pacific Gas and Electric Company (PG&E) Topock Remediation Project, Needles, California. Specifically, this includes material removed from the Earth (i.e., displaced) as a result of drilling, excavation, sampling, testing, construction, grading, and other remedial activities. The management of material that may be disturbed as a result of remedial activities but not displaced from its natural location, such as soil disturbed by foot or vehicle traffic along a pathway, is not within the scope of this protocol. This protocol is applicable to the handling and disposition of displaced materials only. Further, materials that were not part of the natural site condition (e.g., building materials, equipment, waste, debris, or imported fill[1]) are not included in this protocol.

A draft of this protocol (dated October 3, 2012) was included in the Soil Management Plan associated with the Basis of Design Report/Pre-Final (90%) Design Submittal and Construction/Remediation Action Work Plan (September 8, 2014). Subsequent to agency review of the design submittal, this protocol has been revised per comment from the Department of the Interior (DOI) (Comment #803, DOI-333). The October 3, 2012 draft of this protocol included a provision for the long-term storage of material that is determined to be non-hazardous waste but unsuitable for a final disposition decision on-site because contaminants are present above the interim screening level. The 90% design submittal identified an area (located on federal land) for the long-term storage of material that is generated during construction of the final groundwater remedy and is characterized to meet this profile; however, the DOI comment indicates that based on discussions with San Bernardino County, the adjacent leasee of Moabi Regional Park, and internal discussions between the U.S. Bureau of Land Management (BLM) and the DOI, PG&E must find an alternate location for storage. Based on further clarifications from DOI and BLM, PG&E understood that storage of waste soil above screening levels would not be allowed anywhere on federal lands within the project area. The remaining potential storage locations are private properties owned by the Fort Mojave Indian Tribe (FMIT) and PG&E. Given the groundwater remedy facilities already planned to be located on the Topock Compressor Station (TCS) and the TCS's operational needs for the property for natural gas compressor operations, there is space on PG&E property only to temporarily store a small number of soil bins at a time while awaiting analysis prior to final disposition. There is no available space on PG&E property to store waste soil on a longer term basis. Nor have the FMIT identified any locations on the Tribe's property within the project area for this purpose. PG&E also contacted treatment storage and disposal facilities (TSDFs) and was told that the TSDFs would accept the waste soil for disposal, but not storage.

Given the above, PG&E determined that there was no available alternate location for the long-term storage of material with concentrations above the interim screening levels. Therefore, this protocol has been revised to exclude this provision.

---

[1] For the purpose of this protocol, imported fill is defined as unconsolidated mixtures of sand, silt, and gravel (engineered gradations, or otherwise) that were not originally derived from inside the defined project boundary. Specific examples of imported fill material may include road base material, shading material used in pipeline trenches, or crushed rock used for railroad ballast.

1.0 Introduction

PG&E carefully plans Topock Remediation Project activities to minimize both the disturbance and displacement of site material. The land and soils are to be handled and managed with care and respect. Therefore, the protocol established in this plan is intended to minimize the amount of displaced material that leaves the site and instead, provide for eventual return, reuse, or restoration of the material onto the lands from which it was displaced. Through the application of this protocol and its incorporation into future work plans involving material displacement, it is anticipated that the goal of careful and respectful handling of soil material will be fulfilled.

In addition to addressing Tribal requests, this protocol was developed to comply with Mitigation Measure CUL-1a-8 as set forth in the certified Environmental Impact Report (EIR) and Mitigation Monitoring and Reporting Plan (MMRP) adopted by the California Department of Toxic Substances Control (DTSC). This measure requires PG&E to develop a Cultural Impact Mitigation Program (CIMP) as part of the final design of the approved groundwater remedy, and specifically subparagraph (g) requires the CIMP to include protocols for handling soil cuttings[2]. DTSC adopted this measure following its determination that the project area is a significant historical resource for California Environmental Quality Act (CEQA) purposes (Final EIR, p. 4.4-57). Similarly, as part of the consultation process for the Programmatic Agreement (PA) under Section 106 of the National Historic Preservation Act (NHPA), ~~the U.S. Bureau of Land Management (~~BLM~~)~~ determined that a traditional cultural property (TCP) eligible for inclusion on the National Register of Historic Places exists within the Area of Potential Effect (APE). Throughout this document, the term "site" refers to the project area~~ within the APE~~.

[2] Mitigation Measure CUL-1a-8(g) states the following: Protocols for the repatriation of clean soil cuttings generated during construction activities and during drilling associated with repair/replacement activities during operations and maintenance phases. The soil cuttings shall be managed in compliance with applicable laws and regulations on site.

2.0 Statement from Fort Mojave Indian Tribe

The following statement was made by the Fort Mojave Indian Tribe regarding the site background and cultural significance:

> *The Topock site and adjacent lands are part of a larger geographical area referred to as a Traditional Cultural Landscape (TCL). The TCL is the ancestral home of the Fort Mojave Indian Tribe and other Native American Tribes including the Hualapai Nation, Colorado River Indian Tribes, Quechan Nation, Cocopah Tribe, and Yavapai-Prescott Nation. This entire TCL is of tribal religious significance. In some areas and at certain times, tribal members carry out various cultural activities and religious ceremonies.*
>
> *The very nature of the remedial activities being performed at the Topock Compressor Station involve disturbance to the TCL. Such activities as drilling, soil sampling, excavation, construction, monitoring, testing, vehicle movement, foot traffic, geophysical and other surveys, emplacement of markers, and discharge of water, solids, and other material disturb the sanctity of the land that is held in the hearts of Native Americans.*
>
> *In particular, the removal and disturbance of soils, both surficially and from the subsurface, is of concern to the Tribes because such actions are regarded as profound disruptions of the sacred landscape. While the nature and significance of this concern is not easily understood by non-Native Americans, perhaps the following excerpt, attributed to the Duwamish Chief Sealth, begins to aid in the understanding:*
>
>> *Every part of this country is sacred to my people. Every hillside, every valley, every plain and grove has been hallowed by some fond memory or some sad experience of my tribe. Even the rocks that seem to lie dumb as they swelter in the sun along the silent seashore in solemn grandeur thrill with memories of past events connected with the fate of my people, and the very dust under your feet responds more lovingly to our footsteps than to yours, because it is the ashes of our ancestors, and our bare feet are conscious of the sympathetic touch, for the soil is rich with the life of our kindred. (Chief Sealth, 1854)*
>
> *The Pacific Gas & Electric Company (PG&E), in its implementation of the remedial actions required by the United States Department of the Interior (DOI) and the California Department of Toxic Substances Control (DTSC) must commit to performing these actions in a manner that is respectful of Native American values.*

3.0 General Protocol for Management of Displaced Material (Mitigation Measure: CUL-1a-8[g])

This section presents each element of the protocol for the management of displaced material, including work planning, handling and short-term storage, contamination assessment, ~~long-term storage,~~ and final disposition. A graphical presentation of key elements of this process, and associated decision points, is presented on Figure 1 at the end of this document.

Commented [CM1]: Note – This figure has been revised (not in redline) to remove the long-term storage pathway. Other elements of the figure are unchanged.

3.1 Work Planning

PG&E is required to prepare a work plan whenever a field activity is performed at the Topock site in support of a regulatory requirement or action. Through the established federal regulatory review process, these work plans are made available for review by process stakeholders and by the governments of affected Native American Indian Tribes (referred to as “Tribes” throughout this document) via the consultation process set forth in the PA’s Consultation Protocol, consistent with Section 106 of the NHPA. In addition to the information describing the scope of work, field logistics and other implementation details, work plans that involve activities that displace site material also describe the process for the management and disposition of the materials. Work plans finalized subsequent to the development of this protocol will include specific description of the process for involving the input of Tribe(s) regarding the management of the material that will be displaced as a result of the work. Key procedural information to be included in the work plan will include, but not be limited to, the following:

- Summary of measures planned to minimize the amount of disturbance that will be incurred.
- Notification procedures to inform the Tribe(s), involved regulatory agencies, and affected land owner(s) regarding the proposed activities that will disturb/displace soil or other materials.
- The location of proposed disturbance activities (e.g. access pathways) and displacement activities (e.g. drilling or sampling locations), including maps.
- Estimation of the volume and type(s) of material that will be displaced.
- The location and methodology for short-term storage of displaced material (see Section 3.2).
- Methods that will be used to assess whether contaminants are present (see Section 3.3).
- Methods that will be used to minimize the volume of material that may be displaced during work including specific measures, such as field screening and material segregation strategies, to try and minimize the volume of material that requires disposal. ~~require long-term storage (see Section 3.4)~~.
- ~~The location and methodology for long-term storage (see Section 3.4).~~
- The anticipated location and methodology for final on- or off-site disposition (see Section 3.5).

3.2 Handling and Short-term Storage

Material that is displaced as a result of Topock Remediation Project activities including drilling, excavation, sample collection, testing, construction, grading, or other activities will be handled on-site in accordance with the project-specific work plan. Displaced material that must be characterized for key chemical properties prior to identifying the appropriate final disposition method will be stored for the short term. Short-term storage areas and the protocol for handing material in these areas may vary by project. Depending on the type and volume of material displaced, location, land owner considerations, and other pertinent factors, short-term storage methods may include storage devices (e.g. bins) or properly maintained stockpiles that prevent this material from commingling with other areas of the environment. In some cases, short-term storage for characterization may not be necessary. For example, displaced material that is pre-characterized or characterized rapidly as work is conducted will be managed directly for ~~long-term storage or~~ final disposition~~, as appropriate~~ (see Section~~s~~ ~~3.4 and~~ 3.~~5~~4~~, respectively~~).

Specific material handling and short-term storage details will be defined in the approved work plan for a given activity. Key details to be identified in the work plan include:

- The mode and location of short-term storage.
- The method of transfer from the point of origin to short-term staging area.
- Best management practices/regulatory requirements to prevent releases of the potentially contaminated material during transfer and storage.
- Best management practices to protect the material from weather, erosion, contamination, and vandalism while located in the short-term staging area(s).
- Method for segregation of soils based by location, as practicable and appropriate.

A key element of this handling protocol is the development of an inventory of all material displaced by Topock Remediation Project activities. Key information maintained in this inventory will include:

- Material displacement authorization – Specific work plan under which the work was conducted.
- Material origin – Specific location of the site.
- Material description (e.g., soil, rock, etc.).
- Date(s) of displacement or accumulation.

- Generating activity (e.g., drilling, excavation, etc.).
- Approximate volume of material stored.
- Short-term storage mode and location – Type of storage (including container identification number, as applicable) and location of short-term storage pending material characterization. In some cases, this information may need to be updated as containers are moved between areas of the site.
- Characterization status – Characterization sample information (e.g., date of submittal and laboratory used), date of receipt of results, and the contamination assessment based on comparison to screening criteria (see Section 3.3).
- ~~Long-term storage mode and location – Type of storage (including container identification number, as applicable) and location of long-term storage pending decision regarding final disposition (see Section 3.4). In some cases, this information may need to be updated as containers are moved between areas of the site.~~
- Final disposition information – Indication of the on-site or off-site final disposition action identified through discussion with Tribe(s), agencies, and the affected land owner(s), as appropriate, based on review of material type and the contamination assessment (see Section 3.~~5~~4).

Once the displaced material has been managed through final disposition, it will no longer be tracked in the displaced material inventory.

3.3 Contamination Assessment

Key chemical property information will be used to determine the final disposition method, and specifically, whether displaced material is suitable for retention on-site for eventual return, reuse, or replacement, or if the material must be removed from the site for disposal in accordance with applicable State and Federal laws and regulations. Key information that will be considered to assess whether the material is contaminated, and therefore, whether the material can remain on-site or not, includes:

- Existing information including knowledge of the history of an area, or laboratory analytical results collected during previous phases of work. Use of existing information may preclude the need for additional analytical testing. When available, this information will be included in the work plan.
- Results of characterization samples collected for laboratory analysis, and observation of the physical properties of the material (e.g., white powder, burned material, boulders, etc.), as defined in the approved work plan for a given activity.
- Screening values for various analytes identified for the purpose of determining the appropriate material disposition method. Tables 1 and 2 at the end of this document present a reference list of analytes and associated screening levels that may be applicable for making decisions related to disposition of displaced site materials. The specific analytes applicable for characterization of displaced material will be determined based on the origin of the material and potential disposition locations. Screening values included on Tables 1 and 2 are defined in the following bullets, which will be modified as screening levels are added to these tables:
  - **Interim Screening Levels (Table 1)** – This is predominantly the background value. However, if the background value is not available then the lesser of the DTSC residential California Human Health Screening Level (CHHSL) or the ecological comparison value is used. If a CHHSL is not available, it is the lesser of the United States Environmental Protection Agency (USEPA) residential regional screening level or the ecological comparison value. This value is the most conservative, and it is assumed that the project-specific cleanup goal and/or Tribal screening level will be equal to or greater than this value.

- **Hazardous Waste Toxicity Characteristic Levels (Table 2) –** These values are used to determine if the material should be classified as a State or Federal hazardous waste. Specifically, total constituent concentrations expressed in milligrams per kilogram (mg/kg) will be compared to the hazardous waste characteristic levels in Table 2, and will be evaluated as follows:

    1. If the total constituent concentration exceeds the total threshold limit concentration (TTLC), the soil represented by the sample will be classified as a non-RCRA California hazardous waste. Additional evaluation of the soluble threshold limit concentration (STLC), as described in step 3 below, will not be performed.
    2. If the total constituent concentration exceeds the numeric value of the RCRA toxicity characteristic (TC) level by about 20 times or more, the toxicity characteristic leaching procedure (TCLP) will be performed. If the constituent concentration in the TCLP leachate exceeds the TC level, the soil represented by the sample will be classified as a RCRA hazardous waste. Additional evaluation of the STLC, as described in step 3 below, will not be performed.
    3. If the sample has not been classified as hazardous waste in steps 1 or 2, the total constituent concentration will be compared to the STLC. If the total constituent concentration exceeds the numeric value of the STLC by about 10 times or more, the California Waste Extraction Test (WET) will be performed. If the constituent concentration in the WET exceeds the STLC, the soil represented by the sample will be classified as a non-RCRA California hazardous waste.
    4. If the sample has not been classified as a hazardous waste in steps 1, 2, or 3, or by other applicable hazardous waste standards, the soil represented by the sample will not be classified or managed as hazardous waste.

These values will be used to determine the final disposition of displaced material by comparing the representative concentration of a given volume of material to the screening values. The methodology for determining the representative concentration will be established in the project-specific work plan and should not be limited to a concentration-by-concentration comparison, but could include statistical estimates or averages based on multiple samples. Material that has a representative concentration that is equal to or below the interim screening level is suitable for return, reuse, or replacement on-site. Material that has a representative concentration that is greater than the interim screening level or is characterized as hazardous waste ~~must~~ will be disposed of off-site in accordance with applicable laws and regulations. ~~Material that has a representative concentration that is greater than the interim screening level, but not classified as a hazardous waste, will be stored on-site until the project-specific cleanup goals are established. Until these goals are established, material that falls into this intermediate category will be retained on-site for "long-term storage" (see Section 3.4).~~

The screening levels included in Tables 1 and 2 must be updated as applicable regulations and project-specific decisions are made. PG&E will review this information as remediation work plans are developed and implemented. As changes are determined appropriate, PG&E will submit revisions to the regulatory agencies and Tribe(s) for review and comment. Only agency approved values will be utilized.

Commented [CM2]: Note – Some of the screening levels on Table 1 have been updated (not in redline) as appropriate based on changes to the regulations since October 2012.

~~3.4 Long-Term Storage~~

~~Following contamination assessment, some material may be determined to be non-hazardous waste but unsuitable for final disposition on-site because contaminants are present above the interim screening level. Per DOI comment on this protocol (received in February 2012), this material cannot be returned to the land until project-specific cleanup goals are finalized in the Record of Decision (ROD) and may be stored until that time. Once these goals are established the contamination will be re-assessed based on existing data, or additional data as determined necessary, using the cleanup goals in place of the interim screening level to determine final disposition (see Section 3.5).~~

~~The long-term storage area(s) and the protocol for handling material in these areas may vary by project. Depending on the type and volume of material that must be stored, location, land owner considerations, and~~

~~other pertinent information, long-term storage methods may include storage devices (e.g. bins) or contained stockpiles that prevent this material from migrating away from the designated storage area(s). Coordination with agencies, Tribe(s), and affected land owners regarding the acceptable mode and location of long-term storage is critical in design of the work plan. Further, specific measures should be incorporated into the implementation of the given work plan, such as field screening and material segregation strategies, to try and minimize the volume of material that may require long-term storage.~~

3.~~5~~4 Final Disposition

Final disposition refers to the final action taken on behalf of the Topock Remediation Project as it relates to the management of material displaced during associated activities. This protocol has been designed with the purpose of minimizing the volume of material that is disposed of off-site. Material determined to have a representative concentration that is equal to or less than the interim screening level or project-specific cleanup goal (once established) will be retained on site for return, reuse, and/or restoration. Material determined to have a representative concentration that is greater than this value will be transported off site for disposal in accordance with applicable laws and regulations or treated on site if appropriate based on the selection of the final soil remedy. Material return, reuse, and/or restoration options associated with final disposition on site are discussed in Section 4.

4.0 Return, Reuse, and/or Restoration of Displaced Material

Final on-site disposition alternatives include the return, reuse, and/or restoration of the displaced material. The preferred disposition alternative(s) will be considered on a case-by-case basis with the regulatory agencies, Tribe(s), and affected land owner(s), as suitable material is identified. Material types may differ by physical or chemical properties, and therefore the preferred on-site disposition alternative may also vary. Alternatives that have been preliminarily identified include, but are not limited to:

- Replacement of material into original borings, trenches, or excavations, from which they were removed.
- Replacement of material into borings, trenches, or excavations other than those from which they were removed.
- Creation of topographical or landscape barriers to protect sensitive areas.
- Creation of berms or other structures (e.g., gabions) to prevent erosion.
- On-site road maintenance (this alternative may require sorting the material for different physical sizes).
- Stockpiling in designated areas.

The above list of final on-site disposition alternatives is preliminary, and should not be considered complete. Further, if material is found to contain concentrations of volatile organic compounds it may not be suitable for return, reuse, and/or restoration near buildings where vapor intrusion would be of concern. Coordination with agencies, Tribe(s), and affected land owners is critical in design of the work plan to identify the preferred on-site disposition alternative(s) and communication milestones, so the material can be efficiently managed.

Material displaced as part of past remediation project activities was managed in accordance with project-specific work plans. As a result, some material has been retained at the site because contaminant concentrations were below the Interim Screening Level~~ (previously displaced material that has exceeded these levels was disposed off-site in accordance with the work plans)~~. Therefore, previously displaced material is available for the return, reuse, and/or restoration alternatives included in the bullets above, or as additional uses are developed. As of June 2012, the estimated volume of material that has been retained and stockpiled through past remediation project activities is approximately 30 to 35 cubic yards.

	Vinyl chloride	59	EPA Residential RSL	See Table 2
	Xylenes, total	650,000	EPA Residential RSL	NE

Notes:

This table presents a reference list of analytes and associated screening levels that may be applicable for making decisions related to disposition of displaced site materials. The specific analytes and screening levels applicable for characterization of displaced material will be determined based on the origin of the material and potential disposition locations.

Interim screening level is background value. If background value is not available then the lesser of the DTSC HHRA Note 3 Residential Screening Levels (DTSC Residential SL) or the ecological comparison value is used. If a DTSC Residential SL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

Background	"Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California" (CH2M HIll 2009c)
DTSC-Residential SLs	Human Health Risk Assessment Note 3 – DTSC-Modified Screening Levels, May 2015.
EPA Residential RSL	United States Environmental Protection Agency Residential Soil Regional Screening Level (THQ=1.0), June 2015.
ECV	Ecological Comparison Values; ECV were calculated as needed for constituents detected during the Part A Phase I sampling (Arcadis 2008)
HHRA Note 2	DTSC Human Health Risk Assessment (HHRA) Note 2: Remedial Goals for Dioxins and Dioxin-like Compounds for Consideration at California Hazardous Waste Sites – Interim (May 2009).
SF RWQCB ESL	San Francisco Bay Regional Water Quality Control Board Environmental Screening Levels for residential direct exposure (2013)
*	One or more screening levels (EPA Residential RSL, DTSC-Residential SLs, ECV, or Soil SL) have values lower than the background level.

Notes:

NE	not established
mg/kg	milligrams per kilogram
mg/L	milligrams per liter
EPA HW	Environmental Protection Agency Hazardous Waste Code
TC	Toxicity Characteristic
TTLC	Total Threshold Limit Concentration
STLC	Soluble Threshold Limit Concentration
RCRA	Resource Conservation and Recovery Act
TCLP	Toxicity Characteristic Leaching Procedure
WET	California Waste Extraction Test

Hazardous waste critiera exist for kepone, 2,4-D, mirex, pyridine, and 2,45-TP (Silvex); however, since they are not contaminants of potential concern at the Topock site, they are excluded from this table.

a Total Threshold Limit Concentration (TTLC) from 22 CCR 66261.24(a)(2). Calculated based on the concentration of the elements, not the compounds.

b Screening level is 10x Soluble Threshold Limit Concentraction (STLC). If screening level is exceeded in total analysis, California Waste Extraction Test (WET) should be run to evaluate whether STLC is exceeded.

c Screening level is 20x RCRA Toxicity Characteristic (TC). If screening level is exceeded in total analysis, Toxicity Characteristic Leaching Procedure (TCLP) should be run to evaluate whether RCRA TC is exceeded.

d Soluble threshold limit concentration from 22 CCR 66261.24(a)(2), measured using the WET. Calculated based on the concentration of the elements, not the compounds.

e RCRA TC level from 22 CCR 66261.24(a)(1), measured using the TCLP.

f A waste is assigned a RCRA waste code for each constituent where the results of the TCLP equal or exceed the RCRA TC level.

g If o-, m- and p-Cresol concentrations cannot be differentiated, the total cresol (D026) concentration is used. The regulatory level of total cresol is 200 mg/L.

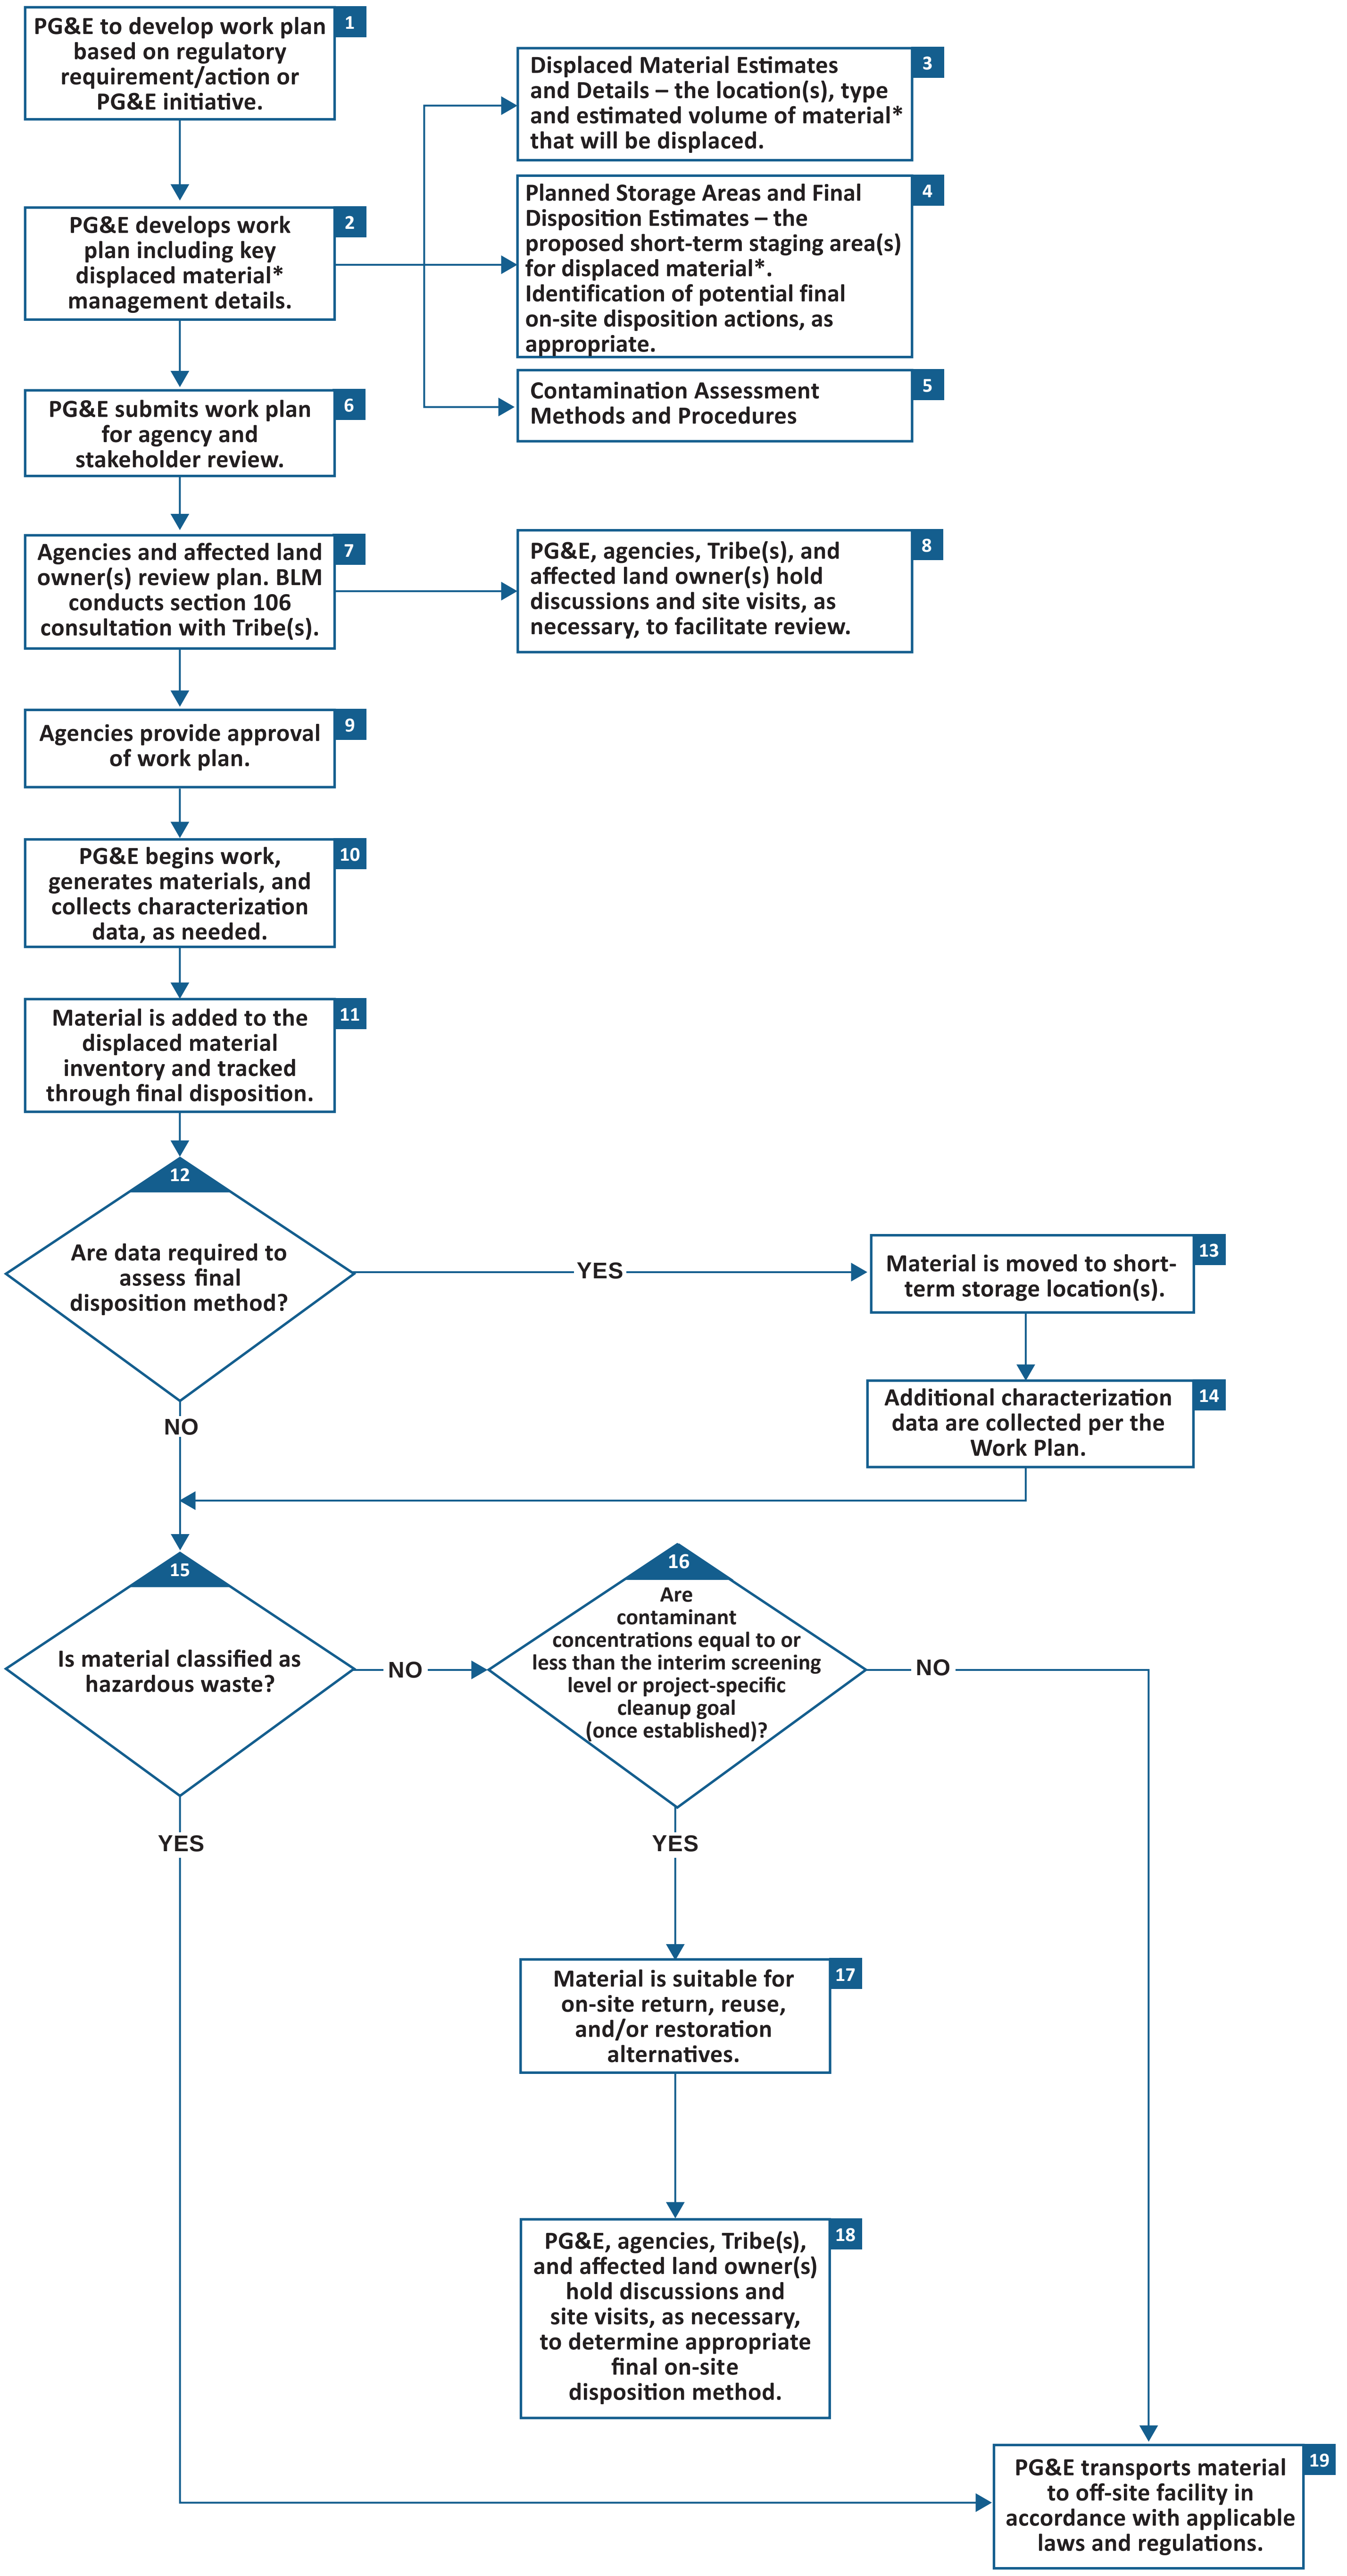
h This footnote letter skipped intentionally.

i In the case of asbestos and elemental metals, the specified concentration limits apply only if the substances are in a friable, powdered or finely divided state. Asbestos includes chrysotile, amosite, crocidolite, tremolite, anthophyllite, and actinolite.

j TTLC and STLC exclude barite. TTLC excludes barium sulfate.

k For STLC, if the waste does not exceed the RCRA TC or exhibit another RCRA hazardous characteristic, the STLC is 560 mg/L, not 5 mg/L.

l For TTLC, excludes molybdenum disulfide.



Notes:

* Throughout this figure the term "material" is defined as soil and rock that may be displaced (i.e., removed from the Earth) as a result of work activities including drilling, excavation, sample collection, testing, construction, grading, or other activities. This does not include materials that were not part of the natural site condition (e.g. building materials, equipment, or imported fill).

Throughout this figure, the term “site” refers to the area within the Area of Potential Effect (APE).

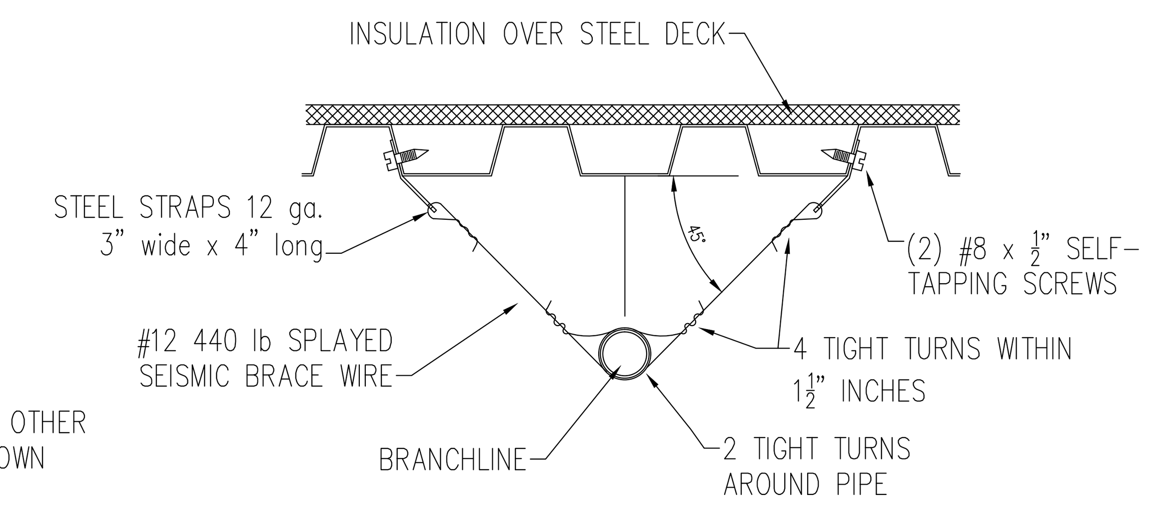
BRANCH LINE RESTRAINT

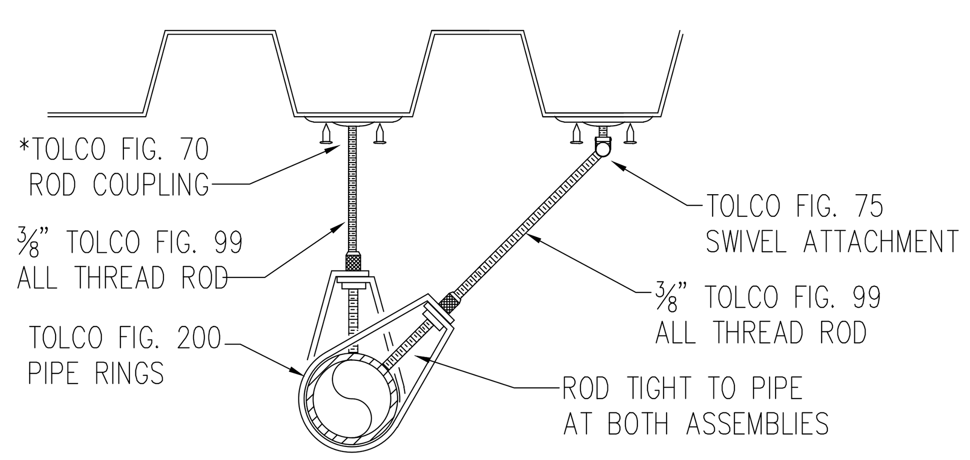
(FOR PIPE HUNG w/ ROD LONGER THAN 6")



BRANCH LINE RESTRAINT

(FOR PIPE HUNG w/ ROD LONGER THAN 6")

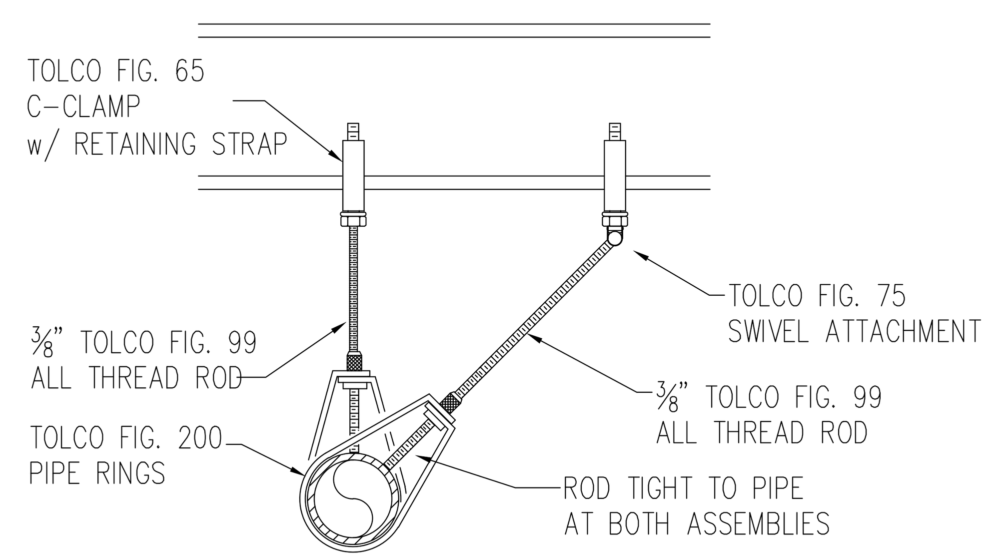
RESTRAINT TO BE INSTALLED WITHIN 24" OF HANGER PER NFPA 13. ROD TO BE RUN DOWN TIGHT TO PIPE PER NFPA 13.



TYPICAL BRANCH LINE RESTRAINT

(FOR PIPE HUNG w/ ROD LONGER THAN 6")

HANGER WITHIN 6" OF RESTRAINT WIRE PER NFPA 13 9.3.6.2. ROD TIGHT TO PIPE PER GENERAL NOTE #6 & NFPA 13 FIG. A.9.2.3.4.3(b)



TYPICAL BRANCH LINE RESTRAINT

(FOR PIPE HUNG w/ ROD LONGER THAN 6")

HANGER WITHIN 6" OF RESTRAINT WIRE PER NFPA 13 9.3.6.2. ROD TIGHT TO PIPE PER GENERAL NOTE #6 & NFPA 13 FIG. A.9.2.3.4.3(b)

BRANCH LINE RESTRAINT NOTES
(FOR PIPE HUNG W/ ROD LONGER THAN 6")

1. BRANCH LINE RESTRAINT SHALL BE PROVIDED BY THE USE OF ONE OF THE FOLLOWING (PER NFPA 13, 2013 ED., SECTION 9.3.6):
   - 1.1. LISTED SWAY BRACE ASSEMBLY (SEE SEISMIC BRACING DETAILS).
   - 1.2. WRAPAROUND U-HOOK SATISFYING THE REQUIREMENTS OF 9.3.5.5.11
   - 1.3. NO. 12, 440 LB WIRE INSTALLED AT LEAST 45° FROM THE VERTICAL PLANE AND ANCHORED ON BOTH SIDES OF THE PIPE. (WIRE RESTRAINT SHALL BE LOCATED WITHIN 24" OF A HANGER WHICH IS OF A TYPE THAT WILL PREVENT UPWARD MOVEMENT PER 9.3.6.2.
   - 1.4. CPVC HANGERS UTILIZING TWO POINTS OF ATTACHMENT.
   - 1.5. HANGER NOT LESS THAN 45° FROM VERTICAL INSTALLED WITHIN 6" OF THE VERTICAL HANGER ARRANGED FOR RESTRAINT AGAINST UPWARD MOVEMENT, PROVIDED IT IS UTILIZED SUCH THAT L/R DOES NOT EXCEED 400, WHERE THE ROD SHALL EXTEND TO THE PIPE OR HAVE A SURGE CLIP INSTALLED. MAX LENGTH OF ⅜" ROD @ L/R OF 400 = 30"
2. THE END SPRINKLER ON A LINE SHALL BE RESTRAINED. PER 9.3.6.3.
3. BRANCH LINES SHALL BE LATERALLY RESTRAINED AT INTERVALS NOT EXCEEDING THOSE SPECIFIED IN TABLE 9.3.6.4(A) BASED ON BRANCH LINE DIAMETER AND THE VALUE OF CP. (PER 9.3.5.9.3, CP = .35)
4. WHERE BRANCH LINES ARE SUPPORTED BY RODS LESS THAN 6" LONG MEASURED BETWEEN THE TOP OF THE PIPE AND THE POINT OF ATTACHMENT TO THE BUILDING STRUCTURE, THE REQUIREMENTS OF 9.3.6.1 THROUGH 9.3.6.4 SHALL NOT APPLY AND ADDITIONAL RESTRAINT SHALL NOT BE REQUIRED. (PER 9.3.6.5.)
5. SPRIGS 4 FT OR LONGER SHALL BE RESTRAINED AGAINST LATERAL MOVEMENT. (9.3.6.6)
6. DROPS AND ARMOVERS SHALL NOT REQUIRE RESTRAINT. (9.3.6.7)

Cp value per NFPA 13 – 2013 table 9.3.5.9.3

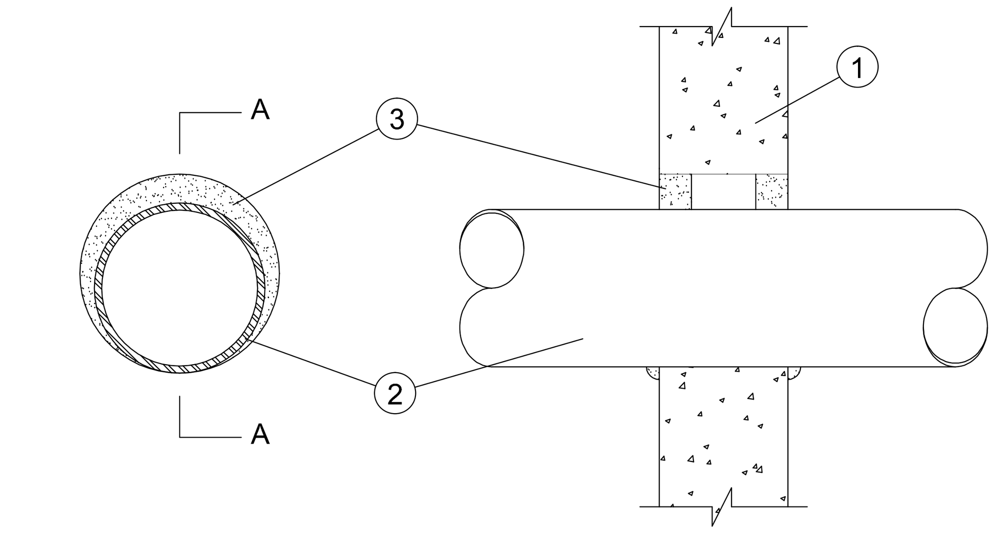
U.L. SYSTEM NO. WJ1067

METAL PIPE THROUGH A SLEEVE IN CONCRETE FLOOR,WALL,OR BLOCK WALL

F RATING = 1 & 2-HR.
T RATING = 0-HR.
L RATING AT AMBIENT = 0 LESS THAN 1 CFM/SQ. FT.
L RATING AT 400° = 4 CFM/SQ. FT.



SECTION A-A

1. WALL ASSEMBLY :
   A. MINIMUM 5" THICK LIGHTWEIGHT OR NORMAL WEIGHT CONCRETE WALL.
   B. U.L. CLASSIFIED CONCRETE BLOCK WALL (MINIMUM 8" BLOCK).
2. PENETRATING ITEM TO BE ONE OF THE FOLLOWING :
   A. MAXIMUM 30" DIAMETER SCHEDULE 10 OR HEAVIER STEEL PIPE.
   B. MAXIMUM 6" NOMINAL DIAMETER COPPER PIPE.
   C. MAXIMUM 6" NOMINAL DIAMETER STEEL CONDUIT.
   D. MAXIMUM 4" NOMINAL DIAMETER EMT.
3. HILTI FS-ONE HIGH PERFORMANCE INTUMESCENT FIRESTOP SEALANT: MIN. 5/8" THICKNESS APPLIED WITHIN ANNULUS, FLUSH WITH BOTH SURFACES OF WALL. AT THE POINT OR CONTINUOUS CONTACT LOCATIONS BETWEEN PIPE AND WALL, A MIN 1/2" DIA BEAD OF FILL MATERIAL SHALL BE APPLIED AT PIPE-WALL INTERFACE ON BOTH SURFACES.

NOTES : 1. MAXIMUM DIAMETER OF OPENING = 32-1/4".
2. "ANNULAR SPACE = MINIMUM 0", MAXIMUM 1-7/8".
3. PIPE TO BE CENTERED WITHIN THE FIRESTOP SYSTEM.

SEE HILTI FIRESTOP INSTALLATION MANUAL FOR ADDITIONAL INSTRUCTIONS
HILTI, INC. TULSA, OK 1-800-879-8000

* PIPES 4" AND LARGER SHALL BE PROVIDED WITH A FLEXIBLE COUPLING WITHIN 12" OF EACH SIDE OF PENETRATION.(NFPA 13)

PENETRATION DETAIL

(NOT TO SCALE)

EARTHQUAKE BRACING NOTES

1. EARTHQUAKE BRACING SHALL BE PROVIDED PER NFPA 13, 2013 ed., SECTION 9.3.5.
2. LOADS ARE DETERMINED BY ANALYSIS PER 9.3.5.5.3 (SEE ANNEX E & CALCULATIONS).
3. LONGITUDINAL BRACES SHALL BE ALLOWED TO ACT AS LATERAL BRACES WHERE THEY ARE INSTALLED WITHIN 24" OF PIPING WHICH IS BRACED LATERALLY AND VICE VERSA PER 9.3.5.6.27 & 9.3.5.5.8.
4. EACH RUN OF PIPE BETWEEN A CHANGE IN DIRECTION SHALL BE PROVIDED WITH BOTH LATERAL AND LONGITUDINAL BRACING. EXCEPTION: PIPE RUNS LESS THAN 12 ft. PER 9.3.5.7.2.
5. WHERE THERE IS A CHANGE IN DIRECTION, THE CUMULATIVE DISTANCE BETWEEN LATERAL SWAY BRACES SHALL NOT EXCEED THE MAXIMUM PERMITTED DISTANCE IN ACCORDANCE WITH 9.3.5.5.2.2 (40 FT).

GENERAL NOTES

1. THE AUTOMATIC SPRINKLER SYSTEM SHALL CONFORM TO THE REQUIREMENTS OF THE 2013 EDITION OF NFPA 13.
2. PENETRATIONS OF RATED ASSEMBLIES SHALL BE FIRE STOPPED. (SEE DETAIL)
3. ALL ELECTRICAL WIRING TO BE PERFORMED BY OTHERS.
4. ARMOVERS LONGER THAN 24" SHALL BE PROVIDED WITH A HANGER.
5. THE NEW SYSTEM IS HYDRAULICALLY CALCULATED. (SEE PIPING PLAN)
6. NEW PIPING SHALL BE SUPPLIED FROM NEW UNDERGROUND.
7. UPON COMPLETION, THE OVERHEAD SYSTEM SHALL BE TESTED AT 200 PSI FOR TWO (2) HOURS. (BEFORE TIE-IN)
8. BUILDING CONSTRUCTION IS OF NON-COMBUSTIBLE CONSTRUCTION.
9. OWNER:
10. FOR INSPECTION CALL:
11. EXCLUSIONS (WORK BY OTHERS):
    1. Installation of Systems.
    2. Wiring of Fire Alarm Systems.
    3. All Underground Fire Line and Hydrant Design (By Civil).
    4. Structural Calculations.
    5. Plan Review, Permit and Water Dept. Flow Fees

HANGER NOTES

1. ALL HANGER ASSEMBLIES ARE PER NFPA 13 & MANUFACTURER DETAILS.

2. PER CBC AND NFPA 13 THE BUILDING STRUCTURE MUST BE CAPABLE OF SUPPORTING THE ADD LOAD OF THE WATER FILLED PIPE PLUS A MINIMUM OF 250 LBS.

3. HANGER SPACING SHALL BE PER NFPA 13 TABLE 9.2.2.1(A).

9.2.4 LOCATION OF HANGERS ON MAINS

9.2.4.1 UNLESS THE REQUIREMENTS OF 9.2.4.2, 9.2.4.3, 9.2.4.4, 9.2.4.5 OR 9.2.4.6 ARE MET, HANGERS FOR MAINS SHALL BE IN ACCORDANCE WITH 9.2.2, BETWEEN EACH BRANCH LINE OR ON EACH SECTION OF PIPE, WHICHEVER IS THE LESSER DIMENSION.

9.2.4.2: FOR WELDED OR MECHANICAL OUTLETS ON A CONTINUOUS SECTION OF PIPE, HANGER SPACING SHALL BE ACCORDING TO TABLE 9.2.2.1(A).

9.2.4.3: FOR CROSS MAINS IN STEEL PIPE SYSTEMS IN BAYS HAVING TWO BRANCH LINES, THE INTERMEDIATE HANGER SHALL BE PERMITTED TO BE OMITTED PROVIDED THAT A HANGER ATTACHED TO A PURLIN IS INSTALLED ON EACH BRANCH LINE LOCATED AS NEAR TO THE CROSS MAIN AS THE LOCATION OF THE PURLIN PERMITS. REMAINING BRANCH LINE HANGERS SHALL BE INSTALLED IN ACCORDANCE WITH 9.2.3.

9.2.4.7: A SINGLE SECTION OF PIPE SHALL NOT REQUIRE A HANGER WHEN THE CUMULATIVE DISTANCE BETWEEN HANGERS ON THE MAIN DOES NOT EXCEED THE SPACING REQUIRED BY TABLE 9.2.2.1(A).

HANGER SPACING TABLE PER NFPA Table 9.2.2.1(a)

Assessment of Biological Resources for the Proposed Sewer and Fire Water Lines for the Construction Headquarters: Final Groundwater Remedy,Topock Compressor Station, California

PREPARED FOR:	Virginia Strohl/PG&E
PREPARED BY:	Russell Huddleston/CH2M HILL
COPIES:	Curt Russell /PG&E Marjorie Eisert/CH2M HILL
DATE:	August 3, 2015

Introduction

This technical memorandum provides a general assessment of biological resources that could be affected by the proposed sewer and fire water lines that may be installed in the future and are associated with the construction headquarters (CHQ) facilities that would be located to the west of Park Moabi, south of the National Trails Highway.

The CHQ and associated infrastructure would be located entirely on federal lands managed by the Bureau of Land Management that are currently leased to San Bernardino County. Therefore, no additional impacts would occur to the Havasu National Wildlife Refuge lands.

Site Description

The CHQ will be located in an area that was recently (early 2013) cleared and graded for a paint ball game sponsored by Park Moabi. Initially, connections from the CHQ to the County sewer line and fire water services will not be constructed. However, sewer and fire water pipelines may be added in the future should connections to the County facilities become available. There are currently two alternatives being considered for the potential sewer and fire water pipeline alignment. For alternative 1, the sewer and fire water pipeline would extend to the west-southwest for approximately 250 feet, in roughly the same alignment as the potable water and power distribution lines. The pipelines would then turn to the northwest and continue approximately 250 feet to the north side of the National Trails Highway. Under this alternative, the alignment would cross a wash within the existing dirt roadway (that would be improved as part of the CHQ). From the north side of the road, the alignment would then continue approximately 1,750 feet along the north shoulder of the National Trails Highway where it would tie into existing pipelines in the developed part of Park Moabi (Figure 1).Under alternative 2, sewer and fire water pipelines would extend approximately 250 feet northwest from the CHQ, crossing a wash feature and continue to the north side of the National Trails Highway. The alignment would then make a 90 degree turn to the northeast and continue approximately 1,400 feet along the north shoulder of the National Trails Highway where it would tie into existing pipelines in the developed part of Park Moabi (Figure 1).

The following sections discuss potential biological issues associated with the proposed potential alignments for the sewer and fire water pipeline alternatives.

Wildlife

Both alternatives are largely located in disturbed areas that provide low quality habitat for wildlife species. No desert tortoise or sign (e.g., burrows, scat, remains) has been found in this area. A number of special-status bird species including bank swallow (*Riparia riparia*), Bell's vireo (*Vireo belli*), southwest willow flycatcher (*Empidonax traillii extimus*), yellow-billed cuckoo (*Coccyzus americanus*), and Yuma clapper rail
