ATTACHMENT C6

Area of Concern 12 Data Gaps Evaluation Results

1.0 Introduction and Background

This attachment presents the results of the Data Gaps Evaluation for Area of Concern (AOC) 12 – Fill Areas at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the data gaps evaluation is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report.

1.1 Background

AOC 12 consists of three subareas located near the Transwestern gas pipeline meter station (Transwestern Meter Station) east of the compressor station, as shown in Figure C6-1. These three subareas (identified as AOC 12a, AOC 12b, and AOC 12c) were identified through employee interviews as locations that may contain buried debris. AOC 12a was reportedly a disposal area for construction-related debris. A few small pieces of concrete are visible at the surface in the area identified as AOC 12a. The exact nature of the materials placed into this area and the date(s) of placement are unknown. Initially, AOC 12a was the only disposal area identified in AOC 12 (CH2M HILL, 2006).

Two potential disposal locations were subsequently identified from interviews with former employees, as described in the Soil Part A Phase 1 Work Plan (CH2M HILL, 2006). There is no visible debris at these two sites. These two locations are adjacent to the northwestern corner (AOC 12b) and southwestern corner (AOC 12c) of the Transwestern Meter Station. Location 12b reportedly was used to bury asbestos-containing material and two drums of unused unknown chemicals. Location 12c was apparently a small ravine (about 6 feet deep) that was reportedly used to bury asbestos-containing material and possibly other debris. AOC 12a and 12b are located on property owned by Havasu National Wildlife Refuge, and AOC 12c is located on both Havasu National Wildlife Refuge and PG&E property.

1.2 Site Conceptual Model

The depths of buried materials, if any, in AOCs 12a, 12b, and 12c, are not known. Chemicals of potential concern/chemicals of ecological potential concern (COPC/COPECs) may be present in fill material and buried waste and may have affected subsurface soil underneath the debris and laterally in the immediate vicinity of the debris. Subsurface soil would therefore be the primary source medium. Potential migration from subsurface soil to groundwater was identified as a potential secondary pathway, as shown in Table C6-1.

Because debris reportedly was buried at AOC 12a, 12b, and 12c, a geophysical survey was conducted over those areas. Part A Phase 1 trenches were excavated, and soil samples were collected in the areas that former PG&E employees indicated debris had been buried.

1.2.1 AOC 12 Data

Historical sampling has not occurred at AOC 12.

During the 2008 Part A Phase 1 Soil Investigation, five trenches were excavated to assess the AOC12a, AOC12b, and AOC12c, as shown in Figure C6-1. Prior to trenching activities, a geophysical survey was performed at each AOC 12 subarea to attempt to locate buried debris. The results of the surveys found two linear features crossing AOC 12a, a natural gas pipeline approximately 3 to 4 feet in diameter, and an anode flux wire associated with the pipeline, buried between the upper 1 foot below ground surface (bgs) and 3 to 4 feet bgs. In AOC 12a and AOC 12b, results indicated two undifferentiated utilities extending east from aboveground storage tank bunker pipe stub-outs. During the trenching activities, debris was observed in only one trench, AOC12c-T1. Debris consisted of a large piece of concrete (at approximately 1.5 feet bgs), a small piece of wire (at approximately 5 feet bgs), an 18-inch wooden slat, plastic debris, and a bung cover from a polyethylene drum. Additional information about the trenching activities is presented in Appendix B of the Data Gaps Evaluation Report.

Seventeen soil samples[1] (ranging from 0 to 11 feet bgs) were collected from 11 sample locations (AOC12a-T1a, AOC12a-T1c, AOC12a-T2a, AOC12a-T2b, AOC12b-T1a, AOC12b-T1b, AOC12c-T1a through AOC12c-T1c, AOC12c-T2a, and AOC12c-T2b), as shown in Figure C6-1. Part A Phase 1 soil samples collected in AOC 12 were analyzed for Title 22 metals, hexavalent chromium, volatile organic compounds (VOCs), semivolatile organic compounds, polycyclic aromatic hydrocarbons (PAHs), total petroleum hydrocarbons (TPH), pH, asbestos, pesticides, and polychlorinated biphenyls (PCBs). Ten percent of the Phase 1 soil samples collected in AOC12 were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL). Surface soil samples were not analyzed for VOCs. Soil results were validated, and the data quality evaluation is included in Appendix D of the Data Gaps Evaluation Report.

All Part A Phase 1 data are Category 1 and were used as inputs to the four data quality objective decisions.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of COPCs and COPECs at AOC 12. Laboratory analytical results for Part A Phase 1 soil samples at AOC 12 are presented in Tables C6-2 through C6-8. Table C6-9 presents a statistical summary of soil analytical results for COPCs and COPECs that were either (1) detected above the laboratory reporting limits or (2) not detected but where the reporting limits for one or more samples was greater than the interim screening value.

2.1 Summary of AOC12 Soil Data

Antimony, beryllium, cadmium, hexavalent chromium, mercury, silver, thallium, cyanide, TPH-gasoline, TPH-diesel, pesticides, VOCs, most PCBs, and most semivolatile organic

---

[1] Not including quality control samples.

compounds were not detected in soil samples collected in AOC 12. Table C6-9 lists the 36 constituents that were detected at AOC 12, including four calculated quantities (benzo(a)pyrene equivalents, total low molecular weight PAHs, total high molecular weight PAHs, and total PCBs). Ten of these constituents (aluminum, calcium, di-n-butyl phthalate, iron, magnesium, manganese, potassium, sodium, Aroclor-1254, and total PCBs) were detected in the TAL/TCL samples.

Twenty-nine of the constituents detected at AOC 12 (arsenic, barium, total chromium, lead, molybdenum, nickel, vanadium, aluminum, calcium, iron, magnesium, manganese, potassium, sodium, benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, pyrene, total low molecular weight PAHs, total high molecular weight PAHs, Aroclor-1254, total PCBs, and TPH-motor-oil) were detected at concentrations below their respective interim screening levels. Six constituents (cobalt, copper, selenium, zinc, benzo(a)pyrene, and benzo(a)pyrene equivalents) were each detected one time at a concentration exceeding their interim screening levels.

2.2 Nature and Extent Evaluation

The following subsection discusses the nature and extent of detected COPCs and COPECs detected above interim screening levels at AOC 12. As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Section 2.5 of this attachment summarizes the constituents that may require further evaluation, and Section 5.0 of this attachment provides the recommended follow-up sampling for the Part A Phase 2 soil investigation.

2.2.1 Cobalt

Cobalt was detected in 17 of 17 soil samples collected from AOC 12. One detected concentration of cobalt (14 milligrams per kilogram [mg/kg] at AOC12b-T1a at 2 to 3 feet bgs) slightly exceeded the interim screening level of 12.7 mg/kg (background threshold value [BTV]) and the ecological comparison value (ECV) (13 mg/kg) once, as shown in Tables C6-2 and C6-9. This detected concentration did not exceed United States Environmental Protection Agency residential and commercial/industrial regional screening levels (RSLs) (23 mg/kg and 300 mg/kg, respectively). The cobalt concentration a sample collected approximately 35 feet to the northeast within this same trench did not exceed the screening levels. No samples were collected to the west, south, or east at this trench location. No deeper samples were collected at this location.

2.2.2 Copper

Copper was detected in 16 of 17 soil samples collected from AOC 12. One detected concentration of copper (18 mg/kg at AOC12b-T1a at 2 to 3 feet bgs) slightly exceeded the interim screening level (16.8 mg/kg) (BTV) once, as shown in Tables C6-2 and C6-9, but did not exceed the ECV (20.6 mg/kg) or residential and commercial/industrial California human health screening level (CHHSLs) (3,000 mg/kg and 38,000 mg/kg, respectively). The copper concentration in a sample collected approximately 35 feet to the northeast within this trench did not exceed the screening levels. No samples were collected to the west, south, or east at this trench location. No deeper samples were collected at this location.

2.2.3 Selenium

Selenium was detected in one of 17 soil samples collected from AOC 12. The detected concentration of selenium (2.5 mg/kg at AOC12b-T1b at 2 to 3 feet bgs) slightly exceeded the interim screening level (1.47 mg/kg) (BTV/ECV), as shown in Tables C62 and C6-9, but did not exceed the residential or commercial/industrial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). Selenium was not detected in a sample collected approximately 35 feet to the southwest within this trench. No samples were collected to the west, north, or east at this trench location. No deeper samples were collected at this location.

2.2.4 Zinc

Zinc was detected in 17 of 17 soil samples collected from AOC 12. One detected concentration of zinc (77 mg/kg at AOC12c-T1a at 0 to 0.5 foot bgs) slightly exceeded the interim screening level (58 mg/kg) (BTV/ECV), as shown in Tables C6-2 and C6-9, but did not exceed the residential and commercial/industrial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively). The zinc concentration in a sample collected approximately 15 feet to the north within this trench and in two other samples in an adjacent trench to the northeast and east did not exceed the interim screening level. No samples were collected to the west or south at this trench location. Concentrations of zinc in deeper samples at this location did not exceed screening levels.

2.2.5 Benzo(a)pyrene, Benzo(a)pyrene Equivalents, and PAHs

Benzo(a)pyrene was detected in three of 17 soil samples collected from AOC 12. One detected concentration of benzo(a)pyrene (39 micrograms per kilogram [µg/kg] at AOC12c-T1b at 3 to 4 feet bgs) slightly exceeded the interim screening level (38 µg/kg) (residential CHHSL). Several other PAHs were detected in soil samples collected from AOC 12 but had concentrations below their respective interim screening levels. To assist with evaluation of PAHs for human health, benzo(a)pyrene equivalents were calculated for each of the soil samples collected at AOC 12, as shown in Table C6-4. One benzo(a)pyrene equivalent value (58 µg/kg at AOC12c-T1b at 3 to 4 feet bgs) exceeded the interim screening level (38 µg/kg) (residential CHHSL), as shown in Table C6-4. The exceedences in this one sample are bounded by other samples collected approximately 20 feet to the north and 15 feet to the south within this trench and two other samples in an adjacent trench to the east and southeast. No samples bound this exceedence to the west. This exceedence is vertically bounded by a sample collected at 10 to 11 feet bgs.

2.2.6 Target Analyte List/Target Compound List Constituents

As described above, aluminum, calcium, iron, magnesium, manganese, potassium, sodium, di-N-butyl phthalate, Aroclor-1254, and total PCBs were detected in the AOC 12 soil samples analyzed for the complete TAL/TCL suite of compounds. These constituents are discussed below.

Aluminum was detected in two of two surface soil samples collected from AOC 12. Both detected concentrations of aluminum (4,500 mg/kg at AOC12a-T1a and12,000 mg/kg at AOC12c-T1a) are below the interim screening level (16,400 mg/kg) (BTV), as shown in Tables C6-3 and C6-9. Neither of the detected concentrations exceeded the residential or commercial/industrial RSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in two of two surface soil samples collected from AOC 12. Both detected concentrations of calcium (10,000J mg/kg at AOC12a-T1a and 31,000 mg/kg at AOC12c-T1a) are below the interim screening level (66,500mg/kg) (BTV), as shown in Tables C6-3 and C6-9. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium.

Iron was detected in was detected in two of two surface soil samples collected from AOC 12. Both detected concentrations of iron (9,900J mg/kg at AOC12a-T1a and 23,000 mg/kg at AOC12c-T1a) are below the interim screening level (55,000 mg/kg) (residential regional screening level [RSL]), as shown in Tables C6-3 and C6-9. A BTV and an ECV have not been established for iron.

Magnesium was detected in two of two surface soil samples collected from AOC 12. Both detected concentrations of magnesium (AOC12a-T1a [3,000 mg/kg] and AOC12c-T1a [8,300 mg/kg]) are below the interim screening level (12,100 mg/kg) (BTV), as shown in Tables C6-3 and C6-9. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium.

Manganese was detected in two of two surface soil samples collected from AOC 12. Both detected concentrations of manganese (130 mg/kg at AOC12a-T1a and290 mg/kg at AOC12c-T1a) are below the interim screening level (402 mg/kg) (BTV/ECV), as shown in Tables C6-3 and C6-9. Neither of the detected concentrations exceeded the residential or commercial/industrial RSLs (1,800 mg/kg and 23,000 mg/kg, respectively).

Potassium was detected in two of two surface soil samples collected from AOC 12. Both detected concentrations of potassium (1,300 mg/kg at AOC12a-T1a and 2,700 mg/kg at AOC12c-T1a) are below the interim screening level (4,400 mg/kg) (BTV), as shown in Tables C6-3 and C6-9. Residential and commercial CHHSLs and an ECV have not been established for potassium.

Sodium was detected in two of two surface soil samples collected from AOC 12. Both detected concentrations of sodium (210 mg/kg at AOC12a-T1a and340 mg/kg at AOC12c-T1a) are below the interim screening level of 2,070 mg/kg (BTV), as shown in Tables C6-3 and C6-9. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for sodium.

Di-n-butyl phthalate was detected in one of 17 soil samples collected from AOC 12. One detected concentration (1,100 µg/kg at AOC12c-T1c at 10 to 11 feet bgs) exceeded the interim screening level (46.9 µg/kg) (ECV), as shown in Tables C6-5 and C6-9, but did not exceed the residential and industrial RSLs (6,100,000 µg/kg and 62,000,000 µg/kg, respectively). This exceedence is bounded by another sample collected approximately 20 feet to the south within this trench and two other samples in an adjacent trench to the southeast. No samples bound this exceedence to the west, north, or east. No vertical samples bound this exceedance below 10 to 11 feet bgs.

The PCB Aroclor-1254 was detected in one of three soil samples collected from AOC 12. The maximum detected concentration (31 µg/kg at AOC12a-T1 at 0 to 0.5 foot bgs) did not exceed the interim screening level of 220 µg/kg (residential RSL), as shown in Table C6-6. PCBs were not detected above laboratory reporting limits in the sample collected at 2 to 3 feet bgs at location AOC12a-T1. To assist with evaluation of PCBs for ecological risk, total PCB values were calculated at AOC 12. The sample containing Aroclor-1254 also was below the total PCB screening value (ECV) of 204 µg/kg.

As discussed in Section C.2 of Appendix C, PG&E recommends that aluminum, calcium, iron, magnesium, manganese, potassium, sodium, di-N-butyl phthalate, Aroclor-1254, and total PCBs not be considered a COPC/COPEC for this AOC, and no further sampling for these constituents is recommended. This constituent has been fully discussed in Section C.2 of Appendix C.

2.3 Central Tendency Comparison to Background Threshold Values

Four metals (cobalt, copper, selenium, and zinc) were detected above their respective background values in soil samples collected from AOC 12. A central tendency comparison was performed for three of these four metals (cobalt, copper, and zinc) to compare the AOC 12 soil data set for these metals with the corresponding Topock soil background data set to determine whether a difference exists between the two populations and if additional sampling is required for a given metal, as discussed in Table C6-10 of this attachment and in Figure 3-1 of the Data Gaps Evaluation Report.

Metals in either the AOC 12 data set or background data set that were detected infrequently (less than five detects) or had a limited number of results (less than eight) were not tested. There were insufficient detections of selenium at AOC 12 to conduct the central tendency comparison.

No statistical difference between the two populations was noted for cobalt and copper, as shown in Table C6-10. However, the results identified a statistically significant difference in the populations for zinc. Zinc was only detected above the BTV of 58 mg/kg once at a concentration of 77 mg/kg in a soil sample collected at 2 to 3 feet bgs. After careful review of AOC 12 site data and background data set for zinc, the statistical difference between the two populations is not considered significant enough to warrant additional sampling for zinc at AOC 12.

2.4 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, a qualitative review indicates that decision error has been held to an acceptable level. Sufficient data of acceptable quality have been attained through collection of Part A soil samples in areas most likely to have been impacted by buried debris. The sample locations were collected in the areas that former PG&E employees indicated debris had been buried.

Based on the review of the data for AOC 12, the nature and extent of all detected COPCs and COPECs have been defined. No additional sampling is recommended in Part A Phase 2 soil investigation.

3.0 Decision 2 – Data Sufficient to Estimate Representative Exposure Point Concentrations

For Decision 2, data were evaluated to determine if the AOC 12 data are sufficient to conduct human health and ecological risk assessments based on the criteria described in Section 4.0 of the Data Gaps Evaluation Report. The principal consideration for Decision 2 was whether there were sufficient data to estimate a representative exposure point concentration (EPC). Data reviewed were all from Phase 1; no historical sampling was conducted at this AOC.

Table C6-11 summarizes the results of the evaluation to determine whether data are sufficient to estimate a representative EPC. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value. In general, existing data are adequate to support EPC development for detected chemicals that exceeded one or more comparison values (three metals and PAHs), as described below.

3.1 Metals

Sufficient data (numbers of samples and detections) are available to calculate EPCs using ProUCL for cobalt and zinc in three of four exposure intervals. The 0-to-0.5-foot-bgs interval data are adequate to support the risk assessment for cobalt and zinc because the maximum detected concentrations are less than two times the applicable interim screening value (the ECV for cobalt or BTV for zinc). For selenium, additional data collection is not expected to significantly change the results of the risk assessment because the compound is very infrequently detected (i.e., additional non-detects would be expected) and, consequently, additional data are not expected to strongly influence the EPC.

3.2 Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene equivalents using ProUCL.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

The following preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, are needed to resolve Decision 3. Additional evaluation will be performed as appropriate, as data are collected to resolve Decision 1. Data collected to satisfy Decision 1 – Nature and Extent evaluation will provide the final representative data set that will be used to assess the threat to groundwater.

The analysis of AOC 12 was divided into three separate analyses based on the AOC 12 subareas shown in Figure C-1 in Appendix C.

4.1 AOC 12a

There were no concentrations of metals that exceeded the BTVs at AOC 12a; therefore, comparison to the soil screening levels (SSLs) was not required for AOC 12a, and a current or potential threat to groundwater from this subarea was ruled out.

4.2 AOC 12b

Table C6-12 presents the results of the tiered analysis for AOC 12b. Three metals (cobalt, copper, and selenium) were detected at concentrations above the BTVs. None of these three metals exceeded the calculated SSLs, as shown in Table C6-13. Therefore, numerical modeling was not required for AOC 12b, and a current or potential threat to groundwater from this subarea was ruled out.

4.3 AOC 12c

Table C6-12 presents the results of the tiered analysis for AOC 12c. Only zinc was detected at a concentration above the BTV. However, zinc was not detected at concentrations that exceeded the calculated SSLs, as shown in Table C6-14. Consequently, numerical modeling was not required for AOC 12c, and a current or potential threat to groundwater from this subarea was ruled out.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Gaps Evaluation Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study (CMS/FS). The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fence line include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite)
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil washing technologies).
- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies)
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- If present, volumes of white powder and debris.

The following is a summary of data for AOC 12 that are currently available to support CMS/FS:

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. The lateral and vertical extent of the COPCs and COPECs is discussed in Section 2.2 of this attachment. Data results for selected constituents are shown in Tables C6-2 through C6-8, and data gaps associated with lateral and vertical delineation are discussed in Section 6.0 of this attachment.

5.2 Waste Characterization Parameters

Only partial waste characterization data are available to characterize the soil and other materials to be potentially removed for remedial action and disposed of in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations (TTLCs). The maximum concentrations of these metals for each of the units were compared to the TTLCs, and none of the metal concentrations exceeded the TTLCs, as shown in Table C6-15. The maximum detected concentrations were also compared to the soluble threshold limit concentrations (STLCs), and none of the concentrations in AOC 12 exceeded 10 times the STLC, as shown in Table C6-15. In addition, none of the metals concentrations exceeded 20 times the toxicity characteristic leaching procedure (TCLP), as shown in Table C6-15. Because none of the metals concentrations have the potential to exceed STLC or TCLP thresholds, additional leachability testing is not required if soil excavation and offsite disposal is chosen as a remedy.

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 soil investigation was limited to grain size analysis only. Specific soil physical properties data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 in the Data Gaps Report. Additional soil physical parameter data are needed to support the CMS/FS.

5.4 Surface and Subsurface Features

While there is extensive information regarding surface and subsurface features at AOC 12, additional information may be required once areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are known for AOC 12. However, subsurface utilities, including gas transmission pipelines and any culverts or other features, may have to be more precisely defined to evaluate the feasibility and cost of certain remedial alternatives and to prepare construction specifications.

6.0 Summary of Data Gaps and Potential Phase 2 Soil Sample Locations to Fill Identified Gaps

Based on the review of the data for AOC 12, the nature and extent of all detected COPCs and COPECs has been defined, and sufficient data are available to address Decisions 2 and

3. No additional sampling is recommended in Phase 2. Data regarding soil physical properties will be collected at units where additional samples are required to address data gaps for Decisions 1, 2, and/or 3. The remaining data required to address Decision 4 data gaps will be collected following the completion of the risk assessment. No additional sampling is recommended in the Part A Phase 2 soil investigation.

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

TABLE C6-11
Decision 2 Data Gaps Summary AOC 12
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

	Adequate EPC?		**Maximum Detected Value**	**> HHCV or Background as Applicable? [1]**	**> ECV or Background as Applicable? [1]**	**Proposed Sample ID**	**Notes**
Compound/Depth	**Y or N**	**Det/# results**		**Y or N**	**Y or N**		
Metals							
Cobalt				**23 mg/kg**	**13 mg/kg**		
0-0.5 ft bgs	N	2 of 2	8.4 mg/kg	N	N	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	7 of 7	14 mg/kg	N	Y		
0-6 ft bgs	Y	8 of 8	14 mg/kg	N	Y		
0-10 ft bgs	Y	14 of 14	14 mg/kg	N	NA		
Selenium				**380 mg/kg**	**1.47 mg/kg (bckg)**		
0-0.5 ft bgs	NA	0 of 2	NA mg/kg	N	N	None	Compound exceeds ECV. Although there are insufficient detections to allow calculation of a 95% UCL on the mean, additional data collection is not expected to yield sufficient detections to strongly influence the EPC as additional sampling would likely result in additional non-detect values.
0-3 ft bgs	N	1 of 7	2.5 mg/kg	N	Y		
0-6 ft bgs	N	1 of 8	2.5 mg/kg	N	Y		
0-10 ft bgs	N	1 of 14	2.5 mg/kg	N	NA		
Zinc				**23000 mg/kg**	**58 mg/kg (bckg)**		
0-0.5 ft bgs	N	2 of 2	77 mg/kg	N	Y	None	Compound exceeds ECV and may exceed background. Existing data adequate to calculate 95% UCL for all exposure intervals except 0 - 0.5 ft bgs. While this is insufficient to calculate an EPC using ProUCL for this exposure interval, the maximum concentration is low (i.e., does not exceed two times the lowest comparison value). Therefore, using the maximum result as the EPC is not expected to significantly impact the results of the risk assessment
0-3 ft bgs	Y	7 of 7	77 mg/kg	N	Y		
0-6 ft bgs	Y	8 of 8	77 mg/kg	N	Y		
0-10 ft bgs	Y	14 of 14	77 mg/kg	N	NA		
Polycyclic Aromatic Hydrocarbons							
PAHs (BaP TEQ)				**38 µg/kg**	**NA**		
0-0.5 ft bgs	N	2 of 2	19 µg/kg	N	NA	None	Compound exceeds HHCV. Existing data adequate for EPC.
0-3 ft bgs	N	4 of 7	19 µg/kg	N	NA		
0-6 ft bgs	Y	5 of 8	58 µg/kg	Y	NA		
0-10 ft bgs	Y	6 of 14	58 µg/kg	Y	NA		

Footnotes:

[1] The higher value of either the HHCV/ECV or background was selected as the screening criteria and are included in these columns for the respective compound in **BOLDED BLUE FONT**. Values based on background are indicated with "(bckg)" next to the value.

Acronyms and Abbreviations:

AOC - area of concern
BaP TEQ - benzo(a)pyrene toxic equivalents
ECV - ecological comparison values
EPC - exposure point concentration
ft bgs - feet below ground surface
HHCV - human health comparison values
mg/kg - milligrams per kilogram
µg/kg - micrograms per kilogram
N - no
NA - not applicable
95% UCL - 95 percent upper confidence limit on the mean (calculated by ProUCL Version 4.00.04; USEPA, 2009)
Y - yes

TABLE C6-12

APPENDIX C7

Area of Concern 14 Data Gaps Evaluation Results

1.0 Introduction and Background

This attachment presents the results of the Data Gaps Evaluation and Part A Phase 2 Sampling Program for Area of Concern (AOC) 14 – Railroad Debris Site at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the data gaps evaluation is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report.

1.1 Background

AOC 14 – Railroad Debris Site is located approximately 1,000 feet north of the compressor station and is currently bounded by the Burlington Northern Santa Fe railroad tracks to the north, Interstate 40 (I-40) to the south, Bat Cave Wash to the west, and a former access road to the east. The primary plateau of AOC 14 is approximately 100 feet above the bottom of Bat Cave Wash.

The Railroad Debris site is approximately 1.5 acres in area and first appears in an aerial photograph dated 1947, prior to the establishment of the compressor station. In that photograph, a mound of soil apparently related to construction of the rail line is present on the site. In subsequent aerial photographs dated 1955, a white patch and other materials are present on this site. A dirt road that runs from the north end of the compressor station to this area is also visible on the 1955 aerial photographs. A white patch can be seen on aerial photographs from the same period (mid 1950s) on the ground adjacent to the sludge-drying beds (Solid Waste Management Unit 5). The white material is probably dehydrated lime sludge from the Permutit water-conditioning system. Former employees report that the lime sludge was trucked to the Railroad Debris Site and sprayed on the ground (CH2M HILL, 2006). AOC 14 currently contains miscellaneous construction debris including chunks of asphalt, railroad ties, and piping. Asbestos-containing material has also been identified at this site.

Employee reports suggest that a removal action for some of the debris and white powdery material was conducted in the mid-1990s; however, no documentation regarding the removal has been found (CH2M HILL, 2006). The contours of the site suggest that some excavation may have occurred in the southern portion of the area. The southern two-thirds of the area are somewhat lower in elevation than the surrounding areas, and a long, low soil mound/berm is present immediately north of this area. Some white powdery material remains in the embankment adjacent to I-40, and it appears that a thin lens of additional material has been uncovered by erosion on the southern side of the soil mound. In addition, a 1998 investigation of the area indicated that a layer of white powdery material is present below the current soil surface to approximately 5 feet below ground surface (bgs) (PG&E,

1999a). This layer has variable thickness and, in some areas, is underlain and overlain by a mix of the white powdery material and gravel.

An asbestos-containing material removal action was completed at this location in 1999 (PG&E, 1999b). In November 1998, during soil sampling at AOC 14, a small amount of friable construction debris and transite were found. The friable material contained over 1 percent asbestos. The transite was non-friable and, after sampling, the transite was left in the trench and was covered with clean fill material. PG&E removed the friable asbestos-containing material on April 14, 1999 and disposed of the material at an appropriate landfill. Two shallow confirmation samples of the underlying soils were collected. At one sample location, asbestos was detected in the underlying soil. Additional sampling was implemented to characterize the extent of the asbestos in the soil underlying the loose construction material near this sample. On June 1, 1999, 14 additional samples were taken, and no asbestos was detected in any of the sample locations.

1.1.1 New Potential Burn Area

Field observations made by the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) in 2009 identified potential burn material along the I-40 road cut near the southwest corner of AOC 14. During additional employee interviews conducted by PG&E in late 2009 and early 2010, a former PG&E Topock Compressor Station employee reported periodic burning of primarily office garbage on the western edge of the AOC 14 bench area, as shown in Figures C7-1 through C7-7. The employee reported that AOC 14 was used for dumping and garbage burning until the freeway was built in the 1960s (PG&E, 2010). While several soil borings were installed and soil samples were collected during the Phase 1 investigation in 2008 from the general area identified as the area used for burning, no specific attempts were made to delineate or sample any burned material.

1.1.2 Potential Southern Debris Area

As discussed above, an employee identified the current AOC 14 as a location where waste was disposed of and burned; however, the employee also indicated the area north of the compressor station and south of I-40, informally known as the MW-24 bench (named because monitoring well MW-24 is located in this area), was also used as a potential waste disposal area. Miscellaneous construction debris is present in the MW-24 bench area. In January 2008, during trenching activities in the MW-24 bench area associated with installation of a control panel related to the upland *in-situ* pilot test, debris consisting mostly of treated wood, concrete, and scrap steel/tin (including a possible fragment of a storage tank) were encountered. DTSC and the Department of the Interior were notified of this discovery in an e-mail dated January 12, 2008. Three debris samples were collected on January 18, 2008 and were analyzed for Title 22 metals, hexavalent chromium, semivolatile organic compounds (SVOCs), and pH. In addition, two soil samples were collected on January 31, 2008 following sample collection and handling protocols outlined in the PG&E Program Quality Assurance Project Plan. The MW-24 bench area soil samples were analyzed for Title 22 metals, hexavalent chromium, SVOCs, polycyclic aromatic hydrocarbons (PAHs), total petroleum hydrocarbons (TPH), and pH. Analytes detected in soil and debris samples above interim screening levels include metals, and PAHs, as discussed in Tables C7-3 and C7-5. While data from these samples are included in tables presenting results for specific analytical parameters, these data were collected in an area that is geographically separate from AOC 14 and thus are not included on the summary table of sample statistics (Table C7-9).

As this area appears to be related to AOC 14, the new debris area is will be evaluated with AOC 14. The proposed sampling approach for the MW-24 Bench Area is presented in Section 7.0.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 14 based on the above site history and background, as shown in Figure C7-2. Table C7-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 14. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the Soil Part A Data Quality Objective [DQO] Tech Memo, which is included as Appendix A to the Data Summary Report.

The primary sources of contamination at AOC 14 are disposal of debris and asbestos-containing material, lime sludge, and potentially residuals from burning of office garbage. The primary release mechanisms are direct releases of contaminated particulates or leaching of contaminants from the debris, lime sludge, and/or burned material. Contaminants present in these materials could have been deposited on surface soil as particulates, or entered surface soil as dissolved constituents through infiltration of rainfall. In addition, the lime sludge was reportedly sprayed on the ground, and while the majority of the water in the sludge would have evaporated, some of the liquid in the sludge could have infiltrated into underlying soils. Because some material is buried, constituents could also have affected shallow and subsurface soils in the immediate vicinity of the debris, lime sludge, and/or residual burned material. Contaminants released from debris located in the higher (eastern) portion of AOC 14 could also have been transported to the lower portions of the unit through surface runoff. Primary source media therefore consist of surface, shallow, and subsurface soils. Contaminants could have leached from surface soils and shallow soil into underlying deeper soils. Potential migration from subsurface soil to groundwater was identified as a potential secondary pathway. If released, volatile organic compounds (VOCs) in surface soils would be expected to have been degraded by heat and light, and are likely no longer present.

Windblown dust contamination from small particles of debris or contaminated surface soil within AOC 14 is a potential secondary release mechanism. Windblown contamination, if any, is expected to be limited to surface soils. Surface runoff from AOC 14 to Bat Cave Wash could also have transported chemicals of potential concern/chemicals of potential ecological concern (COPCs/COPECs) in surface soil or small pieces of debris from AOC 14 to Bat Cave Wash.

Part A Phase 1 and historical soil and white powder samples were collected throughout AOC 14. Based on the site history, background, and conceptual site models, Part A Phase 1 and historical soil and debris samples were collected in areas with known debris/disposal activity. White powder samples were collected based on observations. Grid-based soil sampling was also conducted across the AOC. Sampling has not been conducted to investigate the potential burning of office garbage west of the AOC 14 boundary and debris disposed to the east of AOC 14 as these areas were only recently discovered (2009/2010).

1.2.1 AOC 14 Data

Twenty historical soil samples (at depths ranging from 0 to 6 feet bgs) were collected from 20 locations (S1-20, S2-6, S2-62, S2-130, S3-15, S3-72, S3-120, S4-4, S4-95, S4-160, S8-30, RR-1 through RR-3, RR-5, RR-6, RR-8, RR-10, and RR-11) in AOC 14, as shown in Figure C7-1. In addition, historical samples also included 11 white powder material samples (at depths ranging from 0 to 4 feet bgs) collected at GS-1, GS-2, S2-6, S2-62, S3-72, S4-4, S4-95, RR-4, RR-7, RR-9, and RR-12); and two black sandy material samples (S2-62 and S8-23 collected at 3 feet bgs).

Historical soil and white powder material samples were analyzed for five constituents: total chromium, hexavalent chromium, copper, nickel, and zinc. The black material samples were analyzed for metals, SVOCs, PAHs, and TPH. The railroad tie sample was analyzed for total chromium, lead, zinc, PAHs, and SVOCs.

During the 2008 Part A Phase 1 Soil Investigation, 79 soil samples (from 0 to 0.5, 2 to 3, 5 to 6, 9 to 10, and 14 to 15 feet bgs) were collected from 17 sample locations (AOC14-1 through AOC14-13 and AOC14-SS-1 through AOC14-SS-4), as shown in Figure C7-1. Phase 1 soil samples collected in AOC 14 were analyzed for Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, pH, asbestos, pesticides, and polychlorinated biphenyls (PCBs). Surface soil samples were not analyzed for VOCs. Ten percent of the Phase 1 soil samples collected in AOC 14 (eight soil samples) were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL). In addition, synthetic precipitation leaching procedure (SPLP) extraction was conducted on a soil sample collected at 5 to 6 feet bgs at sample location AOC14-13 and a soil sample collected at 5 to 6 feet bgs at sample location AOC14-2. The leachate from the SPLP extractions was analyzed for total and hexavalent chromium. The leachate results from the SPLP extractions are presented in Table C7-2. Soil results were validated and the data quality evaluation is included in Appendix D of the Data Gaps Evaluation Report.

In addition, white powder material was observed and sampled at 3.25 feet bgs at sample location AOC14-2, and debris (suspected transite) was observed and sampled at 1.5 feet bgs at sample location AOC14-13. The white powder material and debris samples were analyzed for the same analytical suite as listed above for the Part A Phase 1 soil samples.

All historical and Part A Phase 1 data considered Category 1 were used as inputs to the four DQO decisions.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of COPCs and COPECs at AOC 14. Laboratory analytical results for historical and Part A Phase 1 soil samples and the white powder sample at AOC 14 are presented in Tables C7-3 through C7-8. Table C7-9 presents a statistical summary of soil analytical results for COPCs and COPECs that were either detected above the laboratory reporting limits or not detected but where the reporting limits for one or more samples was greater than the interim screening value. White powder data are not included in this soil data statistical summary. Soil data are discussed first, followed by a discussion of the white powder sample data.

2.1 Summary of AOC 14 Soil Data

Antimony, beryllium, cadmium, silver, cyanide, TPH-gasoline, and PCBs were not detected in samples collected from AOC 14. Table C7-9 lists the 43 constituents detected in soil at AOC 14, including three calculated quantities (benzo(a)pyrene equivalents, total low molecular weight PAHs, and total high molecular weight PAHs). Nine of these constituents (aluminum, calcium, iron, magnesium, manganese, potassium, sodium 4,4-dichlorodiphenyldichloroethylene [4,4-DDE], and 4,4-dichlorodipheynyltrichloroethane [4,4-DDT]) were detected in the TAL/TCL samples.

Thirty of the constituents detected at AOC 14 (arsenic, barium, cobalt, nickel, thallium, vanadium, aluminum, calcium, iron, magnesium, manganese, potassium, sodium, 4-methylphenol, bis(2-ethylhexyl)phthalate, acenaphthylene, anthracene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, pyrene, total low molecular weight PAHs, TPH-diesel, and TPH-motor-oil) were detected at concentrations below their respective interim screening levels. Thirteen constituents were detected one or more times at concentrations exceeding the interim screening levels, including eight metals (total chromium, hexavalent chromium, copper, lead, mercury, molybdenum, selenium, and zinc), two pesticides (4,4-DDE and 4,4-DDT), benzo(a)pyrene, and two calculated quantities (benzo(a)pyrene equivalents and total high molecular weight PAHs).

Five constituents (total chromium, hexavalent chromium, copper, lead, and molybdenum) were detected at concentrations exceeding the interim screening level four or more times; the distribution of these constituents are shown in Figures C7-1 and C7-3 through C7-6.

Four sample locations associated with AOC 1 (AOC1-T6a through AOC1-T6c and SS-6) are located in the area that may potentially receive AOC 14 runoff into Bat Cave Wash. To provide further context for the evaluation of potential data gaps at AOC 14, the data from these sample locations are also shown in Figures C7-1 and C7-3 through C7-6. It should be noted that these samples are located in the bottom of the wash approximately 100 feet below the elevation of AOC 14. Soil samples (24Soil-01 and 24Soil-02) collected in the potential southern debris area located south of I-40 are also shown in Figures C7-1 and C7-3 through C7-6.

2.2 Nature and Extent Evaluation

The following subsection discusses the nature and extent of COPCs and COPECs detected at concentrations exceeding the interim level. As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent have been adequately delineated. Section 2.5 of this sub-appendix summarizes the constituents that may require further evaluation, and Section 6.0 of this sub-appendix provides the recommended follow-up sampling for the Part A Phase 2 soil investigation.

2.2.1 Total Chromium

Total chromium was detected in 99 of 99 soil samples collected at AOC 14. Detected concentrations of total chromium exceeded the interim screening level (39.8 milligrams per kilogram [mg/kg]) (background value/ecological comparison value [ECV]) four times (with a maximum detected concentration of 74.9 mg/kg at RR-6), as shown in Tables C7-3 and C7-9 and in Figure C7-1. None of the detected concentrations of total chromium exceeded the United States Environmental Protection Agency 2008 residential or commercial/industrial regional screening levels (RSLs) (280 mg/kg and 1,400 mg/kg, respectively). The four samples with detections exceeding the background threshold value (BTV)/ECV are located near the southwest corner of AOC 14. Samples with concentrations below the screening levels surround these locations laterally and vertically. The maximum detected concentration is only approximately twice the ECV.

2.2.2 Hexavalent Chromium

Hexavalent chromium was detected in 13 of 99 soil samples collected at AOC 14. Detected concentrations of hexavalent chromium exceeded the interim screening level (0.83 mg/kg) (BTV) eight times (with a maximum detected concentration of 5.8 mg/kg at RR-5), as shown in Tables C7-3 and C7-9 and in Figure C7-3. None of the detected concentrations of hexavalent chromium exceeded the ECV (139.6 mg/kg) or DTSC residential and commercial/industrial California human health screening levels (CHHSLs) (17 mg/kg and 37 mg/kg, respectively). Most of the samples with detections above the BTV are located near the southwest corner and southern boundary of AOC 14; two samples (AOC14-3 and S2-6) are located near the western boundary of the AOC. Samples with concentrations below the interim screening level surround the southwest locations laterally and vertically; the lateral extent of hexavalent chromium is not bounded at locations AOC14-2 and S2-6.

2.2.3 Copper

Copper was detected in 97 of 99 soil samples collected at AOC 14. Detected concentrations of copper exceeded the interim screening level (16.8 mg/kg) (BTV) four times (with a maximum detected concentration of 44 mg/kg at AOC14-2), as shown in Tables C7-3 and C7-9 and in Figure C7-4. One of the detected concentrations exceeded the ECV (20.6 mg/kg); none of the detections exceeded the residential or commercial/industrial CHHSLs (3,000 mg/kg and 38,000 mg/kg, respectively). Three of samples with detections above the BTV are located near the southwest corner and southern boundary of AOC 14; one sample is located in the northeastern corner (AOC14-8). Samples with concentrations below the interim screening level surround all of these locations laterally and vertically.

2.2.4 Lead

Lead was detected in 79 of 79 soil samples collected at AOC 14. Detected concentrations of lead exceeded the interim screening level (8.39 mg/kg) (BTV/ECV) 10 times (with a maximum concentration of 21 mg/kg at AOC14-2), as shown in Tables C7-3 and C7-9 and Figure C7-5. None of the detected concentrations exceeded the residential or commercial/industrial CHHSLs (80 mg/kg and 320 mg/kg, respectively). Five of the samples with lead above the BTV are located along the western boundary of AOC 14 and five are located in the southwest area that also had background exceedances for total and hexavalent chromium, and lead. One sample is located in the northwestern corner (AOC14-5). Samples with concentrations below the interim screening level surround most of these locations laterally and vertically. The distribution of lead exceedences is not consistent with the site-specific conceptual site model for AOC 14 (i.e., in or near the disposal areas), suggesting other potential sources. The lead present at AOC 14 is most likely from other anthropogenic sources, which would cause a more widespread distribution of lead, as discussed in Appendix C, Section C.3.

2.2.5 Mercury

Mercury was detected in one of 79 soil samples collected at AOC 14 at a concentration of 0.25 mg/kg in AOC14-SS1 at 2 to 3 feet bgs. The detected concentration of mercury exceeded the interim screening level (0.0125 mg/kg, ECV) as shown in Tables C7-3 and C7-9. The detected concentration did not exceed the residential or commercial/industrial CHHSLs (18 mg/kg and 180 mg/kg). The ECV (0.0125 mg/kg) is below the capability of the instrumentation to detect mercury. The 78 nondetected sample results had reporting limits that exceeded the ECV. These reporting limits ranged from 0.099 to 0.11 mg/kg.

2.2.6 Molybdenum

Molybdenum was detected in 15 of 79 soil samples collected form AOC 14. Detected concentrations of molybdenum exceeded the interim screening level (1.37 mg/kg) (BTV) 10 times (with a maximum concentration of 2.4 mg/kg at AOC14-6. AOC14-7, and AOC14-12), as shown in Tables C7-3 and C7-9 and in Figure C7-6. Three detected concentrations exceeded the ECV (2.25 mg/kg); none of the detected concentrations exceeded residential and commercial/industrial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). The lateral extent of concentrations exceeding the interim screening level/ ECV is limited to the northern and western portions of AOC 14. Samples with concentrations below the screening levels surround most of these locations, with the exception of AOC14-3, AOC14-13, and AOC14-SS-4. At all locations, the deepest samples have concentrations below the screening levels.

2.2.7 Selenium

Selenium was detected in three of 79 soil samples collected from AOC 14. As shown in Tables C7-3 and C7-9, two detected concentrations (AOC14-12 [1.5 mg/kg at 5 to 6 foot bgs] and AOC14-13 [1.6 mg/kg at 9 to 10 feet bgs]) barely exceeded the interim screening level (1.47 mg/kg) (BTV/ECV) but did not exceed the residential and commercial/industrial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). These locations are located near the southwest corner of AOC 14. Samples with concentrations below the interim screening level surround these locations laterally and vertically.

2.2.8 Zinc

Zinc was detected in 99 of 99 soil samples collected at AOC 14. Detected concentrations of zinc exceeded the interim screening level of 58 mg/kg (BTV/ECV) twice (AOC14-1 [70 mg/kg at 0 to 0.5 foot bgs] and RR-6 [243 mg/kg at 0 feet bgs]), as shown in Tables C7-3 and C7-9. None of the detected concentrations exceeded residential and commercial/ industrial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively). These locations are located near the southwest corner of AOC 14. Samples with concentrations below the interim screening level surround these locations laterally and vertically.

2.2.9 Benzo(a)pyrene, Benzo(a)pyrene Equivalents, and PAHs

Benzo(a)pyrene was detected in seven of 79 soil samples collected from AOC 14. One sample (AOC14-12 at 5 to 6 feet bgs) had a detected concentration of benzo(a)pyrene of 84 micrograms per kilograms (µg/kg) which exceeded the interim screening level of

38 µg/kg (residential CHHSL). Several other PAHs were detected in soil samples collected from AOC 14, but concentrations were below their respective interim screening levels. To assist with evaluation of PAHs for human health, benzo(a)pyrene equivalents were calculated for each of the soil samples collected at AOC 14, as shown in Table C7-5. The benzo(a)pyrene equivalent interim screening level of 38 µg/kg (residential CHHSL) was exceeded in one sample (130 µg/kg at AOC14-12 at 5 to 6 feet bgs), as shown in Tables C7-5 and C7-9. This location is located near the southwest corner of AOC 14. Samples with concentrations below the interim screening level surround this location laterally and vertically. The distribution of PAH exceedences is not consistent with the site-specific CSM for AOC 14 (i.e., in the disposal area), suggesting other potential sources. The PAHs present at AOC 14 are most likely from other anthropogenic and naturally occurring sources (i.e., combustion of fossil fuels, wild fires, volcanic activities, industrial facilities, petroleum oils, asphalt binders, and vehicle exhaust), which would cause a more widespread distribution of PAHs, as discussed in Appendix C, Section C.3.

To assist with evaluation of PAHs for ecological risk, detected concentrations of low molecular weight PAHs and high molecular weight PAHs were summed and compared to the PAH low molecular weight and PAH high molecular weight ECVs (10,000 µg/kg and 1,160 µg/kg, respectively). One of the sums of detected concentrations exceeded the PAH high molecular weight ECV (AOC14-12 at 5 to 6 feet bgs contained 1,400 µg/kg high molecular weight PAHs), and none of the detected sums exceeded the PAH low molecular weight ECV.

2.2.10 Asbestos

Seventy-nine soil samples were analyzed for asbestos. Bulk samples analyzed by polarized light microscopy indicated that asbestos fibers were present in 16 of the 72 soil samples, as shown in Table C7-8. Further analysis of these soil samples by California Air Resources Board Method 435 and transmission electron microscopy indicated that asbestos was present in only two soil samples (AOC13-2 at 14 to 15 feet bgs and AOC14-SS1 at 5 to 6 feet bgs) at trace levels (detected concentration of less than 0.1 percent, where the detection limit was less than 0.1 percent).

2.2.11 Target Analyte List/Target Compound List Constituents

Aluminum, calcium, iron, magnesium, manganese, potassium, sodium, 4-methylphenol, bis (2-ethylhexyl) phthalate, 4,4-DDE, and 4,4-DDT were detected in the AOC 14 soil samples analyzed for the complete TAL/TCL suite of compounds. These constituents are discussed below.

Aluminum was detected in eight of eight surface soil samples collected from AOC 14. The maximum detected concentration of aluminum was 9,000 mg/kg at AOC14-5, which is below the interim screening level (16,400 mg/kg) (BTV), as shown in Tables C7-4 and C7-9. Remaining detected concentrations of aluminum ranged from 3,000 to 8, 800 mg/kg. None of the detected concentrations exceeded residential and commercial CHHSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in nine of nine soil samples collected from AOC 14, both surface and subsurface (3 and 4 feet bgs) were collected. The maximum detected concentration of calcium was 48,000 mg/kg at AOC14-1, which is below the interim screening level

(66,500 mg/kg) (background value), as shown in Tables C7-4 and C7-9. Remaining detected concentrations of calcium ranged from 11,000 to 37,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium.

Iron was detected in nine of nine soil samples collected from AOC 14, both surface and subsurface (3 and 4 feet bgs) were collected. The maximum detected concentration of iron was 23,100 mg/kg at s1-20, which is below the interim screening level of 55,000 mg/kg (residential RSL), as shown in Tables C7-4 and C7-9. Remaining detected concentrations of iron ranged from 6,800 to 20,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for iron.

Magnesium was detected in nine of nine soil samples collected from AOC 14, both surface and subsurface (3 and 4 feet bgs) were collected. The maximum detected concentration of magnesium was 8,500 mg/kg at AOC14-1, which is below the interim screening level (12,100 mg/kg) (background value), as shown in Tables C7-4 and C7-9. Remaining detected concentrations of magnesium ranged from 2,600 to 8,330 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium.

Manganese was detected in eight of eight surface soil samples collected from AOC 14. The maximum detected concentration of manganese was 290 mg/kg at AOC14-3, which is below the interim screening level (402 mg/kg) (BTV), as shown in Tables C7-4 and C7-9. Remaining detected concentrations of manganese ranged from 120 to 270 mg/kg. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (1,800 mg/kg and 23,000 mg/kg, respectively).

Potassium was detected in nine of nine soil samples collected from AOC 14, both surface and subsurface (3 and 4 feet bgs) were collected. The maximum detected concentration of potassium was 2,800 mg/kg at AOC14-3, which is below the interim screening level of 4,400 mg/kg (BTV), as shown in Tables C7-4 and C7-9. Remaining detected concentrations of potassium ranged from 690 to 2,700 mg/kg. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for potassium.

Sodium was detected in eight of nine soil samples collected from AOC 14, both surface and subsurface (3 and 4 feet bgs) were collected. The maximum detected concentration of sodium was 850 mg/kg at AOC14-1, which is below the interim screening level (2,070 mg/kg) (BTV), as shown in Tables C7-4 and C7-9. Remaining detected concentrations of sodium ranged from 210 to 630 mg/kg. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for sodium.

4-methylphenol was detected in one of 79 soil samples collected at AOC 14, both surface and subsurface soil samples were collected, as shown in Tables C7-5 and C7-9. The detected concentration was 430 µg/kg at AOC14-2 surface soil sample, which is below the interim screening level of 500 µg/kg (ECV), and well below the residential and commercial/industrial RSLs (310,000 µg/kg and 3,100,000 µg/kg, respectively).

Bis(2-ethylhexyl)phthalate was detected in one of 79 soil samples collected at AOC 14, both surface and subsurface soil samples were collected, as shown in Tables C7-5 and C7-9. The detected concentration was 810 µg/kg AOC4-1 (at 2 to 3 feet bgs), which is below the interim screening level of 2,070 µg/kg, and well below the residential and commercial/industrial RSLs (35,000 µg/kg and 120,000 µg/kg, respectively).

4,4-DDE (2.9 μg/kg at AOC14-2), and 4,4-DDT (3 μg/kg at AOC14-2) were detected above their interim screening levels in one of eight surface soil samples collected from AOC 14. The detected concentrations exceeded the interim screening level of 2.1 μg/kg (ECV), as shown in Tables C7-7 and C7-9. The detected concentrations did not exceed the residential or commercial/industrial CHHSLs (1,600 μg/kg and 6,300 μg/kg, respectively). This location is located in the southwestern corner of the AOC.

As discussed in Section C.2 of Appendix C, PG&E recommends that the metals and organics discussed above not be considered COPCs/COPECs for this SWMU and no further sampling for these constituents is proposed. These constituents have been fully discussed in Section C.2

2.3 Central Tendency Comparison to Background Threshold Values

Seven metals (total chromium, hexavalent chromium, copper, lead, molybdenum, selenium, and zinc) were detected above their background values in soil samples collected from AOC 14. A central tendency comparison was performed for five of these seven metals (total chromium, copper, lead, molybdenum, and zinc) to compare the AOC 14 soil data set for these metals with the corresponding soil background data set to determine whether a difference exists between the two populations and whether additional sampling may be required for a given metal. The comparison results are shown in Table C7-10 of this attachment and in Figure 3-1 of the Data Gaps Evaluation Report.

Metals in either the AOC 14 data set or background data set that were detected infrequently (less than five detects) or had a limited number of results (less than eight) were not tested. There were insufficient detections of hexavalent chromium and selenium to conduct the test.

No statistical difference between the two populations was noted for any of the five metals evaluated (total chromium, copper, lead, molybdenum, and zinc), as shown in Table C7-10.

2.4 White Powder Material, and Debris Samples and Mapping

This subsection discusses the historical white powder samples, white powder material and debris samples collected during the 2008 Part A Phase 1 soil investigation, and the white powder material and debris mapping.

2.4.1 White Powder Material Samples

As described above, 11 samples of historical white powder material and a sample of white powder material from the Soil Part A Phase 1 (location AOC14-2 at 3 to 3.25 feet bgs) were collected and sent to the laboratory for analysis.

DTSC also collected a sample of the AOC 14 white powder material on January 18, 2008 from the bank of the freeway (DTSC AOC 14 – Roadcut). This sample was collected as a comparison sample to the samples of white powder collected from AOC 10 East Ravine. The results of this sampling were summarized in DTSC's June 18, 2008 memo *Field Report: White Powder Occurrences in the East Ravine - Area of Concern (AOC) 10, Pacific Gas and Electric (PG&E) Company Topock Compressor Station, Needles, California PCA 22120 WP 540015-48/36 WR 640233.* The following compounds were detected in the DTSC-AOC14-Roadcut sample: barium, total chromium, cobalt, vanadium, zinc, sodium, calcium, iron, manganese, and potassium. Of these compounds, only calcium was detected above its interim screening level. These data are not included in the summary tables, since there were not collected, analyzed, or validated under the PG&E Program Quality Assurance Program Plan.

Total chromium, copper, nickel, and zinc were all detected in all 11 historical white powder material samples collected at AOC 14. Hexavalent chromium was detected in six of the 11 samples. Only total chromium, hexavalent chromium, and copper were detected above their respective interim screening levels in these samples, as shown in Table C7-3. The maximum detected concentration of total chromium in the historical white powder samples was 45.5 mg/kg, which only slightly exceeds the background value (39.8 mg/kg) and ECV (36.3 mg/kg) and is well below the residential RSL (280 mg/kg). The maximum detected concentration of hexavalent chromium in the historical white powder samples was 15.4 mg/kg, which exceeds the background value (0.83 mg/kg) but is below the residential CHHSL (17 mg/kg) and the ECV (139.6 mg/kg). The maximum detected concentration of copper in the historical white powder samples was 27.9 mg/kg, which exceeds the background value (16.8 mg/kg) and the ECV (20.6 mg/kg) but is well below the residential CHHSL (3,000 mg/kg).

During the 2008 Part A Phase 1 soil investigation, white powder material was encountered only in one location (AOC14-2) at approximately 3 feet bgs. A sample of the white powder material was collected from the 3- to 3.25-foot-bgs interval. Soil samples were also collected above and beneath the white powder material at (at 2 to 3 feet bgs and at 5 to 6 feet bgs) and were sent to the laboratory for analysis. The following compounds were detected in the white powder material sample: arsenic, barium, total chromium, hexavalent chromium, nickel, and vanadium. Of those compounds detected, arsenic (15 mg/kg) and hexavalent chromium (2.16 mg/kg) were detected above their respective interim screening levels, as shown in Table C7-3.

The following compounds were detected in the two soil samples collected at AOC14-2 above and beneath the white powder material: arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, nickel, vanadium, zinc, and TPH-motor-oil. Several PAHs were detected in the sample beneath the white powder material. Of the compounds detected, total chromium (42 mg/kg both samples) and hexavalent chromium (1.04 and 1.32 mg/kg) were detected above their respective interim screening levels in both samples. Copper (19 mg/kg) and lead (21 mg/kg) were detected above their respective interim screening levels in the deeper sample. Asbestos was also detected in the soil sample collected beneath the white powder material.

2.4.2 Debris Samples

As previously mentioned in Section 1.1, two historical debris samples (black sandy material) and a sample of debris (suspected transite) were collected and sent to the laboratory for analysis. TPH-diesel (15,000 mg/kg) and TPH-motor-oil (17,000 mg/kg) were the only constituents detected above laboratory detection limits in the two black sandy material samples. These concentrations exceed the initial screening levels for TPH-diesel (540 mg/kg) and TPH-motor-oil (1,800 mg/kg); however, the risk assessment will evaluate the constituents contained in these samples, and no further sampling is recommended at this time to address the presence of this material. During the 2008 Part A Phase 1 soil investigation, debris (suspected transite) was encountered in one location (AOC14-13 at 0.5 to 1.5 feet bgs) near the surface, and a sample was collected. A soil sample was also collected beneath the debris at 5 to 6 feet bgs and was sent to the laboratory for analysis. The following compounds were detected in the debris sample: arsenic, barium, total chromium, hexavalent chromium, copper, lead, molybdenum, nickel, zinc, several PAHs, and TPH-motor-oil. Of those compounds detected, arsenic (18 mg/kg), total chromium (63 mg/kg), copper (33 mg/kg), lead (16 mg/kg), molybdenum (98 mg/kg), and nickel (57 mg/kg) were detected above their respective interim screening levels, as shown in Table C7-3. The debris sample contained 25 percent asbestos.

The following compounds were detected in the soil sample collected at 5 to 6 feet bgs, beneath the debris: arsenic, barium, total chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, zinc, and TPH-motor-oil. Of those compounds detected, only molybdenum (2 mg/kg) was detected above its interim screening level. The soil sample identified asbestos fibers present using polarized light microscopy, but further analysis of the soil beneath the debris by California Air Resources Board Method 435 indicated that asbestos was not detected above the detection limit.

2.4.3 White Powder Material and Debris Mapping

As part of the conditional approval of the Soil Part A Work Plan (CH2M HILL, 2006), DTSC requested that the white powder material and debris observed in AOC 14 be mapped. PG&E mapped white powder material during the Part A Phase 1 field investigation in 2008. The extent of the white powder material in AOC 14 was documented by walking the perimeter of the visible white powder material, recording the GPS coordinates, and plotting those areas on a figure. There were six areas of white powder material observed in AOC 14. Sampling locations AOC14-1, AOC14-2, AOC14-11, AOC14-12, and AOC14-13 were collocated within white powder areas.[1] During drilling activities at AOC 14, white powder material and/or debris was encountered in boring AOC14-2 (at 2 to 3.5 foot bgs). More detailed results of the white powder material mapping are presented in Appendix B of the Data Gaps Evaluation Report.

In May 2009, PG&E conducted a site walk at AOC14 in to map the debris areas. Debris was observed on the hill above AOC 14 towards the east. The debris consisted of concrete rubble, transite, cans, and miscellaneous trash; these debris areas are shown in Figures C7-1 to C7-6. No sampling has occurred in these debris areas. Nature and extent of contamination in these debris areas have not been defined. Additional characterization of debris may be needed to assess if asbestos containing materials are present. Section 6.0 of this attachment presents the proposed Phase 2 sample locations within these debris areas.

Additional debris was also identified on the west side of AOC 14 near a small cut in the Bat Cave Wash embankment near the northwestern edges of AOC 14. Some debris was noted on the side of the embankment. The nature and extent of the debris toward Bat Cave Wash have not been defined. Three soil borings (AOC1-T6a, -T6b, and -T6c were installed in a transect across Bat Cave Wash downslope from the western edge of AOC 14. Eleven soil samples (not including quality control samples) were collected. With the exception of two detects of lead (12 and 8.5 mg/kg in the 10-foot samples from AOC1-T6a and AOC1-T6b, respectively), metals were not detected above their respective interim screening levels. PAHs were detected in the surface samples in all three locations but below interim

---

[1] White powder material samples were also collected during prior investigation efforts; see Table C7-3.

screening levels. Additional samples are proposed to fully assess impacts from AOC 14. Section 6.0 of this attachment presents the potential Phase 2 sampling to assess potential impacts from this debris area. The potential Phase 2 sample locations are needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

2.5 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review indicates than decision error has been held to an acceptable level. Sufficient data of acceptable quality have been attained by the collection of soil samples in areas most likely to have been impacted by the disposal of debris and asbestos-containing material, and lime sludge. Some of the newly-identified burn area, debris, and white powder areas have not been sampled.

Review of the nature and extent discussions above indicates that the lateral and vertical extent of samples with concentrations exceeding the screening levels is confined primarily to the southwestern corner of the AOC 14 boundary. Within this area, the lateral and/or vertical extents of hexavalent chromium, molybdenum, PAHs, and pesticides have not been defined.

There are two sources of white powder material at Topock Compressor Station: (1) the lime treatment sludge, which is typically low in COPC concentrations, and (2) the concentrated minerals resulting from evaporation of cooling tower blowdown water. The white powder material found at AOC 14 contains a maximum total chromium concentration of 45 mg/kg and relatively low concentrations of other metals. This indicates that the likely source of this white powder material is the lime treatment sludge from the lime-based water conditioning system that was in use at Topock until 1962; thus, chemical data are consistent with anecdotal employee reports.

Because the white powder material found at AOC 14 is likely the lime treatment sludge, and due to the fact that there was extensive sample coverage in the entire area (26 historical and 17 Phase 1 locations), no additional sampling of the white powder material in AOC 14 is recommended.

Based on review of the data and the Part A DQO, three data gaps were identified to resolve Decision 1 – Nature and Extent, and limited additional sampling is recommended in Phase 2 to fill the following data gaps:

1. Data gap #1 – Western extent of PAHs, metals, and pesticides contamination in the southwestern corner of AOC 14.
2. Data gap #2 – Nature and extent of contamination in the newly identified burn area west of AOC 14 and the newly identified debris area east of AOC 14.
3. Data gap #3 – Nature and extent of contamination in the newly identified debris area in the MW-24 bench area.

The potential Phase 2 soil sample locations to fill the data gaps are presented in Section 6.0.

3.0 Decision 2 – Data Sufficient to Estimate Representative Exposure Point Concentrations

For Decision 2, data were evaluated to determine if the AOC 14 data are sufficient to conduct human health and ecological risk assessments based on the criteria described in Section 4.0 of the Data Gaps Evaluation Report. The principal consideration for Decision 2 was whether there were sufficient data to estimate a representative exposure point concentration (EPC). Data reviewed were all available Category 1 data (including historical data from investigations in 1998 and 2000) at AOC 14. The sample designated as "white powder" (AOC14-2 at 3 to 3.25 feet bgs) was included in the data reviewed as a conservative measure, assuming that exposure to white powder areas would not differ significantly from exposure to surrounding soil areas. Similarly, because the precise physical characteristics (and consequently the potential exposure mechanism) of the samples identified as "black sandy material (i.e., asphalt material)" cannot be determined based on the available data reports, these samples were included in the data reviewed based on the same rationale.

Table C7-11 summarizes the results of the evaluation to determine whether data are sufficient to estimate a representative EPC. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value. Existing data are adequate to support EPC development for detected chemicals that exceeded one or more comparison values (10 metals, three Contract Laboratory Program inorganics, PAHs, total DDT [i.e., DDT-R]), TPH-diesel, and TPH-motor-oil, as described below. Phase 2 data will be added to the existing data set to calculate the final EPC (i.e., after Decision 1 is satisfied).

3.1 Metals

Sufficient data (numbers of samples and detections) are available to calculate EPCs for arsenic, total chromium, copper, lead, nickel, and zinc using ProUCL. For the remaining metals (antimony, mercury, molybdenum, and selenium), additional data collection is not expected to significantly change the results of the risk assessment either because the compound is very infrequently detected (antimony and mercury) (i.e., additional nondetects would be expected) or because the maximum detected concentration is below or only slightly greater than the lowest comparison value (molybdenum and selenium).

3.2 Inorganics

Sufficient data (numbers of samples and detections) are available to calculate EPCs for calcium, magnesium, and sodium using ProUCL.

3.3 Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene toxicity equivalents and high molecular weight PAHs using ProUCL.

3.4 Pesticides

4,4-DDE and 4,4-DDT were detected in a single sample at concentrations near the detection limit, as shown in Table C7-7. The data are insufficient to allow calculation of an EPC using ProUCL. The total concentration of DDT and metabolites (DDT-R) is approximately three times the ECV. However, collection of additional data is not expected to yield sufficient detections to strongly influence the EPC; therefore, no additional data collection is recommended to support EPC development.

3.5 Petroleum Hydrocarbons

Sufficient data (number of samples and detections) are available to calculate EPCs for TPH-diesel and TPH-motor-oil using ProUCL.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

The following preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1 are needed to resolve Decision 3. Additional evaluations will be performed as appropriate as data are collected to resolve Decision 1. Data collected to satisfy Decision 1 – Nature and extent evaluation will provide the final representative data set that will be used to assess the threat to groundwater.

Table C7-12 presents the results of the tiered analysis for AOC 14. Nine metals were detected at concentrations above the BTVs. Of those nine, hexavalent chromium, molybdenum, and thallium exceeded the calculated soil screening levels, as shown in Table C7-13. Numerical modeling was conducted to evaluate the potential of these three metals to leach into groundwater. Based on the initial screening model, the potential for molybdenum to leach to groundwater was ruled out. Based on the screening model, the potential for hexavalent chromium or thallium to leach to groundwater could not be ruled out.

4.1 Thallium

At AOC 14, only one sample had a detectable concentration of thallium (2.2 mg/kg). This single detection prompted the additional analysis. The simulated leaching concentrations of thallium were likely due to the following three factors:

- Nondetects in the initial concentration profile were input as one-half of the detection limit, resulting in a non-zero concentration and mass throughout the simulated vadose zone. Further, the reporting limit for thallium in AOC 14 samples was as high as 22 mg/kg; therefore, the assumed concentration for that interval was elevated.
- Thallium has a very low K_d (dissociation constant)[2] of 3.2 milliliters per gram.
- The background upper tolerance limit for thallium in groundwater is very low at 0.908 micrograms per liter.

Additional data are not needed for thallium; however, further refinement of the vadose leaching zone model and assumptions are proposed.

4.2 Hexavalent Chromium

The simulated leaching concentration of hexavalent chromium at AOC 14 is likely due to the fact that the initial screening approach assigned the maximum concentration found at each

---

[2] The distribution coefficient describes how strongly a chemical adsorbs to soil solids.

depth interval across the entire interval, even though many other samples with far lower concentrations were observed at each level.

Additional data are needed to better define the lateral extent of hexavalent chromium. The model will be refined by discretizing the area spatially to more realistically simulate vadose zone contaminant concentrations. Additional proposed soil borings described in Decision 1 will also be used to support the model refinement.

The vertical extent of hexavalent chromium is fully defined at AOC 14, with no exceedances of BTVs at the deepest samples collected; therefore, a current threat to groundwater has been ruled out.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Summary Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study (CMS/FS). The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fenceline include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite).
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil-washing technologies).
- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies).
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- Volumes of white powder and debris.

The following is a summary of available data for AOC 14 that is currently available to support CMS/FS:

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. The results of COPCs and COPECs are shown in Figure C7-1 and Figures C7-3 to C7-6, and data gaps associated with lateral and vertical delineation are discussed in Section 6.0.

5.2 Waste Characterization Parameters

Only partial waste characterization data are available to characterize the soil and other materials to be potentially removed for remedial action and disposed in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations (TTLCs). The maximum concentrations of these metals were compared to the TTLCs, and none of the metals in AOC 14 exceeded the TTLCs, as shown in Table C7-14. The maximum detected concentrations were also compared to the soluble threshold limit concentrations (STLC), and only one of the metals concentrations in AOC 14 (total chromium at 74.9 mg/kg at RR-6 at 0 feet bgs) exceeded 10 times STLC, as discussed in Table C7-14. Because there was only one exceedance, and the concentration is relatively close to 10 times the STLC, this detection is not considered a data gap. Finally, soil metals concentrations were also compared the TCLP and none of the metals detected exceeded 20 times the TCLP, as shown in Table C4-14. Additional data regarding potential COPC/COPEC leachability include SPLP analysis for total and hexavalent chromium, as shown in Table C7-2. SPLP analysis was conducted only for soil samples (no white powder or debris samples were tested using SPLP).

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 investigation was limited to grain size analysis only. Specific soil physical properties data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 of the Data Gaps Report.

5.4 Surface and Subsurface Features

While there is extensive information regarding surface and subsurface features at AOC 14, additional information may be required once areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are known for AOC 14. However, subsurface utilities, including gas transmission pipelines and any culverts or other features, may have to be more precisely defined to evaluate the feasibility and cost of certain remedial alternatives, and prepare construction specifications.

5.5 Volumes of White Powder and Debris

Preliminary mapping has been conducted to identify the extent and type of debris present in AOC 14; findings of this mapping are presented in Section 3.0 and in Appendix B to this Data Summary Report. Additional soil physical parameter data are needed to support the CMS/FS.

6.0 Summary of Data Gaps Evaluation and Potential Phase 2 Soil Sample Locations to Fill the Identified Gaps

Based on the Part A DQO, data gaps were identified for three of the four decisions and are summarized below by decisions:

- **Decision 1 – Nature and Extent** – The following data gaps were identified to resolve this decision:
  - Data gap #1 – Western extent of benzo(a)pyrene, metals, and pesticides contamination in the southwestern corner of AOC 14.

  - Data gap #2 – Nature and extent of contamination in the newly identified burn area west of AOC14 and the newly identified debris area east of AOC 14.
  - Data gap #3 – Nature and extent of contamination in the newly identified debris area in the MW-24 bench area.
- **Decision 2 (Data Sufficient to Estimate Representative Exposure Point Concentrations)**: No data gap was identified for this decision.
- **Decision 3 (Potential Threat to Groundwater from Residual Soil Concentrations)** – No data gap was identified for this decision.
- **Decision 4 (Data Sufficient to Estimate Soil Properties and Contaminant Distribution in Support of the CMS/FS) –** the following data gap was identified to resolve this decision**:**
  - Data gap #4 – Soil physical parameters to support the corrective measures study/ feasibility study.

In an effort to reduce intrusive sampling, a portable X-ray fluorescence (XRF) analyzer will be used to assist with identifying possible sample locations in debris areas on the slope east of AOC 14 (Data Gap #2). Up to 20 XRF samples will be collected in the debris area. Corrected XRF results will be compared to applicable screening levels on Data Gap Evaluation Report Table 3-1 on a point-by-point basis. (For field screening purposes, XRF concentration readings will be adjusted using least squares regression equation calculated from the RCRA facility investigation/remedial investigation samples analyzed in the lab and by the XRF.) If the applicable screening levels are not exceeded, no further sampling will occur at that location. However, if applicable screening levels are exceeded, soil samples will be collected at 0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet below ground surface at that location and will be submitted to the laboratory for analysis for hexavalent chromium, PAHs, Title 22 metals, and asbestos.

Table C7-15 summarizes the potential Phase 2 sample locations, depths, rationale for each location, and analytes. Potential Phase 2 sample locations are also shown in Figures C7-1 and C7-3 through Figure C7-7. The potential Phase 2 sample locations are needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

6.1 Access Restrictions

AOC 14 – Railroad Debris Site is currently bounded by the Burlington Northern Santa Fe railroad tracks to the north, I-40 to the south, Bat Cave Wash to the west, and the former access road to the location to the east. The bottom of Bat Cave Wash is located approximately 100 feet below AOC 14 and I-40 is approximately 10 feet below AOC 14. Access to the site is limited to foot traffic only crossing over the railroad tracks, which requires a Burlington Northern Santa Fe permit. Heavy equipment would need to be craned onto the site from I-40.

7.0 MW-24 Bench Evaluation

As discussed above, an employee identified the current AOC 14 as a location where waste was disposed of and burned; however, the employee also indicated the area north of the compressor station and south of I-40, informally known as the MW-24 bench (named because monitoring well MW-24 is located in this area), was also used as a potential waste disposal area. Miscellaneous construction debris is present in that MW-24 bench area. In January 2008, during trenching activities in the MW-24 bench area associated with installation of a control panel related to the upland *in-situ* pilot test, debris consisting mostly of treated wood, concrete, and scrap steel/tin (including a possible fragment of a storage tank) were encountered. The evaluation of MW-24 Bench area will consist of the following:

1. Asbestos Survey of debris
2. Debris mapping of large debris across the area.
3. Geophysical surveying across the bench area to further characterize buried waste.
4. XRF analyzer will be used to assess surface soils in the bench area. Figure C7-7 shows a 50-foot grid over the bench area; one XRF samples will be collected from each grid cell (not shown on figure). Corrected XRF results will be compared to applicable screening levels on Data Gap Report Table 3-1 on a point-by-point basis. (For field screening purposes, XRF concentration readings will be adjusted using least squares regression equation calculated from the RCRA facility investigation/remedial investigation samples analyzed in the lab and by the XRF.)
5. Up to 18 soil borings (AOC14-26 through AOC14-43) will also be advanced in the 50-foot grid in the bench area. Soil borings may be limited to areas of anomalies identified by geophysical and to areas with elevated XRF concentrations. Soil samples will be collected at 0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet bgs at each grid point and will be submitted to the laboratory for analysis for pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, and pH.

In addition, DTSC directed PG&E (email date March 24, 2011) to:

- Collect soil samples in an area that DTSC identified as a potential burn waste outcrop along the western ramp up from Bat Cave Wash.
- Define the lateral and vertical extents of waste and any associated contamination at the MW-24 Bench waste pit observed in January 2008 during implementation of the Upland In-situ Pilot Study.

PG&E is proposing to collect three surface soil samples in the potential burn waste outcrop, soil samples will be analyzed for hexavalent chromium, Title 22 metals, TPH, PCBs, and dioxins/furans. Trenching is proposed to define lateral and vertical extent of buried debris discovered during the Upland In-site Pilot study. The trenching may extend up to 20 feet below ground surface and will not extend beyond the boundaries of the MW-24 Bench area shown on FigureC7-7. Five soil samples will be collected from the bottom of the trenches (one centered in the former trench and laterally at the end reaches of debris). The soil samples will be analyzed for, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, and pH.

TABLE C7-3

Sample Results: Metals
AOC 14 - Railroad Debris Site
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

[6] White powder sample

[7] debris sample

[8] black sandy material

Results greater than or equal to the interim screening level are circled; however, if the interim screening level is equal to the background value, only results greater than the interim screening level are circled.

*	Reporting limits greater than or equal to the interim screening level.
USEPA	United States Environmental Protection Agency
DTSC	California Department of Toxic Substances Control
CHHSL	California human health screening levels
NE	not established
mg/kg	milligrams per kilogram
ft bgs	feet below ground surface
N	primary sample
FD	field duplicate
---	not analyzed
ND	not detected at the listed reporting limit
J	concentration or reporting limit estimated by laboratory or data validation

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

Sample Results: Polycyclic Aromatic Hydrocarbons

AOC 14 - Railroad Debris Site

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

[6] White powder sample

[7] debris sample

[8] black sandy material

Results greater than or equal to the interim screening level are circled.

*	Reporting limits greater than or equal to the interim screening level.
USEPA	United States Environmental Protection Agency
DTSC	California Department of Toxic Substances Control
CHHSL	California human health screening levels
NE	not established
µg/kg	micrograms per kilogram
ft bgs	feet below ground surface
N	primary sample
FD	field duplicate
---	not analyzed
ND	not detected at the listed reporting limit
J	concentration or reporting limit estimated by laboratory or data validation

[1] For SVOCs, interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used. For TPHs, interim screening level is the Regional Water Quality Control Board environmental screening level.

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

TABLE C7-11

Decision 2 Data Gaps Summary AOC 14 - Railroad Debris Site

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

	Adequate EPC?		Maximum Detected Value	> HHCV or Background as Applicable? [1]	> ECV or Background as Applicable? [1]	Proposed Sample ID	Notes
Compound/Depth	Y or N	Det/# results		Y or N	Y or N		
Metals							
Antimony				**30 mg/kg**	**0.285 mg/kg**		
0-0.5 ft bgs	NA	0 of 14	NA mg/kg	N	N	None	Compound exceeds ECV. Detection limit exceeds ECV. Although there are insufficient detections to allow calculation of a 95% UCL on the mean, additional data collection is not expected to yield sufficient detections to strongly influence the EPC, because additional sampling would likely result in additional non-detect values.
0-3 ft bgs	N	2 of 30	1.1 mg/kg	N	Y		
0-6 ft bgs	N	2 of 48	1.1 mg/kg	N	Y		
0-10 ft bgs	N	2 of 65	1.1 mg/kg	N	NA		
Arsenic				**11 mg/kg (bckg)**	**11.4 mg/kg**		
0-0.5 ft bgs	Y	14 of 14	6.8 mg/kg	N	N	None	Compound exceeds HHCV and ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	30 of 30	11 mg/kg	N	N		
0-6 ft bgs	Y	48 of 48	15 mg/kg	Y	Y		
0-10 ft bgs	Y	65 of 65	15 mg/kg	Y	NA		
Chromium-Total				**280 mg/kg**	**39.8 mg/kg (bckg)**		
0-0.5 ft bgs	Y	31 of 31	74.9 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	56 of 56	74.9 mg/kg	N	Y		
0-6 ft bgs	Y	79 of 79	74.9 mg/kg	N	Y		
0-10 ft bgs	Y	96 of 96	74.9 mg/kg	N	NA		
Copper				**3000 mg/kg**	**20.6 mg/kg**		
0-0.5 ft bgs	Y	31 of 31	44 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.

TABLE C7-11

Decision 2 Data Gaps Summary AOC 14 - Railroad Debris Site

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth	Adequate EPC? Y or N	Adequate EPC? Det/# results	Maximum Detected Value	> HHCV or Background as Applicable?[1] Y or N	> ECV or Background as Applicable?[1] Y or N	Proposed Sample ID	Notes
Mercury				**18 mg/kg**	**0.0125 mg/kg**		
0-0.5 ft bgs	NA	0 of 14	NA mg/kg	N	N	None	Compound exceeds ECV and no background value has been established. Detection limits are elevated relative to the ECV. Additional data collection is likely to yield additional non-detected values. The EPC has been defined within the limits of the analytical instrumentation.
0-3 ft bgs	N	3 of 30	0.25 mg/kg	N	Y		
0-6 ft bgs	N	3 of 48	0.25 mg/kg	N	Y		
0-10 ft bgs	N	3 of 65	0.25 mg/kg	N	NA		
Molybdenum				**380 mg/kg**	**2.25 mg/kg**		
0-0.5 ft bgs	N	3 of 14	1.6 mg/kg	N	N	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	7 of 30	2.4 mg/kg	N	Y		
0-6 ft bgs	Y	14 of 48	2.4 mg/kg	N	Y		
0-10 ft bgs	Y	15 of 65	2.4 mg/kg	N	NA		
Nickel				**1600 mg/kg**	**27.3 mg/kg (bckg)**		
0-0.5 ft bgs	Y	31 of 31	15.8 mg/kg	N	N	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	56 of 56	47 mg/kg	N	Y		
0-6 ft bgs	Y	79 of 79	47 mg/kg	N	Y		
0-10 ft bgs	Y	96 of 96	47 mg/kg	N	NA		
Selenium				**380 mg/kg**	**1.47 mg/kg (bckg)**		
0-0.5 ft bgs	NA	0 of 14	NA mg/kg	N	N	None	Compound exceeds ECV. Although there are insufficient detections to allow calculation of a 95% UCL on the mean, additional data collection is not expected to yield sufficient detections to strongly influence the EPC because additional sampling would likely result in additional non-detect values and because the maximum detected value is only slightly greater than the lowest comparison value.
0-3 ft bgs	N	2 of 30	0.99 mg/kg	N	N		
0-6 ft bgs	N	3 of 48	1.5 mg/kg	N	Y		
0-10 ft bgs	Y	5 of 65	1.6 mg/kg	N	NA		
Zinc				**23000 mg/kg**	**58 mg/kg (bckg)**		
0-0.5 ft bgs	Y	31 of 31	243 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	55 of 56	243 mg/kg	N	Y		
0-6 ft bgs	Y	77 of 79	243 mg/kg	N	Y		
0-10 ft bgs	Y	94 of 96	243 mg/kg	N	NA

0-0.5 ft bgs	Y	9 of 14	252 mg/kg	N	NA	None	Compound exceeds HHCV. Existing data adequate for EPC.
0-3 ft bgs	Y	21 of 30	17000 mg/kg	Y	NA		
0-6 ft bgs	Y	33 of 48	17000 mg/kg	Y	NA		
0-10 ft bgs	Y	37 of 65	17000 mg/kg	Y	NA		

Footnotes:

[1] The higher value of either the HHCV/ECV or background was selected as the screening criteria and are included in these columns for the respective compound in **BOLDED BLUE FONT**. Values based on background are indicated with "(bckg)" next to the value.

Acronyms and Abbreviations:
AOC - area of concern
BaP TEQ - benzo(a)pyrene toxic equivalents
ECV - ecological comparison values
EPC - exposure point concentration
ft bgs - feet below ground surface
HHCV - human health comparison values
HMW PAH - high molecular weight polycyclic aromatic hydrocarbons
mg/kg - milligrams per kilogram
µg/kg - micrograms per kilogram
N - no
NA - not applicable
95% UCL - 95 percent upper confidence limit on the mean (calculated by ProUCL Version 4.00.04; USEPA, 2009)
Y - yes

mg/kg	miligrams per kilogram
mg/L	milligrams per liter
ND	not detected in any of the samples
NE	not established
‡	maximum reporting limit greater than or equal to the STLC.

24 Bench Samples not included in table summary.

TABLE C7-15
Proposed Phase 2 Soil Sampling Locations at AOC 14 – Railroad Debris Site
Soil Investigation Part A Phase 1 Data Gaps Evaluation Results,
PG&E Topock Compressor Station, Needles, California

Location ID	**Depths (ft bgs)**	**Description/Rationale**	**Analytes**	**Proposed Collection Methods**[a]
AOC14-14	0, 2, 5, 9, and 14	Evaluate newly identified potential burn area	Dioxin and furans	Rotosonic
AOC14-15	0, 2, 5, 9, and 14	To resolve data gaps #1, #2, and #3 - Define lateral and vertical extent of exceedences in southwestern corner and assess the newly identified potential burn area west of AOC14 and collect additional parameters to support CMS	Dioxin and furans, pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH , soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Rotosonic
AOC14-16	0, 2, 5, 9, and 14	To resolve data gap #2 - Assess the newly identified potential burn area west of AOC14	Dioxin and furans, pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-17	0, 2, 5, 9, and 14	To resolve data gap #2 - Assess the newly identified potential burn area west of AOC14	Dioxin and furans, pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-18	0	To resolve data gap #3 – To assess stained soil	Hexavalent chromium, PAHs, Title 22 metals, TPH, PCBs, dioxin and furans	Hand tools
AOC14-19	0	To resolve data gap #3 – To assess stained soil	Hexavalent chromium, PAHs, Title 22 metals, TPH, PCBs, dioxin and furans	Hand tools
AOC14-20	0	To resolve data gap #3 – To assess stained soil	Hexavalent chromium, PAHs, Title 22 metals, TPH, PCBs, dioxin and furans	Hand tools
AOC14-21	Bottom of trench	To resolve data gaps #3 and #4 – To define lateral and vertical extent of buried debris and collect additional parameters to support CMS	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH , soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Backhoe
AOC14-22	Bottom of trench	To resolve data gap #3 – To define lateral and vertical extent of buried debris near pilot study area	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Backhoe
AOC14-23	Bottom of trench	To resolve data gap #3 – To define lateral and vertical extent of buried debris near pilot study area	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Backhoe

TABLE C7-15
Proposed Phase 2 Soil Sampling Locations at AOC 14 – Railroad Debris Site
Soil Investigation Part A Phase 1 Data Gaps Evaluation Results,
PG&E Topock Compressor Station, Needles, California

Location ID	**Depths (ft bgs)**	**Description/Rationale**	**Analytes**	**Proposed Collection Methods**[a]
AOC14-24	Bottom of trench	To resolve data gaps #3 and #4– To define lateral and vertical extent of buried debris near pilot study area and collect additional parameters to support CMS	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Backhoe
AOC14-25	Bottom of trench	To resolve data gap #3 – To define lateral and vertical extent of buried debris near pilot study area	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Backhoe
AOC14-26 (contingent)	0, 2, 5, 9, and 14	To resolve data gap #3 – To define lateral and vertical extent of potential buried debris. Sample location is contingent upon geophysical survey and XRF results	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-27 (contingent)	0, 2, 5, 9, and 14	To resolve data gap #3 – To define lateral and vertical extent of potential buried debris. Sample location is contingent upon geophysical survey and XRF results	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-28 (contingent)	0, 2, 5, 9, and 14	To resolve data gap #3 – To define lateral and vertical extent of potential buried debris. Sample location is contingent upon geophysical survey and XRF results	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-29 (contingent)	0, 2, 5, 9, and 14	To resolve data gap #3 – To define lateral and vertical extent of potential buried debris. Sample location is contingent upon geophysical survey and XRF results	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-30 (contingent)	0, 2, 5, 9, and 14	To resolve data gap #3 – To define lateral and vertical extent of potential buried debris. Sample location is contingent upon geophysical survey and XRF results	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-31 (contingent)	0, 2, 5, 9, and 14	To resolve data gap #3 – To define lateral and vertical extent of potential buried debris. Sample location is contingent upon geophysical survey and XRF results	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-32 (contingent)	0, 2, 5, 9, and 14	To resolve data gap #3 – To define lateral and vertical extent of potential buried debris. Sample location is contingent upon geophysical survey and XRF results	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic
AOC14-33 (contingent)	0, 2, 5, 9, and 14	To resolve data gap #3 – To define lateral and vertical extent of potential buried debris. Sample location is	Pesticides, PAHs, VOCs, SVOCs, Title 22 metals, hexavalent chromium, PCBs, TPH, pH	Rotosonic

APPENDIX C8

Undesignated Area 1 Data Gaps Evaluation Results

1.0 Introduction and Background

This sub-appendix presents the results of the Data Gaps Evaluation for Undesignated Area (UA) 1 – Potential Pipeline Disposal Area at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. Analytical data have not been collected at UA 1; therefore, the process for the data gaps evaluation that is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report is not used to assess this area. This sub-appendix presents the background information regarding this area, including the geophysical survey that was conducted as part of the 2008 field activities, and proposed further investigation at this area.

2.0 Background

During site historical data gathering, a former employee identified an area just north of the gas pipeline road near the former evaporation ponds as a potential historical asbestos-containing material disposal site. The former employee described 20-foot lengths of asbestos-covered metal pipes as having been buried in a trench immediately north of the pipeline road, across from the northern boundary of the former pounds, shown on Figure C8-1 as UA-1.

During the 2008 field investigation, a geophysical survey was performed in UA 1 to evaluate the potential presence of buried asbestos-wrapped metal pipes in this area and to identify the location of underground utility infrastructure. Results of the geophysical survey did not suggest the presence of buried pipes in this area; however, several small metallic anomalies and two undifferentiated utilities (UUs) were observed sporadically across the UA 1 area. One UU was truncated in the north and extended out of the survey area in the south, and the other UU was located in the southern portion of the survey area trending east-west within the alignment of the access road adjacent to UA 1. The UU within the access road was identified as the former wastewater transference pipeline that transferred non-hazardous waste water from the compressor station to the evaporation ponds. This pipeline was abandoned in place in 2007 when it was replaced with a new transfer pipeline. The complete geophysical survey results are presented in Appendix B to the Data Gaps Evaluation Report.

Following the geophysical survey, further visual assessment of the area in the vicinity of UA 1 identified miscellaneous pipe band clamps and small quantities of insulation on the ground surface at a second location approximately 200 to 250 feet to the east of UA 1. A pronounced soil mound approximately 100 feet long by 25 feet wide was also observed in this area and is shown in Figure C8-1 as UA-1A.

During a follow-up interview with the same former employee in early 2011, the employee indicated that he did not remember the burial location with precision. He indicated that the original location, the second location described in the preceding paragraph, and a third location to the west of the originally identified location are all potential locations for the burial. The third locations is shown on Figure C8-1 as UA-1B. The employee indicated that the burial occurred in the 1970s or 1980s and his memory did not allow him to precisely determine which of the three locations are the most likely burial site. Therefore, PG&E intends to investigate all three potential areas identified by the former employee.

3.0 Historical Aerial Photographs Review of Undesignated Area 1 – Potential Pipe Disposal Area

As requested by the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) in a December 13, 2010 e-mail, PG&E performed a detailed historical aerial photograph analysis near UA-1 and the immediate surrounding area to determine/identify evidence of soil disturbances, including potential pipe disposal (Figure C8-1). All available and applicable historical aerial photographs which span from 1936 to 2004 were reviewed in detail. The date for one of the aerial photographs reviewed is not known with certainty, although it was taken after 1973 and before 1989. Additionally, aerial photographs from the late 1940s, 1947, 1951, 1957, 1960, 1966, 1970, 1973, 1976, 1981, 1983, 1995, 2001, 2005, and 2006 were also viewed but did not show UA-1 or the immediate vicinity; therefore, these aerial photographs are not discussed further in this document.

Table C8-1 presents a summary of the information observed in each of the applicable aerial photographs reviewed. The aerial photographs are presented in Figures C8-2 through C8-18. The approximate location of UA-1 is shown in these figures.

TABLE C8-1
Summary of Aerial Photographs, 1936 to 2004
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
PG&E Topock Compressor Station, Needles, California

Year	Description
1936, 1942, and 1944 (Figures C8-2, C8-3, and C8-4)	UA-1 and the surrounding area are undeveloped. An undeveloped desert road with a north-south orientation is located in the general area of UA-1 (see arrows in figures). No evidence of other constructed features or other soil disturbance is visible in UA-1 or surrounding area.
1953 (Figure C8-5)	The compressor station (built in 1951) is present in this aerial photograph (see arrow #1 in figure). The pipeline right-of-way (ROW) and road south of UA-1 is now visible (see arrow #2 in figure). There are several smaller roads/paths/turnaround loops stemming off the pipeline ROW (see arrow #3 in figure). What appears to be a small constructed structure is present north of the pipeline ROW (see arrow #4 in figure). Soil disturbance appears to be limited to ROW clearing and road construction.
1955 & 1956 (Figures C8-6 and C8-7)	The small constructed structure north of the pipeline ROW is no longer visible (see arrow in figures). No significant changes in manmade features or soil disturbance in UA-1 and the surrounding area can be seen between the 1953, 1955, and 1956 aerial photographs.

TABLE C8-1
Summary of Aerial Photographs, 1936 to 2004
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
PG&E Topock Compressor Station, Needles, California

Year	Description
1961 and 1962 (Figures C8-8 and C8-9)	A new pipeline ROW and/or pipeline road is visible to the north and parallel to the existing pipeline ROW (see arrow #1 in figures). Several access roads connecting the new pipeline ROW and the existing pipeline ROW are visible (see arrow #2 in figures). No evidence of other constructed features or other soil disturbance is visible in UA-1 or the surrounding area.
1964 (Figure C8-10)	Several white areas near the pipeline ROWs are visible in this photograph (see arrow #1 in figure). These white areas were not identified in the previous aerial photos, perhaps because those photos were overexposed. A black feature is visible to the south of the pipeline road (see arrow #2 in figure). No other changes can be seen between the 1961 and 1962 photographs and the 1964 photograph.
1967 (Figure C8-11)	No significant changes in manmade features or soil disturbance in UA-1 and the surrounding area can be seen between 1964 and 1967 photographs.
1969 (Figure C8-12)	The white areas near the pipeline ROWs are no longer visible in this photograph. No significant changes in constructed features or soil disturbance in UA-1 and the surrounding area can be seen between 1967 and 1969 photographs.
1975 (Figure C8-13)	The old evaporation ponds are visible south of the pipeline ROW (see arrow #1 in figure). No other changes in constructed features or soil disturbance in UA-1 and the surrounding area can be seen between 1969 and 1975 photographs.
Undated Photo: Sometime Between 1973 and 1989 (Figure C8-14)	What appears to be a constructed structure is visible south of the UA-1 area along the pipeline ROW (see arrow #1). The old evaporation ponds are visible south of the pipeline road (see arrow #2). Dark marks or shadows appear on a portion of the pipeline road to the east of the UA-1 area (see arrow #3).
1992, 1994, 1997, and 2004 (Figures C8-15, C8-16, C8-17, and C8-18)	The northern-most pipeline ROW was widened significantly (see arrow #1 in figures) for the installation of the new Mojave Gas Pipeline in 1992. The old and new evaporation ponds are visible south of the pipeline road (see arrows #2 and #3 in figures).

4.0 Proposed Further Investigation

Per the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) 2007 conditional approval and additional clarification in 2010, PG&E has expanded the potential work area, as shown in Figure C8-1. As directed by DTSC in the December 13, 2010 email, PG&E proposes to perform an additional geophysical survey at the original UA-1 location to further evaluate the two UUs observed in the original UA-1 area. In addition, PG&E proposes to conduct a geophysical survey in both of the new areas (UA-1A and UA-1B) identified during the latest interview with the former employee to attempt to verify the presence of the buried pipelines and their specific placement. If the geophysical surveys provide new information regarding the two UUs in the original UA-1 location or indicate the type of anomalies suggestive of buried metal piping in the UA-1 alternate locations, PG&E will present/discuss the information with agencies and stakeholders.

ATTACHMENT C9

Unidentified Area 2 Data Gaps Evaluation Results

1.0 Introduction and Background

This attachment presents the results of the Data Gaps Evaluation for Undesignated Area (UA) 2 – Former 300B Pipeline Liquids Tank Area at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the data gaps evaluation is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report.

1.1 Background

PG&E's 300B pipeline was formerly equipped with a 900-gallon-capacity aboveground drip tank. The 300B Pipeline Liquids Tank was formerly used to collect pipeline liquids from the 300B natural gas pipeline. The drip tank was located southeast of the plant on a shelf in the hill next to a section of old Route 66, as shown in Figure C9-1. (All tables and figures appear at the end of this attachment.) The tank was 2 feet, 10 inches in diameter and 20 feet long. It was an aboveground tank located on two concrete saddle supports. The tank pad was unpaved (CH2M HILL, 2006). In 1994, oil-stained soil was observed underneath and immediately adjacent to a portion of the tank, and an initial site investigation was performed on December 2, 1994. Samples were analyzed for total petroleum hydrocarbons in the motor-oil range (TPH-motor-oil). Low levels of TPH-motor-oil were detected at 1.2 and 2 feet below ground surface (bgs) (CH2M HILL, 2006). The tank was subsequently removed in 1995. One surface soil sample was collected on April 16, 1996 to characterize the stained soil for future disposal. The soil sample was analyzed for total recoverable petroleum hydrocarbons (TRPH), volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), and California Assessment Method 17 metals. TRPH was detected at an elevated concentration. Metals, VOCs, SVOCs, and PCBs were sampled at a location coincident with the highest level of TRPH, and analytical results indicated no elevated concentrations of these constituents; therefore, TRPH was considered the only constituent of concern.

A closure plan was submitted in May 1996 to remove the TRPH-impacted soil (Trident, 1996a). The cleanup was implemented and soil excavation was conducted between July 18, 1996 and September 26, 1996. Four rounds of excavation were performed, with a total excavation depth of 5.5 feet bgs. Confirmation samples were collected after each round of excavation. The cleanup target was 1,000 milligrams per kilogram (mg/kg) TRPH. Samples collected during the last two sampling events indicated that the soil remaining in place below and adjacent to the excavation contained TRPH at concentrations ranging from less than analytical detection limits to 150 mg/kg. The soil excavation and sampling results are documented in the Closure Certification Report (Trident, 1996b).

The County of San Bernardino, County Fire Department, Hazardous Materials Management Division issued a closure letter on June 9, 1997 confirming the completion of the site investigation and remedial action for the contaminated soil at this site.

The California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) requested additional sampling at this site. The area of potential contamination is small (20 feet by 40 feet). Based on DTSC's request, the Soil Part A Work Plan recommended further characterization at UA 2 (CH2M HILL, 2006).

A graphical conceptual site model has been developed for UA 2 based on the above site history and background and is shown in Figure C9-1. Table C9-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for UA 2. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the Soil Part A Data Quality Objective Tech Memo, included as Appendix A to the Data Gaps Evaluation Report.

The primary sources of contamination in UA 2 consisted of potential historic spills while filling or emptying the tank, and potentially historic leaks from the tank. Any constituents released would have been released in liquid form and released to surface soil. Surface soil is therefore the primary source medium. The majority of the affected soil has been removed, as documented by post-remediation confirmation sampling. Because the materials released in this area were pipeline liquids (i.e., primarily low-volatility hydrocarbons), they had limited migration potential; however, some contaminants could have infiltrated from surface soil into underlying shallow soil. Potential migration from subsurface soil to groundwater was identified as a potential secondary pathway. During extreme wet weather events, it is possible that some constituents may have been transported from the unit to the adjacent pipeline road in surface run-off. If released, VOCs in surface soils would be expected to have been degraded by heat and light and are likely no longer present.

Part A Phase 1 and historical soil samples were collected in the area in and around where the former aboveground storage tank had been located.

1.2 C9UA 2 Data

Historical sampling occurred at UA 2; however, the data are considered Category 3, which are not usable for site characterization or risk assessments. Historical sample location HDTP is shown on Figure 9-1. Historical sample location could not be located because previous reports do not provide a figure showing this location.

During the 2008 Part A Phase 1 Soil Investigation, 17 soil samples (from 0 to 0.5, 0.5 to 1, 2 to 3, and a few at 5 to 6 feet bgs) were collected from five sample locations (UA2-300B-1 through UA2-330B-5), as shown in Figure C9-2. Phase 1 soil samples collected in UA 2 were analyzed for Title 22 metals, hexavalent chromium, VOCs, SVOCs, polycyclic aromatic hydrocarbons (PAHs), TPH, pH, pesticides, and PCBs. Ten percent of the Phase 1 soil samples (two samples) were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL). Soil results were validated, and the data quality evaluation is included in Appendix D to the Data Gaps Evaluation Report.

All validated Phase 1 data are Category 1 and were used as inputs to the four data quality objectives decisions.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of chemicals of potential concern (COPCs) and chemicals of potential ecological concern (COPECs) at UA 2. Laboratory analytical results for Phase 1 soil samples at UA 2 are presented in Tables C9-2 through C9-7. Table C9-8 presents a statistical summary of soil analytical results for COPCs and COPECs that were either detected above the laboratory reporting limits or not detected but where the reporting limits for one more samples was greater than the interim screening value.

2.1 Summary of UA 2 Soil Data

Antimony, beryllium, cadmium, hexavalent chromium, mercury, selenium, silver, thallium, cyanide, TPH in the gasoline range (TPH-gasoline), pesticides, and PCBs were not detected in any soil samples collected in UA 2.

Table C9-8 lists the 28 constituents, including three calculated quantities (benzo(a)pyrene equivalents, total low molecular weight PAHs, and total high molecular weight PAHs) detected at UA 2. Seven of the detected constituents (aluminum, calcium, iron, magnesium, manganese, potassium, and sodium) were detected in the TAL/TCL samples.

Twenty-three of the 28 detected constituents (total chromium, cobalt, copper, molybdenum, nickel, vanadium, aluminum, calcium, iron, magnesium, potassium, sodium, 4-methylphenol, bis(2-ethylhexyl)phthalate, benzo(b)fluoranthene, benzo(g,h,i)perylene, chrysene, phenanthrene, total low molecular weight PAHs, total high molecular weight PAHs, benzo(a)pyrene equivalents, TPH in the diesel range [TPH-diesel], and TPH-motor-oil) were detected at concentrations below their respective interim screening levels. Five constituents (arsenic, barium, lead, manganese, and zinc) were detected one or more times at concentrations exceeding interim screening levels.

Arsenic and zinc were detected four or more times above their respective interim screening levels; the distribution of these constituents are shown in Figures C9-2 and C9-3.

2.2 Nature and Extent Evaluation

The following subsection discusses the nature and extent of detected COPCs and COPECs detected above interim screening levels at UA 2. As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Section 2.5 of this attachment summarizes the constituents that may require further evaluation, and Section 6.0 of this attachment provides the recommended follow-up sampling for the Part A Phase 2 soil investigation.

2.2.1 Arsenic

Arsenic was detected in 17 of 17 soil samples collected at UA 2. Detected concentrations of arsenic exceeded the interim screening level (11 mg/kg) (background threshold value

[BTV]) seven times (maximum concentration of 24 mg/kg at UA2-300B-1), as shown in Tables C9-2 and C9-8 and Figure C9-2. All seven of these detected concentrations of arsenic also exceeded the ecological comparison value (ECV) (11.4 mg/kg).

Although the site data set for arsenic appears to exceed background, the arsenic concentrations detected at UA 2 may represent a different background population from the sample population used to establish background comparison concentrations. UA 2 is located on bedrock, whereas the majority of the samples comprising the background data set were collected from alluvial material. The potential for the arsenic concentrations detected at this unit to represent background concentrations was evaluated statistically and visually via probability plots, see Section 2.4 of this attachment for more information.

The lateral and vertical extents of arsenic concentrations exceeding the interim screening level have been defined to natural boundaries (i.e., dirt road to the north, bedrock at 5.5 feet bgs, bedrock outcropping to the east and south, and steep slope to the west).

2.2.2 Barium

Barium was detected in 17 of 17 soil samples collected from UA 2. Detected concentrations of barium exceeded the interim screening level (410 mg/kg) (background value/ECV) twice (at UA2-300B-2 [520 mg/kg at 0.5 to 1 feet bgs and UA2-300B-3 [890 mg/kg at 5 to 6 feet bgs]), as shown in Tables C9-2 and C9-8. None of the detected concentrations exceeded residential and commercial/industrial DTSC California human health screening levels (CHHSLs) (5,200 mg/kg and 63,000 mg/kg, respectively). These locations are located along the northwestern boundaries of this area.

The lateral and vertical extents of the barium concentrations exceeding the interim screening level have been defined to natural boundaries (i.e., dirt road to the north, bedrock at 5.5 feet bgs, bedrock outcropping to the east and south, and steep slope to the west).

2.2.3 Lead

Lead was detected in 17 of 17 soil samples collected at UA 2. Detected concentrations of lead exceeded the interim screening level (8.39 mg/kg) (background value/ECV) once (13 mg/kg at UA2-300B-5), as shown in Tables C9-2 and C9-8. The detected concentration did not exceed the residential or commercial/industrial CHHSLs (80 mg/kg and 320 mg/kg, respectively). This location is surrounded by locations that have concentrations below the screening level. At these locations, the deepest samples have concentrations below the screening levels.

The lateral and vertical extents of the lead concentrations exceeding the interim screening level have been defined.

2.2.4 Zinc

Zinc was detected in 17 of 17 soil samples collected at UA 2. Detected concentrations of zinc exceeded the interim screening level (58 mg/kg) (BTV/ECV) 10 times (maximum detected concentration of 65 mg/kg at UA2-300B-3 and UA2-300B-5), as shown in Tables C9-2 and C9-8 and Figure C9-3. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively).

The lateral and vertical extents of zinc concentrations exceeding the interim screening level have been defined to natural boundaries (i.e., dirt road to the north, bedrock at 5.5 feet bgs, bedrock outcropping to the east and south, and steep slope to the west).

2.2.5 Target Analyte List/Target Compound List Constituents

As described above, aluminum, calcium, iron, magnesium, manganese, potassium, and sodium were detected in the two UA 2 soil samples analyzed for the complete TAL/TCL suite of compounds. Manganese is the only TAL/TCL constituent that was detected at concentrations exceeding its interim screening level in soil samples collected from UA 2.

Aluminum was detected in both surface soil samples collected from UA 2. Aluminum was detected at 11,000 mg/kg at both locations UA2-300B-1 and UA2-300B-5; this concentration is below the interim screening level (16,400 mg/kg) (BTV) as shown in Tables C9-3 and C9-8. The detected concentration did not exceed the residential or commercial/industrial CHHSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in both surface soil samples collected from UA 2. Detected concentrations of calcium (UA2-300B-1 [21,000 mg/kg] at 0 to 0.5 foot bgs and UA2-300B-5 [26,000 mg/kg] at 0 to 0.5 foot bgs) are below the interim screening level (66,500 mg/kg) (BTV), as shown in Tables C9-3 and C9-8. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium.

Iron was detected in both surface soil samples collected from UA 2. Detected concentrations of iron (UA2-300B-1 [20,000 mg/kg] at 0 to 0.5 foot bgs and UA2-300B-5 [27,000 mg/kg] at 0 to 0.5 foot bgs) are below the interim screening level (55,000 mg/kg) (residential regional screening level), as shown in Tables C9-3 and C9-8. A BTV and an ECV have not been established for iron.

Magnesium was detected in both surface soil samples collected from UA 2. Detected concentrations of magnesium (UA2-300B-1 [7,400 mg/kg] at 0 to 0.5 foot bgs and UA2-300B-5 [8,900 mg/kg] at 0 to 0.5 foot bgs) are below the interim screening level (12,100 mg/kg) (BTV), as shown in Tables C9-3 and C9-8. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium.

Manganese was detected in both surface samples collected from UA 2. Detected concentrations of manganese exceeded the interim screening level (402 mg/kg) (BTV/ECV) twice (UA2-300B-1 [670 mg/kg at 0 to 0.5 foot bgs] and UA2-300B-5 [840 mg/kg at 0 to 0.5 foot bgs), as shown in Tables C9-3 and C9-8. Neither of the detected concentrations exceeded residential and commercial/industrial CHHSLs (1,800 mg/kg and 23,000 mg/kg, respectively).

Potassium was detected in both surface soil samples collected from UA 2. Detected concentrations of potassium (UA2-300B-1 [2,900 mg/kg] at 0 to 0.5 foot bgs and UA2-300B-5 [2,400 mg/kg] at 0 to 0.5 foot bgs) are below the interim screening level (4,400 mg/kg) (BTV), as shown in Tables C9-3 and C9-8. Residential and commercial CHHSLs and an ECV have not been established for potassium.

Sodium was detected in both surface soil samples collected from UA 2. Detected concentrations of sodium (UA2-300B-1 [230 mg/kg] at 0 to 0.5 foot bgs and UA2-300B-5

[210 mg/kg] at 0 to 0.5 foot bgs) are below the interim screening level of 2,070 mg/kg (BTV), as shown in Tables C9-3 and C9-8. Residential and commercial/industrial CHHSLs, regional screening levels, and an ECV have not been established for sodium.

As discussed in Section C.2 of the main text of Appendix C, PG&E recommends that none of the inorganic compounds discussed above (aluminum, calcium, iron, magnesium, manganese, potassium, and sodium) be considered a COPC/COPEC for this area, and no further sampling is recommended for these constituents. These constituents have been fully discussed in Section C.2 of Appendix C.

2.3 Central Tendency Comparison to Background Values

Five metals (arsenic, barium, lead, manganese, and zinc) were detected above their respective background values in soil samples collected from UA 2. A central tendency comparison was performed for four of the five metals (arsenic, barium, lead, and zinc) to compare the UA 2 soil data set for these metals with the corresponding Topock soil background data set to determine whether a difference exists between the two populations and whether additional sampling is required for a given metal, as shown in Table C9-9 and Figure 3-1 of the Data Gaps Evaluation Report.

Metals in either the UA 2 data set or background data set that were detected infrequently (less than five detects) or had a limited number of results (less than eight) were not tested. There were insufficient detections of manganese at UA 2 to conduct the test.

Results from the Gehan test indicated that site concentrations for arsenic, barium, lead, and zinc may exceed background, as shown in Table C9-9. The lateral and vertical extents of arsenic, barium, lead, and zinc have been adequately defined, as discussed above. Physical limitations (i.e., bedrock, bedrock outcroppings, and roads) prevent further samples at UA 2 for arsenic. Barium was detected in two soil samples at concentrations exceeding the BTV (410 mg/kg). Lead was detected in one soil sample at a concentration exceeding the BTV (8.39 mg/kg). Zinc was detected in ten soil samples at concentrations exceeding the BTV (58 mg/kg); however, the maximum detected concentration (65 mg/kg) only exceeds the BTV slightly.

After careful review of UA 2 site data and background data set for arsenic, barium, lead, and zinc, the difference between the two populations and concentrations detected is not considered substantial enough to warrant additional sampling at UA 2, especially in consideration of the physical limitations and characteristics of the site. Further evaluation of the arsenic data is provided in Section 2.4, below.

2.4 Arsenic Concentrations Background Assessment

Although the site data set for arsenic appears to exceed background, the arsenic concentrations detected at UA 2 may represent a different background population from the sample population used to establish background comparison concentrations. UA 2 is located on bedrock, whereas the majority of the samples comprising the background data set were collected from alluvial material. The potential for the arsenic concentrations detected at this unit to represent background concentrations was evaluated statistically and visually via probability plots. The distribution of detected arsenic concentrations at UA 2 is consistent with a single population or background data set.

As discussed in Section 2.2.1, arsenic was detected in all 17 samples collected from UA 2, and seven of the detected concentrations exceed the BTV developed for Topock. A probability plot was constructed for the arsenic data from UA 2 to evaluate the distribution of the data. Probability plots provide a visual tool for identifying possible inflections or breakpoints in the data set. They graph actual concentrations against theoretical quantiles of the potential true distribution of the data. Inflections or breakpoints may serve as evidence that multiple populations appear in the data, which could be consistent with the presence of some site-impacted concentrations along with some un-impacted (potential background) concentrations. The distribution of arsenic concentrations for UA 2 is a relatively smooth curve consistent with a true normal distribution of the data, as shown in Figure C9-4.[1] There are no breakpoints or inflections suggestive of two separate populations of arsenic concentrations (i.e., a background concentrations and an elevated site-related concentration).

One needs to temper expectations of how straight the line for a normal distribution will be with typical sample sizes. Relatively small jumps or steps in the data set are often a part of random variability. One should also be careful not to associate the natural horizontal widening of points in the lower and upper tails of the data distribution with the determination of a breakpoint or the identification of outliers. This can be seen in the 12 randomly-generated example plots using data generated from a true normal 100-point distribution with sample size of 17, as shown in Figure C9-4. As can be seen from comparing the 12 example plots with the UA 2 data presented in Figure C9-5, the randomly-generated true normal distributions are similar in appearance to the plot of the site data. While the above analysis does not conclusively demonstrate that the detected concentrations of arsenic are, in fact, representative of a site-specific background, it does indicate that the interpretation that these concentrations represent site background concentrations is consistent with the distribution of the data.

2.5 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review indicates that decision error has been held to an acceptable level. Sufficient data of acceptable quality have been attained through collection of historical and Part A soil samples in areas most likely to have been impacted by the former aboveground storage tank.

Based on the review of the data for UA 2, the nature and extent of all detected COPCs and COPECs have been defined, and no follow-up sampling is recommended for Phase 2.

3.0 Decision 2 – Data Sufficient to Estimate Representative Exposure Point Concentrations

For Decision 2, data were evaluated to determine if the UA2-300B data are sufficient to conduct human health and ecological risk assessments based on the criteria described in Section 4.0 of the Data Gaps Evaluation Report. The principal consideration for Decision 2

---

[1] Often, the chosen distribution is the normal distribution even though it is not a certainty that the true distribution is either normal or any other given distribution. Other distributions can be considered.

was whether there were sufficient data to estimate a representative exposure point concentration (EPC). Data reviewed were validated Phase 1 data.

Table C9-10 summarizes the results of the evaluation to determine whether data are sufficient to estimate a representative EPC. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value. In general, existing data are adequate to support EPC development for detected chemicals that exceeded one or more comparison values (arsenic, barium, lead, zinc, and manganese).

In the shallowest exposure interval (0.0 to 0.5 foot bgs), there were five samples and five detected concentrations for metals. While this is insufficient to calculate an EPC using ProUCL, the maximum concentration is low (i.e., does not exceed two times the lowest comparison value). Therefore, using the maximum result as the EPC is not expected to significantly impact the results of the risk assessment. Further, as previously described in Sections 2.2.1 and 2.3, although arsenic was detected above the BTV (11 mg/kg), a separate statistical evaluation was conducted, examining the distribution of arsenic specific to the UA2-300B area, which supports that the arsenic detected in this area is reflective of background conditions. Accordingly, additional samples for arsenic in the 0- to 0.5-foot interval will not affect the results of the risk assessment.

For manganese, there are only two samples, and the maximum value is slightly greater than two times the BTV, which is the applicable comparison value. (The ECV [220 mg/kg] is less than the BTV.) Using the maximum detected concentration of 840 mg/kg as the EPC rather than collecting additional samples to increase the data set is not expected to significantly change the outcome of the ecological risk assessment. This is because the additional sampling is not expected to provide very different results; there is no known source of manganese at UA 2. There is no information to indicate that manganese was associated with the operation of the 300B pipeline or aboveground drip tank.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

The following preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, are needed to resolve Decision 3. Additional evaluation will be performed as appropriate, as data are collected to resolve Decision 1. Data collected to satisfy Decision 1 – Nature and Extent evaluation will provide the final representative data set that will be used to assess the threat to groundwater.

Table C9-11 presents the results of the tiered screening analysis for UA 2. Four metals had concentrations in excess of their respective BTVs. None of these metals exceeded the calculated soil screening level, as shown in Table C9-12; therefore, numerical modeling was not required for UA 2, and a current or potential threat to groundwater has been ruled out.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Gaps Evaluation Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study (CMS/FS). The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fence line include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite).
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil washing technologies).
- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies).
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- If present, volumes of white powder and debris.

The following is a summary of data for UA 2 that are currently available to support CMS/FS.

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. The lateral and vertical extent of the COPCs and COPECs is discussed in Section 2.2 above. Data results for selected constituents are shown in Figures C9-2 and C9-3, and data gaps associated with lateral and vertical delineation are discussed in Section 6.0 of the Data Gaps Evaluation Report.

5.2 Waste Characterization Parameters

Only partial waste characterization data are available to characterize the soil and other materials to be potentially removed for remedial action and disposed in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations (TTLCs). The maximum concentrations of these metals for each of the units were compared to the TTLCs, and none of the metal concentrations exceeded the TTLCs, as shown in Table C9-13. The maximum detected concentrations were also compared to the soluble threshold limit concentrations (STLCs), and none of the metal concentrations in UA 2 exceeded 10 times STLC, as shown in Table C9-13. In addition, none of the concentrations exceeded 20 times TCLP, as shown in Table C9-13. Because none of the metals concentrations has the potential to exceed STLC or TCLP thresholds, additional leachability testing is not required if soil excavation and offsite disposal is chosen as a remedy.

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 soil investigation were limited to grain size analysis only. Specific soil physical properties data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 in the Data Gaps Evaluation Report. Additional soil physical parameter data are needed to support the CMS/FS.

5.4 Surface and Subsurface Features.

While there is extensive information regarding surface and subsurface features at UA 2, additional information may be required once areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are known for UA 2. However, subsurface utilities, including gas transmission pipelines and any other features, may have to be more precisely defined to evaluate the feasibility and cost of certain remedial alternatives and to prepare construction specifications.

6.0 Summary of Data Gaps and Potential Phase 2 Soil Sample Locations to Fill Identified Gaps

Based on the review of the data for UA 2, the nature and extent of all detected COPCs and COPECs has been defined, and no further sampling is required to address data quality objective Decisions 2 and 3. Data regarding soil physical properties will be collected at units where additional samples are required to address data gaps for Decisions 1, 2, and/or 3. The remaining data required to address Decision 4 data gaps will be collected following the completion of the risk assessment. No additional sampling is recommended in the Part A Phase 2 Soil Investigation.

Tables

TABLE C9-1
Conceptual Site Model – UA 2
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California

Primary Source	Primary Source Media	Potential Release Mechanism	Secondary Source Media	Potential Secondary Release Mechanism
Incidental leaks or spills from former aboveground storage tank	Surface Soil	Percolation and/or infiltration	Surface Soil	Wind erosion and atmospheric dispersion of surface soil
			Subsurface Soil	Potential volatilization and atmospheric dispersion/enclosed space accumulation
			Potential Groundwater	Potential extracted groundwater[a]

[a] Quantitative evaluation of the groundwater pathway completed in the groundwater risk assessment (ARCADIS, 2009); Part A Phase 1 data will be reviewed in the data gaps assessment to evaluate potential fate impacts or current localized impacts to groundwater from soil.

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

TABLE C9-8

Constitiuent Concentrations in Soil Compared to Screening Values
UA 2 - Former 300B Pipeline Liquids Tank Area
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

Notes:

[1] CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

[2] ARCADIS. 2008. "Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil." May 28. ARCADIS. 2009. "Topock Compression Station - Final Technical Memorandum 4: Ecological Comparison Values for Additional Detected Chemicals in Soil" July 1

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

TABLE C9-10

Decision 2 Data Gaps Summary - UA 2

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

	Adequate EPC?		Maximum Detected Value	> HHCV or Background as Applicable? ^{1}	> ECV or Background as Applicable? ^{1}	Proposed Sample ID	Notes
Compound/Depth	Y or N	Det/# results		Y or N	Y or N		
Metals							
Arsenic				**11 mg/kg (bckg)**	**11.4 mg/kg**		
0-0.5 ft bgs	N	5 of 5	14 mg/kg	Y	Y	None	Compound exceeds HHCV and ECV. Existing data adequate for EPC with the exception of the 0-0.5 ft bgs exposure interval. Arsenic is believe to be within local background in bedrock for this area as discussed in Sections 2.3 and 2.4 of the text.
0-3 ft bgs	Y	15 of 15	24 mg/kg	Y	Y		
0-6 ft bgs	Y	17 of 17	24 mg/kg	Y	Y		
0-10 ft bgs	Y	17 of 17	24 mg/kg	Y	NA		
Barium				**5200 mg/kg**	**410 mg/kg (bckg)**		
0-0.5 ft bgs	N	5 of 5	290 mg/kg	N	N	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	15 of 15	520 mg/kg	N	Y		
0-6 ft bgs	Y	17 of 17	890 mg/kg	N	Y		
0-10 ft bgs	Y	17 of 17	890 mg/kg	N	NA		
Lead				**80 mg/kg**	**8.39 mg/kg (bckg)**		
0-0.5 ft bgs	N	5 of 5	13 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC with the exception of the 0-0.5 ft bgs exposure interval. While this is insufficient to calculate an EPC using ProUCL for this exposure interval, the maximum concentration is low (i.e., does not exceed two times the lowest comparison value). Therefore, using the maximum result as the EPC is not expected to significantly impact the results of the risk assessment.
0-3 ft bgs	Y	15 of 15	13 mg/kg	N	Y		
0-6 ft bgs	Y	17 of 17	13 mg/kg	N	Y		
0-10 ft bgs	Y	17 of 17	13 mg/kg	N	NA		
Zinc				**23000 mg/kg**	**58 mg/kg (bckg)**		
0-0.5 ft bgs	N	5 of 5	62 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC with the exception of the 0-0.5 ft bgs exposure interval. While this is insufficient to calculate an EPC using ProUCL for this exposure interval, the maximum concentration is low (i.e., does not exceed two times the lowest comparison value). Therefore, using the maximum result as the EPC is not expected to significantly impact the results of the risk assessment.
0-3 ft bgs	Y	15 of 15	65 mg/kg	N	Y		
0-6 ft bgs	Y	17 of 17	65 mg/kg	N	Y		
0-10 ft bgs	Y	17 of 17	65 mg/kg	N	NA		

TABLE C9-10

Decision 2 Data Gaps Summary - UA 2
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth	Adequate EPC?		Maximum Detected Value	> HHCV or Background as Applicable? [1]	> ECV or Background as Applicable? [1]	Proposed Sample ID	Notes
	Y or N	Det/# results		Y or N	Y or N		
Contract Laboratory Program Inorganics							
Manganese				**1800 mg/kg**	**402 mg/kg (bckg)**		
0-0.5 ft bgs	N	2 of 2	840 mg/kg	N	Y	None	Compound exceeds ECV. The small dataset of 2 samples would result in using the maximum concentration, which is approximately two times background, as the EPC for the ERA. Additional sampling is not expected to significantly change the EPC or the outcome of the ERA because manganese at UA2-300B is believed to be naturally occurring; there is no information to indicate that manganese was associated with the operation of the 300B pipeline or above-ground drip tank.
0-3 ft bgs	N	2 of 2	840 mg/kg	N	Y		
0-6 ft bgs	N	2 of 2	840 mg/kg	N	Y		
0-10 ft bgs	N	2 of 2	840 mg/kg	N	NA		

Footnotes:

[1] The higher value of either the HHCV/ECV or background was selected as the screening criteria and are included in these columns for the respective compound in **BOLDED BLUE FONT**. Values based on background are indicated with "(bckg)" next to the value.

Acronyms and Abbreviations:

ECV - ecological comparison values
EPC - exposure point concentration
ERA - ecological risk assessment
ft bgs - feet below ground surface
HHCV - human health comparison values
mg/kg - milligrams per kilogram
N - no
NA - not applicable
Y - yes

TABLE C9-11

Acronyms and Abbreviations

µg/kg	micrograms per kilogram
AOC	Area of Concern
bgs	below ground surface
BTV	background threshold value
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
CHHSL	California human health screening level
COPC	chemical of potential concern
COPEC	chemical of potential ecological concern
CMS/FS	corrective measures study/feasibility study
DOI	United States Department of the Interior
DQO	data quality objective
ECV	ecological comparison value
EPC	exposure point concentration
mg/kg	milligrams per kilogram
ng/kg	nanograms per kilogram
PAH	polycyclic aromatic hydrocarbon
PCB	polychlorinated biphenyl
PG&E	Pacific Gas and Electric Company
RCRA	Resource Conservation and Recovery Act
RFI/RI	RCRA facility investigation/remedial investigation
RSL	regional screening level
SPLP	synthetic precipitation leaching procedure
STLC	soluble threshold limit concentrations
TEQ	toxicity equivalent quotient
TAL	Target Analyte List
TCL	Target Compound List
TCRA	time-critical removal action
TTLC	total threshold limit concentrations

TCLP	toxicity characteristic leaching procedure
VOC	volatile organic compound

APPENDIX C10

Area of Concern 4 Data Gaps Evaluation Results

1.0 Introduction and Background

This attachment presents the results of the data gaps evaluation for Area of Concern (AOC) 4 – Debris Ravine at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the data gaps evaluation is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report.

1.1 Background

AOC 4 is located in the southern portion of the Topock Compressor Station immediately south of the facility fence line and is shown in Figure C10-1. AOC 4 is a narrow, steep-sided arroyo that drains into the Bat Cave Wash at the southwest corner of the compressor station. It is a ravine which drains into the Bat Cave Wash. AOC 4 is located on PG&E property, except for a small portion of the westernmost end that extends onto Havasu National Wildlife Refuge. The Refuge is managed by the United States Fish and Wildlife Services. Laterally, AOC 4 extends from the point directly south of the water tanks to the junction with Bat Cave Wash and then from the north slope of the ravine to directly south from the end of a small access road and west to the west side of the storage area. The operational history at AOC 4 is not well documented; however, over the years, fill material and debris have been deposited over the northern and eastern slopes, with some debris accumulating in the bottom of the ravine. It appears that burning of trash occurred within AOC 4. Chemicals of potential concern (COPCs) and chemicals of potential ecological concern (COPECs) for AOC 4 identified in the *Revised Final RCRA Facility Investigation and Remedial Investigation Report. Volume 1 – Site Background and History* (CH2M HILL, 2007) (RFI/RI) Volume 1 include Title 22 metals, hexavalent chromium, polycyclic aromatic hydrocarbons (PAHs), and asbestos. Subsequent to the RFI/RI, dioxins and polychlorinated biphenyls (PCBs) were identified in additional debris samples from AOC 4 and have been identified as COPCs and COPECs.

In June 2009, the United States Department of the Interior (DOI) issued an Action Memorandum Time-critical Removal Action (TCRA) at the AOC 4 - Debris Ravine, at the Topock Compressor Station (DOI, 2009) and directed PG&E to initiate activities necessary to implement and perform TCRA actions at AOC 4. The history of previous investigations and Agency direction leading up to the AOC 4 are described in the approved *Final Work Plan for Time-Critical Removal Action at AOC 4 Debris Ravine, PG&E Topock Compressor Station, Needles, California* (Alisto et al., 2009), hereafter referred to as the Final TCRA Work Plan.

The TCRA was conducted in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and, as an interim remedial action, was intended to stabilize and mitigate the threat of release of contaminated material. The TCRA interim action was not intended as a substitute for additional investigative or remedial activities that may be required under the Resource Conservation and Recovery Act (RCRA) or be the final remedy for AOC 4. An implementation report (Alisto et al., 2011) for the TCRA at AOC 4 has been prepared to document the field work and present the results of the field activities for the project. The conclusions of the TCRA at AOC 4 are summarized below.

The TCRA objectives were met by the removal action. Removal was conducted in safely accessible areas of AOC 4. The excavation, screening, and confirmation approach followed the Final TCRA Work Plan, including the quality criteria established in the data quality objectives (DQO) and quality assurance program addendum. For areas on PG&E property, the TCRA target end point concentrations (TECs) were based on commercial/industrial CHHSL and/or RSLs. In order to comply with the stated intent and objectives of the AOC 4 TCRA, the TECs for native alluvial material were based on ten times the commercial/industrial CHHSL and/or RSLs. This reduced the amount of native alluvium to be removed, but also removed material that may have presented an imminent and substantial endangerment to public health, or welfare or the environment. Table C10-1 presents the TCRA TECs for native and non-native material, as well as the Part A RFI/RI interim screening levels. For areas of AOC 4 on Havasu National Wildlife Refuge property, the target endpoints for the removal are background levels for metals and ecological comparison values (ECVs) for organics, which align with the Part A RFI/RI interim screening levels.

Based on the confirmation data set and installation of erosion control measures, the potential threat of release of contaminated material from AOC 4 has been stabilized and mitigated. AOC 4 confirmation soil data has been carried forward to the RFI process and will be used in this data gaps evaluation to identify potential data gaps.

Additional post-construction activities are ongoing at this AOC and include inspection and maintenance of SoilTac soil stabilization and the gabion at the downstream end of the Debris Ravine. SoilTac soil stabilizer will be reapplied as necessary, based on inspections. Slopes in the former debris ravine are generally stable and resistant to erosion. Inspection will also include examining steep slopes in native alluvium for indications of slope movement or instability. Run-on controls were left in place above the upper slope. Also above the upper slope, concrete barriers were installed to keep Topock Compressor Station personnel activities at a safe distance from steeper areas of the slope.

The check dam and the gabion below the slot canyon will be maintained under a periodic inspection program, with special attention to pre- and post-rainfall inspections. Soil that accumulates above the dam or the gabion after rainfall events may be removed.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 4 based on the above site history and background, as shown in Figure C10-2. Table C10-2 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 4. The conceptual site model represents conditions prior to the TCRA at AOC 4. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the *Data Quality Objectives – Part A Soil Investigation at the Pacific Gas and Electric Company Topock Compressor*

Station, Needles, California (CH2M HILL, 2010), which is included as Appendix A to the Data Gaps Evaluation Report.

The primary sources of contamination at AOC 4 are disposal of debris (including asbestos-containing material) and residuals from burning of compressor station waste. The primary release mechanisms are direct releases of contaminated particulates or leaching of contaminants from the debris and/or burned material. Contaminants present in these materials could have been deposited on surface soil as particulates or entered surface soil as dissolved constituents through infiltration of rainfall. Because some material is buried, constituents could also have affected shallow and subsurface soils in the immediate vicinity of the debris and/or residual burned material. Contaminants released from debris located on the slopes of AOC 4 could also have been transported to the lower portions of the unit and eventually into Bat Cave Wash through surface runoff. Primary source media therefore consist of surface, and subsurface soils. Contaminants could have leached from surface soils and shallow soil into underlying deeper soils. Potential migration from subsurface soil to groundwater was identified as a potential secondary pathway. If released, volatile organic compounds (VOCs) in surface soils would be expected to have been degraded by heat and light and are likely no longer present.

Windblown dust contamination from small particles of debris or contaminated surface soil within AOC 4 is a potential secondary release mechanism. Windblown contamination, if any, is expected to be limited to surface soils. Surface runoff from AOC 4 to Bat Cave Wash could also have transported COPCs/COPECs in surface soil or small pieces of debris from AOC 4 to Bat Cave Wash.

1.3 AOC 4 Data

One-hundred and sixteen confirmation surface soil samples and three gabion surface soil samples (AOC4-GB10, AOC4-GB11, and AOC4-GB12) were collected to represent soil conditions upon completion of the TCRA, as shown in Figure C10-3. The confirmation and gabion surface soil samples were analyzed for Title 22 metals, mercury, hexavalent chromium, semivolatile organic compounds, PCBs, and dioxins/furans analyses.

In addition, three soil samples collected from one location (AOC4-1) were collected during the 2008 Soil Part A Phase 1 investigation are still representative of existing site conditions. The samples were collected at sample depth 0 to 0.5, 0.5 to 1, and 2 to 3 feet below ground surface (bgs). Samples at this location were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL), including Title 22 metals, hexavalent chromium, VOCs, semivolatile organic compounds, PAHs, total petroleum hydrocarbons, pH, pesticides, and PCBs. The soil samples collected between 0 and 1 foot bgs were not analyzed for VOCs.

All TCRA and Part A Phase 1 data are considered Category 1 and can be used as inputs to the four DQO decisions for Solid Waste Management Unit 1.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of COPCs and COPECs at AOC 4. Laboratory analytical results for AOC 4 are presented in Tables C10-3 through C10-9. Table C10-10 presents a statistical summary of soil analytical results for

COPCs and COPECs that were either detected above laboratory reporting limits or not detected and reporting limits for one or more samples were greater than the interim screening value. The soil data are discussed first, followed by the data for the white powder sample.

Beryllium, selenium, silver, molybdenum, cyanide, and thallium were not detected in soil samples collected in AOC 4. Table C10-10 lists the 58 detected constituents.

Twenty-five constituents were detected one or more times at concentrations exceeding their respective interim screening levels: antimony, barium, cadmium, total chromium, hexavalent chromium, cobalt, copper, lead, mercury, nickel, vanadium, zinc, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, indeno(1,2,3-cd)pyrene, total high molecular weight PAHs, benzo(a)pyrene equivalents, Aroclor 1254, Aroclor 1260, total PCBs, dioxins TEQ (toxicity equivalent quotient), dioxin TEQ Avian, and dioxin TEQ Mammals.

Twenty constituents (barium, total chromium, hexavalent chromium, cobalt, copper, lead, mercury, nickel, vanadium, zinc, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, PAH high molecular weight, benzo(a)pyrene equivalents, Aroclor 1254, total PCBs, dioxin TEQ, dioxin TEQ Avian, and dioxin TEQ Mammals) were detected at concentrations exceeding the interim screening level four or more times; the distribution of these constituents are shown in Figures C10-3 through C10-17, with the exception of benzo(a)anthracene, benzo(a)pyrene, and benzo(b)fluoranthene, which are being evaluated by benzo(a)pyrene equivalents and PAH high molecular weight figures.

2.1 Nature and Extent Evaluation for Soil

The following subsection discusses the nature and extent of detected COPCs and COPECs detected above interim screening levels at AOC 4. As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Section 2.3 of this sub-appendix summarizes the constituents that may require further evaluation, and Section 6.0 of this sub-appendix provides the recommended follow-up sampling for the Part A Phase 2 soil investigation. The potential Phase 2 sample locations are PG&E's initial assessment of candidate locations for additional characterization. These locations represent sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation. PG&E anticipates that all candidate locations identified may not be necessary for such purposes.

During the TCRA at AOC 4, bedrock was exposed in much of the southeast portion of AOC 4; no further vertical delineation is possible in this area. Vertical delineation is also limited by bedrock in many of the areas at AOC-4.

2.1.1 Antimony

Antimony was detected in three of 122 soil samples collected at AOC 4. Detected concentrations of antimony exceeded the interim screening level (0.285 milligrams per kilogram [mg/kg]) ECV) three times (maximum detected concentration of 2.7 mg/kg at AOC4-K05), as shown in Table C10-3. No samples of the detected concentrations of antimony exceeded the California human health screening level (CHHSL) for residential use

(30 mg/kg) or the commercial/industrial regional screening level (380 mg/kg). The lateral and vertical extents of antimony exceeding the interim screening level have been defined.

2.1.2 Arsenic

Arsenic was detected in 30 of 122 soil samples collected at AOC 4. Detected concentrations of arsenic did not exceed the interim screening level (11 mg/kg; background threshold value [BTV]/CHHSL for residential and commercial use), as shown in Table C10-3. No samples of the detected concentrations of arsenic exceeded the ECV of 11.4 mg/kg. The lateral and vertical extents of arsenic have been defined.

2.1.3 Barium

Barium was detected in 122 of 122 soil samples collected at AOC 4. Detected concentrations of barium exceeded the interim screening level (410 mg/kg; BTV)/ECV) 13 times (maximum detected concentration of 1,300 mg/kg at AOC4-B03), as shown in Tables C10-3 and C10-10 and Figure C10-3. No samples of the detected concentrations of barium exceeded the CHHSL for residential use (5,200 mg/kg) or the commercial/industrial regional screening level (63,000 mg/kg). The lateral and vertical extents of barium exceeding the interim screening level have been defined.

2.1.4 Cadmium

Cadmium was detected in three of 122 soil samples collected at AOC 4. Detected concentrations of barium exceeded the interim screening level (1.1 mg/kg; BTV/ECV) twice (with a maximum detected concentration of 1.7 mg/kg at AOC4-B03), as shown in Tables C10-3 and C10-10. No samples of the detected concentrations of cadmium exceeded the CHHSL for residential use (39 mg/kg) or the commercial/industrial regional screening level (500 mg/kg). The lateral and vertical extents of cadmium exceeding the interim screening level have been defined.

2.1.5 Total Chromium

Total chromium was detected in 123 of 123 soil samples collected at AOC 4. Detected concentrations of total chromium exceeded the interim screening level (39.8 mg/kg (BTV/ECV) 59 times (maximum detected concentration of 160 mg/kg at AOC4-D04), as shown in Tables C10-3 and C10-10 and Figure C10-4. No samples of the detected concentrations of total chromium exceeded the residential screening level (RSL) for residential use (280 mg/kg) or the commercial/industrial regional screening level (1,400 mg/kg). The lateral extent of concentrations exceeding the interim screening level show are scattered throughout the AOC. The lateral extent of chromium concentrations exceeding the interim screening level has not been defined in most of the AOC; however, topographic conditions (steep slopes) prevent additional sampling to the west and south. With the exception of a few detections slightly above the BTV, the lateral extent of total chromium in the flat area adjacent to the compressor station, in the northern part of the AOC, has been defined. The vertical extent of total chromium concentrations has not been defined across much of the AOC. Based on the shallow depth to bedrock across most of AOC 4, additional sampling for delineating vertical extent is limited to the northern portion of AOC, where bedrock is not near the surface.

2.1.6 Hexavalent Chromium

Hexavalent chromium was detected in 25 of 122 soil samples collected at AOC 4. Detected concentrations of hexavalent chromium exceeded the interim screening level (0.83 mg/kg BTV) 15 times (maximum detected concentration of 16 mg/kg at AOC4-K05), as shown in Tables C10-3 and C10-10 and Figure C10-5. None of the detected concentrations of hexavalent chromium exceeded the residential screening level (CHHSL) of 17 mg/kg, the commercial/industrial CHHSL of 37 mg/kg, or the ECV (139.6 mg/kg). Lateral extent of hexavalent chromium concentrations above interim screening levels has largely been defined, although two samples (AOC4-P04 and AOC4_Q04) in the northwest area of the AOC have not been bound to the north, and two samples (AOC4-J06_J07 and AOC4-M10) in the bottom of the ravine are bounded by topography. Vertical delineation is also incomplete in several locations, especially near the west center and at the eastern boundary; however, given the shallow depth to bedrock in these areas, additional sampling is not recommended to delineate vertical extent.

2.1.7 Cobalt

Cobalt was detected in 123 of 123 soil samples collected at AOC 4. Detected concentrations of cobalt exceeded the interim screening level (12.7 mg/kg) (BTV) 19 times (maximum detected concentration of 20 mg/kg at AOC4-D03), as shown in Tables C10-3 and C10-10 and Figure C10-6. Ten samples exceeded the ECV (13 mg/kg). None of the detected concentrations exceeded residential or commercial/industrial CHHSLs (23 mg/kg and 300 mg/kg, respectively). Remaining detected concentrations exceeding the interim screening level ranged from 13 to 20 mg/kg. Lateral extent of cobalt concentrations above interim screening levels have largely been defined, although four samples (AOC4-B-06_07, AOC4-C06_07, AOC4-J06_J07, and AOC4-L07_L08) in the bottom of the ravine have not been bounded to the south, and three locations (AOC4-K02, AOC4-L01, and AOC4-L02) near the top center of the AOC have not been bounded to the east. However, these values are very close to the BTV and adjacent to the access road to the water tanks. Vertical delineation is also incomplete in several locations; however, given the shallow depth to bedrock in the area of exceedances, additional sampling is not recommended to delineate vertical extent.

2.1.8 Copper

Copper was detected in 123 of 123 soil samples collected at AOC 4. Detected concentrations of copper exceeded the interim screening level (16.8 mg/kg) (BTV) 54 times (maximum detected concentration of 790 mg/kg at AOC4-B03), as shown in Tables C10-3 and C10-10 and Figure C10-7. Forty-two samples exceeded the ECV (20.6 mg/kg). None of the detected concentrations exceeded residential or commercial/industrial CHHSLs (3,000 mg/kg and 38,000 mg/kg, respectively). Remaining detected concentrations exceeding the interim screening level ranged from 17 to 210 mg/kg. The lateral extent of copper concentrations exceeding the interim screening level has been defined in the northern portion of the AOC. The lateral extent of copper is undefined to the south, east, and west; however, topographic conditions (steep slopes) prevent additional sampling to the west and south. Additional sampling is recommended in the southeastern corner of the AOC and along the upper access road. The vertical extent of copper concentrations has also not been defined; however, given the shallow depth to bedrock in areas of exceedances, additional sampling is not recommended to delineate vertical extent.

2.1.9 Lead

Lead was detected in 122 of 123 soil samples collected at AOC 4. Detected concentrations of lead exceeded the interim screening level (8.39 mg/kg) (BTV/ECV) 24 times (maximum detected concentration of 220 mg/kg at AOC4-B03), as shown in Tables C10-3 and C10-10 and Figure C10-8. Two of the detected concentrations exceeded the residential CHHSL and no detected concentrations exceeded the commercial/industrial CHHSL (80 mg/kg and 320 mg/kg, respectively). The lateral extent of lead concentrations above interim screening levels has largely been defined. The vertical extent of lead concentrations has also not been defined; however, based on the shallow depth to bedrock across most of AOC 4, additional sampling for delineating vertical extent is limited to the northern portion of AOC, where bedrock is not near the surface.

2.1.10 Mercury

Mercury was detected in five of 122 samples collected at AOC 4. Detected concentrations of mercury exceeded the interim screening level (0.0125 mg/kg; ECV) five times (maximum detected concentration of 0.52 mg/kg at AOC4-B03), as shown in Tables C10-3 and C10-10 and Figure C10-9. None of the detected concentrations exceeded the residential and commercial/industrial CHHSLs (18 mg/kg and 180 mg/kg, respectively). The ECV of 0.0125 mg/kg is below the capability of the instrumentation to detect mercury. As a result, the non-detected sample results had reporting limits that exceeded the ECV. These reporting limits ranged from 0.098 to 0.11 mg/kg. The five sample locations with detectable concentrations of mercury are surrounded by samples with non-detect concentrations. While the precise extent of mercury concentrations above the ECV cannot be determined with the available data, further investigation is unlikely to yield more usable data. The detected mercury concentrations are also collocated with other locations with metals concentrations above background. The uncertainties with regard to mercury will be addressed in the risk assessment and corrective measures study/feasibility study (CMS/FS).

2.1.11 Nickel

Nickel was detected in 122 of 122 soil samples collected from AOC 4. As shown in Tables C10-3 and C10-10 and Figure C10-10, detected concentrations exceeded the interim screening level (27.3 mg/kg) (BTV/ECV) 52 times (maximum detected concentration of 75 mg/kg at AOC4-D02). There were no exceedances of the residential and commercial/industrial CHHSLs (1,600 mg/kg and 16,000 mg/kg, respectively). The lateral extent of nickel concentrations exceeding the interim screening level has been defined in the south and southeastern corner of the AOC. Topographic conditions (steep slopes) prevent additional sampling to the west and south, and the compressor station is immediately to the north of the AOC. The vertical extent of nickel concentrations has not been defined. Based on the shallow depth to bedrock across most of AOC 4, additional sampling for delineating vertical extent is limited to the northern portion of AOC, where bedrock is not near the surface.

2.1.12 Vanadium

Vanadium was detected in 122 of 122 soil samples collected at AOC 4. Detected concentrations of vanadium exceeded the interim screening level (52.2 mg/kg) (BTV) 38 times (maximum detected concentration of 100 mg/kg at AOC4-D02), as shown in

Tables C10-3 and C10-10 and Figure C10-11. Thirty-eight samples exceeded the ECV (13.9 mg/kg). None of the detected concentrations exceeded residential or commercial/industrial CHHSLs (390 mg/kg and 5,200 mg/kg, respectively). Remaining detected concentrations exceeding the interim screening level ranged from 53 to 95 mg/kg. The lateral extent of vanadium concentrations exceeding the interim screening level has not been defined in most of the AOC; however, topographic conditions (steep slopes) prevent additional sampling to the west and south. With the exception of a few detections slightly above the BTV, the lateral extent of vanadium in the flat area adjacent to the compressor station, in the north part of the AOC has been defined. The vertical extent of vanadium concentrations has also not been defined; however, given the shallow depth to bedrock in areas of exceedances, additional sampling is not recommended to delineate vertical extent.

2.1.13 Zinc

Zinc was detected in 122 of 122 soil samples collected at AOC 4. Detected concentrations of zinc exceeded the interim screening level (58 mg/kg) (BTV/ECV) 13 times (maximum detected concentration of 410 mg/kg at AOC4-B03), as shown in Tables C10-3 and C10-10 and Figure C10-12. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively). The lateral extent of zinc concentrations exceeding the interim screening level has been defined in most of the AOC. The vertical extent of zinc concentrations has not been defined; however, based on the shallow depth to bedrock across most of AOC 4, additional sampling for delineating vertical extent is limited to the northern portion of AOC, where bedrock is not near the surface.

2.1.14 Benzo(a)pyrene, Benzo(a)pyrene Equivalents, and PAHs

Benzo(a)pyrene was detected in 48 of 122 soil samples collected from AOC 4. Detected concentrations of benzo(a)pyrene exceeded the interim screening level (38 micrograms per kilograms [µg/kg]) (residential CHHSL) 16 times. Benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene and indeno(1,2,3-cd)pyrene were also detected at concentrations exceeding the interim screening levels. Benzo(a)anthracene was detected in 52 of 122 soil samples and exceeded the interim screening level (380 µg/kg) (residential CHHSL) six times. Benzo(b)fluoranthene was detected in 60 of 122 soil samples and exceeded the interim screening level (380 µg/kg) (residential CHHSL) six times. Benzo(k)fluoranthene was detected in 40 of 122 soil samples and exceeded the interim screening level (380 µg/kg) (residential CHHSL) two times. Ideno(1,2,3-cd)pyrene was detected in 45 of 122 soil samples and exceeded the interim screening level (380 µg/kg) (residential CHHSL) one time. To assist with evaluation of PAHs for human health, benzo(a)pyrene equivalents were calculated for each of the soil samples collected at AOC 4, as shown in Table C10-5. Benzo(a)pyrene equivalents values exceeded the interim screening level of 38 µg/kg (residential CHHSL) 26 times (maximum calculated concentration of 1,110 µg/kg at AOC4-C01), as shown in Tables C10-5 and C10-10 and Figure C10-13. The lateral extent of benzo(a)pyrene equivalent concentrations exceeding the interim screening level has not been defined in the east, south, and southeastern corner of the AOC. The vertical extent of benzo(a)pyrene equivalent concentrations has also not been defined; however, given the shallow depth to bedrock, additional sampling is not recommended to delineate vertical extent.

To assist with evaluation of PAHs for ecological risk, detected concentrations of low molecular weight PAHs and high molecular weight PAHs were summed and compared to the PAH low molecular weight and PAH high molecular weight ECVs (10,000 µg/kg and 1,160 µg/kg, respectively). None of the sums of detected concentrations exceeded the PAH low molecular weight. Twelve of the sums of detected concentrations exceeded the PAH high molecular weight ECVs, as shown on Figure C10-14. PAH high molecular weight sums exceeding the interim screening level have not been defined in the south-southeastern corner of the AOC. The vertical extent has also not been defined; however, given the shallow depth to bedrock, additional sampling is not recommended to delineate vertical extent.

2.1.14 Polychlorinated Biphenyls

Three PCB isomers were detected in soil samples from AOC 4: Aroclor 1016, Aroclor 1254, and Aroclor 1260, as shown on Tables C10-8 and C10-10. These constituents are discussed below.

Aroclor 1016 was detected in eight of the 120 in the surface soil samples collected from AOC 4. None of the samples was above the interim screening level of 3,900 µg/kg (residential RSL) (maximum detected concentration of 60 µg/kg).

Aroclor 1254 was detected in 70 of the 120 in the surface soil samples collected from AOC 4 (Figure C10-15). Twenty-six samples were above the interim screening level of 220 µg/kg (residential RSL) (maximum detected concentration of 5,900 µg/kg). The remaining detected concentration of Aroclor 1254 ranged from 19 µg/kg to 2,900 µg/kg. The lateral extent of Aroclor 1254 concentrations exceeding the interim screening level has not been defined in the eastern part of the AOC. The vertical extent of Aroclor 1254 concentrations has also not been defined; however, given the shallow depth to bedrock, additional sampling is not recommended to delineate vertical extent.

Aroclor 1260 was detected in 11 of the 120 in the surface soil samples collected from AOC 4. One sample was above the interim screening level of 220 µg/kg (residential RSL); the detected concentration was 640 µg/kg. The remaining detected concentration of Aroclor 1260 ranged from 19 µg/kg to 120 µg/kg.

To assist with evaluation of PCBs for ecological risk, detected concentrations of Aroclors were summed and the total PCB values were compared to the ECV. Twenty-six samples were above the interim screening level of 204 µg/kg (ECV). The maximum calculated value for total PCBs was 6,000 µg/kg, as shown in Tables C10-8 and C10-10 and Figure C10-16. The lateral extent of total PCB values exceeding the interim screening level has not been defined in the eastern part of the AOC. The vertical extent of total PCBs has also not been defined; however, given the shallow depth to bedrock, additional sampling is not recommended to delineate vertical extent.

2.1.15 Dioxins and Furans

Dioxins and furans are compared to TEQ, TEQ Avian, and TEQ Mammals. Pentadioxin (1,2,3,7,8-PeCDD) and 2,3,7,8 tetracholordibenzo (2,3,7,8-TCCD) are the only two dioxins with individual interim screening levels. Dioxins and furans were detected in 118 of the 119 surface soil samples collected from AOC 4, as shown in Tables C10-9 and C10-10 and Figure C10-17. Thirty-four samples were above the TEQ Avian interim screening level of 16 nanograms per kilogram (ng/kg) (ECV) (maximum detected concentration of 280 ng/kg). Thirteen samples were above the TEQ human interim screening level of 50 ng/kg (residential RSL) (maximum detected concentration of 250 ng/kg). One hundred and two samples were above the TEQ Mammals interim screening level of 1.6 ng/kg (ECV) (maximum detected concentration of 250 ng/kg). The lateral extent of TEQ exceeding the interim screening level (ECV) has not been defined; however, the lateral extent of TEQ values exceeding residential and commercial RSLs has been defined except at the mouth of the ravine near Bat Cave Wash. The vertical extent of TEQ has not been defined; however, given the shallow depth to bedrock in most of the AOC, additional sampling for vertical extent is not recommended except near the mouth of the ravine in Bat Cave Wash.

2.1.16 Target Analyte List/Target Compound List Constituents

TAL/TCL compounds were analyzed in one sample during the Soil Part A investigation. Aluminum, calcium, iron, magnesium, manganese, potassium, sodium, bis(2ethylhexyl)phthalate, methyl acetate, cyanide, Aroclor 1016, Aroclor 1254, and Aroclor 1260 were detected in the AOC 4 surface soil sample (AOC4-1) the complete TAL/TCL suite of compounds. Aroclor 1016, Aroclor 1254, and Aroclor 1260 are discussed in Section 2.1.14. The remaining constituents are discussed below.

Aluminum was detected in one of one surface soil samples collected. The maximum detected concentration of aluminum was 8,400 mg/kg, which is below the interim screening level (16,400 mg/kg) (BTV), as shown in Tables C10-4 and C10-10. The detected concentration did not exceed the residential and commercial CHHSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in one of one surface soil samples collected. The maximum detected concentration of calcium was 21,000 mg/kg, which is below the interim screening level (66,500 mg/kg) (background value), as shown in Tables C10-4 and C10-10. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium.

Iron was detected in one of one surface soil samples collected. The maximum detected concentration of iron was 20,000 mg/kg, which is below the interim screening level of 55,000 mg/kg (residential RSL), as shown in Tables C10-4 and C10-10. Residential and commercial/industrial CHHSLs and an ECV have not been established for iron.

Magnesium was detected in one of one surface soil samples collected. The maximum detected concentration of magnesium was 7,900 mg/kg, which is below the interim screening level (12,100 mg/kg) (background value), as shown in Tables C10-4 and C10-10. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium.

Manganese was detected in one of one surface soil samples collected. The maximum detected concentration of manganese was 310 mg/kg, which is below the interim screening level (402 mg/kg) (BTV/ECV), as shown in Tables C10-4 and C10-10. The detected concentrations did not exceed residential and commercial/industrial CHHSLs (1,800 mg/kg and 23,000 mg/kg, respectively).

Potassium was detected in one of one surface soil samples collected. The maximum detected concentration of potassium was 2,500 mg/kg, which is below the interim screening level of

4,400 mg/kg (BTV), as shown in Tables C10-4 and C10-10. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for potassium.

Sodium was detected in one of one surface soil samples collected. The maximum detected concentration of sodium was 270 mg/kg, which is below the interim screening level of 2,070 mg/kg (BTV), as shown in Tables C10-4 and C10-10. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for sodium.

Bis(2-ethylhexyl)phthalate and methyl acetate were detected in one of one soil sample collected at AOC 4 at 2 to 3 feet bgs at location AOC4-1, as shown in Tables C10-6 and C10-10. The detected concentrations were 810 µg/kg and 12 µg/kg, respectively. Both are below respective interim screening levels of 2,870 µg/kg and 22,000,000 µg/kg.

As discussed in Section C.2 of Appendix C, PG&E recommends that the TAL/TCL metals and organics discussed above not be considered COPCs/COPECs for this AOC, and no further sampling for these constituents is proposed except for the detected Aroclor 1016, Aroclor 1254, and Aroclor 1260. These constituents have been fully discussed in Section C.2

2.2 Central Tendency Comparison to Background Threshold Values

Seventeen metals (antimony, barium, beryllium, cadmium, total chromium, hexavalent chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, and zinc) were detected above their respective Topock site-specific BTVs in soil samples collected from AOC 4. A central tendency comparison was performed for eight of these 17 metals (barium, total chromium, cobalt, lead, nickel, vanadium, and zinc) to compare the AOC 4 soil data set for these metals with the corresponding Topock soil background data set to determine whether a difference exists between the two populations and if additional sampling is required for a given metal, as shown in Table C10-11.

Metals in either the AOC 4 data set or background data set that were detected infrequently (less than five detects) or had a limited number of results (less than eight) were not tested. There were insufficient detections of antimony, beryllium, cadmium, molybdenum, selenium, silver and thallium at AOC 4 to conduct the test, and there were insufficient detections of hexavalent chromium and mercury in the background data set to allow for a central tendency comparison.

As shown in Table C10-11 and in plots on Figure 3-1 in Data Gaps Report, results from the Gehan test indicated that site concentrations for barium, total chromium, cobalt, copper, lead, nickel, vanadium, and zinc may exceed background. Additional sampling is being proposed to define lateral extent of copper and vertical extent for total chromium, lead, nickel, and zinc. The lateral and vertical extents of barium, cobalt, and vanadium have been adequately defined.

2.3 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review indicates that the decision error has been held to an acceptable level. Post-remediation sampling indicates sufficient data of acceptable quality have been attained in areas likely to have been impacted by incidental disposal of debris.

Based on the DQOs, the following data gaps were identified to resolve Decision 1:

- Data Gap #1 - Lateral extent of various metals, PAHs, PCBs, and dioxins/furans to the east and near the south-southeastern corner of the AOC.
- Data Gaps #2 – Vertical extent of various metals, PCBs, and dioxins/furans across the AOC; however, given the shallow depth to bedrock, additional sampling is limited to the northern portion of AOC, where bedrock is not near the surface.
- Data Gap #3 – Lateral and vertical extent of metals, PAHs, PCBs, and dioxins/furans at the mouth of the ravine near and in Bat Cave Wash.

The potential Phase 2 soil sample locations to fill the identified data gaps are presented in Section 6.0.

3.0 Decision 2 – Data Sufficient to Estimate Representative Exposure Point Concentrations

For Decision 2, data were evaluated to determine if the AOC 4 data are sufficient to conduct human health and ecological risk assessments based on the criteria described in Section 4.0 of the Data Gaps Report. The principal consideration for Decision 2 was whether there were sufficient data to estimate a representative exposure point concentration (EPC). Data reviewed were all available data at AOC 4, including data collected after the TCRA conducted in 2010, data collected during the gabion installations at the confluence of Bat Cave Wash and Area F of AOC 4 in 2010, and historical data remaining in place.

Table C10-12 summarizes the results of the evaluation to determine if data are sufficient to estimate a representative EPC. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value. In general, existing data are adequate to support EPC development for detected chemicals that exceeded one or more comparison values (11 metals, dioxins/furans, PAHs, and PCBs) as described below.

3.1 Metals

Sufficient data (numbers of samples and detections) are available to calculate EPCs for barium, total chromium, cobalt, copper, lead, mercury, nickel, vanadium, and zinc using ProUCL. For the remaining metals (antimony and cadmium), although sufficient data are not available to calculate EPCs (based on the 95 percent upper confidence limit on the mean), additional data collection is not expected to significantly change the results of the risk assessment because the compounds are very infrequently detected (i.e., additional non-detects would be expected).

3.2 Dioxins/Furans

Sufficient data (numbers of samples and detections) are available to calculate EPCs for dioxins/furans (human, bird, and mammal TEQs) using ProUCL.

3.3 Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene toxic equivalents and high molecular weight PAHs using ProUCL.

3.4 Polychlorinated Biphenyls

Sufficient data (numbers of samples and detections) are available to calculate EPCs for total PCBs using ProUCL.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

Table C3-13 presents the results of the tiered screening analysis for AOC 4 following debris and sediment removal. Ten metals had concentrations in excess of their respective background threshold value. Of those 10, cobalt, hexavalent chromium, and vanadium had one or more concentrations exceeding the calculated soil screening levels.

The hydrogeologic setting at AOC 4 is distinct from other AOCs at Topock because of the presence of shallow bedrock and deep groundwater. Bedrock is present at or near the surface across much of the AOC area, and is present at depths of 40 to 50 feet below ground surface in the northern part. The depth to groundwater is between 150 and 200 feet bgs. Numerical simulation of unsaturated flow and transport through fractured bedrock is a very complex undertaking, and requires a dual domain formulation of the unsaturated flow equations, which requires a large number of parameters that are highly site-specific. Because most of the parameters cannot be measured, parameter estimates would be highly uncertain, resulting in an inherently non-unique solution, that is, solutions to the equations would be highly variable and uncertain. Thus, simulation of a fractured rock domain was not performed. However, vadose zone modeling was performed, assuming the vadose zone at AOC 4 was comprised of soil. Assuming the fractured rock is a porous medium is a conservative approach in this extremely arid environment. At AOC 4, the bedrock is a minimally fractured, competent crystalline metadiorite. Fractures, particularly at depth, are not common, and the apertures relative to the pore scale, are large. Thus, except for extremely rare events, the fractures likely act as a capillary barrier to water flow.

The screening level model was able to rule out the threat to groundwater from hexavalent chromium and cobalt. The potential for vanadium to leach to groundwater could not be ruled out based on the screening level model.

4.1 Vanadium

Because there is no MCL for vanadium, the calculated background threshold value (BTV) of 59.9 µg/L was initially used in the SSL calculation. Although the potential for vanadium to leach to groundwater could not be ruled out, it is highly unlikely that the metal is a threat to groundwater at AOC 4 for the following reasons:

- The depth to water at AOC 4 is at least 150 feet below ground surface. For vanadium to reach the water table, the presence of interconnected fractures in the competent crystalline bedrock would be required through the 150 feet to the water table.
- The modeling assumed that the results of the deepest sample (42 mg/kg) at a depth of 5 feet below ground surface extended to the water table.
- The modeling was conducted using a porous media approach, and therefore neglects the capillary barrier effect that the fractures likely provide in this arid environment.

- Vanadium has not been identified as a groundwater COPC at the Topock. Vanadium has been detected in Topock monitoring wells at concentrations above the UTL very infrequently. Monitoring wells MW-10 and MW-11 have one sample each (out of 22 and 13 total samples, respectively) that had vanadium detections above the UTL, which is within the statistical limits of the UTL.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Gaps Evaluation Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the CMS/FS. The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fence line include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite), as discussed in Table 6-1 in the Data Gaps Evaluation Report.
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil washing technologies).
- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies), as discussed in Table 6-1 in the Data Gaps Evaluation Report.
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- If present, volumes of white powder and debris.

The following is a summary of data for AOC 4 that are currently available to support CMS/FS.

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. The lateral and vertical extents of the COPCs and COPECs are discussed in Section 2.2, data results for selected constituents are shown in Figures C10-3 through C10-17, and data gaps associated with lateral delineation are discussed in Section 6.0.

5.2 Waste Characterization Parameters

Partial waste characterization data are available to characterize the soil and other materials for a potential removal action and disposed in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations (TTLC). The maximum concentrations of these metals for each of the units were compared to the TTLCs, and no metals exceeded the TTLCs, as shown in Table C10-14. The maximum detected concentrations were also compared to the soluble threshold limit concentrations (STLCs). Concentrations of barium and copper exceeded 10 times the STLC once, total chromium exceeded 10 times the STLC 37 times, and lead exceeded 10 times the STLC four times, as shown in Table C10-14. In addition, total chromium also exceeded 20 times the toxicity characteristic leaching procedure (TCLP) in four samples and lead also exceeded 20 times the TCLP once, as indicated in Table C10-14. Because these two metals have the potential to exceed STLC or TCLP thresholds, additional leachability testing for waste characterization purposes may be required if soil excavation and offsite disposal is chosen as a remedy. For the purposes of supporting the CMS/FS, the lack of STLC or TCLP analysis is not considered a data gap, for the existing total concentrations are sufficient for the purposes of evaluating various remedial alternatives.

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 investigation was limited to grain size analysis only. Specific soil physical property data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 of the Data Gaps Evaluation Report.

5.4 Surface and Subsurface Features

There is extensive information regarding surface and subsurface features at AOC 4, but additional information may be required once remaining areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are considered part of AOC 4. Similarly, subsurface utilities, including gas transmission pipelines and any culverts or other features, have been defined as part of the TCRA. All areas to be remediated will require a utility clearance prior to intrusive activities; however, no other data gaps pertaining to surface and subsurface features have been identified at this AOC.

Additional soil physical parameter data are needed to support the CMS/FS.

6.0 Summary of Data Gaps and Potential Phase 2 Soil Sample Locations to Fill Identified Gaps

Based on the Part A DQO, data gaps were identified for three of the four decisions and are summarized below by decision:

- **Decision 1 (Nature and Extent)** – the following data gaps were identified to resolve this decision:
  - Data Gap #1 - Lateral extent of various metals, PAHs, PCBs, and dioxins/furans to the east and near the south-southeastern corner of the AOC.
  - Data Gaps #2 – Vertical extent of various metals, PCBs, and dioxins/furans across the AOC; however, given the shallow depth to bedrock, additional sampling is limited to the northern portion of AOC, where bedrock is not near the surface.

  - Data Gap #3 – Lateral and vertical extent of metals, PAHs, PCBs, and dioxins/furans at the mouth of the ravine near and in Bat Cave Wash.

- **Decision 2 (Data Sufficient to Estimate Representative Exposure Point Concentrations).** No data gap was identified for this decision.

- **Decision 3 (Potential Threat to Groundwater from Residual Soil Concentrations).** No data gap was identified for this decision.

- **Decision 4 (Data Sufficient to Support the CMS/FS) – the following data gap was identified to resolve this decision:**

  - Data gap #4 – Soil physical property parameters to support the CMS/FS.

Table C10-15 summarizes the potential Phase 2 sample locations, depths, description/ rationale for each location (i.e., which data gaps they would address), and analytes. Potential Phase 2 sample locations are also shown in Figure C10-18. The potential Phase 2 sample locations are PG&E's initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation. PG&E anticipates that all candidate locations identified may not be necessary for such purposes.

Notes:

1 Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

2 Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used.

3 Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used.

4 ARCADIS. 2008. "Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil." May 28. ARCADIS. 2009. "Topock Compression Station - Final Technical Memorandum 4: Ecological Comparison Values for Additional Detected Chemicals in Soil." July 1.

5 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

Results greater than or equal to the interim screening level are circled.

NE = not established
USEPA = United States Environmental Protection Agency
DTSC = California Department of Toxic Substances Control
CHHSL = California human health screening levels
-- = not analyzed
FD = Field Dupliicate
ft bgs = feet below ground surface
J = concentration or reporting limit estimated by laboratory or data validation
mg/kg = milligrams per kilogram
N = Primary Sample
ND = not detected at the listed reporting limit

Notes:

1 Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

2 Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used.

3 Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used.

4 ARCADIS. 2008. "Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil." May 28. ARCADIS. 2009. "Topock Compression Station - Final Technical Memorandum 4: Ecological Comparison Values for Additional Detected Chemicals in Soil." July 1.

5 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

Results greater than or equal to the interim screening level are circled.
NE = not established
USEPA = United States Environmental Protection Agency
DTSC = California Department of Toxic Substances Control
CHHSL = California human health screening levels

Calculations:
BaP equivalent = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all PAHs are nondetect, the final qualifier code is U.
PAHLow = Sum of Result of low molecular weight PAHs, zero is used for nondetect values.
PAHHigh= Sum of Result of high molecular weight PAHs, zero is used for nondetect values.
-- = not analyzed
µg/kg = micrograms per kilogram
FD = Field Dupliicate
ft bgs = feet below ground surface
J = concentration or reporting limit estimated by laboratory or data validation
N = Primary Sample
ND = not detected at the listed reporting limit

Notes:

1 Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

2 Residential screening level - residential USEPA regional screening levels

3 Commercial screening level - commercial USEPA regional screening levels

4 ARCADIS. 2008. "Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil." May 28. ARCADIS. 2009. "Topock Compression Station - Final Technical Memorandum 4: Ecological Comparison Values for Additional Detected Chemicals in Soil." July 1.

5 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

Results greater than or equal to the interim screening level are circled.

NE = not established

USEPA = United States Environmental Protection Agency

DTSC = California Department of Toxic Substances Control

CHHSL = California human health screening levels

Calculations:

Total PCBs by Area = Sum of Result of PCBs. Detected values are summed plus ½ the RL for nondetect Aroclors if the Aroclor is detected somewhere in the area. If all aroclors in a particular sa

-- = not analyzed

µg/kg = micrograms per kilogram

FD = Field Dupliicate

ft bgs = feet below ground surface

J = concentration or reporting limit estimated by laboratory or data validation

N = Primary Sample

ND = not detected at the listed reporting limit

C10-9

Sample Results: Dioxin and Furans

Notes:

1 Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological
comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.
2 Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used.
3 Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used.
4 ARCADIS. 2008. "Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil."
May 28. ARCADIS. 2009. "Topock Compression Station - Final Technical Memorandum 4: Ecological Comparison Values for Additional Detected Chemicals in Soil." July 1.
5 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.
Results greater than or equal to the interim screening level are circled.
NE = not established
NA = not applicable
USEPA = United States Environmental Protection Agency
DTSC = California Department of Toxic Substances Control
CHHSL = California human health screening levels
Calculations:
Teq = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all Dioxins and Furans are nondetect, the final qualifier code is U.
TeqBird = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all Dioxins and Furans are nondetect, the final qualifier code is U.
TeqMammals = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all Dioxins and Furans are nondetect, the final qualifier code is U.
-- = not analyzed
FD = Field Dupliicate
ft bgs = feet below ground surface
J = concentration or reporting limit estimated by laboratory or data validation
N = Primary Sample
ND = not detected at the listed reporting limit
ng/kg = nanograms per kilogram
R = rejected by laboratory or data validation

TABLE C10-10

Constituent Concentrations in Soil Compared to Screening Values
AOC 4 – Debris Ravine
Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station Needles,California

---

Notes

[1] CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

[2] ARCADIS. 2008. "Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil." May 28. ARCADIS. 2009. "Topock Compression Station - Final Technical Memorandum 4: Ecological Comparison Values for Additional Detected Chemicals in Soil" July 1

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted.

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

mg/kg	miligrams per kilogram
µg/kg	micrograms per kilogram
ng/kg	nanograms per kilogram
NA	not applicable
ND	not detected in any of the samples
NE	not established
SL	screening level

USEPA	United States Environmental Protection Agency
DTSC	California Department of Toxic Substances Control
CHHSL	California human health screening levels
Water Board	Regional Water Quality Control Board

Calculations:

Regional Water Quality Control Board
Total PCBs by Area = Sum of Result of PCBs. Detected values are summed plus ½ the RL for nondetect Aroclors if the Aroclor is detected somewhere in the area. If all aroclors in a particular sample are nondetect the PCB Total is 0.
PAHLow = Sum of Result of low molecular weight PAHs, zero is used for nondetect values
PAHHigh= Sum of Result of high molecular weight PAHs, zero is used for nondetect values
BaP equivalent = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all PAHs are nondetect, the final qualifier code is U.
Teq = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all Dioxins and Furans are nondetect, the final qualifier code is U.
TeqBird = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all Dioxins and Furans are nondetect, the final qualifier code is U.
TeqMammals = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all Dioxins and Furans are nondetect, the final qualifier code is U.

0-10 ft bgs	Y	70 of 120	6000 µg/kg	Y	NA		

Footnotes:

a. The higher value of either the HHCV/ECV or background was selected as the screening criteria and are included in these columns for the respective compound in **BOLDED BLUE FONT**. Values based on background are indicated with "(bckg)" next to the value.

Acronyms and Abbreviations:

AOC - area of concern
BaP TEQ - benzo(a)pyrene toxic equivalents
ECV - ecological comparison values
EPC - exposure point concentration
ft bgs - feet below ground surface
HHCV - human health comparison values
HMW PAH - high molecular weight polycyclic aromatic hydrocarbons
mg/kg - milligrams per kilogram
µg/kg - micrograms per kilogram
N - no
NA - not applicable
TEQ - toxic equivalents
Y - yes

TABLE C10-13
Results of Tiered Analysis at AOC 4
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California

Metal	**Step 1 Do COPCs/COPECs Exceed Background?**	**Step 2 Do COPCs/COPECs Exceed SSL?**	**Step 3 Does Screening Model Eliminate Potential for Leaching to Groundwater?**
Barium	√		
Cadmium	√		
Chromium	√		
Chromium, Hexavalent	√	√	√
Cobalt	√	√	√
Copper	√		
Lead	√		
Nickel	√		
Vanadium	√	√	
Zinc	√		

SSL = soil screening level.

APPENDIX D

Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station

D.1 Introduction

This data quality evaluation (DQE) assesses the data quality of analytical results for the Part A, Phase 1 Resource Conservation and Recovery Act (RCRA) facility investigation/ remedial soil investigation (RFI/RI) at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station near Needles, California, between August 22, 2008 and December 16, 2008. Samples were collected and analyzed as specified in the *RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A* (CH2M HILL, 2006). The *PG&E Program Quality Assurance Project Plan* (QAPP) (CH2M HILL, 2008a), *Addendum to the PG&E Program Quality Assurance Project Plan for the RCRA Facility Investigation/Remedial Investigation for Soil* (CH2M HILL, 2008b), individual method requirements, internal laboratory quality control criteria, guidelines from the United States Environmental Protection Agency (USEPA) *Contract Laboratory National Functional Guidelines for Inorganic Data Review* (USEPA, 2002), and US*EPA National Functional Guidelines for Organic Data Review* (USEPA, 1999) were used in this assessment. Soil collected between 1988 and 2003 were evaluated in the *Final Soil and Sediment Data Usability Technical Memorandum, PG&E Topock Compressor Station* (CH2M HILL, 2008c).

The goal of this review is to evaluate whether a sufficient number of representative samples were collected and whether the resulting analytical data can be used to support the decision-making process. The procedures for assessing the precision, accuracy, representativeness, completeness, and comparability (PARCC) parameters are addressed in the QAPP (CH2M HILL, 2008a). The following summary highlights the PARCC findings for the Part A, Phase 1 RFI/RI at the Topock Compressor Station.

The overall data quality met the data quality objectives and the project-specific objectives despite some issues with the analysis of a difficult soil matrix, which are summarized in the following statements:

- The completeness objective for the PG&E program is 90 percent for soil samples. The completeness objectives were met for all method/analyte combinations collected except acetone. See Attachment 11.
- Samples were collected and analyzed based on approved methods/procedures, and the results are reported using industry-standard units.
- No data were qualified due to method blank contamination, and a minimum number of samples were qualified due to equipment blank contamination.

- With the exceptions discussed above, the routinely acceptable performance of field and laboratory quality control indicators (field duplicates, field blanks, laboratory blanks, laboratory control sample [LCS], matrix spike/matrix spike duplicate [MS/MSD], and calibrations) show the accuracy and precision of the data meet the project objectives.
- Matrix effects were encountered, resulting in elevated reporting limits.
- Analytical data as qualified meet the data quality objectives (except acetone) and can be used in project decision-making.

D.2 Analytical Data

This DQE report covers 672 soil (and other solid) samples, 63 soil field duplicate samples, and the associated quality control samples (e.g., trip blanks and equipment blanks). These samples were reported by the laboratories in 159 sample delivery groups.

Truesdail Laboratories, Inc. (TLI) of Tustin, California; Advanced Technology Laboratories (ATL) of Signal Hill, California; the ATL satellite laboratory of Las Vegas, Nevada; and Agriculture and Priority Pollutants Laboratories, Inc. (APPL) of Fresno, California performed the required analyses. All laboratories are certified by the California Department of Health Service's Environmental Laboratory Accreditation Program for the analyses included in Table D-1, where appropriate. Samples were analyzed for one or more of the analytes/methods provided in Table D-1.

TABLE D-1
Analytical Parameters
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

Parameter	Method	Laboratory
Percent moisture	D2216 [a]	ATL/TLI
Metals	SW6010B [b]	ATL-NV
Synthetic precipitation leaching procedure chromium	SW6020A [b]	TLI
Hexavalent chromium	SW7199 [b]	TLI
Mercury	SW7471A [b]	ATL-CA
Total petroleum hydrocarbon diesel-range organics/motor oil-range organics	SW8015B-E [b]	TLI
TPH gasoline-range organics	SW8015B-P [b]	ATL-NV
Organochlorine pesticides	SW8081A [b]	ATL-CA
Polychlorinated biphenyls	SW8082 [b]	ATL-CA
Volatile organic compounds	SW8260B [b]	ATL-NV
Semivolatile organic compounds	SW8270C [b]	ATL-CA
Polynuclear aromatic hydrocarbons	SW8270 Selected Ion Monitoring (SIM) [b]	ATL-CA
Dioxins and furans	SW8290 [b]	APPL
Cyanide	SW9012A [b]	TLI
pH	SW9045 [b]	TLI

TABLE D-1
Analytical Parameters
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

Parameter	Method	Laboratory

[a] American Society for Testing and Materials – ASTM – 2005.

[b] SW-846 Test Methods for Evaluating Solid Waste, 3rd Edition, revision 4, 1996.

The assessment of data includes a review of:

- Chain of custody documentation.
- Holding time compliance.
- Required quality control samples at the specified frequencies.
- Method blanks.
- LCS.
- Surrogate spike recoveries.
- MS/MSD samples.
- Field duplicate precision.
- Initial and continuing calibration criteria.

Field samples were also reviewed to ascertain field compliance and data quality issues. This review includes evaluation of field duplicates, as well as equipment blank and trip blank data.

Data flags were assigned according to the QAPP (CH2M HILL, 2008a). These flags, as well as the reason for each flag, are entered into the electronic database and can be found in Attachments 1 through 10 to this DQE report. Multiple flags are routinely applied to specific sample method/matrix/analyte combinations, but there will be only one final flag. A final flag is applied to the data and is the most conservative of the applied validation flags. The final flag also includes matrix and blank sample effects.

The data flags are listed and defined below:

- J = Analyte was present but the reported value might not be accurate or precise (estimated).
- R = Data were unusable due to deficiencies in the ability to analyze the sample and meet quality control criteria.
- U = Analyte was not detected at the specified reporting limit.
- UJ = Analyte was not detected and the specified reporting limit might not be accurate or precise (estimated).

D.3 Data Assessment

Data assessment includes a review of the activities described in the following sections.

D.3.1 Holding Times

Holding time exceedances result in the possible loss of target analytes due to degradation or chemical reactions that usually cause a negative bias to sample results. Detected and non-detected sample results exceeding the method recommended holding time were qualified as estimated and flagged “J” and “UJ.” Refer to the site-specific tables in Attachments D1 through D10 for the data discussed below.

- **Background (BKG).** All holding time acceptance criteria were met for the background samples.
- **Solid Waste Management Unit (SWMU) 1 (Former Percolation Bed).** Seven samples for polychlorinated biphenyls (PCBs) (SW8082) were analyzed outside the recommended holding time. The seven samples were not scheduled for PCB analysis in the original sampling plan, and the PCB analysis was requested after the holding time had been exceeded. See Attachment D2, Table D2-1.
- **Area of Concern (AOC) 1 (Area around Former Percolation Bed).** One sample for PCB (SW8082) was analyzed outside the recommended holding time. This sample was not scheduled for PCB analysis in the original sampling plan, and the PCB analysis was requested after the holding time had been exceeded. See Attachment D3, Table D3-1.
- **AOC 4 (Debris Ravine).** Two samples for hexavalent chromium [Cr(VI)] (SW7199), 14 samples for total petroleum hydrocarbon diesel-range organics (TPH-DRO) (SW8015B-E), one sample for pesticides (SW8081A), one sample for PCBs (SW8082), 14 samples for semivolatile organic compounds (SVOCs) (SW8270C), 17 samples for polynuclear aromatic hydrocarbons (PAHs) (SW8270sim), one sample for cyanide (SW9012), and two samples for pH (SW9045) were analyzed outside the recommended holding time. With the exception of the two samples for Cr(VI), the remaining samples were mistakenly held in the field (stored at 4° Celsius) past the recommended holding time.
- Due to the complex nature of the “wood” samples for Cr(VI) the laboratory made several attempts to extract the Cr(VI) using the standard soil extraction method (SW3060A) prior to a successful extraction that allowed analysis to proceed. The final analysis was delayed past the recommended holding time due to the difficulty of the matrix. See Attachment D4, Table D4-1.
- **AOC 9 (Southeast Fence Line -Outside Visitor Parking Area).** One sample for total petroleum hydrocarbons motor-oil-range organics (TPH-MO) (SW8015B-E) and two samples for PCBs (SW8082) were analyzed outside the recommended holding time. The original motor-oil fraction result was greater than the calibration range, and the analyst overlooked the need for reanalysis until after the sample was outside the holding time. The samples for PCBs were not scheduled for PCB analysis in the original sampling plan, and the analysis was requested after the holding time had been exceeded. See Attachment D5, Table D5-1.
- **AOC 10 (East Ravine).** Six samples for mercury (SW7471A), five samples for TPH-DRO (SW8015B-E), and five samples for PCBs (SW8082) were analyzed outside the recommended holding time. In the original sampling plan, the six samples for mercury analysis were designated as supplemental samples, with the analysis to be determined

after results from contiguous samples could be evaluated. The mercury analysis was requested after the holding time had been exceeded. The five samples for TPH-DRO were analyzed a few days outside the recommended holding time due to lab capacity issues. The samples for PCBs were not scheduled for PCB analysis in the original sampling plan, and the analysis was requested after the holding time had been exceeded. See Attachment D6, Table D6-1.

- **AOC 11 (Topographic Low Area).** Thirty-nine samples for mercury (SW7471A), 12 samples for TPH-DRO (SW8015B-E), six samples for total petroleum hydrocarbons gasoline-range organics (TPH-GRO) (SW8015B-P), two samples for PCBs (SW8082), and five samples for volatile organic compounds (VOCs) (SW8020B) were analyzed outside the recommended holding time. In the original sampling plan, the 39 samples for mercury analysis were designate as supplemental samples, with the analysis to be determined after results from contiguous samples could be evaluated. The mercury analysis was requested after the holding time had been exceeded. The five samples for TPH-DRO were analyzed a few days outside the recommended holding time due to lab capacity issues. The six samples for TPH-GRO were received in the lab just outside the 48-hour preservation requirement for frozen samples. The samples for PCBs were not scheduled for PCB analysis in the original sampling plan, and the analysis was requested after the holding time had been exceeded. See Attachment D7, Table D7-1.
- **AOC 12 (Fill Area).** One sample for PCB (SW8082) was analyzed outside the recommended holding time. This sample was not scheduled for PCB analysis in the original sampling plan, and the PCB analysis was requested after the holding time had been exceeded. See Attachment D8, Table D8-1.
- **AOC 14 (Railroad Debris Site).** Eighteen samples for TPH-DRO (SW0815B-E), two samples for SVOCs (SW8270C), two samples for PAHs (SW8270SIM), and two samples for pH (SW9045) were analyzed outside the recommended holding time. Fifteen of the TPH-DRO samples were analyzed a few days outside the recommended holding time due to lab capacity issues. The remaining three TPH-DRO, two SVOC, two PAH, and two pH samples were mistakenly held in the field (stored at 4^o Celsius) past the recommended holding time. See Attachment D9, Table D9-1.
- **300B (Former 300B Pipeline Liquids Tank).** All holding time acceptance criteria were met in this area of concern.

D.3.2 Method Blanks

Method blanks are used to monitor and evaluate each preparation or analytical batch for potential contamination throughout the analytical process from sources such as glassware, reagents, instrumentation, and other potential contaminant sources within the laboratory. If a target analyte is detected in the method blank, similar detections in the samples are possibly artifacts of laboratory contamination.

Method blanks were analyzed at the required frequency. No target analytes were detected in the method blanks that affected the reporting limit for the associated samples.

D.3.3 Equipment Blanks

Equipment blanks are used to assess the effectiveness of sampling equipment decontamination procedures. Target analytes detected in equipment blanks may indicate that field equipment was not thoroughly decontaminated and/or samples could have been cross contaminated. Equipment blanks are collected at a frequency of one per sampling crew per day where non-dedicated equipment is used. Where equipment blank detections occur, reporting levels are adjusted up to reflect the possibility the results detected in a sample are actually a manifestation of contamination. Detected sample results greater than five times the equipment blank result and non-detected sample results are considered to be unaffected. Refer to the site-specific tables in Attachments 1 through 10.

- **BKG.** Sodium (SW6010B), a target analyte, was detected at or above the reporting limit for an equipment blank. Four associated samples with detected sodium results that were less than five times the equipment blank result were qualified as not detected and were flagged as “U.”
- **SWMU 1.** Sodium (SW6010B), a target analyte, was detected at or above the reporting limit for two equipment blanks. Seven associated samples with detected sodium results that were less than five times the equipment blank results were qualified as not detected and were flagged as “U.”
- **AOC 1.** Copper (SW6010B), a target analyte, was detected at or above the reporting limit for an equipment blank. Two associated samples with detected copper results that were less than five times the equipment blank result were qualified as not detected and were flagged “U.” Sodium (SW6010B), a target analyte, was detected at or above the reporting limit for three equipment blanks. Four associated samples with detected results that were less than five times the equipment blank result were qualified as not detected and were as flagged “U.”
- **AOC 4.** Sodium (SW6010B), a target analyte, was detected at or above the reporting limit for an equipment blank. One associated sample’s detected sodium result that was less than five times the equipment blank result was qualified as not detected and flagged “U.”
- **AOC 9.** All equipment blank acceptance criteria were met in this area of concern.
- **AOC 10.** All equipment blank acceptance criteria were met in this area of concern.
- **AOC 11.** Sodium (SW6010B), a target analyte, was detected at or above the reporting limit for an equipment blank. One associated sample’s detected sodium result that was less than five times the equipment blank result was qualified as not detected and was flagged as “U.”
- **AOC 12.** All equipment blank acceptance criteria were met in this area of concern.
- **AOC 14.** All equipment blank acceptance criteria were met in this area of concern.
- **300B.** All equipment blank acceptance criteria were met in this area of concern.

D.3.4 Calibration

Initial calibration and periodic verification are essential to generating defensible analytical data. Initial calibrations that do not meet method requirements result in data that may be either positively or negatively biased. Periodic calibration verification ensures that the instrument has not been adversely affected by the sample matrix or other instrument failures that would increase or decrease the sensitivity or accuracy of the method. The inability to meet initial or continuing calibration analyses may result in qualifying the data as estimated or rejecting the data for project decision-making purposes. Refer to the site-specific tables in Attachments D1 through D10.

All initial calibrations were performed as required by the methods and met the method criteria.

- **BKG.** All continuing calibration verification (CCV) standard acceptance criteria were met for the background samples.
- **SWMU 1.** One CCV for bromoform (SW8060B) had a recovery that was less than the lower control limit (LCL). Two associated non-detect results were qualified as estimated and were flagged as “UJ.” See Attachment D2, Table D2-1.
- **AOC 1.** One CCV for bromoform (SW8060B) had a recovery that was less than the LCL. Seven associated non-detected results were qualified as estimated and were flagged as “UJ.” See Attachment D3, Table D3-1.
- **AOC 4.** One CCV for gasoline (SW8015B-P) had a recovery that was less than the LCL. Five associated non-detect results were qualified as estimated and were flagged as “UJ.” One CCV for endrin aldehyde (SW8081A) had a low-bias recovery. One associated non-detected result was qualified as estimated and was flagged as “UJ.” See Attachment D4, Table D4-1.
- **AOC 9.** One CCV for bromoform (SW8060B) had a recovery that was less than the LCL. Five associated non-detected results were qualified as estimated and were flagged as “UJ.” One Cr(VI) sample result was greater than the linear range of the initial calibration range. The sample was qualified as estimated and was flagged as “J.” See Attachment D5, Table D5-1.
- **AOC 10.** One CCV for 4,4´-DDT (dichlorodiphenyltrichloroethane), endosulfan I, endrin aldehyde, methoxychlor, and toxaphene (SW8081A) had recoveries that were less than the LCL. The associated non-detected results from one sample were qualified as estimated and were flagged as “UJ.” One CCV for bromoform (SW8060B) had a recovery that was less than the LCL. Seven associated non-detected results were qualified as estimated and were flagged as “UJ.” See Attachment D6, Table D6-1.
- **AOC 11.** One CCV for bromoform (SW8060B) had a low-bias recovery. Fourteen associated non-detected results were qualified as estimated and were flagged as “UJ.” See Attachment D7, Table D7-1.
- **AOC 12.** One CCV for acrolein (SW8060B) had a recovery that was less than the LCL. Seven associated non-detected results were qualified as estimated and were flagged as “UJ.” See Attachment D8, Table D8-1.

- **AOC 14.** One CCV for bromoform (SW8060B) had a recovery that was less than the LCL. Two associated non-detected results were qualified as estimated and were flagged as "UJ." See Attachment D9, Table D9-1.
- **300B.** All CCV acceptance criteria were met in this area of concern.

D.3.5 Field Duplicates

Field duplicates are collected and analyzed to determine if field collection activities or the sample matrix influence the precision of the analytical measurements obtained at the sample site. Soils samples are inherently more variable than water samples, despite homogenizing and lead to larger relative percent differences (RPD). Large RPDs do not necessarily indicate lack of precision when associated with soil samples. Detected and non-detected results were qualified as estimated and were flagged as "J" and "UJ." Refer to a list of field duplicate pairs and reference the site-specific tables in Attachments D1 through D10.

- **BKG.** All field duplicate acceptance criteria were met for the background samples.
- **SWMU 1.** One field duplicate pair had an RPD greater than the upper control limit (UCL) for chromium (SW6010B, 20 percent). One field duplicate pair had an RPD greater than the UCL for nickel (SW6010B, 20 percent). One field duplicate pair had an RPD greater than UCL for cobalt (SW6010B, 20 percent). One field duplicate pair had RPDs greater than the UCL for barium, cobalt, chromium, and nickel (SW6010B, 20 percent). Two field duplicate pairs had RPDs greater than the UCL for acetone (SW8260B, 30 percent). See Attachment D2, Table D2-1.
- **AOC 1.** One field duplicate pair had a RPD greater than the UCL for chromium (SW6010B, 20 percent). One field duplicate pair had an RPD greater than the UCL for lead (SW6010B, 20 percent). One field duplicate pair had RPDs greater than the UCL for lead (SW6010B, 20 percent) and acetone (SW8260B, 30 percent). One field duplicate pair had an RPD greater than the UCL for lead, nickel, zinc (SW6010B, 20 percent), and Cr(VI) (SW7199, 20 percent). See Attachment D3, Table D3-1.
- **AOC 4.** One field duplicate pair had an RPD greater than the UCL for Cr(VI) (SW7199, 20 percent). One field duplicate pair had RPDs greater than the UCL for anthracene, benzo(a)anthracene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and fluoranthene (SW8270SIM, 30 percent). One field duplicate pair had RPDs greater than the UCL for benzo(a)anthracene, benzo(a)pyrene, chrysene, fluoranthene, and pyrene (SW8270SIM, 30 percent). See Attachment D4, Table D4-1.
- **AOC 9.** One field duplicate pair had an RPD greater than the UCL for acetone (SW8260B, 30 percent). One field duplicate pair had RPDs greater than the UCL for chrysene, phenanthrene, (SW8270SIM, 30 percent), and chromium (SW6010B, 20 percent). One field duplicate pair had RPDs greater than the UCL for 1-methylnaphthalene and 2-methylnaphthalene (SW8270SIM, 30 percent). See Attachment D5, Table D5-1.
- **AOC 10.** One field duplicate pair had an RPD greater than the UCL for lead (SW6010B, 20 percent). One field duplicate pair had an RPD greater than the UCL for acetone (SW8260B, 30 percent). One field duplicate pair had RPDs greater than the UCL for lead, zinc (SW6010B, 20 percent) and acetone (SW8260B, 30 percent). One field duplicate pair

had RPDs greater than the UCL for benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenz(k)fluoranthene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, pyrene (SW8270SIM, 30 percent), and acetone (SW8260B, 30 percent). See Attachment D6, Table D6-1.

- **AOC 11.** One field duplicate pair had RPDs greater than the UCL for barium, calcium (SW6010B, 20 percent), alpha chlordane, and gamma chlordane (SW8081A, 50 percent). One field duplicate pair had RPDs greater than the UCL for TPH-DRO (SW8015B-E, 50 percent) and acetone (SW8260B, 30 percent). One field duplicate pair had RPDs greater than the UCL for fluoranthene, phenanthrene, and pyrene (SW8270SIM, 30 percent). See Attachment D7, Table D7-1.
- **AOC 12.** All field duplicate acceptance criteria were met in this area of concern.
- **AOC 14.** One field duplicate pair had an RPD greater than the UCL for acetone (SW8260B, 30 percent). One field duplicate pair had an RPD greater than the UCL for copper (SW6010B, 20 percent). See Attachment D9, Table D9-1.
- **300B.** All field duplicate acceptance criteria were met in this area of concern.

D.3.6 Laboratory Control Samples

A LCS measures laboratory accuracy. Accuracy is the degree of agreement between a measured value and the expected value. The LCS is prepared from laboratory deionized or reagent-grade water and spiked with known amounts of the target analytes of interest. Recovery of analytes outside of quality control limits generally indicates a problem with the analytical procedure. A low LCS recovery indicates that the target analyte in associated samples is likely biased low. Associated detected and non-detected sample results were qualified as estimated and were flagged as “J” and “UJ.” Likewise, a high LCS recovery indicates that the target analyte in associated samples is likely biased high. All of the LCS recoveries recovered outside the quality control limits were biased high for the Part A, Phase 1 samples. Associated detected results were qualified as estimated and were flagged as “J.” Non-detected results associated with a high-bias recovery were not qualified. Refer to the site-specific tables in Attachments D1 through D10.

- **BKG.** LCSs were analyzed at the required frequency and were recovered within quality control limits.
- **SWMU 1.** One LCS for TPH-MO (SW8015B-E) had a recovery that was greater than the UCL (120 percent). Five associated detected sample results were qualified as estimated and were flagged as “J.” One LCS for TPH-MO (SW8015-E) had a recovery that was greater than the UCL (120 percent). Ten associated detected sample results were qualified as estimated and were flagged as “J.” See Attachment D2, Table D2-1.
- **AOC 1.** One LCS for TPH-MO (SW8015B-E) had a recovery that was greater than the UCL (120 percent). One associated detected sample result was qualified as estimated and was flagged as “J.” Another LCS for TPH-MO (SW8015B-E) had a recovery that was greater than the UCL (120 percent). Ten associated detected sample results were qualified as estimated and were flagged as “J.” See Attachment D3, Table D3-1.

- **AOC 4.** LCSs were analyzed at the required frequency and were recovered within quality control limits.
- **AOC 9.** One LCS for TPH-MO (SW8015B-E) had a recovery that was greater than the UCL (120 percent). Three associated detected sample results were qualified as estimated and were flagged as "J." The RPD of acenaphthylene (SW8270SIM) between the results for two LCSs was greater than the UCL (126 percent). Sixteen associated non-detected sample results were qualified as estimated and were flagged as "UJ." See Attachment D5, Table D5-1.
- **AOC 10.** One LCS for TPH-MO (SW8015B-E) had a recovery that was greater than the UCL (120 percent). Three associated detected sample results were qualified as estimated and were flagged as "J." See Attachment D6, Table D6-1.
- **AOC 11.** One LCS for TPH-MO (SW8015-E) had a recovery that was greater than the UCL (120 percent). Nine associated detected sample results were qualified as estimated and were flagged as "J." One LCS for benzo(k)fluoranthene (SW8270SIM) had a recovery that was greater than the UCL (129 percent). Seven associated detected sample results were qualified as estimated and were flagged as "J." See Attachment D7, Table D7-1.
- **AOC 12.** One LCS for TPH-MO (SW8015B-E) had a recovery that was greater than the UCL (120 percent). Two associated detected sample results were qualified as estimated and were flagged as "J." One LCS for benzo(k)fluoranthene (SW8270SIM) had a recovery that was greater than the UCL (129 percent). One associated detected sample result was qualified as estimated and was flagged as "J." See Attachment D8, Table D8-1.
- **AOC 14.** One LCS for TPH-MO (SW8015B-E) had a recovery that was greater than the UCL (120 percent). Two associated detected sample results were qualified as estimated and were flagged as "J." One LCS and LCS duplicate for TPH-MO (SW8015B-E) had recoveries that were greater than the UCL (120 percent). Four associated detected sample results were qualified as estimated and were flagged as "J." See Attachment D9, Table D9-1.
- **300B.** One LCS and LCS duplicate for TPH-MO (SW8015-E) had recoveries that were greater than the UCL (120 percent). Six associated detected sample results were qualified as estimated and were flagged as "J." See Attachment D10, Table D10-1.

D.3.7 Matrix Spike Samples

Matrix spike recoveries are used to evaluate the effect of the sample matrix on the recovery of target analytes. A sample is fortified with a known quantity of a target analyte and is carried through the same preparation and analytical procedures as the non-spiked sample. Matrix spike recoveries outside the quality control limits may indicate that the sample's matrix is affecting the method's ability to accurately quantify the target analyte in the associated sample or samples from similar locations. A low matrix spike recovery generally indicates a negative bias in the sample data. Associated parent detected and non-detected sample results are qualified as estimated and are flagged as "J" or "UJ." When the matrix spike, MSD, or both have recoveries that are below 10 percent and the associated parent sample has a detected result, the result is qualified as estimated and is flagged as "J" (low bias). However, an associated non-detected parent sample result is considered unusable and is flagged as "R." A high matrix spike recovery indicates a potential positive bias to the associated sample data. The associated parent detected results are qualified as estimated and are flagged as "J." Non-detected parent results associated with a high-bias recovery are not qualified. If a matrix spike and an MSD are analyzed, an RPD greater than the quality control criteria may further indicate that the sample matrix is affecting the precision of the method for the target analyte that did not meet criteria. Refer to the site-specific tables in Attachments D1 through D10.

- **BKG.** The MS/MSD samples for the background data set had recovery of antimony and barium (SW6010B), target analytes, outside the control limits established in the QAPP (75 to 125 percent). The associated parent analytes were qualified as estimated and were flagged as "J." See Attachment D1, Table D1-1.

- **SWMU 1.** The MS/MSD samples for SWMU 1 had recovery of target analytes outside the control limits established in the QAPP. Nine target analytes were qualified as estimated: antimony (SW6010B), Cr(VI) (SW7199), 4,4-DDE (dichlorodiphenyldichloroethylene), dieldrin, endrin ketone (SW8081A), 2,4-dinitrophenol, acetophenone, benzaldehyde, and caprolactam (SW8270C). Four benzoic acid (SW8270C) results were unusable (flagged as "R") due to MS/MSD recoveries less than 10 percent. Three serial dilution sample results had RPDs greater than the UCL. Three target analytes were qualified as estimated: iron, magnesium, and potassium (SW6010B); the associated sample results were qualified as estimated. See Attachment D2, Table D2-1.

- **AOC 1.** The MS/MSD samples for AOC1 had recovery of target analytes outside the control limits established in the QAPP. Three target analytes were qualified as estimated: caprolactam, hexachlorocyclopentadine (SW8270C), and antimony (SW6010B). Two benzoic acid (SW8270C) results were unusable due to MS/MSD recoveries of less than 10 percent and were flagged as "R." The serial dilution for a potassium sample result had an RPD greater than the UCL, and the associated sample was qualified as estimated. See Attachment D3, Table D3-1.

- **AOC 4.** The MS/MSD samples for AOC 4 had recovery of target analytes outside the control limits established in the QAPP. Twenty-six target analytes were qualified as estimated: antimony, barium, chromium, copper, lead, potassium, sodium, zinc (SW6010B), 4,4-DDE, alpha-BHC (benzene hexachloride), alpha chlordane, beta-BHC, delta-BHC, dieldrin, endosulfan sulfide, endrin ketone, gamma-BHC, heptachlor, heptachlor epoxide (SW8081A), Aroclor-1260 (SW8082) benzaldehyde (SW8270C), benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, chrysene, and pyrene (SW8270SIM). Two MS/MSD samples for benzoic acid and caprolactam (SW8270C) had recoveries less than 10 percent, and the sample non-detected results were rejected (flagged as "R"). One copper and lead (SW6010B) MS/MSD pair had RPDs greater than the UCL, and the associated sample results were qualified as estimated. One Cr(VI) (SW7199) sample had a high bias post-digestion spike (PDS) and was qualified as estimated. See Attachment D4, Table D4-1.

- **AOC 9.** The MS/MSD samples for AOC 9 had recovery of target analytes outside the control limits established in the QAPP. Seven target analytes were qualified as estimated: antimony (SW6010B), 1,1-biphenyl, 1,2,4,5-tetrachlorobenzene, acetophenone, benzaldehyde, benzoic acid, and caprolactam (SW8270C). The serial dilution for one sample had an RPD greater than the UCL for barium, iron, magnesium, and manganese (SW6010B), and the sample was qualified as estimated. See Attachment D5, Table D5-1.

- **AOC 10.** The MS/MSD samples for AOC 10 had recovery of target analytes outside the control limits established in the QAPP. Twenty-one target analytes were qualified as estimated: aluminum, antimony, barium, copper, iron, lead, zinc (SW6010B), 4,4-DDE, alpha-BHC, alpha chlordane, beta-BHC, delta-BHC, dieldrin, endosulfan sulfide, endrin ketone, gamma-BHC, heptachlor, heptachlor epoxide (SW8081A), Aroclor-1260 (SW8082) benzoic acid, and caprolactan (SW8270C). One lead (SW6010B) MS/MSD pair had an RPD greater than the UCL, and the associated sample was qualified as estimated. The serial dilution for one sample had an RPD greater than the UCL for barium, iron, and magnesium (SW6010B), and the sample was qualified as estimated. See Attachment D6, Table D6-1.

- **AOC 11.** The MS/MSD samples for AOC 11 had recovery of target analytes outside the control limits established in the QAPP. Four target analytes were qualified as estimated: antimony, barium (SW6010B), Cr(VI) (SW7199), and caprolactam (SW8270C). The serial dilution for one sample had an RPD greater than the UCL for aluminum, barium, calcium, iron, magnesium, manganese, and zinc (SW6010B), and the sample was qualified as estimated. A PDS was also outside the control limits for calcium (SW6010B), and the sample was qualified as estimated. See Attachment D7, Table D7-1.

- **AOC 12.** The MS/MSD samples for AOC 12 had recovery of target analytes outside the control limits established in the QAPP. Eight target analytes were qualified as estimated: antimony, barium, magnesium (SW6010B), 1,2,4,5-tetrachlorobenzene, 2,3,4,6-tetrachlorophenol, acetophenone, benzaldehyde, and caprolactam (SW8270C). A PDS was also out of the control range for calcium and iron (SW6010B), and the associated sample was qualified as estimated. See Attachment D8, Table D8-1.

- **AOC 14.** The MS/MSD samples for AOC 14 had recoveries of target analytes outside the control limits established in the QAPP. Seven target analytes were qualified as estimated: antimony, barium (SW6010B), 1,2,4,5-tetrachlorobenzene, acetophenone, benzaldehyde, benzoic acid, and caprolactam (SW8270C). One benzoic acid (SW8270C) result was unusable due to a matrix spike recovery less than 10 percent and was flagged as “R.” A PDS was also out of the control range for barium, chromium, potassium, vanadium, and zinc (SW6010B), and the associated sample was qualified as estimated. See Attachment D9, Table D9-1.

- **300B.** The MS/MSD samples for area 300B had recovery of target analytes outside the control limits established in the QAPP. Two target analytes were qualified as estimated: antimony and barium (SW6010B). Two MS/MSD samples for benzoic acid and caprolactam (SW8270C) had recovery of less than 10 percent, and the sample results for benzoic acid and caprolactan (SW8270C) were rejected and were flagged as “R.” See Attachment D10, Table D10-1.

D.3.8 Surrogates

Surrogates are primarily used in organic chromatography methods and are added prior to sample preparation. The surrogates are added to all samples, standards, and blanks in an analytical run and provide a measurement to determine recovery for every sample matrix. Surrogate compounds are chosen to represent the various chemistries of the target analytes in a specific method. They are often specified by the method and are deliberately selected for their improbability of occurring as environmental contaminants. The results are compared to the acceptance criteria as established by the method or the QAPP.

Sample results with surrogate recoveries outside the acceptance criteria were qualified as estimated and were flagged as “J” for all detected results, qualified as estimated and flagged as “UJ” for all non-detect results where the surrogate recovery is equal to or greater than 10 percent, and rejected and flagged as “R” if the surrogate recovery is less than 10 percent. Refer to the site-specific tables in Attachments D1 through D10.

- **BKG.** All surrogate acceptance criteria were met for the background sample set.
- **SWMU 1.** One non-detect sample had surrogate recovery less than the LCL for TPH-DRO (SW8015B-E), four non-detect TPH-GRO (SW8015B-P) samples had a surrogate recovery less than the LCL, and one sample with detected TPH-DRO (SW8015B-E) had a surrogate recovery greater than the UCL. The samples results were qualified as described above. See Attachment D2, Table D2-1.
- **AOC 1.** Seven non-detect TPH-DRO/TPH-MO (SW8015B-E) samples had surrogate recoveries less than the LCL; two of the seven samples had less than 10 percent surrogate recovery. One detected TPH-MO (SW8015-E) sample had a surrogate recovery greater than the UCL. One detected PAH (SW8270SIM) sample had a surrogate recovery greater than the UCL; the samples results were qualified as described above. See Attachment D3, Table D3-1.
- **AOC 4.** One non-detect TPH-GRO (SW8015B-P) sample had a surrogate recovery less than the LCL. One sample had surrogate recovery less than the LCL for pesticides (SW8081A) and PCB (SW8082). The detect sample results were qualified as estimated and were flagged as “J”; the non-detect sample results were qualified as estimated and were flagged as “UJ.” See Attachment D4, Table D4-1.
- **AOC 9.** One sample had surrogate recovery less than the LCL for TPH-DRO (SW8015B-E). Three non-detect TPH-GRO (SW8015B-P) samples had a surrogate recovery less than the LCL. One PAH (SW8270SIM) sample had a surrogate recovery greater than the UCL, and the samples results were qualified as described above. See Attachment D5, Table D5-1.
- **AOC 10.** Four samples had surrogate recovery less than the LCL for TPH-DRO (SW8015B-E). Six non-detect TPH-GRO (SW8015B-P) samples had a surrogate recovery less than the LCL; one of the six samples had less than 10 percent surrogate recovery. One sample had surrogate recovery less than the LCL for pesticides (SW8081A). One PAH (SW8270SIM) sample had a surrogate recovery greater than the UCL. The samples results were qualified as described above. See Attachment D6, Table D6-1.

- **AOC 11.** Two samples had surrogate recovery less than the LCL for TPH-DRO (SW8015B-E). Three non-detect TPH-GRO (SW8015B-P) samples had a surrogate recovery less than the LCL. One TPH-MO (SW8015B-E) sample had a surrogate recovery greater than the UCL. See Attachment D7, Table D7-1.
- **AOC 12.** One non-detect TPH-GRO (SW8015B-P) sample had a surrogate recovery less than the LCL. See Attachment D8, Table D8-1.
- **AOC 14.** Four samples had surrogate recovery less than the LCL for TPH-DRO (SW8015B-E), and seven non-detect TPH-GRO (SW8015B-P) samples had a surrogate recovery less than the LCL. One TPH-MO (SW8015B-E) sample had a surrogate recovery greater than the UCL. One PAH (SW8270SIM) sample had a surrogate recovery greater than the UCL. One VOC (SW8260B) sample had a surrogate recovery greater than the UCL. The samples results were qualified as described above. See Attachment D9, Table D9-1.
- **300B.** One sample had surrogate recovery less than the LCL for TPH-DRO (SW8015B-E). See Attachment D10, Table D10-1. The samples results were qualified as described above.

D.3.9 Other

D.3.9.1 Internal Standards

Internal standards have similar chemical characteristics to those of the analytes and provide an analytical response that is distinct from the analyte and not normally subject to interference. The internal standards are added prior to analysis for the purpose of determining analyte concentrations. The internal standard’s response is referenced against a relative response factor, and the sample’s analyte concentration can be corrected for matrix effects. Sample results with internal standard relative response factors outside the acceptance criteria are qualified and flagged as “J” for all detected results, qualified and flagged as “UJ” for all non-detect results where the internal standard recovery is equal to or greater than 10 percent, and rejected and flagged as “R” if the surrogate recovery is less than 10 percent. See the site-specific table in Attachments 1 through 10 for the data discussed below. Three investigation areas had samples results that were flagged due to internal standards results.

- **AOC 4.** One VOC (SW8260B) sample had an internal standard recovery less than the LCL; the associated analytes were qualified as described above. One PAH (SW8270SIM) sample had an internal standard recovery greater than the UCL; the associated detected analytes were qualified as described above. See Attachment D4, Table D4-1.
- **AOC 14.** One VOC (SW8260B) sample had four internal standards recovered at less than the LCL; the associated analytes were qualified as described above. See Attachment D9, Table D9-1.
- **300B.** One VOC (SW8260B) sample had an internal standard recovery less than the LCL; the associated analytes were qualified as described above. See Attachment D10, Table D10-1.

D.3.9.2 Contamination

VOC soil samples were collected following the Method SW5035A protocols. Based on Method SW5035A there are multiple methods of preservation. Because soil samples that contain carbonate minerals may effervesce upon contact with sodium bisulfate preservative (the "normal" preservative), to reduce the possibility of gas forming in the samples vials, the VOC samples were collected using a minimum of three pre-weighed vials—two containing reagent water and one preserved with methanol.

During the process of VOC analysis, ATL determined that the reagent water certified pre-weighed vials it received from its supplier were contaminated with acetone. After analyzing approximately a dozen vials from new cases within the lot purchased, the laboratory determined the concentration of acetone varied from non-detect to over 2,000 micrograms per kilogram. Because of the highly variable concentration, it was decided to reject all detected acetone results. Acetone data from seven of the investigation areas were rejected. See the site-specific table in Appendix H of the Data Gaps Report for the data discussed below.

- **SWMU 1.** Twenty-two of 132 samples had acetone detects; acetone detects were rejected and flagged as "R." See Attachment D2, Table D2-1.
- **AOC 1.** Twelve of 90 samples had acetone detects; acetone detects were rejected and flagged as "R." See Attachment D3, Table D3-1.
- **AOC 9.** Nine of 19 samples had acetone detects; acetone detects were rejected and flagged as "R." See Attachment D5, Table D5-1.
- **AOC 10.** Thirty-one of 57 samples had acetone detects; acetone detects were rejected and flagged as "R." See Attachment D6, Table D6-1.
- **AOC 11.** Twenty-four of 38 samples had acetone detects; acetone detects were rejected and flagged as "R." See Attachment D7, Table D7-1.
- **AOC 12.** Six of 16 samples had acetone detects; acetone detects were rejected and flagged as "R." See Attachment D8, Table D8-1.
- **AOC 14.** Twenty-six of 75 samples had acetone detects; acetone detects were rejected and flagged as "R." See Attachment D9, Table D9-1.

D.3.9.3 Retention Time Window

Retention time is one form of measurement associated with liquid and gas chromatography. Ion chromatography introduces a sample, either manually or with an auto sampler, into a sample loop of known volume. A buffered aqueous solution known as the mobile phase carries the sample from the loop onto a column that contains some form of stationary phase material. The time it takes for an analyte to move from the injection loop, through the column, to the detector is referred to as the retention time. Because retention times vary with the identity of the component, they are used for qualitative analysis. Once the laboratory has established a retention time window (the laboratory averages the retention time of multiple standards and calculates a retention time window by using ± 3 times the standard deviation from the average), the retention time is used to positively identify the analyte in subsequent samples.

When a sample's chromatogram has a "suspect peak" (that is believed to be the analyte in question, but is not within the retention time window), the analyst should dilute and re-analyze the sample with the suspect peak to positively identify the analyte. If the sample is not re-analyzed, a detect sample result is qualified and flagged as "J"; a non-detect result is qualified and flagged as "UJ."

Two Cr(VI) samples from SWMU 1 had a chromatogram peak that was not within the retention time window. The detected results were qualified and flagged as "J." See Attachment D2, Table D2-1.

D.3.9.4 Matrix Interference

Matrix interference was encountered in many of the soil samples. Some interferences are listed in the method for metals (SW6010B), and others can be inferred from poor MS/MSD (all methods), surrogate (organic methods), or internal standard (mass spectrometer methods) recovery. Matrix interference may require a dilution, resulting in the sample being reported at an elevated reporting level. Alternatively, matrix interference may require the sample result be qualified due to poor MS/MSD, surrogate, or internal standard recovery.

D.3.10 Laboratory Duplicates

Laboratory duplicates measure laboratory precision. RPDs that exceed method criteria indicate imprecision in some aspect of the analytical procedure.

The laboratory analyzed duplicate aliquots of field samples at the required frequency. The quality control acceptance criteria for laboratory duplicates were met for all methods.

D.3.11 Chain of Custody/Sample Receipt

Samples are collected under chain of custody to ensure that sample integrity is documented and known from the time of collection through receipt at the laboratory, where custody is relinquished to the laboratory.

Each sample was documented in a completed chain of custody and was received by the laboratory courier in good condition. All discrepancies identified by the laboratory were promptly resolved.

All samples were transported to the laboratories by couriers provided by the laboratories.

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

J = the analyte is present but reported value may not be accurate or precise (estimated).

UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC exceedances.

R = the result is rejected.

Validation Reasons:

CCV<LCL = Continuing calibration recovery less than the lower control limit.

FD>RPD = Field duplicate’s relative percent difference is greater than the control limit.

HT>UCL = Holding time exceeded the upper control limit.

LCS>UCL = Laboratory Control Sample greater than upper control limit.

MS<LCL = Matrix spike recovery less than lower control limit.

RejectContamination = Result was rejected due to possible contamination.

TABLE D1-1

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason

SD<LCL = Matrix spike duplicate recovery less than lower control limit.
SerDil = Serial Dilution is greater than 10% RPD.
Sur<LCL = Surrogate recovery less than lower control limit.
Sur>UCL = Surrogate recovery greater than upper control limit.

Laboratory Accuracy and Precision Summary							
979047	SWMU1-3-1013	SW7199	Chromium, hexavalent	mg/kg	1.55	J	LabA&P
978925	SWMU1-WP10-2070	SW7199	Chromium, hexavalent	mg/kg	0.494	J	LabA&P

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

J = the analyte is present but reported value may not be accurate or precise (estimated).

UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC exceedances.

R = the result is rejected.

Validation Reasons:

CCV<LCL = Continuing calibration recovery less than the lower control limit.
FD>RPD = Field duplicate’s relative percent difference is greater than the control limit.
HT>UCL = Holding time exceeded the upper control limit.
LabA&P = Laboratory Accuracy and Precision
LCS>UCL = Laboratory Control Sample greater than upper control limit.
MS<LCL = Matrix spike recovery less than lower control limit.
Reject Contamination = Result was rejected due to possible contamination.
SD<LCL = Matrix spike duplicate recovery less than lower control limit.
SerDil = Serial Dilution is greater than 10% RPD.
Sur<LCL = Surrogate recovery less than lower control limit.
Sur>UCL = Surrogate recovery greater than upper control limit.

N002236	SWMU1-WP-T3a-2076	SW6010B	Sodium	mg/Kg	330	U	EB>RL	8200

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:
U = the analyte is qualified as “not detected” due to blank contamination.

Validation Reasons:
EB>RL = Equipment blank contamination greater than the RL.

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

J = the analyte is present but reported value may not be accurate or precise (estimated).

UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC exceedances.

R = the result is rejected.

TABLE D3-1
Topock Soil RFI/RI Part A – AOC 1
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason

Validation Reasons:
CCV<LCL = Continuing calibration recovery less than the lower control limit.
FD>RPD = Field duplicate's relative percent difference is greater than the control limit.
HT>UCL = Holding time exceeded the upper control limit.
LCS>UCL = Laboratory Control Sample greater than upper control limit.
MS<LCL = Matrix spike recovery less than lower control limit.
RejectContamination = Result was rejected due to possible contamination.
SD<LCL = Matrix spike duplicate recovery less than lower control limit.
SerDil = Serial Dilution is greater than 10% RPD.
Sur<LCL = Surrogate recovery less than lower control limit.
Sur>UCL = Surrogate recovery greater than upper control limit.

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

J = the analyte is present but reported value may not be accurate or precise (estimated).

UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC exceedances.

R = the result is rejected.

Validation Reasons:

CCV<LCL = Continuing calibration recovery less than the lower control limit.
FD>RPD = Field duplicate's relative percent difference is greater than the control limit.
HT>UCL = Holding time exceeded the upper control limit.
IS<LCL = Internal Standard recovery less than lower control limit.
IS>UCL = Internal Standard recovery greater than upper control limit.
LCS>UCL = Laboratory Control Sample greater than upper control limit.
MS<LCL = Matrix spike recovery less than lower control limit.
MS>UCL = Matrix spike recovery greater than upper control limit.
MSRPD = Relative percent difference between matrix spike and matrix spike duplicate greater than control limit.
PDS>UCL = Post digestion spike recovery greater than upper control limit.
RejectContamination = Result was rejected due to possible contamination.
SD<LCL = Matrix spike duplicate recovery less than lower control limit.
SD>UCL = Matrix spike duplicate recovery greater than upper control limit.
SerDil = Serial Dilution is greater than 10% RPD.
Sur<LCL = Surrogate recovery less than lower control limit.
Sur>UCL = Surrogate recovery greater than upper control limit.

Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason	Equipment Blank Result µg/L
N002224	AOC4-T5a-3068	SW6010B	Sodium	mg/Kg	3400	U	EB>RL	2200

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:
U = the analyte is qualified as “not detected” due to blank contamination.

Validation Reasons:
EB>RL = Equipment blank contamination greater than the RL.

TABLE D5-1
Topock Soil RFI/RI Part A – AOC 9
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason
N002211	AOC9-9-4022	SW8260B	Acetone	µg/Kg	300	R	Reject Contamination

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

J = the analyte is present but reported value may not be accurate or precise (estimated).

UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC exceedances.

R = the result is rejected.

Validation Reasons:

CCV<LCL = Continuing calibration recovery less than the lower control limit.

FD>RPD = Field duplicate’s relative percent difference is greater than the control limit.

HT>UCL = Holding time exceeded the upper control limit.

LCS>UCL = Laboratory Control Sample greater than upper control limit.

LCSRPD = Laboratory Control Sample’s relative percent difference is greater than control limit.

MS<LCL = Matrix spike recovery less than lower control limit.

RejectContamination = Result was rejected due to possible contamination.

SD<LCL = Matrix spike duplicate recovery less than lower control limit.

SerDil = Serial Dilution is greater than 10% RPD.

Sur<LCL = Surrogate recovery less than lower control limit.

Sur>UCL = Surrogate recovery greater than upper control limit.

>ICLinearRange = The result reported exceeds the linear range of the calibration

TABLE D5-3
Topock Soil RFI/RI Part A - AOC9 - Equipment Blank Contamination Summary
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason	Equipment Blank Result µg/L
NA	NA	NA	NA	NA	NA	NA	EB>RL	NA

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

U = the analyte is qualified as “not detected” due to blank contamination.

Validation Reasons:

TABLE D5-3

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:
J = the analyte is present but reported value may not be accurate or precise (estimated).
UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC exceedances.
R = the result is rejected.

Validation Reasons:
CCV<LCL = Continuing calibration recovery less than the lower control limit.
FD>RPD = Field duplicate’s relative percent difference is greater than the control limit.
HT>UCL = Holding time exceeded the upper control limit.
LCS>UCL = Laboratory Control Sample greater than upper control limit.
MS<LCL = Matrix spike recovery less than lower control limit.
MS>UCL = Matrix spike recovery greater than upper control limit.
MSRPD = Relative percent difference between matrix spike and matrix spike duplicate greater than control limit.
RejectContamination = Result was rejected due to possible contamination.

TABLE D6-1
Topock Soil RFI/RI Part A – AOC 10
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason

SD<LCL = Matrix spike duplicate recovery less than lower control limit.
SD>UCL = Matrix spike duplicate recovery greater than upper control limit.
SerDil = Serial Dilution is greater than 10% RPD.
Sur<LCL = Surrogate recovery less than lower control limit.
Sur>UCL = Surrogate recovery greater than upper control limit.

TABLE D6-3
Topock Soil RFI/RI Part A - AOC10 - Equipment Blank Contamination Summary
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason	Equipment Blank Result µg/L
NA	NA	NA	NA	NA	NA	NA	EB>RL	NA

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:
U = the analyte is qualified as “not detected” due to blank contamination.

Validation Reasons:
EB>RL = Equipment blank contamination greater than the RL.

Attachment D7

Summary of Samples Qualified in AOC 11

TABLE D7-1
Topock Soil RFI/RI Part A – AOC 11
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason
N002180	AOC11e-2-6052	SW8260B	Acetone	µg/Kg	100	R	Reject Contamination
N002180	AOC11e-SS-2-6083	SW8260B	Acetone	µg/Kg	99	R	Reject Contamination

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

J = the analyte is present but reported value may not be accurate or precise (estimated).

UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC exceedances.

R = the result is rejected.

Validation Reasons:

CCV<LCL = Continuing calibration recovery less than the lower control limit.

FD>RPD = Field duplicate’s relative percent difference is greater than the control limit.

HT>UCL = Holding time exceeded the upper control limit.

LCS>UCL = Laboratory Control Sample greater than upper control limit.

MS<LCL = Matrix spike recovery less than lower control limit.

MS>UCL = Matrix spike recovery greater than upper control limit.

PDS>UCL = Post digestion spike recovery greater than upper control limit.

RejectContamination = Result was rejected due to possible contamination.

SD<LCL = Matrix spike duplicate recovery less than lower control limit.

SerDil = Serial Dilution is greater than 10% RPD.

Sur<LCL = Surrogate recovery less than lower control limit.

Sur>UCL = Surrogate recovery greater than upper control limit.

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

J = the analyte is present but reported value may not be accurate or precise (estimated).

UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC exceedances.

R = the result is rejected.

Validation Reasons:

CCV<LCL = Continuing calibration recovery less than the lower control limit.
FD>RPD = Field duplicate’s relative percent difference is greater than the control limit.
HT>UCL = Holding time exceeded the upper control limit.
LCS>UCL = Laboratory Control Sample greater than upper control limit.
MS<LCL = Matrix spike recovery less than lower control limit.
MS>UCL = Matrix spike recovery greater than upper control limit.
PDS>UCL = Post digestion spike recovery greater than upper control limit.
RejectContamination = Result was rejected due to possible contamination.
SD<LCL = Matrix spike duplicate recovery less than lower control limit.
SD>UCL = Matrix spike duplicate recovery greater than upper control limit.
SerDil = Serial Dilution is greater than 10% RPD.
Sur<LCL = Surrogate recovery less than lower control limit.
Sur>UCL = Surrogate recovery greater than upper control limit.

TABLE D8-3
Topock Soil RFI/RI Part A - AOC12 - Equipment Blank Contamination Summary
Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station, Needles, California

SDG	Sample ID	Method	Analyte	Units	Final Result	Validation Flag[a]	Validation Reason	Equipment Blank Result µg/L
NA	NA	NA	NA	NA	NA	NA	EB>RL	NA

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

U = the analyte is qualified as “not detected” due to blank contamination.

Validation Reasons:

EB>RL = Equipment blank contamination greater than the RL.

[a] This is the qualifier flag for the analyte/method combination associated with the Validation Reason.

Validation Flags:

J = the analyte is present but reported value may not be accurate or precise (estimated).

UJ = the analyte is not detected and the specified detection limit value may not be accurate (estimated) due to QC

TABLE D9-1

exceedances.

R = the result is rejected.

Validation Reasons:

CCV<LCL = Continuing calibration recovery less than the lower control limit.
FD>RPD = Field duplicate’s relative percent difference is greater than the control limit.
HT>UCL = Holding time exceeded the upper control limit.
IS<LCL = Internal Standard recovery less than lower control limit.
LCS>UCL = Laboratory Control Sample greater than upper control limit.
MS<LCL = Matrix spike recovery less than lower control limit.
MS>UCL = Matrix spike recovery greater than upper control limit.
PDS>UCL = Post digestion spike recovery greater than upper control limit.
RejectContamination = Result was rejected due to possible contamination.
SD<LCL = Matrix spike duplicate recovery less than lower control limit.
SD>UCL = Matrix spike duplicate recovery greater than upper control limit.
SerDil = Serial Dilution is greater than 10% RPD.
Sur<LCL = Surrogate recovery less than lower control limit.
Sur>UCL = Surrogate recovery greater than upper control limit.

APPENDIX E

Additional Detected Inorganic Compounds Background Investigation

E.1 Introduction

This appendix summarizes the data evaluation and calculation of representative background concentrations for the additional detected inorganic compounds (aluminum, calcium, iron, magnesium, manganese, potassium, and sodium) at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station, located in eastern San Bernardino County, California, approximately 15 miles southeast of Needles, California.

The evaluation and calculation approaches used to evaluate the additional detected organic compounds data followed the approaches used in the *Soil Background Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (hereafter referred to as the 2009 Soil Background Investigation) (CH2M HILL, 2009). The additional detected inorganic compounds were not analyzed or evaluated in the initial soil background investigation since they are not a constituent of potential concern at the compressor station. However, the United States Department of the Interior requested that a portion of soil samples be analyzed for the Contract Laboratory Procedure Target Analyte List/Target Compound List, which includes the additional inorganic compounds. These additional inorganic compounds will be carried through the risk assessment unless they can be screened out based on detected concentrations being at or below representative background concentrations at the PG&E Topock Compressor Station. Thus, it is useful to evaluate soil background concentrations for these constituents. Since the existing soil samples collected as part of the 2009 Topock Soil Background Investigation were still within the acceptable limits of the analytical hold time, these soil samples were analyzed for the Contract Laboratory Procedure Target Analyte List/Target Compound List using United States Environmental Protection Agency Method 6010B.

E.2 Combined Soil Background Additional Inorganic Compounds Data Evaluation

A combination of visual evaluation, statistical evaluation, and professional judgment were used to evaluate existing background data and establish a soil background data set. The additional inorganic compound dataset used for this background evaluation is provided in Attachment E1. To determine whether significant (practical or statistical) differences exist among the soil types and soil depths, two types of evaluation were performed:

1. Visual evaluation using graphical tools such as scatter and box-and-whisker plots

2. Statistical evaluation of the data using the analysis of variance (ANOVA), which includes a post hoc evaluation technique known as Tukey's test (Mason, Gunst, and Hess, 1993)

E.2.1 Visual Evaluation

To examine the relationship between depths and concentrations, the following depth partitioning was performed:

1. **Partition soil into two depth intervals.** The first interval consists of the 0 to 0.5 foot below ground surface (bgs), and the second interval consists of all subsurface depths (1, 2, 5, and 9 feet bgs). Note that most sample depths were recorded as the top of the sample interval. This corresponds to the surface and subsurface intervals.
2. **Partition soil into four depth intervals.** The first interval is 0 to 0.5 foot bgs, the second interval consists of 1 and 2 feet bgs, the third interval consists of 5 and 6 feet bgs, and the fourth interval consists of 9 and 10 feet bgs. These intervals are the surface interval, near-surface interval, typical maximum exposure depth for ecological receptors, and maximum depth for human receptors.

Scatter plots were prepared for each constituent, displaying the concentrations by soil type and depth intervals. Figures E-1 and E-2 present the scatter plots for the two-depth and four-depth partitioning, respectively. In these plots, blue closed symbols represent detected values while green open symbols represent proxy values of one-half of the reporting limit (i.e., non-detect samples). The detection frequencies for each partition are included at the top of each plot. In general, these plots suggest fairly consistent concentration spreads across each depth and soil type.

Additional visual evaluation was performed using the box-and-whisker plots, as shown in Figures E-3 and E-4. The box-and-whisker plot for each constituent presents the concentrations by soil type and depth separately.

Box-and-whisker plots present information on the central tendency, variability, and skewness for a sample data set by sketching the center 50 percent of the concentrations with a box and illustrating the tail regions of the distribution with whiskers. For concentrations that extend further from the center than the whiskers, individual data symbols are plotted.

Specifically, these box-and-whisker plots are constructed as follows:

- The height of the box represents the interquartile range (IQR). The IQR is the distance between the 25th and the 75th percentiles.
- The horizontal line in the box interior represents the median.
- The vertical lines issuing from the box extend to the minimum and maximum measured values (as long as these minimum and maximum values do not extend further from the box than a distance of 1.5 times the IQR).
- Individual data symbols are used for concentrations that exceed the whiskers.

Scatter plots were also prepared for each constituent, presenting concentrations by soil type and depth separately (Figures E-5 and E-6). These plots demonstrate an overall similarity across the soil types and depths for nutrient concentrations.

E.2.2 Statistical Evaluation

In addition to the visual evaluation, statistical evaluation was also performed to determine whether statistically significant differences (whether they carry practical significance or not) exist among the soil types and soil depths.

E.2.2.1 Analysis of Variance

To determine whether the mean values of multiple groups are statistically different from one another, a nonparametric ANOVA, using the ranks of the data as opposed to the concentrations themselves, was used for the background nutrient data. The ANOVA probabilities were compared to a significance level of 0.05. A more detailed discussion of ANOVA is presented in the 2009 Soil Background Investigation (CH2M HILL, 2009).

The ANOVA screening results suggest observed differences (at a significance level of 0.05) in the following groups: (1) between soil types (calcium and sodium), (2) between the two depth partitions (aluminum, calcium, iron, and sodium) and (3) between the four depth partitions (aluminum, iron, and sodium).

It is important to note that while the probabilities provide a quantitative measure of the degree of difference or similarity between soil types and depths, they should not be treated as precise representations of the actual confidences involved. For that to be true, the data would need to be balanced between the different partitions both in number of samples and variability. While this is not the case with most environmental evaluations, the ANOVA still offers useful insight into how similar the concentrations from the various partitions are to one another.

Realistic expectations from an evaluation of almost any data set with varying soil types and depths would suggest the presence of statistically significant differences for multiple constituents. Statistical differences from an ANOVA screening represent differences between partitions greater than the random variability in the data. Thus, if variability is small, even relatively minor differences between partitions (from a practical standpoint) may be statistically significant. From professional experience, it is not realistic to expect that all soil types or depths be statistically similar to one another in an evaluation (using ANOVA at a 0.05 significance level), regardless of the data set. As such, it is prudent to consider the practical significance of any statistical differences to gauge the usefulness of partitioning by soil type and/or depth. Complete reliance on statistical tests typically leads to varied assignments of soil types or depths, which can be problematic in actual site comparisons since many actual site samples tend to straddle two or more of these partitions. The statistical information provides an indication of the parameters that should be the focus of professional review.

E.2.2.2 Post Hoc Evaluation (Tukey’s Test)

In addition to the ANOVA screen, a post hoc evaluation technique, otherwise known as a test of contrasts, was done to determine which soil types (and subsequently depths) appeared statistically equivalent. Specifically, the Tukey's test (Mason, Gunst, and Hess, 1993) was performed to aid in this analysis. A more detailed discussion of the Tukey's Test is presented in the 2009 Soil Background Investigation (CH2M HILL, 2009).

The results of the Tukey's test are presented as alphabetic characters (A, B, etc.). Tables E-1 through E-5 consolidate the results of the Tukey soil type and depth partitions, with depth partitioned into two depth intervals and four depth intervals, respectively. Differences in soil type groupings and various depth intervals are displayed. The results suggest observed differences of the soil types and depths for aluminum, calcium, iron, magnesium, and sodium. As with the initial ANOVA screening, the tables suggest that professional review (i.e., geologist review) of the soil types and depths should focus on these constituents, since these were the constituents for which multiple soil type or depth categories were suggested using the ANOVA techniques.

E.2.2.3 Combined Data Evaluation Conclusions

A comparison of data collected from the various lithologic units and the two depth intervals and four depth intervals shows that aluminum, calcium, iron, magnesium, and sodium concentrations are very similar (i.e., well within an order of magnitude), and visual observations of the data plotted in the scatter plots in Figures E-5 and E-6 confirm that concentrations for the above-listed constituents are very similar. After careful review of the various graphical plots, the observed statistical differences between soil types or depth intervals are not sufficient to require separation of the data into separate partitions per constituent.

E.2.3 Evaluation of Outliers

With the combination of all soil types and depths for each constituent, the outlier analysis was evaluated by considering all data for each constituent that was detected in each soil type. Similar to the evaluation for soil type and depth differences, a combination of statistical evaluation, visual evaluation, and professional judgment were used to identify potential outliers.

Per United States Environmental Protection Agency guidance (2006), Rosner's test was applied when the sample size for a constituent is more than 25 with a 0.05 significance level. The Rosner's test was applied in such a way that multiple outliers would all be identified as mathematical outliers. A more detailed discussion of Rosner's test is presented in the 2009 Soil Background Investigation (CH2M HILL, 2009). The details of the Rosner's outlier analysis are provided in Table E-6. This table presents the selected transformation that promotes the best adherence to normality with the remaining concentrations (after the potential outlier is removed). It also provides, for each result, the Rosner-calculated statistic along with the critical value to which the statistic is compared. If the statistic is greater than the critical value, that result is considered a mathematical outlier. All results greater than that outlier result are also considered mathematical outliers, even if their statistics did not surpass the critical value. The mathematical outliers identified include two manganese concentrations of 540 and 1,100 milligrams per kilogram (mg/kg) and one potassium concentration of 8,700 mg/kg. These outliers have been removed from the dataset.

In addition, a visual evaluation of scatter plots (included in previous sections) and probability plots included in Figure E-7 were also used to identify potential outliers. No additional outliers were identified by this visual assessment.

The California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) previously recommended that outliers also be identified as those concentrations that exceed 1.5 times the IQR of the dataset above the third quartile as a simpler evaluation of identifying multiple outliers with each calculation (DTSC, 2007). The list of these quartile-based outliers (including nondetect proxy values of one-half the reporting limit) is included in Table E-7 and plots included in Figure E-8. These quartile-based outliers are also presented graphically on a box-and-whisker plot shown in Figures E-3 and E-4.

The dataset (excluding the two manganese and one potassium outliers) was carefully reviewed, and the outlier analysis evaluated both statistical outliers and outliers based on professional judgment. Based on the review of the background data set concentrations, the concentrations are representative of the natural variability of metals in soil.

E.3 Calculation of Background Threshold Values

Summary statistics for each constituent in the background soil data set are presented in Table E-8. These statistics include the mean, median, standard deviation, minimum detection limit, maximum detection limit, minimum detect, maximum detect, number of detects, number of samples, and percent detects for all concentrations retained in the data set after removal of outliers. These statistics also include the background threshold value calculated for the background data as an upper tolerance limit (UTL). These UTLs were targeted to be 95/95 UTLs (which are 95-percent upper confidence limits of the 95th percentile of the background population). The same statistical approaches used in the 2009 Soil Background Investigation for these UTL calculations were used for the nutrient inorganics.

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
California Department of Toxic Substances Control (DTSC). 2007. *Comments and Conditional Approval of the RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan, Part A, Pacific Gas and Electric Company (PG&E), Topock Compressor Station, Needles, California (EPA ID No. CAT080011729)*. August 10.				
Conditions of Approval Included in Cover Letter				
		Condition #1	PG&E shall begin Phase 1 field work within 30 days of receiving all applicable permits associated with the approved portion of the Part A Work Plan.	Comment noted. PG&E completed mobilization within the required time frame.
		Condition #2	Per request of FMIT, PG&E shall prepare a site map depicting all study areas proposed in both Part A (outside the compressor station fence line) and Part B (inside the compressor station fence line) for reference. This site map shall be made available to interested parties upon their requests.	As agreed during the August 29, 2007 conference call, the existing figure in the RFI is adequate. The revised figure was included in the Part B work plan.
		Condition #3	PG&E shall issue a Phase 1 Part A Soil Sampling Data Gaps Evaluation Report within 60 days of completion of the field activities.	Comment noted. PG&E could not provide this report within 60 days of completion of the final field activities (data validation) since DTSC and DOI concurrence was not received on the Data Quality Objectives Technical Memorandum until March 2010. The Data Quality Objectives Technical Memorandum was required to provide a basis for the data evaluation**.**
		Condition #4	PG&E shall prepare a Phase 2 Part A Soil Sampling Work Plan when directed by DTSC after the evaluation of the Phase 1 Part A Soil Sampling Data Gaps Evaluation Report. The Phase 2 Part A Soil Sampling Work Plan shall address, at minimum, the remaining issues deferred to the Phase 2 investigation as specified in the attached GSU comments, as well as discussions and evaluation pertinent to the rejected sections of the Phase 1 Part A Work Plan.	Comment noted. PG&E will provide the Phase 2 Part A Soil Sampling Work Plan within 90 days of being directed by DTSC, provided that this Part A Phase 1 Data Gaps Evaluation Report has been approved by DTSC and DOI prior to the start of the 90-day period.

TABLE F-1

Documentation of Compliance and Response to California Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) Comments

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
		Condition #5	PG&E shall make a reasonable attempt to work with the interested tribes to establish a tribal monitor during the site investigation field work.	PG&E invited Native American monitors to be present every day that work was performed. However, because PG&E can not require the Native American monitors to come to the site for this work, PG&E did not stop work when monitors were not present.
		Condition #6	PG&E shall ensure that all personnel associated with the field work be oriented on tribal sensitivity issues and to reasonably avoid unnecessary disturbance of the sensitive landscape.	Qualified PG&E staff provided this training to all PG&E personnel and contractors involved in the field investigation effort. Each person involved in this effort received the training prior to beginning their assigned work.
		Condition #7	At the request of the Fort Mojave Indian Tribe, DTSC requests that PG&E engage in discussions with the land owner/manager and interested tribes to explore options in managing non-contaminated investigation-derived wastes. PG&E must, however, properly characterize and manage hazardous waste pursuant to the California Code of Regulations, Title 22, Division 4.5, Chapter 12.	This issue was discussed during implementation of the field investigation program. However, direct-push borings are only 1.5 inches in diameter, and it is physically infeasible to put the drill cuttings back into such a narrow hole. Attempting to backfill the hole with native materials also compromises the ability to grout the hole in accordance with regulatory requirements. However, most shallow samples (0.5 foot bgs and 3.0 feet bgs) were collected using hand sampling equipment, and excess soil was backfilled into the sampling hole. Similarly, materials excavated from trenches were placed back into the trenches.
General Comments				
DTSC—The Geologic Services Unit (GSU)	1		The constituents of potential concern (COPCs) for each of the solid waste management units (SWMUs) and areas of concern (AOCs) have been previously identified in a GSU memorandum dated March 29, 2006. COPCs should not be reduced or eliminated without sampling analytical data at this point of the RCRA Facility Investigation (RFI) program. PG&E may provide past analytical data to demonstrate the absence of COPCs as identified in the GSU memorandum in support of a reduced laboratory analytical program which does not include all COPCs. However, in the absence of such information, all COPCs identified for each SWMU or AOC must be evaluated.	All COPCs listed for each unit in the March 29, 2006 comments were included in the analytical suites for each unit. It should be noted that the March 29, 2006 comments did not require analysis of all classes of compounds at all units. The analytical parameters evaluated in the Part A Phase 1 field investigation program, in many cases, exceeded the requirements defined in the March 29, 2006 letter.

Documentation of Compliance and Response to California Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) Comments

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
	2		Due to the sensitive landscape in which the proposed soil sampling will take place, any modifications to the proposed sampling locations identified in the Workplan should only be conducted with prior DTSC approval.	Comment noted. All sampling locations were reviewed by DTSC. One boring (BKG-1) was relocated slightly; the new location was cleared by the agencies, the tribal monitor, and PG&E prior to installation of the boring. At the request of the tribal monitor and archeologist, no borings or trenches were installed and no samples were collected in UA-1.
	3	Section 6.2.4 on page 6-4	The third bullet in Section 6.2.4 on page 6-4 of the Workplan discusses an approach for analyzing Total Petroleum Hydrocarbons, Polycyclic Aromatic Hydrocarbons, and Volatile Organic Compounds (TPH, PAHs, and VOCs respectively). It states that if elevated organics are detected in lower yard samples, then they will be added to the COPCs at each AOC that is hydrologically connected to the compressor station. This approach, however, is not applicable to those AOCs that are not hydrologically connected to the lower yard, but may still be connected to the compressor station. DTSC notes that this lower yard organic screening approach could only be applied to AOC 1 and possibly to AOCs 4 and 14.	The approach to addressing organics was changed as a result of discussions with DTSC and DOI. Samples from all units were analyzed for VOCs, TPH (extractable and purgeable), PAHs, and SVOCs. Ten percent of all samples from each AOC were also analyzed for chemicals on the United States Environmental Protection Agency Contract Laboratory Program Target Analyte List/Target Compound List (TAL/TCL). All samples from the Former 300B Pipeline Liquids Tank area were analyzed for polychlorinated biphenyls (PCBs) using the Contract Laboratory Program protocol.
	4		For all AOCs and solid waste management unit (SWMUs), where potential asbestos-containing materials (ACM) are identified, the materials should be appropriately characterized to determine if the material does not indeed contain asbestos and if the asbestos is friable. Otherwise, the material should be assumed to contain friable asbestos and handled accordingly.	ACM was observed in soil in AOCs 4, 9, and 14. Soil samples collected from AOCs 4, 9, and 14 were analyzed for asbestos. Debris removal was not conducted during the Part A Phase 1 field investigation. Debris removal has occurred in AOC 4 as part of the time-critical removal action (TCRA) that is currently being conducted. In each case, the material will be handled as directed in the comment. Specifically during the AOC removal ACM was segregated from other removed materials for disposal as appropriate.
	5		The proposed soil sampling locations depicted on Workplan figures (6-7, 6-12, 6-16, 6-18, and 6-23) are differentiated into groups representing “Risk/Remediation/Characterization and “To/Toward Background”. In most cases this differentiation appears unfounded and arbitrary. The DTSC toxicologist has indicated that the ecological risk evaluation requires evaluation of inorganic chemicals to background, and organic chemicals to an	Figures showing the revised proposed sampling locations were provided to DTSC and DOI on September 13, 2007, with supplemental modifications for AOCs 1, 10, and 11 provided on July 25, 2008. These figures show only existing and proposed sampling locations.

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			appropriate detection limit below the appropriate ecological screening levels. Therefore, no differentiation is warranted as each soil sampling location should provide the same level of information useful to the evaluation of risk and environmental conditions at the site. The GSU recommends that all future figures and text be prepared and/or revised to acknowledge this issue.	
	6		In order to facilitate an adequate review of the historical activities within the area of potential effect, please provide true photographic enlargements (at a scale which appropriately depicts the investigation area) of all historical aerial photographs. The electronic copies provided with the first draft of Volume 1 of the RFI are useful; however, magnification to a useful scale distorts the image. An alternative to photographic reprints would be to provide electronic images at a resolution which would allow detail to be preserved during magnification. Additionally, pertinent photographs of the PG&E Compressor Station (e.g., those photos kept at the site or at other PG&E offices) should be copied and provided to DTSC.	Additional high-resolution photographs were provided to DTSC on May 11, 2007. DTSC indicated that at the August 29, 2007 conference call that these photographs satisfied its needs. PG&E (via Glenn Caruso) provided construction photos of the Topock Compressor Station. DTSC later requested several pages of photographs that appeared to be missing (letter dated March 20, 2008), and PG&E confirmed that there were no pages of missing photographs.
	7		Two concerns exist regarding the perimeter of the compressor station (the fence line) that separates the Part A off-site soils investigation from the Part B on-site investigation. First, DTSC believes that sampling along historic discharge areas around the perimeter of the facility is warranted. Storm water discharge pipes (storm drains) are documented by PG&E as the suspected source of contamination at some areas of concern at the site (e.g., AOC 9—Southeast Fence Line; AOC-10a—East Ravine). Potential contamination associated with all storm drains that discharge off the site should be evaluated as part of the RFI soils investigation. It would be undesirable to have to wait for erosion channels along slopes to expose discolored, contaminated soil.	During the August 29, 2007 conference call it was agreed that perimeter and storm drain sampling could be conducted during the Part B investigation. Fifteen perimeter and storm drain sampling locations were identified during a site walk with DTSC and DOI on October 18, 2007. These locations are shown on Figure 1 of the Part B Phase 1 proposal, dated September 30, 2008. These sampling locations will be considered during the preparation of the upcoming Final Part B Work Plan (target for mid 2010).

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			Historic releases from the facility to offsite areas should also be investigated near the fence line where contaminant concentrations would be expected to be higher and/or detectable closer to the source of contamination. The Workplan discusses a historic release from Cooling Tower B to the northeast ravine yet sampling along the perimeter of the site to evaluate this release is not proposed. At another area, debris (including apparent transite) is located outside the fence line along the perimeter of the site (see Figure 1). This type of waste is considered significant at other AOCs and should be addressed by PG&E. PG&E should submit a plan to DTSC to evaluate the perimeter of the site. A site survey of the perimeter of the station should be conducted to identify obvious areas requiring characterization. Concern also exists regarding the transition of the on-site area to the off-site area. Contaminant concentrations within an on-site area may be protective for industrial scenarios, but might cause excessive human or ecological risk at off-site areas if contaminated on-site soil is released offsite (via storm drains, wind storms, or storm water run off). Figure 2 illustrates this issue. PG&E's plan to evaluate the perimeter of the site should address this issue.	
Specific Comments				
	1	Section 4.2.2.5	**Calculation of Groundwater Leaching Screening Levels for Metals in Soil** Two documents referenced in this section (Hevesi et al., 2003 and Ronan et al., 1998) do not appear in the full references in Section 11. Please provide the full references so DTSC can evaluate the appropriateness of each document to the current investigation.	PG&E e-mailed DTSC and DOI the full references for the two documents for evaluation in 2007. The Hevesi et al., 2003 reference was also included in the June 23, 2008 *Calculation of Soil Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station* Technical Memorandum.

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			It is also recommended that preliminary calculations be provided for each metal to allow DTSC and other stakeholders to clearly understand the methodology.	Section 4.0 of the Part A work plan provides a detailed description of how the groundwater leaching screening levels will be calculated and the assumptions of the approach. Further, the *Calculation of Soil Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station* Technical Memorandum, submitted to the agencies on August 1, 2008, provided additional information on the proposed methodology for calculation of site-specific soil screening levels for the protection of groundwater (GPL). Please note also that, per this Technical Memorandum, the term GPL has been changed to soil screening level protective of groundwater and is now abbreviated SSL. A key variable in calculating the groundwater leaching screening levels is the areal extent of impacted soils. The screening levels cannot be calculated until the first phase of data are available. As agreed during the August 29, 2007 conference call, the GPL for each AOC will be calculated and included in the Part A Phase 1 Data Gaps Evaluation and Part A Phase 2 Soil Sampling Work Plan.
	2	Section 5.3.1	**Outlier Analysis** Based upon descriptions in the USEPA Data Quality Assessment document (USEPA QA/G9S), it appears that the proposed mathematical outlier tests (Rosner's test and Dixon's Extreme Value test) assume a normal distribution of the dataset. At the point in the dataset evaluation that the outlier test is conducted, a determination of normality has not been conducted. Utilization of a test which assumes normality would be inappropriate. The DTSC recommends identifying outliers as those data points which exceed 1.5 times the inter-quartile range of the dataset above the third quartile [i.e., Q3 + 1.5 (IRQ)] as a simpler evaluation capable of identifying multiple outliers with each calculation.	According to the USEPA guidance *Data Quality Assessment: Statistical Methods for Practitioners* (USEPA, 2006), the outlier analysis approach presented in the work plan is preferable to the box and whisker approach suggested by DTSC. Consequently, the proposed approach was used in the outlier analysis provided in the *Soil Background Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California*, submitted to DTSC and DOI December 12, 2008. However, in response to this comment, PG&E also performed the inter-quartile range analysis, as requested by DTSC. This information is also presented in the December 12 technical memorandum.

Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
	3	Section 6	**Investigation Area Soil Sampling Plan** Comments regarding AOCs and SWMUs are presented below in the AOC/SWMU Specific Comments.	Comment noted.
	4	Section 7	**Soil Sampling Methods** In order to provide completeness of the description of the scope of work, relevant standard operating procedures (SOPs) should be included as attachments to all future workplans rather than inclusion only by reference.	Comment noted. SOPs were included in Appendix E for the Part B investigation work plan and will also be included in the Part A Phase 2 Soil Sampling Work Plan.
	5	Section 7.6	**Trenching** Each exploratory trench should extend no less than six feet below ground surface (bgs) in order to evaluate potential environmental conditions to the depths previously agreed to (see also Specific Comments for AOC12).	Trench depths were increased to ensure that native material would be encountered, where possible. Trench depths in AOC 12 ranged from 3 feet (impenetrable hardpan was encountered at 3.5 feet below ground surface [bgs]) to 11 feet bgs. Trench 12c-T1 apparently did not encounter native material and was terminated at 11 feet bgs. Two samples were typically collected at or near the bottom of each trench. Sidewall samples were also collected in trenches 12a-T1 and 12c-T1a. Trench depths in AOC 4 ranged from 3 to 6 feet bgs; this corresponded to bedrock in trenches AOC4-T1 through AOC4–T3. Samples were typically collected at the bottom of the trenches; surface soil samples (0.5 foot bgs) were also collected at AOC4-T1 and AOC4-T2. Trenches in SWMU 1 ranged from 8 to 22 feet bgs and penetrated from 6 to 20 feet into the slope. Samples were collected at the surface, from intermediate depths, and near the bottom, where feasible.
AOC/SWMU Specific Comments				
	1	Section 6.3	**SWMU 1/AOC 1—Former Percolation Bed** During a site walk of AOC 1 conducted on December 11, 2006, it appeared that excessive sampling density was employed at three soil sampling locations that had been staked out by PG&E. Two of the samples (one identified as WP-NEW-2) were staked in recently discovered white powdery material near the toe of	In accordance with DTSC's recommendation, the sampling plan was revised to provide more even coverage of the newly-discovered white powdery material, and sample locations were adjusted as recommended. Seven trenches were installed to explore the extent of the white powdery material in the bank, and 27 samples were collected for

TABLE F-1

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			the slope on the east side of the wash. The third stake was located just to the west in the wash. PG&E should indicate why such a tight sampling grid is needed. If sufficient rationale does not exist for each sample, DTSC suggests that one of the borings characterizing the white powder be dropped from the investigation and that third boring be moved 10 to 20 feet to the west away from the remaining boring. An additional sample location is suggested near a 55 gallon drum discovered in Bat Cave Wash (see Figure 3). The drum suggests a depositional environment within that specific portion of the wash and is located near boring SSB-8 that detected total chromium above background and Ecological Comparison Values as described in the Workplan. PG&E should locate the drum and determine if it contains waste that would require characterization and disposal. (Figure 3. Easterly view of a 55 gallon drum within Bat Cave Wash in the general vicinity of borings SSB-8 and MW-13.) The fourth bullet on page 6-7 of the workplan discusses elevated iron in well MW-17. Since well MW-17 is not associated with AOC 1, PG&E should clarify or amend the iron discussion.	laboratory analysis. See also discussion in response to General Comment 5. In response to this comment, sample location BCW-1 was added slightly to the north of boring SSB-8 at the location of the drum. The drum did not contain any waste, and was removed from Bat Cave Wash and properly disposed. Well MW-17 was erroneously included in the data table and discussion for AOC 1. Also, the screening level used in the work plan (23,000 mg/kg) was then the current residential PRG. The current soil RSL for iron is 55,000 mg/kg; no soil samples from any monitoring well exceed the current iron RSL.
	2	Section 6.4	**AOC 4 - Debris Ravine** Significant waste has been pushed off the northern edge of the ravine (See Figures 4 to 6). The AOC 4 area delineated on Figure 6-12 of the Workplan should be thoroughly walked and all debris carefully documented and mapped so the distribution of the debris and potential contamination associated with it can be established. The map generated should be provided to DTSC prior to the sampling effort. (Figure 4. Northwesterly view of the north side of the Debris Ravine. Green stained soil visible in Figure 7 within the erosion channel is located within the erosion channel below the black	On June 24, 2009, DOI issued an Action Memorandum entitled *Request for Time-Critical Removal Action Number 4 at AOC 4 Debris Ravine, Pacific Gas and Electric Topock Compressor Station* (DOI, 2009). DOI's Action Memorandum directed PG&E to implement a TCRA at AOC 4. The TCRA is intended to stabilize and mitigate the threat of release of contaminated material and is not intended to substitute for any investigative or remedial activities that may be required under RCRA or to be the final remedy for AOC 4. Debris within AOC 4 is also being removed as part of the TCRA.

			tank on the bench road to the right of the picture. Figure 5. Northerly view of waste that has traveled down the north side of the ravine. Figure 6. Easterly view of waste that has traveled down the north side of the ravine to the floor of the ravine. Wood slats may be from cooling towers.) Borings are needed throughout fill areas to identify the thickness of fill and potentially contaminated soils/wastes. These data are needed to assist in evaluating remedial alternatives during the Corrective Measures Study. PG&E should consider ways to assess the thickness of fill areas and obtain samples along the slope. PG&E may be able to bench slopes or create small pads so that mechanized tools, such as small power augers, could be used to place borings and reach appropriate depths. PG&E might also be able to use an excavator bucket to reach out over the slope and bring soil/fill/waste to the road for evaluation and sampling. Soils that are identified as containing debris should be sampled if the debris is removed during implementation of this phase of the workplan. A DTSC site walk of the site resulted in the addition of sample locations AOC4-14 and 15 as pictured in revised workplan Figure 6-12. Figures 8 and 9 below illustrate the debris (metal, glass, red clay pipe, transite shingles, etc.) that was not originally planned to be sampled in the Workplan. A pile of wood slats (possibly from cooling towers) similar to those in Figure 6 was also identified near the AOC4-14/15 location. Some of the slats were encrusted with scale of unknown composition and toxicity. This wood and scale, and soil from the immediate area should be sampled and analyzed for all COPCs. Concern exists that slope materials will continue to erode and potentially contribute contaminants to the ravine and Bat Cave Wash/Havasu National Wildlife Refuge. (Figure 8. Northwesterly view of debris in foreground placed along old road within the central portion of AOC 4 (Debris Ravine). Figure 9. Southwesterly view of debris in foreground	

TABLE F-1

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			placed along old road within the central portion of AOC 4 (Debris Ravine).)	
			Section 6.4.4 on Page 6-12 of the Workplan appropriately indicates that additional samples will be collected if stained soils are found. Green stained soils have been identified on the northern slope exposed within an erosion channel below a black tank (see Figure 7 below). This stained area should be sampled and analyzed for all COPCs. (Figure 7. Northerly view from the floor of the ravine of green stained soil visible from an erosion channel on the north side of the ravine.)	Comment noted. A sample of the green stained soil was collected (AOC4-STAINED). Sample locations AOC4-GH10 and AOC4-GH30 were collected from the green stained soil area.
	3	Section 6.5	**AOC 9 – Southeast Fence Line** Historical aerial photographs (particularly the oblique images from 1955) identify the presence of a structure (potentially a historic wash rack) near the head of slope. Therefore, the limits of AOC 9 should be expanded approximately 50 feet to the southwest along the slope. Soil sampling shall be expanded in this area. Dark marks in the face of the slope, potentially indicating liquid migration, are also identified in the 1955 aerial photograph and shall be sampled as part of AOC 10.	The limits of AOC 9 were expanded to the southwest to include four samples (AOC9-10 through AOC9-13).
			Sufficient sampling and analysis is not proposed for AOC 9. Sample locations should be included in the former area where visibly contaminated soil had been noted (e.g., area where samples No. 4 to 9 were collected) and where elevated contaminant levels have already been identified (e.g., Sample No. 10). This will provide data on the nature of the contamination and assist in identifying specific constituents of concern for AOC 9. Sampling in potentially clean areas elsewhere will not meet this objective. Sampling for VOCs and SVOCs in these two areas is suggested as the source of contamination emanated from a storm water drainage pipe that has been characterized as possibly draining the facility's steam-cleaning wash rack area. Deeper samples (greater than 3 feet below ground surface) should also be collected from these two areas to determine the vertical extent of contamination. If	In addition to the seven samples originally proposed to delineate the extent of AOC 9, two samples were added near the former elevated detections at borings #4 and #9 (AOC9-8), and boring #10 (AOC9-9). Furthermore, as discussed above, four samples were added to assess potential impacts from the former structure near the top of the slope.

TABLE F-1

Documentation of Compliance and Response to California Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) Comments

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			necessary, PG&E should develop ways to obtain samples along slope. PG&E may be able to bench slopes or create small pads so that mechanized tools, such as small power augers, could be used to obtain samples from appropriate depths. PG&E might also be able to use an excavator bucket to reach out over the slope and bring soil/fill to the road for evaluation and sampling. PG&E must evaluate field conditions and sampling logistics well in advance to minimize amendments to the sampling program just prior to the field effort.	
			Section 6.5.3, Page 6-14, Line 4 of the Workplan refers to a nonexistent Table 3-3 and a total number of samples (49) that does not correlate with the total number of proposed samples (47) contained in Table 3-2 of the Workplan. Table 3-2 should be checked for accuracy for all investigative areas and updated as necessary.	Comment noted. A table showing the number of samples collected at each unit is included in Appendix B of this Part A Phase 1 Data Gaps Evaluation Report. PG&E also understands that DTSC did not require a revised copy of Table 3-2.
	4	Section 6.6	**AOC 10 – East Ravine** During a site visit in July 2006, GSU staff observed small amounts of metal debris in either subarea 10b or subarea 10c. The debris identifies depositional areas in the wash that have been affected by former operations. The location of the metal debris should be confirmed, documented and mapped.	As agreed during the August 29, 2007 conference call, PG&E will conduct the requested mapping was conducted on May 2009, results of the mapping are presented in this Part A Phase 1 Data Gaps Evaluation Report. .
			Page 6-15 of the Workplan describes a white waste layer occurring in subarea 10c. However, the Workplan does not address sample collection, characterization, and delineation of this white layer. Additional sampling and analyses are required to characterize the waste layers (see Phase 2 Recommendations Section).	Five borings were installed in subarea 10c. The referenced white waste layer was not encountered in any of those borings. The data from the three samples collected by DTSC on January 18, 2008 were incorporated into the data gaps evaluation for AOC 10.
			The conceptual model for the East Ravine wash should be updated. The Workplan should acknowledge that prior to the construction of the dams, run off from the site, including potential contaminants, could have moved more freely down the wash during rain events or releases to the drainage. The fourth paragraph on page 6-15 of the Workplan indicates that the	As agreed during the August 29, 2007 conference call, an updated conceptual model for the East Ravine will be included in the Part A Phase 2 Soil Sampling Work Plan.

TABLE F-1

Documentation of Compliance and Response to California Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) Comments

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			easternmost road/dam is not eroded suggesting water has not flowed over it. It is assumed that water could have overtopped this dam in the past as it is assumed that the road/dam is periodically maintained. PG&E has indicated that PG&E personnel have conducted training on earth moving equipment in this general area.	
			VOCs and SVOCs are recommended to be analyzed at location AOC-10a-1 due to the presence of stained soil, possibly old hydrocarbon staining, and at the storm drain discharge location discussed in the preceding paragraph.	As discussed in response to General Comment #3, VOCs, SVOCs, PAH, and TPH-extractable and -purgable were analyzed at all units.
			Samples AOC10-1 and 2 pictured in the original Figure 6-16 of the Workplan were removed in the revised figure. These sample locations should be reinstated because the Workplan indicates, “Because runoff from larger spills near the station access road could have entered the East Ravine, additional sampling along the slope leading into the East Ravine is also required.”	The two samples were reinstated and are shown on the revised Figure 6-16 provided to DTSC and DOI on September 25, 2008.
			Sample AOC-10a-2 appears redundant with sample AOC-10a-1 and should be eliminated unless PG&E has selected it for a specific purpose (e.g., contaminant delineation) or the stained area downslope from AOC 9 is difficult to locate.	Sample AOC-10a-2 was removed from the sampling plan (see revised Figure 6-16 provided to DTSC and DOI on September 25, 2008).
			Additional soil borings seem necessary to evaluate specific potential contaminant pathways and further define the lateral extent of previously identified contamination. DTSC believes these locations should be further evaluated with additional soil borings: • within the defined area of AOC 10c to provide additional data in the area of former sample location L-2-2 (north of previous sample location) for further definition of elevated contaminant concentrations • approximately 60 feet downstream of area AOC 10c on outside of the wash meander to ensure sufficient sample coverage	In response to this comment, the following sampling locations were added to the investigation program (see revised Figure 6-16 provided to DTSC and DOI on September 25, 2008): • Sample AOC10c-5 was added within the defined area of AOC 10c to provide additional data in the area of former sample location L-2-2. • Sample AOC10-3 was added approximately 150 feet downstream of area AOC 10c on outside of the wash meander to ensure sufficient sample coverage. (The sample location formerly named AOC10-3 was relocated slightly and renamed AOC10-6; see discussion in fourth bullet, below.)

TABLE F-1

Documentation of Compliance and Response to California Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) Comments

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			• approximately 20 feet upstream of area AOC 10d on the outside of the wash meander to ensure sufficient sample coverage • one to three samples in depositional areas downstream of AOC10-3 and before the Colorado River to ensure sufficient sample coverage	• Sample AOC10-4 was added approximately 30 feet upstream of area AOC 10d on the outside of the wash meander to ensure sufficient sample coverage. • Two samples were added to the area downstream of the road/dam forming the downstream end of AOC 10d, resulting in a total of three sample locations for this subarea. The sample locations were renumbered for consistency with the numbering of samples in the rest of AOC 10. Two sample locations (AOC10-6 and AOC10-7) are downstream of the former location of AOC10-3 and before the Colorado River to ensure sufficient sample coverage. One sample location (AOC10-5) is south (upstream) of the former location of AOC10-3.
	5	Section 6.7	**AOC 11 – Topographic Low Areas** Section 6.7.4 of the Workplan indicates that samples from subarea 11b and supplemental samples northwest of 11a can only be collected by hand and that only the top two samples will be collected. However, a track mounted limited access rig or equivalent should be utilized to obtain deeper samples.	As requested, PG&E set a target of collecting samples from the 6- and 10-foot-bgs intervals for all samples from AOC 11. Refusal was encountered 3.5 feet bgs in boring AOC11-SS-2; samples were collected from 5 to 6 feet bgs and 9 to 10 feet bgs from all other borings in this AOC.
			It is also recommended that all AOC 11 samples be analyzed for TPH and PAHs and not be held contingent on results from subarea 11a.	All samples from AOC 11, including supplemental samples, were analyzed for TPH and PAHs.
			PG&E has inadvertently eliminated boring location AOC11b-2 from the revised Figure 6-18 dated December 2006. DTSC believes that this boring is warranted to ensure sufficient sample coverage within the depositional area.	As shown in revised Figure 6-18, provided to DTSC and DOI on September 25, 2008, boring location AOC11b-2 was reinstated as requested.
			Figure 6-18 should be expanded to the south and southwest to depict the fence line of the compressor station. This visual depiction will provide assistance with evaluation of potential surface water flow pathways from the compressor station.	As shown in revised Figure 6-18, provided to DTSC and DOI on September 25, 2008, the figure was expanded as requested.

TABLE F-1

Documentation of Compliance and Response to California Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) Comments

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			DTSC staff observed an area south of PG&E's staging area along the access road that should be added to the topographic low area. This area, pictured in Figures 10 and 11, has accepted waste (cement and debris) from PG&E operations and, therefore, warrants investigation similar to other AOC 11 subareas (see Phase 2 Recommendations Section). Figure 6-19 of the Workplan also includes an aerial view of the area. (Figure 10. Easterly view of topographic low area containing cement spoils and debris south of PG&E's staging area along the access road. Figure 11. Easterly view of topographic low area south of PG&E's staging area.)	Comment noted. As requested by DTSC, this area will be addressed in the Part A Phase 2 Soil Sampling Work Plan. It is included as a newly identified area in the discussion of AOC 11 (a portion of subarea AOC-11f).
	6	Section 6.8	**AOC 12 – Fill Area** Section 6.8.1 of the Workplan discusses the history of potential areas filled with waste materials. A detailed evaluation of aerial photographs and topographic maps should be conducted to search for soil disturbance in the area over time to better locate the disposal and fill areas.	As agreed during the August 29, 2007 conference call, this evaluation will be included in the Part A Phase 2 Soil Sampling Work Plan.
			Trenches should encounter native soil unless depth limitations for the selected trenching method are met (e.g., 15 to 20 feet bgs.). Trench logs should be prepared and included in the RFI report.	As requested, the objective in the trenching effort was to ensure that native soil was encountered in each trench. Trench depths in AOC 12 ranged from 3 feet bgs (impenetrable hardpan (native soil) was encountered at 3.5 feet bgs) to 11 feet bgs.
			During the trenching activities associated with AOC 12, soil samples shall be collected and analyzed from within each trench. Samples should be collected at the bottom of each trench at an approximate interval of one sample per 20 feet of trench length and at other areas identified in the field (e.g., debris or discoloration). Trenching without sampling and analysis as proposed in the Work Plan would require an unnecessary return to AOC 12 to conduct sampling. Sampling and analysis is required to assess potential impacts from documented disposal activities. The absence of buried debris and laboratory analytical data indicating no residual chemical contamination would provide the basis for a no further	Soil samples were added at the proposed trench locations. Samples were collected at the bottom of the trench**.** Two samples were collected at the bottom of each trench. In addition, sidewall samples were collected from AOC 12a-T1 and AOC 12c-T1.

TABLE F-1

Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			investigation determination for this AOC. As indicated in General Comment 1 above, laboratory analytes shall consist of those previously identified in the GSU memorandum dated March 29, 2006.	
	7	Section 6.9	**AOC 14 – Railroad Debris Site** The GSU is unclear how the Railroad Debris Site Boundary pictured in Workplan figures (e.g., Figure 6-23) was derived and the rationale for indenting the northwest boundary.	The northwest boundary of this unit was defined by topography. There is a considerable (6 to 10 foot), abrupt rise in elevation in this area and it is difficult to access, even on foot.
			Text and illustrations should be prepared in sufficient detail with respect to the white powdery waste observed from old aerial photographs (circa 1950's and 1960's) to demonstrate that it has been accurately delineated on current site figures.	As agreed during the August 29, 2007 conference call, PG&E will provide an updated delineation of the white powdery material as part of the Part A Phase 2 Soil Sampling Work Plan. This updated delineation will include the expanded discussion of 1950s and 1960s information requested here, the mapping of visible powdery material and 1999 trench logs referenced below, and the relevant information collected during the Part A Phase 1 investigation.
			The May 18, 1964 aerial photograph (Figure 3-18) from the Volume I RFI Report (CH2MHill, 2006) suggests that the white waste is located further south from the railroad tracks than the current Railroad Debris Site Boundary (Figure 6-23) would suggest.	The more northerly boundary (closer to the railroad tracks) for AOC 14 was retained because there was minor surface debris in this area, and it is uncertain whether grading activities could have resulted in impacts beyond the area shown in the 1964 aerial photograph. The samples (ACO14-5 and AOC 14-7) from this area help define the northerly boundary of impacts for this unit.
			The first paragraph of Section 6.9.3 of the Workplan suggests that SVOC, TPH, and PAH results only correlated with the railroad ties and black sandy waste when in fact these analyses were only conducted and detected at the three railroad tie/black sandy waste sample locations. As SVOC, TPH, and PAH analyses have not been conducted within any soils from the Railroad Debris Site, it is recommended that these analytes be evaluated as a COPC for several more (e.g., 10 samples) of the proposed samples to provide sufficient coverage across the site. The SVOC, TPH, and PAH analyses should not just be limited	All soil samples from AOC 14 were analyzed for TPH (extractable and purgeable), PAHs, and SVOCs. In addition, all samples were analyzed for asbestos.

TABLE F-1

Documentation of Compliance and Response to California Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) Comments

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			to sampling under the same three previous waste areas where they were detected. The section also states friable ACM encountered in past sampling events had been removed. A site visit conducted by DTSC in 2006 still observed apparent ACM material (transite) at the surface at AOC 14 supporting the asbestos analyses proposed in the Workplan.	
			Section 6.9.3 of the Workplan indicates that the extent of the white powdery residue will be defined by additional sampling. However, visible white powdery material (see Figure 12 on the following page) should be mapped and documented in figures. Additionally, previous investigations (e.g., PG&E, 1999) for this AOC need to be better summarized to ensure samples are being collected at appropriate locations. Trench logs from previous investigations should be utilized to delineate the known extent of the white material (as well as debris and encountered soils) in map and cross-sectional views. This framework should be developed to ensure the sampling program will meet its objectives. PG&E should identify additional sampling and analysis locations based on the preceding tasks. (Figure 12. Northerly view of AOC 14. White layer visible in the freeway cut on the north side of the I-40 and in the background.)	As agreed during the August 29, 2007 conference call, PG&E will provide an updated delineation of the white powdery material as part of the Part A Phase 2 Soil Sampling Work Plan. This updated delineation will include the expanded discussion of 1950s and 1960s information requested above, the mapping of visible powdery material and 1999 trench logs, and the relevant information collected during the Phase 1 investigation.
			Currently, tables and figures in the Workplan do not indicate which samples encountered soil and which samples were obtained from the white material in the past.	This information will be provided as part of the overall discussion of the white powdery material in this Part A Phase 1 Data Gaps Evaluation Report.
			Several samples of the white material should be collected and analyzed for the complete suite of COPCs to characterize this material. This characterization objective is not clearly stated in the Workplan which focuses on the extent of the white powdery material.	White powdery material was only encountered in two of the samples collected from this unit. Where it was encountered, the interval containing the white powdery material was specifically sampled and analyzed for the full suite of COPCs for this unit.

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			In PG&E's 1999 document regarding the Railroad Debris Site, black material is identified on maps, cross-sections and tables as "Black Material" or "Sandy Black Material". The Workplan identifies the Black Material as "Asphalt Material". The GSU is uncertain if the "Black Material" is actually asphalt and requests that PG&E clarify this issue. The black waste should be clearly defined in the Workplan report and associated boring logs.	As agreed during the August 29, 2007 conference call, this information is provided in this Part A Phase 1 Data Gaps Evaluation Report.
			Table 6-22, AOC 14 Proposed Sampling Plan, Footnotes: Footnote 1 from Table 6-22 indicates that "mechanical equipment" access may be an issue at the site. This does not appear to be a significant concern due to generally flat lying topography (see Figure 12). Unless PG&E obtains prior approval from DTSC, PG&E should utilize mechanical equipment (e.g., a drill rig) to collect samples from the proposed depths specified in the Workplan.	The presence of the railroad tracks to the north and Interstate 40 to the south makes bringing mechanical equipment to this unit difficult. Either location requires a permit to allow access for mechanical equipment. Due to the extreme difficulty of obtaining a permit to cross the railroad tracks, PG&E negotiated a permit with CalTrans to allow mechanical equipment to be lifted onto the site by crane from Interstate 40.
			Footnote 2 indicates that debris and white waste material "may" be sampled and analyzed. DTSC is uncertain of the rationale for not sampling and analyzing debris and waste material.	The white powdery material has already been sampled extensively, and prior comments from DTSC focused on concerns relating to underlying impacts to soil. Because the purpose of this stage of work was to delineate the boundaries of the affected area, it was not certain that any white powdery material or debris would be encountered. As described above, white powdery material was encountered in two locations and was sampled. Apparent ACM was encountered in two boring locations (AOC14-2 and AOC14-13). Samples of this suspect material were sent for asbestos analysis. Consistent with the approach to debris at other locations, surface debris was mapped and the mapping result is included in this Part A Phase 1 Data Gaps Evaluation Report.

	8	Section 6.10	**Undesignated Area 1 – Potential Pipeline Disposal Area** The following additional information should be added to the investigation:	
			• The evaluation of the presence of buried pipes should not be limited to metallic pipes. The geophysical method utilized should evaluate the presence of any buried material with subsequent confirmation of the composition.	The geophysical investigation program for UA-1 included vertical magnetic gradient, electromagnetic, metal detection electromagnetic line locating, and ground-penetrating radar methods to identify buried debris, undifferentiated utilities, and pipelines. Two undifferentiated utilities were identified in UA-1.
			• The suspected dates of disposal should be identified so appropriate aerial photographs can be carefully examined to look for disturbed surface soil where potential burial could have taken place.	A former employee indicated that the suspected time of disposal was in the late 1960s or early 1970s; the exact dates are unknown. Historic photographs from the 1960s through the 1980s were examined; however, areas of disturbed soil were not apparent on the photographs.
			• The facility process from which the asbestos-covered pipes originated should be disclosed to determine if other COPCs should be included in the assessment. With the limited information currently provided, it is recommended that a larger list of COPCs be included in the investigation (currently the only COPC is asbestos). This would require soil sampling that is not proposed in the Workplan.	All available information was provided in the work plan. The potential source of the piping is not known. In accordance with DTSC's request, soil sampling was planned for this unit, and soil samples were to be analyzed for the full suite of COPCs, including ACM. However, as discussed in this Part A Phase 1 Data Gaps Evaluation Report, intrusive sampling was suspended at the request of the DOI.
			• Sampling soil from the trenches is not included in the Workplan. Soil associated with the pipe disposal should be sampled for related COPCs. Additional analyses may be required if soil discoloration, odors, etc. are observed during trenching.	See above response.

TABLE F-1

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			• If the geophysical survey does not locate the pipelines, then the geophysical survey should be expanded and include information obtained from examination of aerial photographs and site reconnaissance. The geophysical search would terminate if the expanded search did not locate geophysical anomalies. Should geophysics not provide valuable information, trenching in the most likely disposal area (disturbed area) is still suggested to confirm the results of the geophysical survey.	Five trenches were proposed in the vicinity of UA-1 These trenches were to be located as appropriate based on the geophysical results. However, as described above, intrusive investigation was suspended at this unit until another geophysical survey is performed at the new suspected disposal area shown on Figure B-5 in Appendix B.
	9	Section 6.11	**Undesignated Area 2 – Former 300B Pipeline Liquids Tank** CH2M Hill, on behalf of PG&E, submitted a technical memorandum, dated April 27, 2007, which summarizes information pertaining to the closure of the Former 300B Pipeline Liquids Tank (Unit). Additional historic information about the Unit has been obtained since the Workplan was prepared. The Tech Memo concludes that the site investigation and closure process at the Former 300B Pipeline Liquids Tank is complete and no further investigation is proposed for this location. However, the GSU's review of the Tech Memo has found that the historic data are insufficient to characterize the nature and extent of the contamination and, therefore, insufficient to asses risk. Only one sample was collected on April 16, 1996 to assess COPCs. Unfortunately, the sample collected was a composite sample from a depth of 0 to four inches bgs and was placed in a glass jar. The composite sample is not appropriate to assess COPCs and the VOC data are invalid due to the poor sampling methodology employed. Reporting limits for PAHs were also significantly elevated (8 mg/kg) and would not be appropriate for risk purposes. It is therefore recommended that the sampling proposed in the Workplan be conducted for the Unit for the COPCs originally established in the 1990's (i.e., TPH, Metals, SVOCs, VOCs, PAHs, and polychlorinated biphenyls).	As shown on Figure 6-25 for the Former 300B Pipeline Liquids Tank area, provided to DTSC and DOI on September 13, 2007, five boring locations were proposed in this area. Samples were to be collected from 0.5., 1, 3, and 6 feet bgs; refusal (bedrock) was encountered in Borings 300B-2, 300B-4, and 300B-5. All samples were analyzed for Cr(VI), cyanide, TPH-extractable and -purgable, Title 22 metals, VOCs, PAHs, SVOCs, and PCBs. Ten percent of the soil samples collected at Former 300B Pipeline Liquids Tank area were also analyzed for TAL metals and pesticides.

	10	Section 6.12	**Identification of Existing White Powdery Residue** Section 6.12.1 of the Workplan should also identify the white powdery material described in the Workplan for AOC 10 – East Ravine. Characterization of this white material is requested as a Phase 2 activity (see Phase 2 Recommendations Section).	As requested, characterization of this material was conducted in AOC10 – East Ravine in May 2009 and results of this characterization are presented in this Part A Phase 1 Data Gaps Evaluation Report, Appendix C Attachment 4 Section 2.5.
Phase 2 AOC/SWMU Sampling Recommendations				
	1		The following comments capture issues which the GSU believes are best addressed during a second round of sampling (Phase 2 sampling) after the Phase 1 data are collected and reviewed and/or after PG&E has developed acceptable workplans to implement the activities identified below. **Phase 2 SWMU 1/AOC 1 Former Percolation Bed** In addition to the sampling proposed for the white powdery material, shallow trenching or potholing combined with careful and precise documentation is recommended to quickly determine and document the extent of the white material based on visual observation. The easterly extent of the white powdery material for this AOC should be delineated to evaluate how far back it extends within the slope leading up to facility operations. Concerns exist that either the material or potentially contaminated soil within this slope could continue to impact the wash over time.	As described in this report, PG&E performed trenching and sampling in this area (see discussion in Attachment 1 of Appendix C). Eight trenches were dug in the eastern side of SWMU 1 to evaluate the extent of white powder on the hillside, as shown in the inset of Figures A1-1 to A1-7 of Attachment 1 to Appendix C. The lateral extent of the white powder material within the hillside of SWMU 1 ***has been*** defined. Trench SWMU1-WP-2h defines the northern extent of the white powder, and the southern extent is defined by Trench SWMU1-WP-10 and the topography and native material outcrop just south of trench SWMU1 –WP-10. Additional sampling near and into the sidewall of Bat Cave Wash is not warranted and additional data would not significantly improve data quality, or risk assessment or site remediation decisions. No additional sample locations for evaluating the extent of white powder material are proposed in the Part A, Phase 2 Soil Investigation.
	2		**Phase 2 AOC 4 Debris Ravine** DTSC believes that one or two additional sampling locations should be added to the Bat Cave Wash where the Debris Ravine discharges to the wash on the Havasu National Wildlife Refuge. This outfall area appears to be visible in the wash as	As shown in the revised sample location figures provided to DTSC and DOI on September 13, 2007, sample AOC4-1 was relocated to the mouth of the Debris Ravine to assess whether AOC 4 may be contributing COPCs to Bat Cave

			seen in the aerial view pictured in Figure 6-12 of the Workplan. The data from these locations will assess potential contaminant transport and deposition that would occur as the ravine discharges to the wash during storm events. GSU staff have noted limited amounts of visible debris material (metal, rubber, concrete) emanating from this outfall area in the wash. Plans for sampling soils that are identified as containing debris should be developed based on the debris mapping to be conducted as part of the Workplan.	Wash.
	3		**Phase 2 AOC 10 East Ravine** During a site visit in July 2006, GSU staff observed small amounts of metal debris in either subarea 10b or subarea 10c. The debris identifies depositional areas in the wash that have been affected by former operations. The location of the metal debris should be confirmed, documented and mapped. Samples and analyses of the soil from this debris area should be conducted during Phase 2.	See response to AOC 10 Specific Comment 4.
			Additional sampling and analysis is required to characterize the white layer occurring in subarea 10c. Shallow trenching or potholing is recommended to quickly determine the extent of the white waste layer. PG&E should indicate exactly where the white waste layer was found in the past and if it was sampled and analyzed. The same requirements apply to the greenish gray layer identified in subarea 10b (CH2MHill, 2006).	See response to AOC 10 Specific Comment 4.

TABLE F-1

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			The Workplan documents that the history of the two small dams in the East Ravine wash located on the Havasu National Wildlife Refuge is uncertain. Furthermore, the source of the soil used to construct the dams is also of unknown origin. DTSC believes that the dams should be investigated since the dams could contain contaminated materials or buried contaminated soils or wastes when they were constructed. DTSC speculates that the dams may have incorporated contaminated soil from the East Ravine wash.	In response to this comment and DOI Condition 3 in DOI's June 4, 2008 letter, PG&E conducted XRF analysis, followed by confirmatory laboratory analysis, of soil samples collected from the embankment area downstream of subarea AOC 10c. This analysis required modification for accessing subareas AOC 10b and 10c. XRF and laboratory analytical data were correlated before the modifications began to provide a threshold value for future laboratory confirmation samples. Cr(VI) was non-detect in all 10 samples, and the maximum Cr(T) concentration detect in 10 samples submitted to the laboratory was 26 mg/kg, indicating that the embankment was not impacted by Cr(T) or Cr(VI). Additional sampling needs for AOC 10 have been identified in this data gaps evaluation report.
			Since there is a storm drain that discharges and feeds the East Ravine from the west, DTSC believes an additional sample point is needed at the storm drain outfall. This area is located in a vegetated area near the intersection of the access road and visitor parking lot. This particular storm drain has existed since at least 1955 as illustrated by visible discharges in oblique aerial photographs of the site dated May 19, 1955. Contaminant concentrations may be concentrated near the storm drain outfalls similar to releases identified at AOC-9 and AOC-10a.	As requested by DTSC, sampling of this area will be addressed in the Part B Soil Sampling Work Plan as part of the perimeter sampling effort.
	4		**Phase 2 AOC 11 Topographic Low Areas** The first paragraph of Section 6.7.1 of the Workplan indicates that the topographic low area designated L6 was separated from AOC 11 and incorporated into AOC1 – Former Percolation Bed. However, review of the AOC 1 section of the Workplan reveals that no investigation of the L6 area is proposed as part of AOC-1. DTSC is puzzled over this oversight and recommends that at least two borings be installed at the L6 area and that the samples be analyzed for the AOC 11 COPCs.	L6 is not a true topographic low area; rather, it is an area at the bottom of the slope roughly in line with sample location AOC1-T1c. Because of the changeable depositional environment in Bat Cave Wash, the cross-wash transect sampling points of AOC1-T1a, -T1b, and -T1c, combined with the proposed Phase 2 perimeter sampling, was determined to be a more effective means of assessing potential discharges from the compressor station. Samples collected from this area were analyzed for the AOC 1 COPCs, as there is no connection between this area and AOC 11.

TABLE F-1

Documentation of Compliance and Response to California Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) Comments

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
				As described in Attachment 2 of Appendix C, further sampling is proposed in the vicinity of AOC1-T1c (proposed locations AOC1-T1e and AOC1-T1h), as well as north of this area in another location that could receive run-off from the compressor station (proposed location AOC1-T2g).
			The second paragraph of Section 6.7.1 on page 6-18 of the Workplan indicates that a release from Cooling Tower B had entered the drainage to the east as do storm drain discharges. Storm drains and potential soil discoloration are observed along the slope above the AOC 11 ravine in the May 19, 1955 oblique aerial photograph of the site. Therefore, sampling along the top of the ravine outside the northeast facility fence line should be conducted. Furthermore, sampling at the base of the storm drain outlets in the area should also be considered as contaminants may be concentrated near the source of releases as observed at AOC-9 and AOC-10a. TPH, PAHs, and possibly VOCs should also be analyzed from these “source” areas. Approximately four locations are suggested for sample collection and analyses to characterize the topographic low area pictured in Figures 10 and 11 of this memorandum.	Phase 1 sample collection at AOC11e was at the maximum feasible upslope location (the rig cannot climb any further up the slope in this area; the slope becomes very steep). Perimeter sampling will be conducted at the top of the slope during the Part B sampling effort. Data from AOC11e and AOC11c were used to evaluate the need to sample on the upper slope of this area, which is very steep and/or directly below the outfall (also located high on the steep slope). Limited (physically feasible) additional sampling is proposed in this area and presented in this Part A Phase 1 Data Gaps Evaluation Report. See response to Specific Comment 5
	5		**Phase 2 AOC 14 Railroad Debris Site** Additional samples are requested to assess contaminant transport via surface run off from the Railroad Debris Site. Current and historic transport should be considered and assessed. PG&E should submit sample locations for DTSC review and approval. DTSC believes the site currently drains to Bat Cave Wash to the west and, therefore, requests that samples from the wash also be obtained at known outfall locations. Metal debris has been observed entering Bat Cave Wash from the Railroad Debris Site area near the northwest corner of the site.	An additional cross-wash transect (AOC1-T6) was added in Bat Cave Wash immediately below AOC 14. Also AOC14 samples AOC14-SS-3 and AOC14-SS-4 were located west of AOC 14 to assess impacts west of the AOC boundary.

TABLE F-1

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
	6		**Phase 2 Identification of Existing White Powdery Residue** The workplan indicates that no sampling program is proposed unless additional white material is identified. It is necessary to provide a general description of a sampling program to guide sampling of white material (e.g., AOC - 10) and any new areas of white material that may also be identified. PG&E should prepare procedures of the investigation program for DTSC review and approval. It should be noted that areas of white residue have been recently identified within Bat Cave Wash and at the Railroad Debris Site.	As noted in the work plan, there is a difference in the two types of white powdery material likely to be present in the Railroad Debris Site and Bat Cave Wash. The material present in the Railroad Debris site is most likely lime sludge from the former water treatment system; this is supported by the relatively low levels of chromium detected in this material in extensive previous investigation. The white powdery material in Bat Cave Wash is more likely due to mineral deposition from former cooling water discharges. Both of these locations were investigated extensively as part of the Phase 1 investigation, and a map of the white powdery material in the two areas is included in this report. The data from the recent DTSC sampling in SWMU 1 and AOC 14 are consistent with the prior data, indicating again that levels of chromium (and all other metals) are low in the white powdery material in AOC 14 and slightly elevated in SWMU 1. No white powdery material was encountered in any borings in the East Ravine. The potential source of the white powdery material in the East Ravine has not been determined. Evaluation of this material will be conducted as described for AOC 10 Specific Comment 4
	7		**Phase 2 Site Perimeter and Storm Drain Sampling** PG&E should prepare a sampling plan for the site perimeter/fence line area and areas associated with historic releases and historic storm drain discharges to address concerns described in General Comment 7 of this memorandum.	See response to General Comment 7.

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
United States Department of the Interior (DOI). 2008. *PG&E Topock Compressor Station Remediation Site – DOI Direction to PG&E on the RFI/RI Soil Investigation Work Plan Part A.* April 24.				
	1		The Federal Agencies are providing the following information for incorporation into the draft RFI/RI Soil Investigation Work Plan Part A (Work Plan). Once these changes have been made, we will review the revised document in order to determine if we can approve it. We look forward to discussing this information further at the planned meeting on May 6th, 2008, in Oakland, CA. 1. Please revise the Work Plan to indicate that PG&E will perform analysis for chemicals on the Target Analyte List/Target Compound List (TAL/TCL) on 10% of all samples in each AOC to be sampled. The chemicals on all four lists must be included. The lists can be found at: http://www.epa.gov/superfund/programs/clp/target.htm. This analysis must include samples collected vertically and horizontally. When the total number of samples in an individual AOC is less than 10, then a minimum of one sample for this suite of analyses must be collected from the AOC to satisfy the 10% requirement. The Federal Agencies will work with PG&E to determine locations where samples for the TAL/TCL scan should be collected.	Comment noted. The requested change to the planned sampling program was made. A list of samples to be analyzed for the complete TAL/TCL list was developed in collaboration with DOI, and the proposed samples were analyzed as proposed.
	2		2. IM-3 Baseline Soil Sampling proposed as part of Part A – The four samples proposed near the effluent pipeline do not appear to satisfy the criteria for background or baseline samples because the pipeline has been in place and operating for over two years. However, these samples could possibly be used to bolster the Category 2 data gaps, if collected from locations that have had no anthropogenic impact. Our understanding is that DTSC personnel will be on site during the Part A Soil Sampling to assist in selecting sampling locations.	The proposed sample locations along the IM No. 3 pipeline were added to replace several data quality Category 2 samples formerly contained in the background data set. As noted in the June 12, 2008 email from Keith Sheets/CH2M HILL to DOI, five potential sampling locations near the IM No. 3 effluent pipeline (Locations Q, R, and S) and IM No. 3 treatment plant (Locations K and N) were selected jointly by representatives from DTSC, PG&E, and the federal agencies during a site visit on May 21, 2008. During the site walk, it was confirmed that there was no evidence of anthropogenic influence on these sample locations, and DOI approved these background sampling locations in its June 4, 2008 letter.

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
	3		3. Please revise the Work Plan to indicate that PG&E will evaluate surface soils in order to asses the nature and extent of potential windborne contaminants to determine whether or not contamination has been deposited on Federal property. Please indicate proposed sampling techniques to be utilized. The Federal Agencies will work with PG&E to determine suitable sampling sites and consultation requirements.	A surface soil sample was collected at each proposed boring location, including all background sampling locations. As expressed at the May 7, 2008 RCRA/CERCLA meeting, PG&E believes that the proposed Part A soil sampling program will adequately address the nature and extent of contaminants via the potential windborne pathway. See also response to Condition 4 in the June 4, 2008 letter below.
	4		4. The BLM completed consultation requirements with respect to the Work Plan and received concurrence from the California State Historic Preservation Officer on the determination that the undertaking will not adversely affect historic properties (see attachment 1). The stipulations that are required in the Work Plan to avoid effects to known historic properties are as follows: - All routes of travel must be clearly identified prior to initiation of the undertaking; - All project participants must be given a pre-implementation briefing; and - Archeological and Native American monitors will be present during implementation of the testing.	The routes of travel were identified on the planned sampling figures provided to DTSC and DOI on September 13, 2007. Pre-project briefings were provided by qualified PG&E staff to all personnel participating in the field work effort. PG&E invited Native American monitors to be present every day that work was performed. However, because PG&E cannot require the Native American monitors to come to the site for this work, PG&E did not stop work when tribal monitors were not present.
	5		5. Tribal Consultation on the Work Plan was completed in December of 2007, and the package was sent to the CA SHPO on January 11th, before the added level of detail about the grading at AOC-10 and AOC-11 was discussed. The grading is an added level of detail that was not specifically described in PG&E's September 13, 2007, letter, or in the Part A Soil Investigation Work Plan submitted for consultation. As a result of the most recent site visit by PG&E and DOI personnel on April 17th, 2008, please revise the Work Plan to incorporate the final decisions made for access pathways to be utilized for AOCs 10 and 11 and sampling locations in Bat Cave Wash. Include design details and	Please see response to Condition 2 in DOI's Conditional Approval Letter for the Phase 1 investigation, below.

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			updated figures that describe your latest proposal as to how and where to access sampling locations on Federal property. Upon receipt of the updated information, the Federal Agencies will determine if the Work Plan will require additional consultation.	
	6		6. The Federal Agencies had previously agreed to allow the Part A Soil Investigation to proceed if the information and analytical results from the investigation would be used to develop DQOs for subsequent sampling efforts. Please state in the Work Plan that the results from Part A will be used to develop DQOs for subsequent sampling efforts in AOCs outside the Compressor Station fence line. This will be necessary to support risk assessment and closure efforts. Please note that the Federal Agencies are preparing a letter that outlines several issues that are broader in scope than just the Part A Soil Sampling Plan. The identified issues will need to be fully addressed and resolved to the satisfaction of the Federal Agencies in order to ensure that the project can move forward expeditiously. The letter will also propose a Senior Managers Meeting between PG&E and the Federal Agencies on June 26, 2008, from 1:00 to 3:00 pm, in Phoenix, AZ, at the BLM State Office.	DQOs were drafted as a result of meetings held between June and September 2008 with representatives from DOI, DTSC, and PG&E to discuss and agree upon DQO Steps 1 through 5. Data from the Phase 1 investigation were required to complete Steps 6 and 7, as outlined in this Report; Step 7 provided the sampling requirements for the Phase 2 investigation. Comment noted.
United States Department of the Interior (DOI). 2008. *PG&E Topock Compressor Station Remediation Site – DOI Conditional Approval of Phase 1 of the Topock RFI/RI Soil Investigation Work Plan Part A, November 16, 2006.* June 4.				
DOI	1		The Bureau of Land Management completed Section 106 consultation requirements with respect to the Work Plan and received concurrence from the California State Historic Preservation Officer on the determination that the undertaking will not adversely affect historic properties (see attachment 1). PG&E will be required to adhere to the following stipulations in order to avoid effects to known historic properties: - All routes of travel must be clearly identified prior to initiation	See response to Comment 4 in April 24, 2008 letter from DOI to PG&E regarding *DOI Direction to PG&E on the RFI/RI Soil Investigation Work Plan Part A* above.

			of the undertaking; - All project participants must be given a pre-implementation briefing - Archeological and Native American monitors will be present during implementation of the testing.	
DOI	2		PG&E will provide updated figures reflecting final decisions made during the May 21st, 2008, site visit for access pathways and sampling locations for AOCs 10 and 11 and Bat Cave Wash. All approved access pathways and sampling locations agreed during the site visit have undergone Section 106 consultation.	The requirements of this condition were addressed in an email from Mike Cavaliere/CH2M HILL sent to DOI and DTSC July 25, 2008. This response (reiterated below) served as the basis for field implementation of the Phase 1 sampling program. “The revised figures for AOC-1 (northern area including Bat Cave Wash), AOC-10, and AOC-11 are attached to this email. The revised access pathways and sampling locations shown on each figure were discussed in the May 21, 2008 site walk with Federal Agencies. In addition, the sampling locations for AOC-1 near the mouth of Bat Cave Wash were revised at the direction of Dawn Arnold/SAIC during a July 15, 2008 phone call and a July 17, 2008 email. Based on direction received on the phone call and the email, one existing sample (BCW-3) was moved and three new samples were added (BCW-4, BCW-5, BCW-6).” In addition, background sample locations BKG-12 through BKG-16 were added during the May 21, 2008 site walk. A revised figure including the background sampling locations was also attached to the July 25, 2008 email.
DOI	3		PG&E will provide construction information related to gain access for soil sampling in the East Ravine including; design specifications for any earth work required on the largest embankment, flood event mitigation measures and a restoration plan.	The requirements of Condition 3 were addressed in a series of conference calls, the results of which were subsequently provided in an email from Mike Cavaliere/CH2M HILL sent to DOI and DTSC July 25, 2008. The content of the email is summarized below and served as the basis for field implementation.

				A drawing with specifications for earthwork required to modify the upper embankment in the East Ravine for access to soil sampling locations within East Ravine (AOC-10) was transmitted to DOI and DTSC on June 12, 2008 via email from Keith Sheets/CH2M HILL. The details provided in these documents were discussed between Mike Cavaliere/CH2M HILL and Bernard Freeman/USFWS, Chief of Division of Engineering on May 28, 2008. PG&E conducted the embankment construction in accordance with the drawing and specifications. Flood water mitigation and embankment restoration were discussed during a June 5, 2008 telephone call between Mike Cavaliere/CH2M HILL and Cindi Hall/USFWS. Soils displaced for embankment modification were compacted using a combination of potable water (which was also used for dust control) and mechanical compaction. Temporary silt fences were installed during investigation activities. It is not anticipated that stormwater will flow over the embankment; observations by PG&E indicate that no more than 1 to 2 feet of standing water have been noted in the past, and the embankment modification leaves the embankment approximately 4 feet in height. No danger of flooding was noted during the Phase 1 investigation. Nonetheless, during storm events, onsite staff will periodically check for standing water in the impoundment behind the embankment. If, based on these observations, standing water may rise to levels near the height of the lowered embankment, PG&E is prepared to raise the effective height of the embankment by either using sandbags and plastic sheeting or by replacing some or all of the material displaced to construct the access pathway, whichever can be implemented most quickly. The access route will remain intact until soil and groundwater investigation activities in the East Ravine are complete, at which time PG&E will develop embankment restoration details in consultation with USFWS, as required.

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
			In addition, PG&E will work with the Fish and Wildlife Service about how to screen and/or sample the soil that will be disturbed for construction purposes in the embankment for elevated Cr VI and Cr III concentrations. In addition, PG&E will work with the Fish and Wildlife Service regarding how to satisfactorily manage any chromium contaminated soil encountered in the embankment.	Screening/sampling of embankment soil disturbed during embankment modification was discussed during a June 19, 2008 conference call including Mike Cavaliere/CH2M HILL, Keith Sheets/CH2M HILL, Shawn Duffy/CH2M HILL, Curt Russell/PG&E, Cindi Hall/USFWS, and Carrie Marr/USFWS. A technical memorandum describing the initial screening process and proposed screening process during field construction was submitted to DOI on September 17, 2008. Screening and sampling in the field were performed in accordance with the procedures outlined in the technical memorandum. A summary of the embankment modification data is included in Appendix B of this Part A Phase 1 Data Gaps Evaluation Report.
DOI	4		PG&E will perform analysis for chemicals on the Target Analyte List/Target Compound List (TAL/TCL) on 10% of all samples in each AOC to be sampled. The chemicals on all four lists must be included. The lists can be found at http://www.epa.gov/superfund/programs/clp/target.htm This analysis will include samples collected vertically and horizontally. When the total number of samples in an individual AOC is less than 10, then a minimum of one sample for this suite of analyses must be collected from the AOC to satisfy the 10% requirement. The Federal Agencies will work with PG&E to determine locations where samples for the TAL/TCL scan should be collected.	PG&E conducted the required analysis as outlined in this condition. The chemical lists found at http://www.epa.gov/superfund/programs/clp/target.htm were used to ensure that the full range of chemical parameters required was analyzed. Sixty-six samples were analyzed for the full TAL/TCL suite of parameters. This included 28 samples from AOC/SWMU-1, seven samples from AOC 4, three samples from AOC 9, nine samples from AOC 10, seven samples from AOC 11, two samples from AOC 12, eight samples from AOC 14, and two samples from UA-2 (the Former 300B Pipeline Liquids Tank). The specific sample locations were identified in concert with DOI and were confirmed in the August 14, 2008 email from Mike Cavaliere/CH2M HILL to Kris Doebbler and other DOI staff. The August 14 email included one modification. Locations AOC14-7 and AOC14-10 were added to the list of locations to be analyzed for the full suite of TAL/TCL parameters in place of locations AOC14-11 and AOC14-13 because it was determined that surface soil samples were not scheduled to be collected at AOC14-11 and AOC14-13.

Topock RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Agency	Comment Number	Section	Comment	Documentation of Compliance or Response to Comments
DOI	5		Four potential sampling locations near the IM-3 effluent pipeline were selected jointly by representatives from CA DTSC, PG&E and the Federal Agencies during the site visit on May 21, 2008. These soil samples will be collected during the Part A Soil Investigation and have already undergone required consultation as part of the IM-3 Baseline project. Soil samples will be taken at multiple depths, including the same lithologic unit from which some previous samples identified as Category 2 data were taken. These samples may be utilized by PG&E to supplement the existing Category 2 dataset. DTSC personnel will be on site during the Part A Soil Sampling field work to assist in selecting sampling locations.	As noted in the June 12, 2008 email from Keith Sheets/CH2M HILL to DOI, five potential sampling locations near the IM No. 3 effluent pipeline (Locations Q, R, and S) and IM No. 3 treatment plant (Locations K and N) were selected jointly by representatives from DTSC, PG&E, and the federal agencies at a site visit on May 21, 2008. During the site walk, it was confirmed that there was no evidence of anthropogenic influence on these sample locations. The resulting background data set therefore consists of Category 1 data only. The five sample locations were used to supplement the existing data set and replaced the Mittelhauser Category 2 data within the background data set. It should be noted that the intention was to supplement the Category 1 background data set, not the Category 2 data set as stated here.
DOI	6		The Federal Agencies had previously agreed to allow the Part A Soil Investigation to proceed if the information and analytical results from the investigation would be used to develop DQOs for subsequent sampling efforts. Please state in the Work Plan that the results from Part A will be used to develop DQOs for subsequent sampling efforts in AOCs outside the Compressor Station fence line. This will be necessary to support risk assessment and closure efforts.	As discussed on June 4, 2008, DOI did not require revision to the RCRA Facility Investigation/Remedial Investigation Work Plan Part A. The reference to a work plan in this condition is any written communication from PG&E to DOI. As required by this condition and as confirmed in the June 12, 2008 email from Keith Sheets/CH2M HILL, the results from Part A Phase 1 will be used to develop DQOs for subsequent sampling efforts at AOCs outside the compressor station fence line. It should be noted that Steps 1 through 5 of the DQO process have already been completed through joint meetings between PG&E, DOI, and DTSC and that it is anticipated that Steps 6 and 7 will be completed in joint meetings, including these and other stakeholders, following completion of the data evaluation process for the Phase 1 sampling.

DOI	7		PG&E will begin implementation of a risk assessment data specification and data gap process using a management tool such as the “Risk Assessors Data Usability Specification Matrix” (or a functional equivalent) provided by DOI via email on May 21. By completing this process and utilizing such a tool, PG&E will be able to identify shortcomings and data gaps upon completion of Phase 1 which can be addressed in the Phase 2 DQOs.	As discussed during the June 4, 2008 RCRA/CERCLA meeting, the matrix outline provided by DOI via email on May 21 is an example of a management tool and not a requirement. There is flexibility in the type and amount of information to be incorporated into the tool. This management tool did not need to be completed or approved prior to the start of field work for the Part A Phase 1 investigation.
			<u>Additional Information for Upcoming Part A Phase 2</u>: 1. PG&E will evaluate surface soils in order to asses the nature and extent of potential windborne contaminants to determine the possibility that contamination originating from the Topock Compressor Station has been deposited on Federal property. The Federal agencies will work with PG&E to determine proposed sampling techniques, analytical suites, suitable sampling sites and consultation requirements	A surface soil sample was collected at each proposed boring location, including all background sampling locations. As expressed at the May 7, 2008 RCRA/CERCLA meeting, PG&E believes that the proposed Part A soil sampling program will adequately address the nature and extent of contaminants via the potential windborne pathway.
			2. PG&E, with input from the Federal agencies, will identify Bat Cave Wash sediment sampling needs within the interior of the tamarisk habitat during the Phase 2 DQO process. Additional Section 106 Consultation will be conducted to address proposed routes and mechanical means to access the interior of the habit to facilitate collection of additional sediment samples.	Comment noted. Sediment sampling needs within the tamarisk habitat will be evaluated during the Phase 2 DQO process.

1.0 Introduction

As described in the main text of this Soil Investigation Work Plan, Pacific Gas and Electric Company (PG&E) is conducting investigative and remedial activities at the Topock Compressor Station in Needles, California. The soil investigation is divided into four components: Part A (the areas outside the compressor station fence line), Part B (the area within the fence line), the Perimeter Investigation Area, and the Storm Drain Investigation Area. This appendix presents the proposed Part B investigation program. The proposed investigation program is based on information regarding historical site usage, the conceptual site models for each investigation area, and the available existing data.

This Soil Part B Work Plan addresses Solid Waste Management Units (SWMUs), Areas of Concern (AOCs), and oily water treatment system units identified in the *Revised Final RCRA Facility Investigation/Remedial Investigation Report, Volume 1 – Site Background and History* (referred to as the RFI/RI Volume 1) (CH2M HILL, 2007a). In addition to the four SWMUs, 10 AOCs, and three units (Units 4.3, 4.4, and 4.5) identified in the RFI/RI Volume 1, this appendix addresses one newly identified SWMU and seven newly identified AOCs, for a total of 25 units. It also addresses the investigation of a recently identified potential burn area; this area will be addressed as part of AOC 13. Each unit is addressed in a separate sub-appendix to this appendix. Investigation areas outside the compressor station fence line are addressed in the *Draft RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A, PG&E Topock Compressor Station, Needles California* (CH2M HILL, 2006a), referred to as the Soil Part A Work Plan. The perimeter areas adjacent to the compressor station fence line and the storm drains leading from the compressor station to areas outside the fence line are also included in Appendix C and D, respectively, of the Soil RFI/RI Work Plan.

A Draft Soil Part B Work Plan was previously submitted to the DTSC and DOI in November 2007 (CH2M HILL, 2007b). Comments on the Draft Soil Part B Work Plan were received from the following:

1. DTSC Geological Services Unit: "Comments on *RCRA Facility Investigation/Remedial Investigation, Soil Investigation Work Plan Part B, PG&E Topock Compressor Station, Needles, California*" (March 25, 2008b)
2. DTSC Human and Ecological Risk Division (HERD): *Draft RCRA Facility Investigation Soil Investigation Work Plan Part B, PG&E Topock Compressor Station, Needles, California* (January 22, 2008)
3. DOI: *Topock Compressor Station RFI/RI Project Document Review Sheet; RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part B* (DOI, 2008)
4. Fort Mojave Indian Tribe: "Fort Mojave Indian Tribe Comments on Pacific Gas & Electric Co. December 2007 document titled *RCRA Facility Investigation Soil Investigation Work plan, Part B, PG&E Topock Compressor Station, Needles, California*" (January 23, 2008)

5. Colorado River Indian Tribes: *RCRA Facility Investigation/Remedial Investigation Work Plan, Part B, PG&E Topock Compressor Station, Needles, CA* (January 18, 2008)

DTSC withdrew its comments on Sections 3.0 and 4.0 (Data Quality Objectives [DQOs] and Data Evaluation) of the Draft Soil Part B Work Plan (all HERD comments and a portion of the DTSC Geological Services Unit comments). DOI withdrew all of their DQO-related comments. The agencies directed PG&E to prepare a separate DQO technical memorandum for the Soil Part B investigation similar to those developed for the Soil Part A investigation.

The Soil Part B DQO Steps 1 through 5 are presented in the technical memorandum *Data Quality Objectives – Part B Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2011) (referred to as the Soil Part B DQO Tech Memo). The Soil Part B DQO Tech Memo is provided in Appendix B1. Steps 6 and 7 will be completed once the initial Part B data have been collected, similar to the process used for the Soil Part A investigation program.

In addition to comments directly on the Draft Part B Work Plan, DTSC also provided comments on compressor station construction-related photographs (*1950s Photographs of the Pacific Gas and Electric Company (PG&E) Topock Compressor Station, Needles, California* (February 12, 2008) (DTSC, 2008b). These comments led to the addition to six new AOCs and one new SWMU.

The units addressed by this Soil Part B Work Plan are as follows:

- SWMU 5 – Sludge-drying Beds (Appendix B2)
- SWMU 6 – Chromate Reduction Tank (Appendix B3)
- SWMU 8 – Process Pump Tank (Appendix B4)
- SWMU 9 – Transfer Sump (Appendix B5)
- SWMU 11 – Sulfuric Acid Tanks (Appendix B6)
- AOC 5 – Cooling Tower A (Appendix B7)
- AOC 6 – Cooling Tower B (Appendix B8)
- AOC 7– Hazardous Materials Storage Area (Appendix B9
- AOC 8 – Paint Locker (Appendix B.10)
- AOC 13 – Unpaved Areas within the Compressor Station (Appendix B11)
- AOC 15 – Auxiliary Jacket Cooling Water Pumps (Appendix B12)
- AOC 16 – Sandblast Shelter (Appendix B13)
- AOC 17 – Onsite Septic System (Appendix B14)
- AOC 18 – Combined Wastewater Transference Pipelines (Appendix B15)
- AOC 19 – Former Hotwell (Appendix B16)
- AOC 20 – Industrial Floor Drains (Appendix B17)
- AOC 21 – Unidentified Round Impoundment in Lower Yard (Appendix B18)
- AOC 22 – Three-sided Structure in Upper Yard (Appendix B19)
- AOC 23 – Former Water Conditioning Building (Appendix B20)
- AOC 24 – Staining and Potential Former API Oil/Water Separator (Appendix B21)
- AOC 25 – Compressor and Generator Engines and Basements (Appendix B22)
- AOC 26 – Former Scrubber Sump (Appendix B23)
- Unit 4.3 – Oily Water Holding Tank, Unit 4.4 – Oil/Water Separator, and Unit 4.5 – Portable Waste Oil Holding Tank (Appendix B24)

In addition, this Work Plan will address two new areas of potential concern that were identified recently based on employee interviews. These new investigation areas are the Teapot Dome Restaurant oil pit and a potential burn area near AOC 17. These units are shown on Figure B-1.

To minimize the number of samples and disturbances to sensitive resources, the Part B supplemental soil investigation program may be conducted in two phases, if needed. Proposed sampling for Phase 1 is described in this work plan. The proposed sampling is designed to collect sufficient information to address Decisions 1 through 5 as defined in the Part B Data Quality Objectives Tech Memo (CH2M HILL 2010a). Following completion of Phase 1 sampling, the newly collected and existing data will be combined and evaluated to determine the need for any further (Phase 2) sampling. Phase 2 sampling will only be necessary where data gaps are identified after evaluation of the combined soil data set (existing data and supplemental Phase 1 data).

1.1 Historical Soil Investigations within the Compressor Station Fence Line

Several rounds of investigation have previously been completed within the fence line of the compressor station. These included closure-related investigations (at SWMUs 5, 6, 8, and 9; AOCs 18 and 26; and Units 4.3–4.5) and investigations conducted relative to potential or suspected past releases (at AOCs 5, 6, 13, 15, and 19). In addition, PG&E has conducted limited sampling to address spills and in coordination with miscellaneous subsurface construction activities (within AOC 13).

Previous investigation activities include soil boring installation and surface soil sampling. The majority of samples were surface soil samples collected by hand; some samples were collected as confirmation samples following soil excavation. Access constraints and safety considerations limited sampling in most areas. Two-hundred-thirty-five soil samples were collected (sample counts do not include duplicate samples collected for quality control purposes). The available data span a wide range of dates, analytical parameters, and data quality. The data quality of all existing data has been evaluated in the *Data Usability Assessment Technical Memorandum, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2006b); the majority of the existing data (65 percent) has been classified as data quality Category 1 or 2. Data classified as data quality Category 1 are suitable for all uses, including risk assessment and remedial action decisions. Data quality Category 2 data are suitable for use in characterization of the chemicals of potential concern (COPCs) at the facility and to help define the nature and extent of contamination. Data quality Category 3 data are suitable only for use in qualitative characterization of the nature and extent of contamination.

1.2 Newly Identified Burn Area

In 2009, at DTSC's direction, PG&E conducted additional interviews with current and former employees to collect new anecdotal information pertaining to historical compressor station practices. To confirm the new anecdotal information collected, additional site walks, including debris mapping, were conducted. The information gathered was provided in letters dated August 14, 2009 (PG&E, 2009a), October 15, 2009 (PG&E, 2009b), January 15, 2010 (PG&E 2010a), and January 29, 2010 (PG&E 2010b). A potential new burn area in AOC 13 was identified as a result of the additional interview and was discussed with the agencies in e-mails dated February 22, 2010 and February 24, 2010.

At the agencies' direction, this new area has been incorporated into this Soil Part B Work Plan and is addressed as part of AOC 13. Available information regarding this new area is provided in Appendix B11.

1.3 Purpose of Soil Part B Phase 1 Investigation Work Plan

This Soil Part B Work Plan has been prepared to:

- Present the combined soil data collected to date for the identified SWMUs, AOCs, and units within the fence line of the compressor station.
- Present the results of the data gaps evaluation using the decision and criteria described in the Soil Part B DQO Steps 1 through 5.
- Present proposed Phase 1 sampling recommendations.

This document identifies potential sample locations based on specific DQO rules as developed at the direction of DTSC and DOI. These potential locations are PG&E's initial assessment of candidate locations for additional characterization. The proposed sampling location figures and tables are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and make further progress toward decision-making for soil remediation. PG&E anticipates that all candidate locations identified may not be necessary for such purposes.

1.4 Work Plan Organization

This Soil Part B Work Plan is organized into three sections, as follows:

- **Section 1.0, Introduction**, contains background information, objectives, and report organization.
- **Section 2.0, Overview of Data Gaps Evaluation Process**, provides an overview of the data gaps evaluation process and the four DQO decisions applicable to the Soil Part A investigation.
- **Section 3.0, Accessibility Evaluation for Areas within the Fence Line**, describes the evaluation conducted to more specifically define accessibility constraints associated with surface and subsurface utilities.
- **Section 4.0, Integration of Perimeter Area and Storm Drain Investigation Data,** summarizes how relevant data collected from these two investigation programs will be integrated into the Part B data evaluation process.
- **Section 5.0, References,** presents a list of works cited when preparing this document.
- **Appendix B1,** provides the Soil Part B DQO Tech Memo.

- **Appendices B2 through B24,** contain the soil investigation programs for the 25 units addressed by this Work Plan.
- **Appendix B25,** provides the accessibility evaluation photograph log.
- **Appendix B26,** provides the response to comments on the 2007 Draft Part B Work Plan.

2.0 Overview of Data Gaps Evaluation Process

The development of the Soil Part B investigation program was based on the DQOs developed for the Soil Part B investigation to ensure that data collected at each stage of the investigation process are of sufficient quantity and quality to enable the specified decisions to be made. The DQO process is a recognized procedure for defining project objectives and decisions and for optimizing sampling and other information-gathering programs to balance uncertainty, site disturbances, and cost in an acceptable manner. The United States Environmental Protection Agency (USEPA) has issued detailed guidance for the seven-step DQO process (USEPA, 2000, 2006a-b):

- Step 1 – State the Problem
- Step 2 – Identify the Decision(s)
- Step 3 – Identify the Inputs to the Decision
- Step 4 – Define the Study Boundaries
- Step 5 – Develop a Decision Rule
- Step 6 – Specify Tolerable Limits on Decision Errors
- Step 7 – Optimize the Design

Below are the five Part B DQO decisions to be made using the combined existing soil data collected to date and the data proposed to be collected:

- **Decision 1:** Determine the nature and extent of residual soil concentrations resulting from historical compressor station practices. If determination of the nature and extent of contamination based on sample data is not feasible or is not warranted, address uncertainties in the risk assessment and/or the corrective measures study/feasibility study (CMS/FS) or interim measures.

- **Decision 2 (Data Sufficiency Evaluation):** Determine representative exposure point concentrations (EPCs) for residual soil contamination resulting from historical compressor station practices. If determination of representative EPCs based on sample data is not feasible, address uncertainties in the risk assessment.

- **Decision 3:** Determine whether residual soil concentrations resulting from historical compressor station practices may threaten groundwater. If so, conduct additional site-specific assessment of the threat[1] or implement response actions to mitigate the threat. If not, no further assessment or response actions are necessary to address threat to groundwater

- **Decision 4.** Determine if residual soil concentrations inside the compressor station fence line resulting from historical compressor station practices pose a potentially unacceptable risk to receptors outside the compressor station fence line via a surface migration pathway. If a potentially unacceptable risk to receptors outside the fence line exists, or if determination of potential risk to receptors outside the fence line based on

---

[1] The forthcoming Topock Compressor Station/East Ravine Groundwater Investigation will aid in assessing potential threats to groundwater from potential source areas within the compressor station as well as evaluating current impacts to groundwater

sample data is not feasible, develop controls to eliminate migration pathways or remove contaminated soil.

- **Decision 5 (Data Sufficiency Evaluation):** Determine the site-specific soil property, contaminant distribution, and transport pathway information necessary to support the CMS/FS, remedial design, and/or interim measures, if required. If full determination of site-specific soil property, contaminant distribution, and transport pathway information based on sample data is not feasible, document impediments and uncertainties in the risk assessment and/or CMS/FS or interim measures.

The DQO process was also used to develop the proposed sampling effort described in this work plan. Although available data are limited, the following evaluations were completed for each of the five DQO decisions to the degree feasible.

- **Decision 1**: The nature and extent of contamination at units with existing Category 1 or 2 data are described and evaluated to determine whether the nature and extent of contamination are adequately understood. The evaluation followed the Decision 1 rules outlined in Figure 2 of the Part B Tech Memo included as Appendix B1.
- **Decision 2**: A data sufficiency evaluation was conducted to determine if sufficient data exist for the entire area within the fence line to calculate representative EPCs for each applicable exposure interval for human receptors. The evaluation followed the Decision 2 Rules outlined in Figure 3 of the Part B Tech Memo included as Appendix B1.
- **Decision 3**: Soil screening levels (SSLs) will be calculated for any metal exceeding background concentrations at one or more locations within the individual Part B investigation areas. Because of the limited existing soil data, this evaluation will occur after the first phase of the Part B investigation. For constituents where the detected concentrations exceed the SSLs, vadose zone modeling will be conducted to further evaluate the potential threat to groundwater. If organic compounds are detected in one or more locations within the investigation areas, vadose zone modeling will be conducted to evaluate the potential threat to groundwater from detected organic compounds. The evaluation will follow the Decision 3 rules outlined in Figure 4 of the Part B Tech Memo included as Appendix B1.
- **Decision 4**: A data sufficiency evaluation will be conducted to determine whether sufficient information regarding surface migration pathways and soil chemical data exist for units with existing Category 1 data to assess whether these areas pose a potential risk to offsite receptors via the surface migration pathway. The evaluation will follow the Decision 4 rules outlined in Figure 5 of the Part B Tech Memo included as Appendix B1.
- **Decision 5**: A data sufficiency evaluation was conducted to determine whether sufficient data exist at units with existing Category 1 or 2 data to support the CMS/FS (specifically, remedial technology feasibility assessment and estimation of soil and debris volumes potentially requiring remediation) and/or interim measures. The evaluation followed the Decision 5 rules outlined in Figure 6 of the Part B Tech Memo included as Appendix B1.

The following subsections describe the process that will be used to evaluate the combined data set and the process that was used to evaluate the five DQO decisions. Due to the limited set available at this stage, the evaluations for Decisions 2, and 5 were conducted for the area within the fence line as a whole; the individual evaluations for Decision 1 are provided in Appendices B2 through B24. Decisions 3 and 4 evaluation will be performed after the Phase 1 investigation.

Once the data to be collected pursuant to this work plan are available, the combined existing and new data will be evaluated using the same process outlined below. Decision 2 will continue to be evaluated for the entire area within the fence line; Decisions 1, 3, 4, and 5 will be evaluated for individual units or groups of units, as appropriate based on combined data set.

2.1 Decision 1 – Nature and Extent

This section presents the inputs and process used and to be used to evaluate Decision 1 – Nature and Extent. Results of the Decision 1 – Nature and Extent evaluation for each unit, including proposed sample locations, are provided in Appendices B2 through B24.

2.1.1 Inputs to Decision 1

The following three types of information are needed and considered when assessing whether the nature and extent of contamination at a site are adequately understood: (1) usable COPCs concentration data, (2) potential fate and transport mechanisms, and (3) screening and comparison values, as described in the Soil Part B DQO Tech Memo provided in Appendix B1. The following subsections describe the inputs required to evaluate Decision 1 – Nature and Extent.

Data Usability

Existing data were evaluated in the *Final Soil and Sediment Data Usability Technical Memorandum, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2008a). All data meeting Category 1 and 2 data quality standards were included in the data set for Decision 1. New data will be validated, and only data meeting Category 1 data quality standards will be included in the combined data set.

The existing Category 1 and 2 data were also reviewed to assess whether they are still considered reliable due to changing site conditions. If site conditions had changed or construction may have affected the samples, the data were assessed to determine whether it is likely that the changes have altered the conditions at particular locations. This data assessment process was limited to surface and near-surface samples, as deeper samples would not be expected to be affected by storm event erosion and deposition or construction projects.

Potential Fate and Transport Mechanisms

A conceptual site model (CSM) for the entire area within the fence line was developed for the *Human Health and Ecological Risk Assessment Work Plan* [RAWP], *Topock Compressor Station, Needles, California* (ARCADIS, 2008a) and RAWP Addendum (ARCADIS, 2009a). The CSM is shown in Figure 7 of the Soil Part B DQO Tech Memo in Appendix B1. The CSM focuses on evaluation of potential exposure pathways to human receptors. Site-specific CSMs, providing a more detailed assessment of contaminant fate and transport mechanisms at each unit, were also developed and are presented in Appendices B2 through B24.

The CSMs rely on the detailed information on the physical characteristics and setting of each unit, including surface features, topography, meteorology, site geology, surface water hydrology, site hydrogeology, and land use. Potential transport mechanisms and fate of COPCs released into the environment within the fence line of Topock Compressor Station are presented in the CSMs; the CSMs also identify potential transport and migration pathways to areas outside the fence line.

Comparison Values

Comparison values were used to screen the existing data and will be used to screen the combined data for the areas within the fence line. Four types of comparison values identified for the Decision 1 evaluation include:

- Soil background threshold values (BTVs) for metals and inorganic compounds, which are discussed in the *Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2009a).
- DTSC California human health screening levels (CHHSLs) for commercial use (California Environmental Protection Agency, Office of Environmental Health Hazard Assessment, 2005).
- USEPA regional screening levels (RSLs) for commercial use for those compounds for which CHHSLs are unavailable or for which the existing CHHSLs are based on outdated toxicity factors (USEPA, 2010).
- California Regional Water Quality Control Board, San Francisco Bay Region (Water Board, 2008) environmental screening levels for total petroleum hydrocarbons in the gasoline, diesel, and motor oil ranges for a residential exposure scenario for human health based on a hazard index of 1.0.
- Project-specific screening levels developed for COPCs identified from Target Analyte List/Target Compound List (TAL/TCL) data (ARCADIS, 2009b)

The comparison values were used to assess the extent of contamination based on the existing data and will be used to evaluate the extent of contamination using the combined data set. The extent of contamination was defined to the commercial comparison values, defined as the commercial screening level. In addition, metals concentrations were compared to the BTV, where available. The comparison values are shown in Tables B-1 through B-8. Exceedance of any comparison values does not indicate the presence or absence of unacceptable risk (potential site-related risks will be evaluated in the baseline risk assessment).

To assess dioxin/furan results dioxin toxicity equivalence quotients (TEQs) were calculated and compared to the DTSC/HERD dioxin TEQs remedial goals instead of the more conservative/outdated 2005 CHHSLs. The DTSC/HERD guidance provides the following dioxin TEQ remedial goals for sites in California (DTSC, 2009):

- 50 nanograms per kilogram: residential exposure scenario (based on 10^{-6} risk level and adjusted by a factor of 10 to account for minimal contribution of soil and dust to dioxin body burden in a University of Michigan dioxin study).

- 200 to 1,000 nanograms per kilogram: commercial/industrial exposure scenario (a range is proposed from a concentration based on 10^{-6} cancer risk [adjusted by a factor of 10 as with the residential value] to a concentration based on a hazard index of 1).

2.1.2 Nature and Extent Evaluation

As outlined in the decision process for Decision 1 in the Soil Part B DQO Tech Memo, the nature and extent evaluation for the combined data set will consist of:

- Identifying newly detected compounds, if any.
- Conducting a point-by-point comparison of all detected compounds to the comparison values.
- Assessing lateral and vertical extent of detected compounds, as well as spatial concentration trends of detected compounds (i.e., changes in concentration laterally and vertically).
- Conducting a central tendency comparison between site and background data sets.

To the degree feasible, these same steps were used to screen the existing data; however, due to the limited nature of the existing data set, a central tendency comparison to background was not conducted. Also, vertical extent data were typically limited due to access challenges encountered within the fence line, and assessment of vertical extent was generally not feasible. The complete Decision 1 data evaluation steps are discussed in more detail below.

If the nature and extent evaluation concludes that additional sampling is not warranted, then no further sampling is required and no further sampling is required to resolve Decision 1. If data gaps are identified and data collection is desirable, the feasibility of collecting the additional samples under current operating conditions were evaluated. The evaluation relied primarily on the accessibility evaluation presented in Section 3.0 of this report. The agencies will have to concur that additional sampling is not feasible or warranted. However, PG&E retains the right to make the final determination regarding the safety of the proposed sampling. If some sampling cannot be performed in a manner that is deemed safe by PG&E, that sampling will be considered infeasible.

2.1.3 Identification of Newly Detected Compounds

The full inorganic and organic suite of analyses included in the Comprehensive Environmental Response, Compensation, Liability Act of 1980 (CERCLA) TAL/TCL includes compounds that have not typically been included in analytical suites for the areas inside the fence line. At the request of DOI, 10 percent of all samples collected during the Soil Part B Phase 1 investigation will be analyzed for the full TAL/TCL suite. TAL/TCL analyses were conducted for the Part A Phase 1 investigation (see Appendix A to the Soil RFI/RI Work Plan), and the results of that evaluation were considered in the development of the Part B sampling program. As a result of the TAL/TCL analyses for areas outside the fence line, polychlorinated biphenyls (PCBs) were added as an analytical suite for most locations within the fence line.

The Part B Phase 1 data and existing data will be combined and reviewed to assess whether, as a result of the full TAL/TCL analysis, any new compounds that qualify as COPCs have been identified in the areas within the compressor station fence line. While a few existing samples were analyzed for one or more constituents on the TAL/TCL, there are too few analyses in the existing data set to assess whether any newly identified compounds may be present.

2.1.4 Point-by-point Comparison with Comparison Values

The initial comparison of COPCs was conducted on a point-by-point basis for all depths (i.e., a simultaneous lateral and vertical assessment). All data for a given area were compared to the comparison values described in Section 2.1.2. (Data tables by constituent group and by individual unit are included in Appendices B2 through B24.) Detected concentrations of a given chemical were flagged for each occurrence of a COPC exceeding the commercial screening level or BTV for metals. The results from the point-by-point comparison were used in conjunction with the spatial trends analysis to assess whether a data gap existed at locations with one or more constituents exceeding the applicable BTV or risk-based comparison value. Other considerations included:

- The frequency and extent to which the commercial screening value was exceeded and, in the case of metals, the frequency of exceedances of the BTVs.
- The influence of topography on both the likely direction of COPC movement and the ability to collect additional samples.
- The proximity of other relevant sample locations to the sample location exceeding the commercial screening level and/or BTV.

The same point-by-point comparison will be completed for the combined data set, and the results from the point-by-point comparison will be used in conjunction with both the spatial trends analysis and the central tendency comparison to assess whether a data gap exists at locations with one or more constituents exceeding the applicable BTV or risk-based comparison value.

Statistical summary tables were also created for each area with existing data and are included in Appendices B2 through B24. The statistical summary tables present the frequency of detection for each COPC detected in soil, the maximum detected concentration, and the number of exceedances of the comparison values described in Section 2.1.2, as well as the comparison values used for Decision 4 (comparison values for Decision 4 must consider potential receptors outside the fence line). Consequently, comparison values for Decision 4 are the same as for the Part A soil investigation program. Soil sample counts presented in the statistical summary tables do not include duplicate (quality control) soil samples. At locations where duplicate samples were collected, the higher of the two values were included in the statistical summary tables. The number of exceedances is the number of detections that are equal to or exceed the respective screening/comparison values. For the BTV, exceedances are the number of detections exceeding the BTV (i.e., if a detected concentration is equal to the BTV, it is considered to be within background).

2.1.5 Evaluation of Lateral and Vertical Extents and Spatial Trends

The lateral and vertical extents of each COPC were evaluated by assessing whether constituent concentrations in the samples were below the applicable commercial screening level or BTV toward the edge of the unit or affected area. Potential hot spots, if any, were identified through the presence of clusters of elevated concentrations of COPCs. In addition, spatial trends were evaluated for those COPCs identified by the point-by-point comparison as having concentrations exceeding the commercial screening level or BTV. Figures showing detected concentrations of compounds were created for all units with existing data and are included in Appendices B2 through B24. For smaller units in close proximity, all data for a given area are presented on one figure (e.g., existing data for SWMUs 5, 6, and 9, and the Units 4.3, 4.4, and 4.5 are shown on one figure). All data for compounds detected at that unit are shown in the figures. Following completion of the Part B Phase 1 investigation, figures will be prepared for individual constituents that are detected multiple times above the commercial screening level and/or BTV.

Where feasible, spatial trends in the existing data set were evaluated both laterally and vertically. For lateral delineation, concentration trends toward the perimeter of each area were reviewed to ensure that concentrations are generally decreasing toward the perimeter. Vertical concentration trends were also reviewed where subsurface samples were available. As noted above, vertical extent data were limited. Evaluation of spatial trends included:

- Lateral concentration trends toward the edge of a unit or affected area (i.e., potential hot spot) within a unit.
- Vertical concentration trends in each boring and throughout a given unit or area.
- Distribution of detections and non-detections of each constituent within a unit or area.
- Where applicable, concentrations trends at an upslope unit or area.

The specific areas where COPC lateral or vertical boundaries are not adequately defined or where concentration trends are not decreasing were identified as locations where data gaps exist. The identified data gaps in the existing data provided the basis for further sampling recommendations for Decision 1. If additional data collection was feasible (i.e., no structures, utilities, topography, or cultural resources preventing step-out sampling or deeper sampling vertically), then additional sampling locations, depths, and/or analytical suites were proposed 1 for the Part B Phase 1 investigation. The evaluation of access constraints is described in Section 3.0. The additional sampling recommendations for each unit are included in Appendices B2 through B24; specific access constraints for each unit are also described in these appendices.

The same data gaps evaluation process will be used to evaluate the combined data set once the Part B Phase 1 investigation data have been collected and the newly validated Part B Phase 1 data have been combined with the existing data.

2.1.6 Central Tendency Comparison

A population (central tendency) comparison will be conducted for those metals detected in soil at concentrations exceeding the respective BTVs. The central tendency comparison assesses whether there is an overall shift of concentrations between the site data versus the background data (i.e., if the site concentrations are higher relative to the background concentrations than random variability could explain). The comparison helps to determine whether an overall shift exists between the background and the combined soil data set for each area.

The comparison will be conducted using the approved *Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California Technical Memorandum* (CH2M HILL, 2009a). Because comparison to the BTV offers information only on the upper tail of the site concentration distribution, in cases where single-point exceedances of the BTV exist, the central tendency comparison offers an opportunity to statistically address whether there is an overall shift of site concentrations relative to background concentrations. This overall shift may be identified as a data gap, and additional sampling may be proposed, if appropriate.

The Gehan test and Wilcoxon Rank Sum test are commonly used to conduct central tendency comparisons. These central tendency tests are discussed both in USEPA and Navy literature (USEPA, 2009; Navy, 2002). These central tendency tests provide a calculated probability, which will be compared to a significance level of 0.05. If the probability is below 0.05, a significant exceedance over background may be present.

Both tests are nonparametric approaches based upon the ranks of the data; however, they handle ties in these ranks differently. For that reason, the Gehan test is recommended when the percent of nondetects is greater than 40 percent or when multiple detection limits exist for a given metal, both of which are expected to be case based on the experience with the Part A investigation. The Gehan test was used for all comparisons conducted for the Part A investigation and will most likely be used to evaluate the combined Part B data set.

The central tendency test will not be performed if a compound is infrequently detected (less than five detects) in either the unit/area data or background data set or has a limited number of results (less than eight) for a unit/area. Using these rules, a central tendency comparison for hexavalent chromium cannot be conducted at any unit because there are insufficient detections of hexavalent chromium in the background data set.

2.2 Decision 2 – Data Sufficiency to Estimate Representative Exposure Point Concentrations

This section presents the process used to evaluate Decision 2 – Data Sufficiency to Estimate Exposure Point Concentrations for the entire area within the fence line. Results of the Decision 2 – Data Sufficiency to Estimate Exposure Point Concentrations, including proposed Part B Phase 1 sample locations if recommended, are presented below.

2.2.1 Inputs to Decision 2

The inputs required for Decision 2 include COPC concentrations in soil inside the fence line of the Topock Compressor Station and depth categories defined in the RAWP (ARCADIS, 2008a). Only COPC data meeting data quality Category 1 standards will be used for the risk assessment. The inputs to Decision 2 also include comparison values described in Section 2.1.2.

2.2.2 Data Sufficiency Evaluation to Estimate Representative Exposure Point Concentrations

Existing soil data were evaluated for sufficiency to estimate a representative EPC by detected compound and exposure depth interval. The evaluation assumes the existing data adequately represent the nature and extent of contamination; this assumption will be verified after Part B Phase 1 data have been collected. Additional sampling was recommended if existing data were insufficient estimate a representative EPC for any constituent in any defined exposure interval within the fence line. The technical approach used to evaluate the data to address Decision 2 is described below.

All soil Category 1 data were evaluated for each of the exposure intervals defined in the RAWP (ARCADIS, 2008a) for potential contact by human populations. Data for each detected compound in each exposure interval were evaluated for:

- Frequency of detection.
- Maximum result.
- Number of detections above comparison values.
- Human health comparison values—commercial criteria.

Frequency of detections and maximum results were evaluated to understand whether the minimum data necessary are available to calculate a representative EPC to be used in the human health risk assessment. A representative EPC could be either: (1) a 95 percent upper confidence limit of the mean (95%UCL) where at least eight results were reported with a minimum of five detections or (2) the maximum concentration reported, if data were not adequate for a 95%UCL and the following criteria were met:

- The maximum was less than or equal to approximately two times the comparison value for human health risk screening, and/or

- Additional data collection appeared unlikely to yield additional detections to support the calculation of a 95%UCL.

Table B-9 summarizes the results of the evaluation to determine whether data are sufficient to estimate a representative EPC. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value. For each compound, the table indicates, for each relevant exposure depth interval, the total number of samples collected, the number of detections, the maximum detected value, and whether there is sufficient information to calculate a representative EPC for that particular compound for the specific exposure interval.

The Decision 2 data evaluation performed using the existing data will be expanded to include the combined data set once the Part B Phase 1 investigation has been completed.

In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support EPC development for detected chemicals that exceeded one or more comparison values, as described below.

Metals

Sufficient data (numbers of samples and detections) are available to calculate EPCs for total chromium, hexavalent chromium, and lead using ProUCL.

Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene toxicity equivalents (B[a]P TEQs) using ProUCL with the exception of the surface soil exposure depth interval (0 to 0.5 foot below ground surface [bgs]). For the surface soil exposure depth interval, there are insufficient samples to calculate an EPC for the B(a)P TEQs (i.e., a total of nine samples, with detectable concentrations of the PAHs in four of the nine samples).

2.3 Decision 3 – Threat to Groundwater from Residual Soil Concentrations

This section presents the inputs and process used to evaluate Decision 3 – Threat to Groundwater from Residual Soil Concentrations and the process that will be used once the Part B, Phase 1 data are available. Results of the Decision 3 evaluation, including proposed Part B Phase 1 sample locations if recommended, are provided below.

2.3.1 Inputs to Decision 3

The inputs required for Decision 3 consist of the nature and extent of soil data from Decision 1, site-specific information required to calculate SSLs protective of groundwater, and screening-level groundwater modeling results, where necessary.

Due to the limited amount of existing soil data the Decision 3 evaluation will be completed after the implementation of the Part B Phase 1 investigation, using the combined existing and new soil data. Key site-specific information required to calculate the SSLs includes:

- Soil BTVs for metals and inorganic compounds, discussed in the *Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2009a) and in Appendix E of the *Draft Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2010).
- Groundwater background values for inorganics, calculated as 95%UCL and presented in *Groundwater Background Study Steps 3 and 4: Revised Final Report of Results, PG&E Topock Compressor Station* (CH2M HILL, 2009b). For organics, groundwater maximum contaminant levels and/or applicable drinking water standards were used.
- Volume and cross-sectional area of the potential source (i.e., unit or area).
- Site-specific recharge and groundwater flow characteristics at each unit.
- Depth to groundwater, geochemical, and hydraulic characteristics of the vadose zone soil.

Inputs required for the screening-level groundwater modeling are the same as those for the SSL calculation, with the addition of transport parameters (dispersion, soil-water partition coefficients). USEPA literature and other technical literature served as the source for these parameters (USEPA, 2005; Xu and Eckstein, 1995).

2.3.2 Threat to Groundwater from Residual Soil Concentrations Evaluation

A conservative, three-tiered approach will be used in the evaluation to assess which units may present a potential current or future threat to groundwater from COPCs in the vadose zone. The approach was presented in technical memorandum entitled *Calculation of Soil*

Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station (CH2M HILL, 2008b) and includes:

- **Step 1:** The initial step in the evaluation process will be to compare the metals concentrations in soil samples from each investigation unit/area to the soil BTV to assess whether the concentrations are at or below background. If no individual COPC concentration from samples collected within a unit is greater than the BTV, then no further analysis is required to assess the potential for leaching into groundwater for that COPC within the unit/area.

  A central tendency comparison will also be performed (as described for Decision 1). The comparison to background levels in Step 1 will also consider the results of the central tendency comparison. If there are any COPCs that are present above the BTV, but the central tendency comparison evaluation concludes that the COPC concentration in the sample population within a unit is not statistically greater than the COPC concentration in the background population, then no further evaluation will be required for that COPC to satisfy Decision 3.

  This evaluation was completed for all metals detected in a given unit/area.

  Because organic compounds (PCBs, pesticides, volatile organic compounds [VOCs], and semivolatile organic compounds [SVOCs]) do not have a soil BTV to compare to, organic compounds will be evaluated in Step 3.

- **Step 2:** For detected COPCs with concentrations above BTVs, the detected concentrations will be compared to the unit- or area-specific SSL. The SSLs will be calculated in accordance with USEPA (1996) and New Mexico Environment Department (2006) guidance, among others. A detailed example SSL calculation was provided in the technical memorandum entitled *Calculation of Soil Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station* (CH2M HILL, 2008b). The SSLs are calculated using highly conservative assumptions so that COPCs that are eliminated from further consideration in this step are eliminated with high confidence. If sample concentrations are at or below the SSL, then no further analysis is required to assess the potential for leaching into groundwater for those COPCs.

  If samples concentrations are above SSLs, the data will be evaluated to assess whether the sample results indicated a potential current threat to groundwater. A potential current threat to groundwater exists if one or both of the following conditions are present:

  - Vertical concentration trends of COPC increase with depth.
  - Soil data indicate elevated concentrations of compounds (as compared to the BTVs) in samples throughout the boring <u>*and*</u> at the depth of the soil/groundwater interface.

  If there are insufficient data to complete this step, a data gap will be identified, and additional proposed sampling locations to collect the needed vertical concentration data will be included in the Part B Phase 2 sampling program. If the evaluation does not indicate a potential current threat to groundwater, then the evaluation will continue with Step 3.

- **Step 3:** If sample concentrations exceeded the SSL but did not indicate a potential current threat to groundwater, a vadose zone flow and transport model will be used to evaluate the potential for leaching into groundwater. Modeling will be performed using the HYDRUS-1D software package (Simunek et al., 1998) and initially is intended as a screening process using highly conservative assumptions. If the modeling results showed no exceedance of the groundwater background values, then no further evaluation will be performed. If the modeling results in a COPC in groundwater at a concentration exceeding groundwater background values, the need for model refinement and possible additional data collection and/or development of a plan for a groundwater assessment will be evaluated. If the deepest sample(s) in a boring or area exceeded the BTV, a data gap may have been identified for Decision 3.[2]

The Step 3 modeling approach and model inputs, and assumptions will be further refined after the implementation of this work plan.

2.4 Decision 4 – Potential Migration to Areas Outside the Fence Line

This section presents the inputs and process to be used to evaluate Decision 4 – Potential Migration to Areas Outside the Fence Line. Due to the limited amount of existing soil data the Decision 4 evaluation will be completed after the implementation of the Part B Phase 1 investigation, using the combined existing and new soil data. The combined data set will be used to complete the Decision 4 evaluation for each unit/area, as applicable.

2.4.1 Inputs to Decision 4

The following three types of information are needed and considered when assessing whether COPCs present within at a site are adequately understood: (1) usable and appropriate COPC concentration data for surface soils, (2) potential transport mechanisms and pathways, and (3) screening comparison values, as described in the Soil Part B DQO Tech Memo provided in Appendix B1 and summarized below. Because Decision 4 pertains to potential migration of constituents in soil from areas within the fence line to areas outside the fence line, only exposed surface soil data are evaluated because only exposed surface soil would be mobilized. Potential groundwater concerns are addressed by Decision 3.

The following subsections describe the inputs required to evaluate Decision 4.

Data Usability

Existing data were evaluated in the *Final Soil and Sediment Data Usability Technical Memorandum, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2008a). All existing surface soil data meeting Category 1 data quality standards will be included in the data set for the Decision 4 evaluation. New data will be validated, and only data meeting Category 1 data quality standards will be included in the combined data set.

---

[2] Note that this may also represent a data gap for Decision 1. However, if concentrations are declining with depth and/or the concentration detected in the lowest sample collected is near the BTV, the available data may be considered adequate for Decision 1.

Potential Transport Mechanisms and Pathways

As described in Section 2.1, a CSM for the entire area within the fence line was developed for the *Human Health and Ecological Risk Assessment Work Plan, Topock Compressor Station, Needles, California* (ARCADIS, 2008a) and RAWP Addendum (ARCADIS, 2009a). Site-specific CSMs providing a more detailed assessment of contaminant fate and transport mechanisms at each unit were also developed and are presented in Appendices B2 through B24. The site-specific fate and transport mechanism address potential transport and migration pathways to areas outside the fence line.

However, while the CSMs provide general information on the types of transport mechanisms and pathways that may be applicable to a specific unit, Decision 4 requires detailed, on-the-ground information regarding specific potential transport pathways from areas with COPC concentrations above screening levels. For example, constituents contained in surface soils in unpaved areas may be transported to areas outside the fence line through runoff via sheet flow or storm drains. To determine whether constituents in surface soil in a specific unpaved area could be transported from areas inside the fence line to areas outside the fence line, the following information would have to be known:

- Surface water flow paths (in which direction(s) would surface water flow from the affected area?).
- Presence of storm drain catch basins, if any, along the surface water flow path(s).
- Presence of berms or other features that would redirect the surface water flow and prevent direct flow to areas outside the fence line.

To know which specific areas outside the fence line could be impacted by the specific affected area inside the fence line, discharge point(s) for any catch basin(s) along the surface water flow path(s) and the direct discharge location for any sheet flow runoff also need to be known.

Comparison Values

Comparison values for Decision 4 must consider potential receptors outside the fence line. Consequently, comparison values for Decision 4 are the same as for the Part A soil investigation program. The six types of comparison values identified for the Decision 4 evaluation are:

- Soil BTVs for metals and inorganic compounds, which are discussed in the *Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2009a) and in Appendix E of the *Draft Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2010).
- Ecological comparison values (ECVs), which are calculated to be protective of the species potentially present in the area outside the fence line (ARCADIS, 2008b, 2009a-b).
- DTSC CHHSLs for residential use (California Environmental Protection Agency, Office of Environmental Health Hazard Assessment, 2005).

- USEPA RSLs for residential use for those compounds for which CHHSLs are unavailable or for which the existing CHHSLs are based on outdated toxicity factors (USEPA, 2009).
- Water Board 2008 environmental screening levels for total petroleum hydrocarbons in the gasoline, diesel, and motor oil ranges for a residential exposure scenario for human health based on a hazard index of 1.0.
- Project-specific screening levels developed for COPCs and below ground surface (COPECs) identified from CERCLA TAL/TCL data, to be developed as needed.

2.4.2 Decision 4 Evaluation Process

The comparison values will be used to assess whether COPCs and COPECs present in surface soil in unpaved portions at any of the units/areas within the fence line could potentially pose a threat to receptors outside the fence line, if released to areas outside the fence line. The COPC/COPEC concentrations in the unpaved portion of each unit/area will be compared to the lowest of the applicable comparison values, defined as the interim screening level. The soil interim screening level for most metals is equal to the corresponding BTV. Certain ECVs, USEPA RSLs, or DTSC CHHSLs for metals are lower than the BTV; in these cases, the BTV will be used in lieu of the ECVs, USEPA RSLs, or DTSC CHHSLs when determining whether delineation is adequate. If a BTV is not available, then the interim screening value is usually the lesser of the DTSC CHHSLs or soil ECVs. As stated above, the USEPA RSL is used instead of the CHHSL in those instances where a CHHSL does not exist or where the toxicity values used in the CHHSL are outdated. The comparison values are shown in Tables B-1 through B-8.

The first step in the data evaluation process for Decision 4 is to determine the paved and unpaved areas of the compressor station. Figure B-2 provides an overview of the paved and unpaved areas. Gravel covered areas were considered unpaved, as there is some potential for constituents in soil to be released to stormwater run-off. The next step in data evaluation for these unpaved areas will then follow the same process as for Decision 1. Once the unpaved areas containing COPCs/COPECs above interim screening levels are identified, potential migration pathways from these areas to areas outside the fence line will be evaluated. It should be noted that exceedances of any comparison values does not indicate the presence or absence of unacceptable risk (potential site-related risks will be evaluated in the baseline risk assessment).

2.5 Decision 5 – Data Sufficiency to Support Corrective Measures Study/Feasibility Study and/or Interim Measures

2.5.1 Inputs to Decision 5

Inputs to Decision 5 consist of soil property and contaminant distribution data (existing data for the evaluation conducted during the preparation of this work plan and the combined existing and validated Phase 1 data) and other information needed to support the CMS/FS decisions and remedial design and/or interim measures. Decision 5 was initially evaluated using Category 1 and 2 existing data; only Category 1 will be used in the combined data set. Inputs to Decision 5 include volumes of soil potentially requiring remediation; specific soil physical and chemical properties that could influence the performance of certain remedial technologies (e.g., porosity, grain size, density, organic carbon content, soil chemical properties); waste characterization parameters for any soils that may need to be transported and disposed of offsite; available migration control options; and potential physical limitations on implementation of various technologies (surface or subsurface structures).

2.5.2 Data Sufficiency to Support Corrective Measures Study/Feasibility Study Evaluation

A preliminary assessment of potential remedial technologies and presumptive remedies guided identification of the data needs to support the CMS/FS and remedial design and/or interim measures. An initial list of suitable remedial technologies was presented in the approved *Final Corrective Measures/Feasibility Study Work Plan, Topock Compressor Station, Needles, California* (CH2M HILL, 2008c), referred to as the CMS/FS Work Plan. The following is a summary of the initial technologies presented in the CMS/FS Work Plan:

- **Excavation and Offsite Disposal:** involves excavation, transportation, and disposal of contaminated material from the Topock site to a permitted offsite disposal facility. Pretreatment may be required to meet disposal requirements of the offsite facility.

- **Excavation and Onsite Treatment:** is an *ex-situ* method that involves excavation of contaminated soil and treatment onsite by either soil washing or chemical reduction.

- **Soil Flushing:** is an *in-situ* method that involves application of water or additive-containing water to soil to enhance contaminant solubility. Soil flushing is used in combination with a groundwater remedial method. Contaminants are leached from soil into the groundwater, which is then remediated.

- **Solidification/Stabilization:** can be either *ex-situ* or *in-situ* and involves use of various chemical additives to physically bind or enclose contaminants within a stabilized mass (solidification) or to chemically reduce the contaminants' mobility by inducing chemical reaction between the stabilizing agent and the contaminants (stabilization).

- ***In-Situ* Chemical Reduction:** involves addition of reagents to react with targeted constituents in soil to chemically convert hazardous contaminants to non-hazardous or less toxic compounds that are more stable, less mobile, and/or inert. Reductants could be applied to soil by infiltrating a liquid reductant from the surface, injecting a liquid reductant through wells, or injecting a gaseous reductant through wells.

- **Capping in Place:** involves construction of a capping system on top of the contaminated area to contain and minimize exposure of the contaminants to the environment.

- **Soil Vapor Extraction:** involves application of a vacuum through a network of wells to remove contaminated vapor from the soil. Volatile contaminants are removed with the vapor stream. A treatment system is typically incorporated to remove the contaminants before the soil vapor is vented to the atmosphere.

- **Thermal Desorption:** involves heating the subsurface to accelerate the movement of contaminants from the soil into the soil vapor. It is typically combined with soil vapor extraction to remove the contaminants from the subsurface. By heating the subsurface, soil vapor extraction can be used for a wider range of contaminants with lower volatility. Heating can also speed up the removal of volatile contaminants, particularly if contaminants are present in the form of non-aqueous phase liquids. Heating can be accomplished by injection of hot air or steam, or through use of electric current.

- ***In-situ* Vitrification**: involves intensive heating of the subsurface to completely melt the soil, which then cools into a glassy, vitrified block. Most organic contaminants are driven off or broken down during the heating. Inorganic contaminants are driven off or incorporated into the vitrified block and sequestered from the surrounding soil or groundwater.
- **Incineration:** involves burning excavated soil at high temperatures in a kiln or furnace. Incinerators are carefully designed to capture and treat the gases generated during combustion. Due to difficulties in permitting incinerators, most incineration is accomplished in offsite hazardous waste treatment facilities rather than with onsite incinerators. Depending on the contaminants present, the ash remaining may require disposal as a hazardous waste.

Treatability studies to collect data on technologies identified during the alternative development process are conducted, as appropriate, to provide additional information for evaluating technologies during the preparation of the CMS/FS. Some of the technologies suitable for final remediation of the compressor station may also be suitable as interim measures if applied on a more limited scale. For example, excavation could be used to address surficial contaminants that have the potential to migrate to areas outside the fence line. In addition, the following migration control measures may be appropriate to the area inside the fence line:

- Paving (a subset of capping technologies). Paving impacted soils with asphalt or concrete will prevent any direct exposure and avoid potential surface migration concerns.
- Stormwater collection. Collecting and treating stormwater runoff would prevent release of elevated levels of contaminants to areas outside the fence line.
- Installing curbs or berms and/or expanding the stormwater collection system. This would allow capture and treatment of stormwater from areas that currently discharge stormwater via sheet flow.

The evaluation of data sufficiency to support Decision 5 (i.e., data requirements for the initial list of suitable remedial technologies listed above) was conducted by assessing the following for each individual unit or area:

- Lateral and vertical extents of COPCs and COPECs potentially posing an excess human health and/or potential migration concern. The lateral and vertical extent information will be used to estimate required remediation volumes to determine the most appropriate and cost-effective remedial approach and/or interim measure for each area potentially requiring remediation. This step cannot be completed until the baseline risk assessment is completed; however, if the nature and extent of contamination are sufficiently defined to satisfy Decisions 1 and 4, sufficient data would be expected to be available to allow the completion of this portion of the evaluation for Decision 5 once the risk assessment has been completed.

- Waste characterization parameters for any soils that may be transported offsite for disposal (i.e., total threshold limit concentrations [TTLC], soluble threshold limit concentrations [STLC], and toxicity characteristic leaching procedure [TCLP]). The TTLC and STLC are waste characterization criteria in the State of California. The TTLC simply requires standard chemical analysis of samples to determine total concentrations of COPCs using published USEPA methods. The detected concentrations are compared to the TTLCs to determine whether total COPC concentrations exceed the hazardous waste criteria. Total chemical concentrations are also compared to a concentration of 10 times the STLC (10 x STLC) and 20 times the TCLP (20 x TCLP) to determine whether leachability testing is required to determine if leachable concentrations of COPCs may exceed hazardous waste criteria. To evaluate COPC leachability relative to the SLTC, samples are analyzed using the Waste Extraction Test specified in the Title 26 of the California Code of Regulations. The TCLP determination is a federal criterion for Resource Conservation and Recovery Act of 1976 (RCRA) waste; leachable concentrations of COPCs determined using the TCLP are compared to applicable RCRA criteria. The Waste Extraction Test uses a tenfold dilution/extraction of the sample, and the TCLP uses a twentyfold dilution/extraction. Consequently, total sample concentrations below 10 times STLC and 20 times TLCP cannot exceed the applicable hazardous waste criteria.
- Specific soil physical properties that may affect the performance of the various technologies (i.e., porosity, grain size, density, organic carbon content). Table B-10 provides specific soil physical properties that are needed for applicable remedial technologies.
- Existing surface and subsurface features (i.e., vegetation, nearby roads and road structures, culverts, subsurface utilities, bedrock, topography) that may affect the implementability of various technologies.
- Storm drain discharge locations for the various catch basins within the compressor station.
- Stormwater flow pathways from various units to catch basins.
- Bermed/unbermed areas of the compressor station (i.e., areas where COPCs could be carried off the compressor station via sheet flow).
- Paved and unpaved areas of the compressor station.

The evaluation of data sufficiency to support Decision 5 was completed by evaluating the data summary for Decision 1 (presented in Attachments B2 through B26) and by comparing the available data to the list presented above and in Table B-10 to determine if any data gaps exist.

Based on the existing data set, the following general types of data gaps currently exist with regard to Decision 5:

- Lateral and vertical extents of COPCs and COPECs potentially posing an excess human health and/or potential migration concern.

- Waste characterization parameters for any soils that may be transported offsite for disposal.
- Specific soil physical properties that may affect the performance of the various technologies.
- Existing surface and subsurface features (i.e., surface and subsurface utilities, structures, and bedrock) that may affect the implementability of various technologies.
- Storm drain discharge locations for the various catch basins within the compressor station.
- Stormwater flow pathways from various units to catch basins.

The full Decision 5 data gaps evaluation cannot be completed until Decision 1 is satisfied. The data gaps and additional sampling recommendations for each unit are described in Section 2.7 and Table B-10.

2.6 Data Quality Objectives Steps 6 and 7

This section summarizes DQO Steps 6 and 7.

2.6.1 Step 6: Acceptable Limits on Decision Error

Step 6 is intended to define acceptable limits on decision errors. A decision error would occur if, based on the available data, the project team chooses the wrong response action in the sense that a different response action would have been chosen if the project team had access to "perfect data" or absolute truth. COPC concentrations are estimated using data that are subject to different variabilities at different stages of development, from field collection to sample analysis. The combination of all these errors is called total study error. In some cases, total study error may lead to a decision error. Total study error is composed of two main components:

- **Sampling design error**. This error (variability) is influenced by the sample collection design, the number of samples, and the actual variability of the COPC concentration over space and time. Sampling must necessarily be limited to specific locations within a potentially impacted area, and this limited sampling may miss some features of the existing variation of the constituent concentration levels. Sampling design error occurs when the data collection design does not capture the complete variability within the media to the extent appropriate for the decision of interest.
- **Measurement error**. This error (variability) is influenced by imperfections in the measurement and analysis system. Random and systematic measurement errors may be introduced in the measurement process during physical sample collection, sample handling, sample preparation, sample analysis, and data reduction.

Potential decision errors can be evaluated quantitatively or qualitatively. For sites such as Topock, where the most appropriate sampling design is non-probabilistic, potential decision errors are evaluated qualitatively. Sample design errors are controlled through use of the CSM. Measurement error is controlled to an acceptable level by implementation of the

PG&E Program Quality Assurance Project Plan (CH2M HILL, 2008d) and by rejection of data that do not meet the criteria specified in the Quality Assurance Project Plan.

Limits on decision error for the Part B soil investigation will be reduced by ensuring with the highest level of confidence feasible that the sample locations are located in the appropriate areas. Appropriate areas consist of areas with known impacts or areas likely to have been impacted. These areas were identified based on site history information and current site conditions (i.e., to identify the release point) and transport pathways (to identify likely contaminant locations). Site-specific CSMs were developed for each of the SWMUs, AOCs, and Units 4.3, 4.4, and 4.5 to assess whether or not the existing and proposed Part B soil investigation samples are located in the areas of impact or likely to have been impacted. During the development of the CSMs and completion of Step 6, uncertainties at each individual unit were assessed for:

- Source of contamination, including release point.
- Potential release mechanisms and transport pathways.
- Topographic conditions and constraints.

As discussed previously, limited information is available regarding the storm drain system and specific stormwater flow pathways in certain portions of the compressor station. These data gaps may affect the evaluation of potential migration to areas outside the fence line and will be addressed as part of the Part B Phase 1 investigation (see discussion in Section 2.4 of this appendix and the storm drain system investigation program discussed in Appendix D of the Soil RFI/RI Work Plan).

2.6.2 Step 7: Optimize the Sampling Design for Obtaining Data

The purpose of Step 7 is to "identify a resource-effective data collection design for generating data that are expected to satisfy the DQOs" (USEPA, 2000) in the context of site-specific constraints. The output of this step is the Phase 1 sampling design presented in this work plan. If necessary, Step 7 will be completed again following the completion of the Part B Phase 1 investigation.

Step 7 for the Part B Phase 1 investigation consisted of documenting the applicable activities of the sample design process to describe the reasons for selecting a sampling scheme, the reasons for selecting specific sampling locations, and the expected performance of the data collection design with respect to qualitative DQOs only, as was done for the Part A Phase 1 soil investigation. In addition, given the many access constraints within the compressor station fence line, access constraints were specifically considered as a final phase in completing Step 7. Access constraints associated with each unit and the resulting effects on the sample design are described for each individual unit in Appendices B2 through B24.

As with done with Part A Phase 1, PG&E has performed an initial assessment of candidate locations for additional characterization. These locations are presented in Appendices B2 through B24 and are summarized in Section 2.7 and Table B-11 of this appendix. PG&E anticipates that all candidate locations identified may not be necessary.

2.7 Data Gaps Evaluation Summary for Part B, Phase 1

This section presents a summary of the data gaps evaluation described in Section 2.0 and in Appendices B2 through B24. As described above, the existing data were used in evaluating whether sufficient data exist to make each of the five decisions. The data gaps evaluation concluded:

- **Decision 1**: Additional sampling to more precisely delineate the nature and extent of COPCs/COPECs is proposed at 24 of the 25 SWMUs, AOCs, and units included in this work plan. No additional sampling is proposed at AOC 25 – Compressor and Generator Engines and Basements because of access restrictions. In addition, sampling is proposed to characterize the newly identified burn area in AOC 13.
- **Decision 2**: In general, with the exception of PAHs in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since SVOC analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.
- **Decision 3**: As described in Section 2.3, additional information is needed to define the nature and extent of soil data from Decision 1, site-specific information is also required to calculate SSLs protective of groundwater, and screening-level groundwater modeling results, where necessary.
- **Decision 4**: As described in Section 2.4, additional information is needed to characterize migration pathways, and define the nature and extent of COPCs/COPECs in surface soil that have the potential to migrate outside the fence line.
- **Decision 5**: As described in Section 2.5, certain waste characterization data and soil physical properties data are needed at all units. To minimize additional borings, soil physical property data are proposed to be collected only at those locations where borings are proposed for other purposes. The remaining information will be collected after the risk assessment has been completed, and the precise areas potentially requiring remediation have been defined.

Table B-12 provides a summary of the proposed additional sampling to address the data gaps identified during this evaluation. These potential locations are PG&E's initial assessment of candidate locations for additional characterization. PG&E anticipates that all candidate locations identified may not be necessary.

3.0 Accessibility Evaluation for Areas within the Fence Line

The Topock Compressor Station is an active industrial facility designed to handle dangerous compressed natural gas, other compressed gases, other fluids with elevated temperatures or hazardous characteristics, and underground electrical systems. Any soil investigation conducted within the fence line must address the many constraints on subsurface intrusion. To further characterize access constraints within the fence line of the compressor station for planning purposes, PG&E conducted an initial assessment of subsurface utilities and aboveground obstructions and also documented access to the various investigation units photographically. Photographs for each of the units are provided in Appendix B25.

3.1 Access and Sampling Feasibility Assessment

To assess accessibility and feasibility of sampling within the fence line of the compressor station, the station was divided into 16 areas shown in Figure B-2. Each of the areas was characterized to define the surface access available within the areas. The primary factors considered in determining the feasibility of sampling in each of the areas included the presence of buildings or other operational aboveground infrastructure, the presence and thickness of paving and/or foundations, and the presence of subsurface utilities (see discussion in Section 3.2, below). Five levels of surface access were identified:

- Level 1 (color code blue; Figure B-2): Away from aboveground operational infrastructure without asphalt or concrete cover.
- Level 2 (color code yellow; Figure B-2): Asphalt or thin concrete cover away from aboveground infrastructure or known dense underground utilities.
- Level 3 (color code purple; Figure B-2): Proximate to aboveground operational infrastructure without asphalt or concrete cover.
- Level 4 (color code orange; Figure B-2): Covered operational structure or area of thick concrete located in proximity to dense underground utilities.
- Level 5 (color code red; Figure B-2): Operational compressor station building or element of operation infrastructure (e.g., aboveground storage tanks)

Feasibility of access also depends on whether only hand sampling is required or whether equipment is required. Potential access for sampling was divided into access for surface (up to 1 foot bgs) and subsurface sampling. Surface sampling in this context refers to samples that can likely be collected using hand tools (such as trowels) only. Some areas may allow use of shovels. In some areas that were rated as accessible for surface sampling (e.g., underneath aboveground pipelines), the soil may be too hard-packed to allow collection of a soil sample or may limit soil collection to a depth of a few inches.

3.2 Initial Assessment of Subsurface Utilities

Because drawings do not exist that show the locations of all underground infrastructure, the initial, partial assessment of subsurface utilities was conducted by identifying the types and total number of utility risers (i.e., utilities penetrating the ground surface) within the 16 major areas within the compressor station. Table B-13 contains a summary of the number and types of risers within each area. As discussed previously, it is Topock Compressor Station policy to minimize operational and safety risks by limiting subsurface intrusion as much as possible. Thus, abandoned utilities are typically left in place. Consequently, it is likely that not all risers lead to active lines; however, given the large number of underground lines in most areas of the compressor station and the difficulty of tracing each line, PG&E did not define which utility risers likely led to active lines and which are associated within inactive lines. Many locations contained electrical conduit containing multiple electrical lines; each conduit was counted as a riser. PG&E did not determine the number of electrical lines associated with each conduit.

For this initial assessment, PG&E also did not define the path of each specific utility associated with a riser. The large number of utilities makes such an assessment infeasible based only on a review of risers.

3.3 Safety Assessment for Sampling within the Compressor Station Fence Line

As the last step in the evaluation, potential access for each of the five types of access was assessed with regard to safety, as shown in Table B-14. Surface sampling in unpaved areas (Level 1 and Level 2) is generally considered to be safe. Surface sampling in paved areas (i.e., immediately below the pavement) away from aboveground structures and dense subsurface utilities may also be safe, provided adequate utility clearance is performed (some risk of damaging unknown utilities would exist simply due to the need to remove the paving material in the area to be sampled). Subsurface intrusion and sampling is considered potentially unsafe in all areas including unpaved open areas or paved open areas, buildings and structures, underneath thick concrete (e.g., thick foundations, loading docks), in the vicinity of buildings and aboveground operational infrastructure, and in areas with dense underground utilities. Table B-14 summarizes the initial safety classifications for the five access types.

4.0 Integration of Perimeter and Storm Drain Investigation Data

As described in Appendices C and D of the Soil RFI/RI Work Plan, soil data will also be collected during the Storm Drain System and Perimeter Area investigation programs. These data will be integrated with the individual SWMU/AOC soil investigation programs, as appropriate. The data evaluation processes described for the Storm Drain System and Perimeter Area investigation programs will be completed before data from these programs are assigned to individual SWMUs/AOCs investigation programs. Typically, data pertaining to potential sources of contamination and migration of contaminants near the facility fence line would be assigned to the Part B program SWMUs/AOCs.

Once a determination has been made regarding the appropriate assignments of the various sample locations in the Storm Drain System and Perimeter Area investigation programs, the appropriate data from these programs will be integrated into the Part B data set. Data gaps evaluation for all five DQO decisions for the Part B investigation will be conducted after the appropriate data from these two investigation programs have been merged into the overall Part B data set. Inclusion of these data in the Part B data set may require adjusting the boundaries of one or more SWMUs/AOCs in the Part B program.

Notes:

1 USEPA residential regional screening level from April 2009 is used.

2 Mercury: mercury, inorganic salts

3 The oral reference dose (RfD) used for the vanadium screening level is derived from the IRIS oral RfD for vanadium pentoxide by factoring out the molecular weight of the oxide ion.

QAPP RL = quality assurance procedures plan reporting limit
DTSC CHHSL = California Department of Toxic Substances Control; California human health screening levels (OEHHA, 2005)
Background = CH2M HILL. 2009. "Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California". May.
--- = data not collected, available or applicable
x = indicates analytes from the Contract Laboratory Program Target Compound and Target Analyte Lists (TCL/TALs)
USEPA = United States Environmental Protection Agency

SL = USEPA regional screening level (USEPA, December 2009)
mg/kg = milligrams per kilogram
NE = regulatory standard not established
NC = not calculated
NA = not available
* = California modified preliminary remediation goal (USEPA 2004)

TABLE B-2

Sediment Analyte Comparison Table - Metals

Soil Investigation Part B Phase 1 Work Plan, PG&E Topock Compressor Station, Needles, California

Analyte	CAS	QAPP RL (mg/kg)	Soil Background Levels (mg/kg)	Consensus-based Concentration		Does RL Exceed Screening Level?
				Threshold (mg/kg)	Probable (mg/kg)	
Antimony	7440-36-0	2	---	NE	NE	---
Arsenic	7440-38-2	0.5	11	9.79	33	No
Barium	7440-39-3	1	410	NE	NE	No
Beryllium	7440-41-7	0.5	0.672	NE	NE	No

Notes:

[1] Calculated using California toxicity values. The EPA Regional SL for Benzo(a)anthracene, Benzo(b)fluoranthene and Indeno (1,2,3-c,d)pyrene residential is 150 µg/kg, commercial is 2100 µg/kg; Dibenzo(a,h)anthracene residential is 15 µg/kg, commercial is 210 µg/kg.

[S] Pyrene is used as a surrogate

QAPP RL = quality assurance procedures plan reporting limit
DTSC CHHSL = California Department of Toxic Substances Control; California human health screening levels (OEHHA, 2005)
SL = USEPA regional screening level, (USEPA, December 2009)
µg/kg = micrograms per kilogram
NE = regulatory standard not established
--- = background concentration could not be established because all background samples were non-detect for this constituent
(sat) = concentration may exceed saturation value
* = California modified preliminary remediation goal (USEPA 2004)
NA = not available
USEPA = United States Environmental Protection Agency

	Pyrene	129-00-0	330	2	NE	NE	1,700,000	17,000,000	---	See note 2	No	No

Notes:

All soil sample results will be reported in dry weight unless otherwise specified in the SAP.

[1] ECVs were calculated as needed for constituents detected during the Part A Phase 1 sampling.

[2] Analytes were analyzed by SW8270SIM to achieve a lower reporting limit.

[3] Calculated using California toxicity values. The EPA Regional SL for Benzo(a)anthracene, Benzo(b)fluoranthene and Indeno (1,2,3-c,d)pyrene residential is 150 µg/kg, commercial is 2100 µg/kg; Dibenzo(a,h)anthracene residential is 15 µg/kg, commercial is 210 µg/kg.

QAPP RL	= quality assurance procedures plan reporting limit
DTSC CHHSL	= California Department of Toxic Substances Control; California human health screening levels (OEHHA, 2005)
µg/kg	= micrograms per kilogram
SL	= USEPA regional screening level, (USEPA, December 2009)
NE	= regulatory standard not established
(sat)	= concentration may exceed saturation value
s1	= pyrene is used as a surrogate.
(max)	= ceiling limit, not a risk-based value
^	= preliminary remediation goal, (USEPA, 2004)
---	= data not collected, available or applicable
x	= indicates analytes from the Contract Laboratory Program Target Compound and Target Analyte Lists (TCL/TALs)
*	= California modified preliminary remediation goal, (USEPA, 2004)
USEPA	= United States Environmental Protection Agency

Polycyclic Aromatic Hydrocarbons						
PAHs (BaP TEQ)				130 µg/kg		
0-0.5 ft bgs	N	4 of 9	320 µg/kg	Y	RA-1	Compound exceeds HHCV. Existing data are insufficient to allow calculation of a 95% UCL on the mean for 0-0.5 ft exposure interval. At a minimum, one more sample with detected BaP TEQ is required to calculate an EPC
0-3 ft bgs	Y	6 of 18	320 µg/kg	Y		
0-6 ft bgs	Y	6 of 18	320 µg/kg	Y		
0-10 ft bgs	Y	6 of 18	320 µg/kg	Y		

Footnotes:

[a] The higher value of either the HHCV or background was selected as the screening criteria and is included in these columns for the respective compound in BOLDED BLUE FONT. Values based on background are indicated with "(bckg)" next to the value.

Acronyms and Abbreviations:

BaP TEQ = benzo(a)pyrene toxic equivalents
EPC = exposure point concentration
ft bgs = feet below ground surface
HHCV = human health comparison values
mg/kg = milligrams per kilogram
µg/kg = micrograms per kilogram
N = No
NA = not applicable
Y = yes

Notes:

[a] Waste Characterization Parameters Include:

TTLC – SW-846 6010B/7471A/7470A

STLC – Title 22, Division 4.5, Chapter 11, Article 5, Appendix II, Waste Extraction Test (WET)

TCLP for metals – SW-846 1311/SW-846 6010B/7470A

If organic compounds are suspected or “solvent like” odors are encountered additional analysis may be warranted. These may include but are not limited to or specifically required for any sample and will be determined on case-by-case basis.

TCLP SW-846 1311 (organic)

Reactivity - Title 22, Division 4.5, Chapter 11, Article 3, Section 66261.23

Ignitability - SW-846 1010/1020

Corrosivity - SW-846 9040

TABLE B-11
Data Quality Objectives – Part B Soil Investigation
Soil Investigation Part B Phase 1 Work Plan,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

STEP 1 Problem Statement	**STEP 2 Decision Statement**	**STEP 3 Inputs to the Decision**	**STEP 4 Study Area Boundaries**	**STEP 5 Decision Rules**
Contaminants in soil in SWMUs/AOCs inside the compressor station fence line resulting from historical compressor station practices may pose an unacceptable risk to humans or the environment, or threaten groundwater. Adequate site-specific information is needed to: • Determine the nature and extent of soil contamination. • Estimate representative EPCs to support human health risk assessment being conducted separately from the Part B soil investigation. • Determine whether residual soil concentrations inside the compressor station fence line pose a threat to groundwater. • Determine whether migration of residual soil concentrations inside the compressor station fence line via a surface migration pathway pose a threat to receptors outside the compressor station fence line. • Determine the site-specific soil property and contaminant distribution information necessary to support the CMS/FS, remedial design, and/or interim measures.	**<u>Decision 1</u>** Determine the nature and extent of residual soil concentrations resulting from historical compressor station practices. If determination of the nature and extent of contamination based on sample data is not feasible or is not warranted, address uncertainties in the risk assessment and/or the CMS/FS or Interim Measures.	• COPCs by AOC/SWMU • Part B and representative Category 1 and 2 historical RFI/RI COPC data grouped by AOC/SWMU • Comparison/screening values (background, risk-based, and regulatory screening values) • CSMs • Geologic/hydrogeologic/hydrologic information • Topographic information • Soil physical and chemical property information • AOC/SWMU location and use history information • Cultural and historical information by AOC/SWMU • Infrastructure information by AOC/SWMU	**Lateral Extent** *For onsite units included in the Final RFI/RI:* Initially, the same as the currently defined boundaries of each SWMU and AOC: Lateral extent will be expanded if/as necessary until COPCs concentrations fall below screening values. If samples are collected outside the fence line in areas that provide significant habitat, then data will be compared with ecological comparison values and constituents of potential ecological concern identified. The lateral extent of AOC 13 is to the fence line, where unpaved areas extend to the fence line. Onsite units included in the Final RFI/RI include SWMUs 5, 6, 8, and 9; Units 4.3, 4.4, and 4.5; and AOCs 5, 6, 7, 8, 13, 15, 16, 17, 18, 19, and 20. *For newly identified areas*: Initially, the tentative outline shown in Part B DQO Tech Memo Figure 1. Newly identified areas include SWMU 11; AOCs 21, 22, 23, 24, 25[a], and 26; the potential burn area near AOC 17; and the motor oil pit at the former Teapot Dome facility. *For the perimeter area:* initially from the facility fence line outward to the toe of the slope. Existing and former storm drain outfalls will initially be investigated during Part B investigation. *For storm drains:* Initially, the lateral extent of the storm drain alignment. **Vertical Extent** Vertical study area boundaries extend from the ground surface to the water table. **Analytical Parameters** *Chemical Parameters (COPC):* • TPH, VOCs, and SVOCs (including PAHs) for SMWUs 5, 6, 8, and 9 • Title 22 metals, Cr(VI), and pH for SWMU 11 • Title 22 metals, VOCs, SVOCs (including PAHs), and pH for Unit 4.3 • Title 22 metals, VOCs, and SVOCs (including PAHs) for Unit 4.4 • TPH, VOCs, and SVOCs (including PAHs) for Unit 4.5 • Title 22 metals, Cr(VI), and pH for AOCs 5, 6, 15, and 19 • VOCs, SVOCs including PAHs, PCBs, TPH, Cr(VI), pH, and Title 22 metals for AOC 7 • TPH, VOCs, and Title 22 metals for AOC 8 • Title 22 metals, Cr(VI), VOCs, TPH, PAHs, PCBs, SVOCs, and asbestos for AOC 13 • Title 22 metals for AOC 16 • Title 22 metals, Cr(VI), VOCs, TPH, PAHs, and SVOCs for AOC 17, and AOC 18 • Title 22 metals, Cr(VI), TPH, VOCs, and PAHs for AOC 20 • Calcium, sodium, Cr(VI), pH, and Title 22 metals for AOC 21 • VOCs and SVOCs including PAHs, PCBs, TPH, Cr(VI), pH, and Title 22 metals for AOCs 22, 23, 24, 25, and 26 • TPH, VOCs, and SVOCs including PAHs, PCBs, and Title 22 metals for the motor oil pit at the former Teapot Dome facility	See Part B DQO Tech Memo Figure 2 for the Decision 1 decision rule

TABLE B-11
Data Quality Objectives – Part B Soil Investigation
Soil Investigation Part B Phase 1 Work Plan,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

STEP 1 Problem Statement	**STEP 2 Decision Statement**	**STEP 3 Inputs to the Decision**	**STEP 4 Study Area Boundaries**	**STEP 5 Decision Rules**
			• VOCs and SVOCs including PAHs, PCBs, TPH, Cr(VI), pH, Title 22 metals, and dioxins/furans for the potential burn area near AOC 17 *Other parameters:* Select samples will be analyzed to characterize the soluble fraction of compounds present at concentrations exceeding 10 x TTLC or 20 x TCLP values. SPLP will be performed on approximately two soil samples per AOC and will be analyzed for Cr(VI) and total chromium. Ten percent of samples will be analyzed for the CERCLA TAL/TCL compounds. **Temporal Boundaries** Validated Part B soil sampling data and representative Category 1 and Category 2 historical RFI/RI data (based on the final Data Usability Assessment).	
	<u>Decision 2</u> Determine representative EPCs for residual soil contamination resulting from historical compressor station practices. If determination of representative EPCs based on sample data is not feasible, address uncertainties in the risk assessment.	• Nature and extent of contamination assessment from Decision 1 • Part B and representative Category 1 historical RFI/RI COPC data grouped by exposure area and depth interval • Comparison/screening values (background, risk-based, and regulatory screening values) • Existing surface and subsurface utilities, pavement, buildings, and other structures • RAWP CSM • Geologic/hydrogeologic/hydrologic information • Topographic information • Soil physical and chemical property information • Site Worker activities and practices by AOC/SWMU, AOC/SWMU location, and use history information • Cultural and historic information by AOC/SWMU • Infrastructure information by AOC/SWMU	**Lateral Extent** Same as for Decision 1. **Vertical Extent** Vertical study area boundaries for Decision 2 are defined by potential maximum exposure depths. *For onsite workers*: the maximum exposure depth is 3 feet bgs. *For maintenance workers*: the maximum exposure depth is defined as 0 to 10 feet bgs. *For potential receptors outside the fence line*: surface interval only (0 to 0.5 foot bgs). For areas within the fence line (i.e., soil that could potentially be transported to areas outside the compressor station fence line); Part A parameters apply in the perimeter area and to storm drain sampling along outfalls outside the fence line. **Analytical Parameters** Same as for Decision 1. **Temporal Boundaries** Validated Part B soil sampling data and representative Category 1 historical RFI/RI data (based on the final Data Usability Assessment).	See Part B DQO Tech Memo Figure 3 for the Decision 2 decision rule
	<u>Decision 3</u> Determine whether residual soil concentrations resulting from historical compressor station practices may threaten groundwater. If so, conduct additional site-specific assessment of the threat, or implement response actions to mitigate the threat. If not, no further assessment or response actions are necessary to address threat to groundwater.	• Nature and extent of contamination assessment from Decision 1 • Data collected from compressor station wells installed during East Ravine Groundwater Investigation • COPCs by AOC/SWMU • Part B and representative Category 1 and 2 historical RFI/RI COPC data grouped by AOC/SWMU • Comparison/screening values (SSLs, groundwater background values, and groundwater/ drinking water ARARs, including maximum contaminant limits) • CSMs • Geologic/hydrogeologic/hydrologic information	**Lateral Extent** Those portions of each AOC/SWMU where COPC concentrations exceed SSLs. **Vertical Extent** Same as for Decision 1. **Analytical Parameters** *Chemical Parameters (COPCs):* Same as for Decision 1. *Other Parameters: Soil Characteristics* (to support modeling): Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes.	See Part B DQO Tech Memo Figure 4 for the Decision 3 decision rule

TABLE B-11
Data Quality Objectives – Part B Soil Investigation
Soil Investigation Part B Phase 1 Work Plan,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

STEP 1 Problem Statement	STEP 2 Decision Statement	STEP 3 Inputs to the Decision	STEP 4 Study Area Boundaries	STEP 5 Decision Rules
		• Sources of recharge within the compressor station • Topographic information • Soil physical and chemical property information • AOC/SWMU location and use history information • Cultural and historic information by AOC/SWMU • Infrastructure information by AOC/SWMU	**Temporal Boundaries** Same as for Decision 1.	
	<u>Decision 4</u> Determine if residual soil concentrations inside the compressor station fence line resulting from historical compressor station practices pose a potentially unacceptable risk to receptors outside the compressor station fence line via a surface migration pathway. If a potentially unacceptable risk to receptors outside the fence line exists, or if determination of potential risk to receptors outside the fence line based on sample data is not feasible, develop controls to eliminate migration pathways or remove contaminated soil.	• Nature and extent of contamination assessment from Decision 1 • Part B and representative Category 1 historical RFI/RI COPC data grouped by depth interval • Mechanisms, directions and rates of migration • Interim screening levels from Soil Part A Program • Existing surface and subsurface utilities, pavement, buildings, and other structures • RAWP CSM • Geologic/hydrogeologic/hydrologic information • Topographic information • Soil physical and chemical property information • AOC/SWMU location and use history information • Cultural and historic information by AOC/SWMU • Infrastructure information by AOC/SWMU	**Lateral Extent** Same as for Decision 1. **Vertical Extent** 0 to 0.5 foot bgs, except within the perimeter area, where the vertical boundary is 1.0 foot bgs. **Analytical Parameters** *Chemical Parameters (COCs):* Same as COPCs for Decision 1. **Temporal Boundaries** Same as for Decision 1.	See Part B DQO Tech Memo Figure 5 for the Decision 4 decision rule
	<u>Decision 5</u> Determine the site-specific soil property, contaminant distribution, and transport pathway information necessary to support the CMS/FS, remedial design, and/or Interim Measures, if required. If full determination of site-specific soil property, contaminant distribution, and transport pathway information based on sample data is not feasible, document impediments and uncertainties in the risk assessment and/or CMS/FS or interim measures.	• Nature and extent of contamination assessment from Decision 1 • Constituents of concern from human health and ecological risk assessments • Remedial action objectives and ARARs • Risk-based and regulatory soil and/or sediment cleanup levels • Estimated soil areas and volumes • Waste classification testing results for soil, as required • Waste comparison/screening levels (TTLC, STLC, RCRA toxicity) • Soil physical and chemical property information • Geologic/hydrogeologic/hydrologic information • Topographic information • Location of paved/unpaved areas	**Lateral Extent** Initially, same as for Decision 1, to be refined based on results of risk assessments and threat to groundwater assessments. **Vertical Extent** Initially, same as for Decision 1, to be refined based on results of risk assessments, threat to groundwater assessments, and remedial alternative practical constraints. **Analytical Parameters** *Chemical Parameters (COCs):* Initially, same as COPCs for Decision 1, to be refined to specific COCs based on results of risk assessments and threat to groundwater assessments. *Soil Characteristics* (to support evaluation of remedial or interim measures): Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes. **Temporal Boundaries** Same as for Decision 1.	See Part B DQO Tech Memo Figure 6 for the Decision 5 decision rule

TABLE B-11
Data Quality Objectives – Part B Soil Investigation
Soil Investigation Part B Phase 1 Work Plan,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

STEP 1 Problem Statement	**STEP 2 Decision Statement**	**STEP 3 Inputs to the Decision**	**STEP 4 Study Area Boundaries**	**STEP 5 Decision Rules**
		• AOC/SWMU location and use history information • Historical information by AOC/SWMU • Infrastructure information by AOC/SWMU		

Notes:

[a] This unit was identified as AOC 26 in the DTSC comments; however, AOC 25 as identified in the DTSC comments is a small, rectangular area carved out of the rock face near AOC 10 (East Ravine) that may have been used for explosives storage. Because the unit is outside the Topock Compressor Station, it will be further evaluated as needed in coordination with the Part A soil investigation.

The list of analytical parameters is based on CSM and will be refined after each round of investigation/data evaluation. COCs will be selected based on the risk assessment.

ARARs = applicable or relevant and appropriate requirements.
COC = constituent of concern.
Cr(VI) = hexavalent chromium.
TPH = total petroleum hydrocarbons.

TABLE B-12
Proposed Part B Phase 1 Sampling Summary
Soil Investigation Part B Phase 1 Work Plan,
Pacific Gas and Electric Company Topock Compressor Station Needles, California

	Additional Number of Samples and Locations Proposed to Address Data Gaps[a]			
Unit	**Decision 1 – Nature and Extent**	**Decision 2 – Data Sufficiency to Calculate EPCs**	**Decision 5 – Data Sufficiency for CMS/FS**	**Other**
SWMU 5	Not applicable	Not applicable	Not applicable	Two additional locations for organics (sub-AppendixB2, Table B2-3)
SWMU 6	Not applicable	Not applicable	Not applicable	One additional locations for organics (sub-AppendixB3, Table B3-3)
SWMU 8	Not applicable	Not applicable	Not applicable	One additional locations for organics (sub-AppendixB4, Table B4-3)
SWMU 9	Not applicable	Not applicable	Not applicable	One additional locations for organics (sub-AppendixB5, Table B5-2)
SWMU 11	Seven additional borings (sub-Appendix B6, Table B6-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 5	Six additional borings (sub-Appendix B7, Table B7-5)	None	Two samples from various depths interval to evaluate soil physical properties	None
AOC 6	Six additional borings (sub-Appendix B8, Table B8-4)	None	Two samples from various depths interval to evaluate soil physical properties	None
AOC 7	Five additional borings (sub-Appendix B9, Table B9-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 8	Two additional borings (sub-Appendix B10, Table B10-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 13	Thirty-four additional borings (sub-Appendix B11, Table B11-10	None	Two sample from various depths interval to evaluate soil physical properties	None
AOC 15	Six additional borings (sub-Appendix B12, Table B12-4)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 16	Four additional borings (sub-Appendix B13, Table B13-4)	None	One sample from various depths interval to evaluate soil physical properties	None

TABLE B-12
Proposed Part B Phase 1 Sampling Summary
Soil Investigation Part B Phase 1 Work Plan,
Pacific Gas and Electric Company Topock Compressor Station Needles, California

	Additional Number of Samples and Locations Proposed to Address Data Gaps[a]			
Unit	**Decision 1 – Nature and Extent**	**Decision 2 – Data Sufficiency to Calculate EPCs**	**Decision 5 – Data Sufficiency for CMS/FS**	**Other**
AOC 17	Five additional borings (sub-Appendix B14, Table B14-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 18	Not applicable	Not applicable	Not applicable	Twelve additional borings (sub-Appendix B15, Table B15-4)
AOC 19	Five additional borings (sub-Appendix B16, Table B16-5)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 20	Eight additional borings (sub-Appendix B17, Table B17-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 21	Two borings (sub-Appendix B18, Table B18-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 22	Two borings (sub-Appendix B19, Table B19-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 23	Three borings (sub-Appendix B20, Table B20-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 24	Two borings (sub-Appendix B21, Table B21-2)	None	One sample from various depths interval to evaluate soil physical properties	None
AOC 25	None; access restrictions prevent sampling	None	None; access restrictions prevent sampling	None
AOC 26	One boring (sub-Appendix B23, Table B23-2)	None	One sample from various depths interval to evaluate soil physical properties	None
Units 4.3, 4.4, and 4.5	Not applicable	Not applicable	Not applicable	Two additional locations for organics (sub-AppendixB24, Table B24-2)

Notes:

[a] Decisions 3 – Potential Threat to Ground water and Decision 4 - Potential Migration to Areas Outside the Fence Line were not assed as part of this work plan because of insufficient data. These decisions will be assessed after the implementation of this work plan.

	TOTAL AREA 16	**36**		**X**		**X**			
	Other: Light Standard, Typical[h]	1		X					

Notes:

[a] Risers are defined as utilities entering or exiting the subsurface. Other utilities may be present (e.g., stormwater lines and/or aboveground piping of various types).

[b] Odorant.

[c] Includes plant water and fire water; does not include wastewater or cooling water.

[d] Emergency shutoff device (disruption of this device triggers an automatic shutdown of the compressor station).

[e] Wastewater (water discharged to or from oily water treatment system).

[f] Main gas pipeline (typically 30- to 34-inch pipeline).

[g] Presence of active anodes indicates water lines must be present (water drip is required to keep anode wet/functioning).

[h] Utility counts for light standards and along fence line are incomplete.

TABLE B-14
Summary of Initial Safety Classifications
Soil Investigation Part B Phase 1 Work Plan,
Pacific Gas and Electric Company Topock Compressor Station Needles, California

		Safety Implications of Sample Collection[a]	
Area Type	**Direct Access to Soil?**	**Surface/Shallow Soils**[b] **(≤ 1 foot bgs)**	**Subsurface (> 1 foot bgs)**
1	Yes	Safe	Unsafe
2	No	Safe[c]	Unsafe
3	Yes	Safe[d]	Unsafe
4	No	Unsafe	Unsafe
5	No	Unsafe	Unsafe

Notes:

[a] The ratings presented are preliminary. Prior to any intrusive work, strict utility locating protocols must be followed.

[b] The term “surface/shallow soils” is intended to apply to depths easily sample using small hand tools. Generally, this infers a depth of 1 foot bgs or less.

[c] Given the presence of asphalt/concrete, any potential exposure/mitigation risks associated with contaminants that may be present are currently mitigated. Thus, risks associated with even shallow excavation are greater than those associated with any contaminants, and excavation is not recommended in these areas.

[d] While there is direct access to surface soils at these locations, aboveground operational structures limit workers’ abilities to collect soil samples deeper then the ground surface.

RED	Operational TCS building or element of operational infrastructure.	NO	UNSAFE	UNSAFE
ORANGE	Covered operational structure or area of thick concrete cover located in close proximity to known dense underground utilities.	NO	UNSAFE	UNSAFE
YELLOW	Asphalt or thin concrete cover away from above ground infrastructure or known dense underground utilities.	NO	SAFE [3]	UNSAFE
PURPLE	Close proximity to above ground operational infrastructure without asphalt or concrete cover.	YES	SAFE [4]	UNSAFE
BLUE	Away from above ground operational infrastructure without asphalt or concrete cover.	YES	SAFE	UNSAFE

Notes:

1. Color code boundaries were established based on field observation only and are not surveyed or based on as-built records. Boundaries are approximate within 10-15 feet.
2. The term "surface/shallow soils" is intended to apply to depths easily sampled using small hand tools. Generally this infers a depth of 1 foot below ground surface, or less.
3. Given the presence of asphalt/concrete, any potential exposure/migration risks associated with contaminants that may be present are currently mitigated. Thus, risks associated with even shallow excavation are greater than those associated with any contaminants, and excavation is not recommended in these areas.
4. While there is direct access to surface soils at these locations, above ground operational structures limit worker s ability to collect soil samples deeper than the ground surface.
5. The locations of known utility corridors are approximate, and not all utilities are known. Prior to any intrusive work, strict utility location protocols must be followed. In consideration of safety, PG&E reserves the right to change/adjust the safety implications of sample collection in each area based on the results of utility location surveys or observations made during excavation.
6. See attached Table X for additional notes related to utilities in each area.

1.0 Introduction

The purpose of this technical memorandum is to document the results of Steps 1 through 5 of the data quality objectives (DQOs) process for the soil investigation inside the fence line of the Topock Compressor Station. The proposed investigation program was described in the *PG&E Topock Compressor Station, Needles, California Draft RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part B* (CH2M HILL, 2007a), referred to as the Draft Soil Part B Work Plan. Steps 1 through 5 of the Soil Part B DQOs were developed in response to California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI) comments on the Draft Soil Part B Work Plan and followed the general approach used for the Soil Part A (outside the fence line) DQOs, Steps 1 through 5, as outlined in the *Data Quality Objectives Steps 1 through 5 – Part A Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (Soil Part A Data Quality Objectives Technical Memorandum) (CH2M HILL, 2010a). Consistent with Part A, Part B Steps 6 and 7 will be completed during working meetings to be held following implementation of the soil investigation. The soil investigation program inside the fence line addresses four Solid Waste Management Units (SWMUs), 11 Areas of Concern (AOCs), and three units within the fence line of the Topock Compressor Station fence line. These areas are SWMU 5, 6, 8, and 9; AOCs 5, 6, 7, 8, 13, 15, 16, 17, 18, 19, and 20; and Units 4.3, 4.4, and 4.5, as shown in Figure 1. (All figures are provided at the end of this technical memorandum.)

Two new areas of potential concern were identified recently based on employee interviews. These new investigation areas are the Teapot Dome Restaurant oil pit and a potential burn area near AOC 17, shown in Figure 1. Also, in its July 20, 2010, comments on the Pacific Gas and Electric Company (PG&E) "Response to Comments to the Draft Soil Part B Work Plan," DTSC requested the addition of seven other areas to the investigation program, including one new SWMU and six new AOCs (DTSC, 2010). The following six units have been added to the soil investigation program:

- SWMU 11: The former and current sulfuric acid tanks associated with the cooling towers

- AOC 21: A round depression near the sludge drying beds
- AOC 22: An unidentified three-sided structure in the upper yard
- AOC 23: The former Water Conditioning Building (now used as a storage building)
- AOC 24: The stained area associated with a potential former oil/water separator located in the lower yard in the vicinity of the northern bank of scrubbers
- AOC 25: The station compressor and auxiliary engines and associated basements
- AOC 26: Former Scrubber Sump

DTSC also requested the addition of a small depression carved out of the rock near AOC 10, which was identified by DTSC as a potential explosives storage area, as AOC 25. This unit is not being added as a new AOC. Based on existing information, it has no known connection to the compressor station. The unit identified as AOC 26 (Compressor and auxiliary Engines and Sumps) in DTSC's comments was therefore renumbered and is now AOC 25.

The DQO process is a recognized procedure for defining project objectives and decisions and optimizing sampling and other information-gathering programs to balance uncertainty, site disturbances, and cost in an acceptable manner. The goal of the DQO process is to ensure that data collected at each stage of the investigation process are of sufficient quantity and quality to enable the specified decisions to be made.

The United States Environmental Protection Agency (USEPA) has issued detailed guidance for the DQO process (USEPA, 2000, USEPA, 2006a-b). The DQO process consists of the following seven steps:

- **Step 1: State the Problem.** Concisely describe the problem to be studied. Review prior studies and existing information to gain a sufficient understanding to define the problem. Identify resources available to resolve the problem and develop the conceptual site model (CSM).
- **Step 2: Identify the Decision(s)**. Identify the principal study questions that require new environmental data to address the contamination problem and the resulting actions that may resolve the problem statement.
- **Step 3: Identify the Inputs to the Decision**. Identify the information and environmental measurements that are needed to resolve principal study questions.
- **Step 4: Define the Study Boundaries**. Specify the spatial and temporal aspects of the environmental media that the data must represent to support the decision.
- **Step 5: Develop a Decision Rule**. For each principal study question, define the statistical parameter(s) of interest, specify action levels, and integrate the previous DQO outputs into "if…then" statements that describe the logical basis for choosing among alternative actions.
- **Step 6: Specify Tolerable Limits on Decision Errors**. Define the decision makers' tolerable decision error rates based on the consequences of making an incorrect decision.

- **Step 7: Optimize the Design**. Evaluate information from the previous steps and generate alternative data collection designs. Choose the most resource-effective design that meets all DQOs.

While the steps of the DQO process are described sequentially above, the iterative nature of the DQO process allows one or more of these steps to be revisited as more information on the problem is obtained. Detailed DQOs for the subsequent phases of the soil investigation will be developed during those phases.

This technical memorandum addresses Steps 1 through 5 of the DQO process for the Soil Part B program. Consistent with Part A, Steps 6 and 7 will be addressed after completion of sampling and analysis at each of the units. An understanding of the characteristics of the data is necessary to guide decisions on the tolerable limits on decision errors.

2.0 Data Quality Objectives

Steps 1 through 5 of the DQO process for the soil investigation were developed by PG&E, at the direction of DTSC and DOI, for all of the investigation areas included in the Draft Soil Part B Work Plan, as well as for the new areas identified in Section 1.0 in tabular form and as decision flow charts. This memorandum incorporates comments on the draft table and flow charts provided by DTSC and DOI. Furthermore, as discussed above, in response to DTSC comments on the PG&E "Comment Response for the Draft Part B Work Plan" (DTSC, 2010) and employee interviews, six additional units and two new investigation areas described in Section 1.0 were incorporated into Table 1 and into this technical memorandum.

The revised DQOs for Steps 1 through 5 are provided in Table 1, and the associated decision flow charts are provided in Figures 2 through 6. This section provides a corresponding detailed description of the assumptions for each step and the process for implementing each step.

2.1 Step 1: Problem Statement

Step 1 consists of defining the problem and includes review of existing information; identification of the planning team; development of a conceptual model of the environmental hazard to be investigated (CSM); identification of available resources, constraints, and deadlines; and a brief discussion of potential remedial/closure options. These components are described in detail below.

2.1.1 Problem Definition

Historic practices at the Topock Compressor Station have resulted in known and potential releases of constituents of potential concern (COPCs) in several locations within the fence line of the station.[1] These locations are defined in the approved *Revised Final RCRA Facility Investigation/Remedial Investigation Report, Volume 1 – Site Background and History* (Revised

---

[1] As discussed in the Risk Assessment Work Plan, ecological exposure inside the Topock Compressor Station is insignificant because of the industrial development of the site and the very limited habitat; therefore, constituents of potential ecological concern will not be defined for areas within the fence line, except when required for the Decision 4 evaluation.

Final RFI/RI Volume 1) (CH2M HILL, 2007b). The Soil Part B program addresses SWMU 5, 6, 8, and 9; AOCs 5, 6, 7, 8, 13, 15, 16, 17, 18, 19, and 20; and Units 4.3, 4.4, and 4.5, as well as the new RCRA units (SWMU 11, and AOCs 21, 22, 23, 24, and 25) and two new investigation areas (the Teapot Dome Restaurant oil pit and the potential burn area near AOC 17). Also covered by these DQOs are the perimeter area in the immediate vicinity of the compressor station fence line, and existing and former storm drains and storm drain outfalls. The existing data regarding the units included in the Soil Part B Program have been documented in the Draft Part B Work Plan; no data are available for the new areas or the perimeter area.

The overall problem statement for the Soil Part B program is:

> *Contaminants in soil in SWMUs/AOCs and new investigation areas inside the compressor station fence line resulting from historical compressor station practices may pose an unacceptable risk to humans or the environment, or threaten groundwater. Adequate site-specific information is needed to:*
>
> - *Determine the nature and extent of soil contamination.*
> - *Estimate representative exposure point concentrations (EPCs) to support human health risk assessment being conducted separately from the Part B soil investigation.*
> - *Determine whether residual soil concentrations inside the compressor station fence line pose a threat to groundwater.*
> - *Determine whether migration of residual soil concentrations inside the compressor station fence line via a surface migration pathway poses a threat to receptors outside the compressor station fence line.*
> - *Determine the site-specific soil property and contaminant distribution information necessary to support the Corrective Measures Study/Feasibility Study (CMS/FS) and/or Interim Measures.*

The nature and extent of soil COPCs associated with former compressor station practices at or affecting these units must be defined to determine whether unacceptable risks or impacts to groundwater occur currently or could occur in the future, whether soil within the fence line potentially poses a threat to receptors outside the fence line because of migration of contamination from areas inside the fence line to areas outside the fence line, whether migration and/or exposure controls are required, and/or to support the CMS/FS, and remedial design and/or Interim Measures, if required. The extent of the soil COPCs must be understood in sufficient detail laterally and vertically to allow the human health risk assessment to be conducted and for appropriate remediation / interim measure decisions to be made.

An assessment must be made whether migration of residual soil concentrations from inside the compressor station fence line poses a potential threat to receptors outside the compressor station fence line. Potential receptors outside the fence line that are not applicable inside the fence line include ecological receptors, tribal users, recreational users, and potential residents. Appropriate screening levels will be used to evaluate potential migration of contaminants from inside the fence line to areas outside the fence line. The proposed screening levels to evaluate potential migration are described in Section 2.5.4.

2.1.2 Conceptual Site Model

A CSM is a schematic representation of how constituents released from a source may be transported to the surrounding environmental media and ultimately may come into contact with human or ecological receptors. A CSM includes known and suspected sources of contamination, types of constituents and affected media, known and potential routes of migration, and known or potential human and environmental receptors.

The CSM developed for the area inside the fence line provides the framework for where and to what depths investigations should occur and the factors that must be considered in developing screening values. The CSM also supports the identification of potential migration and exposure control measures. Information on contaminant transport and migration mechanisms and potentially exposed receptors helps guide the necessary investigation of the lateral and vertical extent of contamination. A detailed CSM for the area inside the fence line was developed for the *Human Health and Ecological Risk Assessment Work Plan* [RAWP], *Topock Compressor Station, Needles, California* (ARCADIS, 2008a). The CSM originally presented in the RAWP was based on knowledge from historical data. The CSM has been updated to address potential releases associated with the new SWMU and AOCs and the new investigation areas and is included as Figure 7. The focus of the CSM included with this DQO TM is on evaluating potential exposure pathways to human receptors. A CSM addressing potential off-site migration pathways will be incorporated into the Combined Soil Work Plan. Individual graphical CSMs will be provided for each unit within the fence line in the Soil RFI/RI Work Plan.

The CSM relies on the detailed information regarding the physical characteristics and setting of the study area, including surface features, meteorology, site geology, surface water hydrology, site hydrogeology, land use, cultural resources, and ecology presented in Appendix A of the Draft Soil Part B Work Plan.

2.1.3 Constituent Release, Migration, and Potential Exposure Pathways

Figure 7 depicts the conceptual contaminant release, migration, and potential exposure pathways for the areas and receptors (i.e., commercial worker and maintenance worker) within the fence line. Conceptual contaminant release, migration, and potential exposure pathways for the areas outside the fence line are presented in the Soil Part A DQO technical memorandum. Those CSMs would apply when assessing potential effects to receptors outside the fence line (including the perimeter area) caused by contaminants migrating from inside the fence line.

As indicated in the CSM shown in Figure 7, the primary sources that could have potentially resulted in releases to the surface soil include incidental spills/releases from the following areas and activities:

- Tanks, sumps, and pipelines
- Buildings and other facilities and areas associated with compressor station operations
- Residue from burning activities
- Former operations in the vicinity of the station (Teapot Dome Oil Pit)
- Dust control (spraying of petroleum materials)

For releases from these primary sources, the primary source medium for the area within the fence line is surface soil. In addition, concrete or structures displaying visible staining may be a source medium to surface water runoff or a potential source to underlying soil. The Teapot Dome Oil Pit or other features extending below the ground surface could have resulted in direct releases to shallow soil and/or subsurface soil. Depending on the depth of the release for these features, the primary source media could be shallow soil and/or subsurface soil. Constituents known to have been released at the Topock Compressor Station consist primarily of nonvolatile compounds. These constituents were released primarily as liquids. Some constituents may also have been released as dust on the station (e.g., from sand blasting) and would have been deposited onto the ground surface. COPCs in surface soil may be ingested or contacted directly by receptors. COPCs may also be entrained as dust in ambient air, leading to potential inhalation exposure and/or surface re-deposition (ARCADIS, 2008a).

Once released to the surface soil, the COPCs in surface soil may be eroded and entrained in stormwater/surface water runoff and subsequently re-deposited as contaminated surface soil in areas outside the Topock Compressor Station. Local topography is the primary feature to consider when examining releases of constituents from the Topock Compressor Station to areas outside the fence line via surface runoff. Constituents could also have been transported offsite by stormwater runoff via storm drains. The compressor station is located on a ridgeline bordered by low areas (washes and ravines) on the north, east, west, and southwest sides of the station. Higher-elevation terrain is located to the south and southeast. In the past, runoff from the compressor station and discharges from storm drains would have preferentially entered and/or accumulated in low-lying areas, including the Debris Ravine (AOC 4), the East Ravine (AOC 10), other topographic low areas (AOC 11), and Bat Cave Wash (SWMU 1/AOC 1), contiguous with the compressor station fence line and potentially contaminating surface soil. Runoff may also have carried COPCs from the upper portions of the compressor station to the lower yard.

In addition to addressing potential worker exposures to soil inside the fence line, the sampling conducted for Part B will also be designed to help determine whether residual soil concentrations in the surface soil from historic compressor station practices could migrate offsite, as discussed further in Section 2.7.4. However, any potential exposures to COPCs that have been transported via surface water runoff to areas outside the Topock Compressor Station will be addressed in the context of Part A soil risk assessment.

As indicated in the CSM, contaminants in surface soil may percolate or infiltrate into the subsurface to affect subsurface soil and groundwater as secondary source media. Contaminated subsurface soil may be ingested, contacted directly, or inhaled as dust during intrusive events (maintenance and construction).

As indicated in the CSM, groundwater potentially impacted by subsurface soil contamination could subsequently migrate to extraction wells, leading to potential ingestion and dermal contact exposure routes.

2.1.4 Potentially Exposed Human Receptors

As described in the RAWP (ARCADIS, 2008a), the Topock Compressor Station is an operating facility and will remain as such for the foreseeable future. Thus, the human receptors that could be exposed to soils within the compressor station fence line consist of the following:

- Commercial workers
- Maintenance workers

Commercial workers at the Topock Compressor Station could be incidentally exposed to soil as they perform their duties at the compressor station. Activities may include, but are not limited to, office work and equipment maintenance and monitoring. Commercial workers would be expected potentially to come into contact with surface soil and shallow subsurface soil in the 0-to-3-foot-depth interval. Maintenance workers' activities may include, but are not limited to, repair and maintenance of equipment, facilities, and subsurface utilities. Maintenance workers may come into contact with subsurface soils extending to 6 feet below ground surface (bgs) (subsurface soil I) or possibly as deep as 10 feet bgs (subsurface soil II) during excavation and/or grading activities associated with utility work or equipment maintenance/repair within the fence line of the compressor station.

Consistent with the Soil Part A Data Quality Objectives Technical Memorandum (CH2M HILL, 2010a) and as described in the RAWP (ARCADIS, 2008a), the assumption was made that, in the future, the groundwater within the compressor station could be hypothetically used as a potable source of water, even though residential use is not planned for the compressor station. Therefore, the hypothetical future groundwater user is included in Figure 7.

As described in Section 2.1.1, the offsite migration evaluation will consider whether offsite human receptors could be exposed to surface soil impacted by chemicals originating within the fence line of the compressor station through the offsite migration pathway. The specific pathways through which offsite receptors could be exposed to constituents that have migrated outside the fence line are defined in the RAWP (ARCADIS, 2008a) and the Soil Part A Data Quality Objectives Technical Memorandum (CH2MHILL, 2010a).

2.1.5 Potentially Exposed Ecological Receptors

As described in the RAWP (ARCADIS, 2008a), ecological exposure inside the compressor station fence line is insignificant because of the industrial development of the site and the very limited habitat. However, the offsite migration evaluation and the evaluation of the perimeter area will include consideration of offsite ecological exposure, as appropriate. Potentially relevant offsite ecological receptors were identified in the RAWP (ARCADIS, 2008a) and the Soil Part A Data Quality Objectives Technical Memorandum (CH2M HILL, 2010a).

2.1.6 Leaching to Groundwater

A potential indirect exposure route associated with soil is the potential for residual COPCs in soil to leach to groundwater. Potential sources of recharge within the compressor station include precipitation, irrigation, leaking water lines, and use of leachfields. If the rate of leaching is sufficiently high, concentrations of COPCs in groundwater could potentially pose a risk if receptors are exposed to extracted groundwater. There are no current uses of the groundwater at the facility, and no groundwater extraction is occurring within the fence line.

2.1.7 Potential Exposure Depth Intervals

Based on the types of receptors likely to be present at the compressor station, the types of worker activities likely to occur at the compressor station, and the nature of the soils in the area, four exposure depth intervals are of interest: surface soil, shallow soil, subsurface soil I, and subsurface soil II. For human health, exposure intervals for soil are surface soil (0 to 0.5 foot bgs), shallow soil (0 to 3 feet bgs), subsurface soil I (0 to 6 feet bgs), and subsurface soil II (0 to 10 feet bgs). For evaluating the potential for offsite migration, the exposure interval of interest typically is surface soil (0 to 0.5 foot bgs) exposure, although in some areas on the slopes surrounding the compressor station that have a high potential or likelihood for erosion, depths up to 1.0 foot bgs may be of interest.

2.2 Planning Team

The planning team for the Soil Part B program consists of PG&E, DTSC, DOI, the Tribes, and interested stakeholders. Designated representatives from these organizations will meet to evaluate data collected pursuant to the Final Soil Part B Work Plan and to determine whether each of the decisions to be made can be made with a sufficient level of certainty.

2.3 Constraints, Resources, and Deadlines

Resources available to complete the soil RFI/RI and subsequent steps in the RCRA and Corrective Action and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) programs consist of PG&E staff and consultants, DTSC and DOI staff and consultants, interested stakeholders, and Tribal staff and consultants. Resources are limited in terms of available knowledgeable staff and project deadlines (as outlined in the project “rainbow” schedule).

There are substantial physical as well as cultural and environmental constraints on the site investigation effort. Physical constraints within the compressor station are due to buildings and operating equipment in active use; aboveground pipelines set at heights ranging from several inches to more than 10 feet overhead; and subsurface high-pressure gas lines, high voltage electrical lines, and other utilities. It is essential for the compressor station to continue to operate during this investigation, and all samples must be collected within the safety constraints of the facility. Some portions of the perimeter area are located on steep slopes, resulting in physical constraints. The remote location of the compressor station also makes certain investigation activities more difficult. In addition, the compressor station is surrounded by sensitive habitat areas. The site is also located in an area rich in cultural and historical resources. Several federally recognized tribes have identified areas of traditional, religious, and cultural importance in the vicinity of the Topock Compressor Station.

2.4 Step 2: Identify the Decisions

Step 2 consists of identifying the decisions to be made in the Soil Part B program. Activities completed in this step consist of identifying the principal study questions, defining the alternative actions that may be taken based upon the range of possible outcomes, and combining the alternative actions and the principal study questions into decision statements.

The Part B soil investigation sampling and analysis activities are intended to provide site-specific information to accomplish the following:

- Determine the nature and extent of soil contamination.
- Estimate representative exposure point concentrations (EPCs) to support the human health risk assessment being conducted separately from the Part B soil study.
- Determine whether residual soil concentrations pose a potential threat to groundwater.
- Determine whether concentrations of COPCs within the fence line potentially pose an unacceptable risk to ecological receptors outside the fence line.
- Support development of the CMS/FS, remedial design, and Interim Measures, if needed.

Based on these objectives, five principal study questions were identified. The principal study questions and alternative outcomes of the questions are discussed below, with a decision statement provided for each (Decision Statements are summarized in Table 1):

1. What are the nature and extent of residual soil COPC concentrations resulting from historic compressor station practices?

   The alternative outcomes of this question are: (1) the nature and extent of residual soil concentrations are fully defined based on sample data, or (2) it is infeasible or unwarranted to fully define the nature and extent of concentrations based on sample data, and uncertainties will be addressed in the risk assessment and/or the CMS/FS or Interim Measures.

   Decision Statement: Determine the nature and extent of residual soil concentrations resulting from historic compressor station practices. If determination of the nature and extent of soil concentrations based on sample data is not feasible or is not warranted, address uncertainties in the risk assessment and/or CMS/FS or Interim Measures.

2. What are representative EPCs for residual soil contamination resulting from historic compressor station practices?

   The alternative outcomes of this question are: (1) representative EPCs can be determined based on sample data, or (2) it is infeasible to determine representative EPCs based on sample data, and uncertainties will be addressed in the risk assessment.

   Decision Statement: Determine representative EPCs for residual soil contamination resulting from historic compressor station practices. If determination of representative EPCs based on sample data is not feasible, address uncertainties in the risk assessment.

3. Do residual soil concentrations resulting from historic compressor station practices pose a potential threat to groundwater?

   The alternative outcomes of this question are: (1) conclude that a threat to groundwater may exist, warranting either further site investigation or remedial action to protect groundwater, or (2) conclude that no threat to groundwater exists and no further action is needed to protect groundwater.

Decision Statement: Determine whether residual soil concentrations resulting from historic compressor station practices may threaten groundwater. If so, conduct additional site-specific assessment of the threat[2] or implement response actions to mitigate the threat. If not, no further assessment or response actions are necessary to address threat to groundwater.

4. Do residual soil concentrations resulting from historic compressor station practices pose a potentially unacceptable risk to receptors outside the fence line via the surface migration pathway?

   The alternative outcomes of this question are: (1) conclude that a potentially unacceptable risk to receptors outside the fence line may exist, warranting either remediation or interim measures, or (2) conclude that no potentially unacceptable risk to receptors outside the fence line exists, and no further action is needed to protect receptors outside the fence line.

   Decision Statement: Determine whether residual soil concentrations inside the fence line resulting from past compressor station practices pose a potentially unacceptable risk to receptors outside the compressor station fence line via the surface migration pathway. If a potentially unacceptable risk to receptors outside fence line exists, or if determination of potential risk to receptors outside fence line based on sample data is not feasible, develop controls to eliminate migration pathways or remove contaminated soil.

5. What are the site-specific soil properties, contaminant distribution data, and transport pathway information required to support development of the CMS/FS, remedial design, and /or Interim Measures, if required?

   The alternative outcomes of this question are: (1) site-specific soil property, contaminant distribution, and transport pathway information required to support development of the CMS/FS, remedial design, and/or Interim Measures can be fully determined based on sample data, or (2) it is infeasible to fully determine site-specific soil property, contaminant distribution, and transport pathway information based on sample data and impediments to data collection will be documented, and uncertainties will be addressed in the risk assessment and/or CMS/FS or Interim Measures.

   Decision Statement: Determine the site-specific soil property, contaminant distribution, and transport pathway information required to support development of the CMS/FS, remedial design and Interim Measures, if required. If full determination of site-specific soil property, contaminant distribution, and transport pathway information based on sample data is not feasible, then document impediments and address uncertainties in the risk assessment and/or CMS/FS or Interim Measures.

---

[2] The forthcoming Topock Compressor Station/East Ravine Groundwater Investigation will aid in assessing potential threats to groundwater from potential source areas within the compressor station as well as evaluating current impacts to groundwater.

2.5 Step 3: Inputs to the Decision

Once the necessary decisions have been determined, the next step is to identify the inputs required to make the decisions. While there may be significant overlap between the inputs required for the various decisions, the inputs for each decision are defined separately to ensure all required inputs have been identified. Inputs for each decision are also listed on Table 1.

2.5.1 Inputs to Decision 1 – Nature and Extent of COPCs

Three types of information have to be available and considered when assessing whether the nature and extent of contamination at a site are adequately understood: (1) usable COPC concentration data, (2) potential contaminant fate and transport mechanisms, and (3) screening and comparison values.

Both existing and new data may provide usable COPC concentrations for soil. Newly collected COPC concentration data must meet data quality criteria (including reporting limits and other criteria) set forth in the *Draft PG&E Program Quality Assurance Project Plan* (QAPP) (CH2M HILL, 2008a) to be considered usable. Existing data were evaluated in the *Final Soil and Sediment Data Usability Assessment Technical Memorandum, PG&E Topock Compressor Station* (CH2M HILL, 2008b). Category 1 and 2 data will be used to delineate the nature and extent of contamination. Collectively, new data meeting the criteria set forth in the QAPP and Category 1 and 2 data identified in the Data Usability Assessment are considered usable COPC data for Decision 1. Sufficient usable data must be available for each unit. These usable COPC concentration data must be compared with background and other screening levels to assess whether the delineation of nature and extent is adequate.

As described in the Revised Final RFI/RI Volume 1 (CH2M HILL, 2007b), five phases of data collection have been completed to date to support characterization of SWMUs and AOCs within the fence line of the compressor station. Data collected from implementation of the Soil Part B Work Plan will be combined with the usable data from the existing data set.

The CSM is an input to Decision 1 because it describes the potential transport mechanisms and fate of COPCs potentially released into the environment. This ensures that site data are collected in the appropriate locations.

Comparison/screening levels identified for Decision 1 include the following:

- Background soil concentrations for inorganic compounds (CH2M HILL, 2009b; CH2M HILL, 2010b)
- DTSC California human health screening levels (CHHSLs) for commercial use (OEHHA, 2005)
- USEPA regional screening levels (RSLs) for commercial use for those compounds for which CHHSLs are unavailable (USEPA, 2010)
- Environmental screening levels (ESLs) developed by staff of the California Regional Water Quality Control Board, San Francisco Bay Region (Water Board) for screening soil

samples analyzed for total petroleum hydrocarbons (TPH) as gasoline, diesel, and motor oil (Water Board, 2008)

- Project-specific screening levels developed for COPCs identified from Target Analyte List/Target Compound List (TAL/TCL) data (ARCADIS, 2009)
- For the perimeter area, the comparison/screening levels agreed on for the Topock Part A Phase 1 Soil Investigation

Screening levels will be used to assess the extent of contamination and do not necessarily indicate the presence of unacceptable risk (which will be evaluated in the baseline human health risk assessment). As noted in the discussion for Step 1 (Sections 2.1.5 and 2.3), physical, cultural, and biological constraints may limit the feasibility of sampling in certain areas within the fence line and in the perimeter area.

The background soil study determined that background metals concentrations are generally consistent throughout the study area and the soil column. There were no detectable ambient levels of polycyclic aromatic hydrocarbons or pesticides in the background soil samples; therefore, background concentrations were not calculated. A series of statistical tests will be conducted to assess whether concentrations of metals constituents detected in the soil at the various units are elevated above background. No single statistical test can be used to determine when concentrations in soil represent background levels. Rather, several tests may be used to support this determination. To evaluate whether the concentrations of metals constituents across the exposure area are comparable to background concentrations, the use of both point estimates (e.g., the 95 percent upper tolerance limit) and statistical distributional tests (comparisons of means and medians) may be used to compare the concentrations of constituents detected to background concentrations.

Background threshold values were also developed for several inorganic compounds detected in TAL/TCL analytical suites during the Soil Part A Phase 1 Investigation, as presented in Appendix E to the Soil Part A Data Quality Objectives Technical Memorandum (CH2M HILL, 2010b). The appendix summarizes the data evaluation and calculation of representative background concentrations for the additional detected inorganic compounds (aluminum, calcium, iron, magnesium, manganese, potassium, and sodium) for the compressor station. The evaluation and calculation approaches used to evaluate the additional detected inorganic compounds data followed the approaches used in the *Soil Background Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2009b).

2.5.2 Inputs to Decision 2 – Data to Support EPC Calculations

The inputs required for Decision 2 include COPC concentrations in soil within the exposure areas and depth categories defined in the RAWP (ARCADIS, 2008a). Only COPC data meeting data quality Category 1 standards may be used for the risk assessment. It should be noted that the inputs to determine data adequacy for Decision 2 will be considered in accordance with the RAWP (see Appendix A for additional details) and independently from Decision 1. However, the representativeness of the estimated EPC for each data group (identified below) is dependent on whether those data considered also satisfy Decision 1 and adequately represent the nature and extent of contamination. Additional data subsequently recommended to satisfy Decision 1 and/or Decision 2 for a data group will also be used in the risk assessment to estimate the representative EPC.

Approaches for developing the human health risk assessment and estimating representative EPCs are specified in the RAWP (ARCADIS, 2008a). The EPC is a conservative estimate of the average chemical concentration in an environmental medium to which a receptor may be exposed. The EPC is constituent-specific. The risk assessment will calculate EPCs based on specific data groupings for each of the depth categories, as discussed below. Therefore, it is critical to consider those data groupings for the depth categories when determining the inputs needed for estimation of representative EPCs.

As discussed in the RAWP (ARCADIS 2008a), the entire area within the fence line is considered one exposure area. The EPCs for direct soil contact (i.e., soil ingestion, dermal contact, and inhalation of particulates) will be estimated for each data group corresponding to the following separate depth categories: 0 to 0.5 foot bgs, 0 to 3 foot bgs, 0 to 6 foot bgs, and 0 to 10 foot bgs. Typically, the soil EPCs will be the 95 percent upper confidence limit (UCL) on the arithmetic mean for the depth category being considered. Additionally, after the data are available, a review may indicate that specific areas of hot spots may warrant specific assessment. In general, the identification of hot spots will be conducted through visual examination of the data, which is a qualitative assessment that includes consideration of relative concentrations in relation to the nearest neighboring sampling locations (both horizontally and vertically), field observations of staining or debris, and topography. Additional assessment may consist of evaluating the site data for outliers which, if conducted, will be done quantitatively using applicable statistical tests and may require additional and/or alternative statistical evaluations for identifying the appropriate EPCs. Potential exposures in the perimeter area will be evaluated in accordance with the Part A decision process previously described in the Part A DQO TM (CH2M HILL, 2010a).

EPCs in air from dust will be modeled from soil data by dividing the concentration of each constituent in the soil by a particulate emission factor. As stated in the preceding paragraph, the EPCs for direct contact pathways, including particulate inhalation, will be estimated using data from the four listed depth intervals, as appropriate, for the worker receptors identified in the RAWP. EPCs in air from volatile organic compounds, if present, will be modeled from soil data based on a volatilization factor equation.

2.5.3 Inputs to Decision 3 – Impacts to Groundwater

The inputs required for Decision 3 consist of information that is required to calculate soil screening levels (SSLs) protective of groundwater and to conduct modeling, where necessary. These inputs are shown in Table 1. Soil background concentrations are also an input to this decision because SSLs will only be calculated for metals where soil concentrations exceed background. SSLs consider the volume and cross-sectional area of the potential source and will thus be developed on a unit-specific basis. Groundwater maximum contaminant levels and groundwater background values will define the maximum allowable concentrations of COPCs in groundwater. USEPA literature and other technical literature will serve as the source for modeling parameters. Infiltration estimates will consider precipitation and other potential sources, such as landscape irrigation, leaking water lines, and leachfields. Existing Category 1 and 2 data, as well as validated new site data, will provide information on the nature and extent of COPCs; depth to groundwater; and geotechnical, geochemical, and hydraulic characteristics of the vadose zone soil.

2.5.4 Inputs to Decision 4 – Data for Evaluation of Potential Risk to Offsite Receptors in a Surface Migration Pathway

Inputs to Decision 4 consist of transport pathway information, contaminant distribution data, and other information needed to estimate potential risks to offsite receptors due to potential migration of contaminants, in a surface migration pathway, from areas within the fence line to areas outside the fence line. Inputs to Decision 4 include Category 1 COPC concentrations in shallow soil in areas where soil may be transported to areas outside the fence line; soil physical and chemical property information; potential mechanisms, directions, and rates of migration; information on structures; and other features that may prevent or facilitate offsite migration.

New and existing analytical data will provide information regarding chemical and physical soil characteristics. New and existing data regarding the nature and extent of COPCs coupled with the comparison/screening levels listed below will identify areas of potential concern with regard to offsite migration. The Decision 4 comparison/screening levels are the same comparison/screening levels agreed upon for the Topock Part A Phase 1 Soil Investigation.

Comparison/screening levels identified for Decision 4 include the following:

- Background soil concentrations for inorganic compounds (CH2M HILL, 2009b; CH2M HILL, 2010b)
- Ecological comparison values developed by ARCADIS for PG&E (ARCADIS, 2008b; ARCADIS, 2009)
- DTSC CHHSLs for residential use (OEHHA, 2005)
- USEPA RSLs for residential use for those compounds for which CHHSLs are unavailable or for which the toxicity factors used to calculate the CHHSLs are outdated (USEPA, 2010)
- ESLs developed by staff of the Water Board for screening soil samples analyzed for TPH-gasoline, TPH-diesel, and TPH-motor-oil (Water Board, 2008)
- Project-specific screening levels developed for COPCs identified from TAL/TCL data (ARCADIS, 2009)
- Consensus-based threshold effect concentrations (TECs) and consensus-based probable effects concentrations (PECs) for constituents in sediment (ARCADIS, 2008a)

2.5.5 Inputs to Decision 5 – Inputs to CMS/FS or Interim Measures

Inputs to Decision 5 consist of soil property, contaminant distribution and transport pathway information, and other information needed to evaluate potential remedies as well as migration and exposure control measures for areas requiring such measures and to determine the most appropriate and cost-effective remedies and/or control measures for each area potentially requiring controls. Inputs to Decision 5 include areas and volumes of soil potentially posing a threat to onsite workers or offsite receptors via the surface migration pathway, specific soil physical and chemical properties that could influence migration and exposure pathways, available transport pathways, and waste characterization parameters for any soils that may need to be removed and transported offsite.

New and existing analytical data will provide information regarding chemical and physical soil characteristics and waste characterization parameters. New and existing data regarding the nature and extent of COPCs coupled with results of the human health risk assessment and output from Decision 4 will provide the areas and volumes of soil potentially requiring remediation or control measures. New and existing data will be supplemented by USEPA and other technical literature regarding physical and chemical properties of COPCs and soils. Transport pathways will be assessed as part of a detailed site reconnaissance.

2.6 Step 4: Study Boundaries

Study boundaries include spatial (lateral and vertical), temporal, and analytical boundaries for each unit or group of units, as appropriate. Boundaries must be defined for each decision individually, as the scale at which data will be evaluated and the data populations of interest may vary for each decision. Temporal boundaries are required because a given medium or unit may change over time. Study boundaries, especially lateral and vertical, are subject to change as additional data are collected. The study boundaries associated with each of the decisions are summarized in Table 1.

2.6.1 Decision 1 Study Boundaries – Nature and Extent of COPCs

2.6.1.1 Lateral Boundaries

Lateral boundaries for Decision 1 are initially the same as the current boundaries of each individual unit as defined in the Revised Final RFI/RI Volume 1 (CH2M HILL, 2007b) and the tentative boundaries for the six additional units and two new investigation areas shown in Figure 1. The tentative boundaries for the six additional units and two new investigation areas will be refined based upon the results of the investigation. For units in the lower yard, such as SWMU 5, AOC 16, AOC 21, AOC 24, and Units 4.3, 4.4, and 4.5, the maximum extent of the lateral boundaries may be constrained by topography in the up-drainage direction. Where units are adjacent, the lateral study boundaries are defined at a clear physical demarcation to the extent feasible.

For AOC 13, the lateral boundary is initially estimated to be the current unpaved areas within the fence line of the compressor station, except where unpaved areas are contained within the footprint of another AOC (e.g., the graveled areas within AOCs 5 and 6 are not part of AOC 13).

The perimeter area is defined as the area extending from the facility fence line to the toe of the slope, outside of the fence line. The study boundary for existing and former storm drain outfalls will initially be defined by the alignment of the drains.

The following steps will be followed when assessing the lateral boundaries for perimeter area and storm drain outfalls:

1. Conduct perimeter area and storm drain outfall sampling (including step-out sampling where needed).
2. Identify perimeter and storm drain outfall locations with COPC concentrations above Part A screening levels.
3. Incorporate downslope soil areas with COPC concentrations above Part A screening levels into the appropriate Part A AOC.
4. Incorporate soil areas with COPC concentrations above Part A screening levels located in flat areas adjacent to compressor station fence into the appropriate Part B AOC, or AOC 13.

Lateral extent will be expanded as necessary and as feasible until COPCs concentrations fall below screening levels.

The lateral boundaries for each unit are summarized in Table 1.

2.6.1.2 Vertical Boundaries

The vertical boundary of the soil investigation for Decision 1 extends from the ground surface to the water table.

2.6.1.3 Analytical Boundaries

Analytical boundaries for Decision 1 include both chemical (COPCs and general chemistry) parameters and soil physical characteristics. Sample location tables were included in the Draft Soil Part B Work Plan (a separate table was provided for each unit). In addition, a comprehensive planned sample table specifying analytes for all proposed samples was provided in Appendix C of the Draft Work Plan. Similar tables will be provided in the Final Work Plan.

Chemical parameters were defined for each individual unit and may be refined following completion of the Phase 1 sampling program. The list of analytical parameters at each unit is based on the site use and release history described in the Revised Final RFI/RI Volume 1 (CH2M HILL, 2007b) and fate and transport mechanisms, as documented in the CSM. The COPCs for each unit are shown in Table 1. A preliminary list of COPCs for each of the new units and uninvestigated areas is also provided in Table 1. Ten percent of the samples collected in all units will be analyzed for the full suite of inorganic and organic analyses per the CERCLA TAL/TCL. Select samples will be analyzed to characterize the soluble fraction of compounds present at concentrations exceeding 10 times the total threshold limit concentration or 20 times the toxicity characteristic leaching procedure values. The samples selected will be determined based on the Title 22 metals analysis results.

2.6.1.4 Temporal Boundaries

All historic RFI/RI and new Part B soil sampling Category 1 data and acceptable Category 2 data (based on the final Data Usability Assessment [CH2M HILL 2008b]) will be evaluated for determination of the nature and extent of contamination.

2.6.2 Decision 2 Study Boundaries – Data to Support Calculation of EPCs

2.6.2.1 Lateral Boundaries

The lateral study boundaries for Decision 2 are the same as for Decision 1.

2.6.2.2 Vertical Boundaries

Vertical study area boundaries for Decision 2 are defined by potential maximum exposure depths. For commercial workers, the maximum exposure depth is 3 feet bgs. Depths up to 10 feet bgs are appropriate for maintenance workers.

2.6.2.3 Analytical Boundaries

The same analytical boundaries for chemical parameters that apply to Decision 1 apply to Decision 2.

2.6.2.4 Temporal Boundaries

The same temporal boundaries that apply to Decision 1 apply to Decision 2; however, only existing Category 1 data will be considered for use in the risk assessment.

2.6.3 Decision 3 Study Boundaries – Impacts to Groundwater

2.6.3.1 Lateral Boundaries

The definition of lateral study boundaries for Decision 3 will be an iterative process. Initially, the lateral study boundaries for Decision 3 will be the same as for Decision 1. Following completion of the data evaluation, Decision 3 study boundaries will be refined to consist of those areas with COPC concentrations exceeding the SSLs.

2.6.3.2 Vertical Boundaries

The vertical study area boundaries for Decision 3 are the same as for Decision 1.

2.6.3.3 Analytical Boundaries

The same analytical boundaries for chemical parameters that apply to Decision 1 also apply to Decision 3. Additional data regarding soil characteristics may be collected if needed to complete any required modeling. Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes.

2.6.3.4 Temporal Boundaries

The temporal boundaries for Decision 3 are the same as for Decision 1.

2.6.4 Decision 4 Study Boundaries – Data for Evaluation of Potential Risk to Offsite Receptors in a Surface Migration Pathway

2.6.4.1 Lateral Boundaries

The lateral boundaries for Decision 4 are the same as for Decision 1.

2.6.4.2 Vertical Boundaries

The vertical boundary for Decision 4 is typically 0.5 foot bgs (i.e., the surface interval from which soils might be transported offsite); however, because the perimeter area has a higher potential for erosion, a deeper vertical boundary of 1.0 foot bgs will be used.

2.6.4.3 Analytical Boundaries

The same analytical boundaries for chemical parameters that apply to Decision 1 apply to Decision 4.

2.6.4.4 Temporal Boundaries

The temporal boundaries for Decision 4 are the same as for Decision 2.

2.6.5 Decision 5 Study Boundaries – Inputs to CMS/FS or Interim Measures

2.6.5.1 Lateral Boundaries

Initially, the lateral study boundaries for Decision 5 will be the same as for Decision 1. The lateral study boundaries will be refined following completion of the risk assessment and assessment of threat to groundwater and practical constraints on soil removal, if required.

2.6.5.2 Vertical Boundaries

Initially, the vertical study boundaries for Decision 5 will be the same as for Decision 1. The vertical study boundaries will be refined following completion of the risk assessment and assessment of threat to groundwater and practical constraints, if required.

2.6.5.3 Analytical Boundaries

The same analytical boundaries for chemical parameters and soil characteristics that apply to Decision 1 also initially apply to Decision 5. Analytical parameters for Decision 5 will be refined to following the soil investigation to consist only of the constituents of concern identified by the risk assessment and assessment of threat to groundwater.

2.6.5.4 Temporal Boundaries

The temporal boundaries for Decision 5 are the same as for Decision 1.

2.7 Step 5: Decision Rule

Decision rules are “if…, then…” statements that describe the actions to be taken depending on the site-specific findings. A decision flow chart was developed for each of the five decisions identified in these DQOs. The decision process depicted in Figures 2 through 6 is described below.

2.7.1 Decision 1 – Nature and Extent of COPCs – Decision Rules and Decision Process

Refer to Figure 2 for the following discussion of the decision rule for Decision 1. The decision rule is applied separately for each AOC, SWMU, and potential new area.

2.7.1.1 Boxes 1 through 3

Once the Part B soil samples have been collected and the data have been validated (Boxes 1 and 2), these data will be combined with existing historic RFI/RI data sets for each unit, where applicable.

The data collected during the soil investigation will be validated as described in the QAPP (CH2M HILL, 2008a) and the *Draft Soil Addendum for the Topock Compressor Station, RCRA Facility Investigation/Remedial Investigation (*CH2M HILL, 2008c*)*. Existing data were evaluated in the Data Usability Assessment (CH2M HILL, 2008b), and only data meeting data quality Category 1 or 2 requirements will be used to assess the nature and extent of COPCs.

During this step, the existing data will also be reviewed to assess whether they are still considered reliable. If site conditions have changed substantially, the data will be assessed to determine whether it is likely that the changes in site conditions have altered the conditions at that particular location. This data assessment process will be limited to surface and near-surface samples, as deeper samples would not be expected to be affected. Any surface or near-surface data for organic COPCs will also be noted, as organic constituents located in surface and near-surface soils may have degraded under the influence of high surface temperatures and/or light. Older data for organic compounds will be compared with newer data for organics in the vicinity.

2.7.1.2 Boxes 4 through 8

Once the new and existing data sets have been combined and reviewed, the combined data set for each unit will first be reviewed to assess whether, as a result of the TAL/TCL analysis, any new compounds that qualify as COPCs have been identified in the areas within the fence line of the compressor station (Box 4). Box 4 consists of the following decision:

Are any new COPCs identified based on the TCL/TAL analysis?

If new compounds have been identified, a decision will be made to determine whether the detected compound represents a new COPC. The decision whether any newly identified compounds may represent a new COPC will be based on multiple factors, including the following:

- Potential for the compound to be related to the compressor station (e.g., potential for the compound to be associated with past activities at the compressor station and/or to be a breakdown product of constituents known to have originated at the compressor station)
- Frequency of detection
- Concentrations detected
- Distribution of detections

The outcome of Box 4 can be:

Yes*: new COPCs have been identified, or*
No*: no new COPCs have been identified.*

It should be noted that it is possible for new compounds to be detected without these compounds necessarily being designated as COPCs. Additional sampling may be warranted in order to make this decision.

If the outcome from the decision in Box 4 is yes, the next step is to determine whether development of screening values will be required for the newly identified COPCs (Box 5A). If the outcome from Box 4 is no, the decision process moves to Box 5C, and the decision process continues with comparison to screening levels (see discussion below).

The decision for Box 5A is:

> *Is development of screening value for new COPCs required?*

The possible outcomes for this decision step are:

> ***No**: Development of screening values is not required.*
> ***Yes**: Development of screening values is required.*

Screening levels may not need to be developed because they already exist (e.g., some screening levels for TAL/TCL inorganic compounds were developed as part of the Soil Part A Phase 1 Investigation). If a screening level does not need to be developed for the compound being evaluated, the process moves to Box 5C, comparison of data to screening values. Development of screening also may not be required if the frequency of detection and/or detected concentrations of these compounds are too low to merit the likely complex effort of developing screening levels. The decision to develop additional screening levels will be made based on the specific data and related information. If screening levels are not developed, the significance of the new COPCs and any associated uncertainties would be addressed in the risk assessment and the RFI/RI report (Box 5D).

If screening levels will be required for any new COPCs, they will be developed by PG&E and will require concurrence from DTSC and DOI (Box 5B). Once appropriate screening levels are available for all COPCs, the lateral and vertical extents of these compounds can be evaluated.

Following the identification of potential new COPCs, all data will then be compared with screening criteria (Box 5C). The combined data tables will flag each occurrence of a COPC exceeding one or more of the screening criteria. The following sets of screening values will be used:

- Background soil concentrations of metals and select TAL/TCL inorganics (CH2M HILL, 2009b; CH2M HILL, 2010b)
- CHHSLs for commercial use, where available (OEHHA, 2005)
- RSLs for commercial use for constituents for which CHHSLs are not available or for which CHHSLs are based on outdated toxicity factors (USEPA, 2010)
- ESLs for commercial use for TPH-gasoline, diesel, and motor oil
- Project-specific screening levels developed for COPCs identified from TAL/TCL data, if needed

The initial comparison will be on a point-by-point basis for all depths (i.e., a simultaneous lateral and vertical assessment). The detected concentrations at each unit will first be compared with either the background concentrations (for metals and inorganics) or the lowest applicable screening criterion for organic compounds (CHHSLs, RSLs, or ESLs, as applicable).

As a further check for metals, a population (central tendency) comparison such as the Wilcoxon Rank Sum Test or Gehan Test will be performed for the population of detected concentrations to the applicable background data set, provided there are sufficient detections of the metal in question to allow a meaningful statistical comparison to be made.

If any COPCs are present above background concentrations or the lowest applicable screening criterion for organic compounds, the locations of the COPC concentrations exceeding the initial screening will be examined to determine whether nearby samples provide an adequate perimeter (lateral) or base (vertical) of samples to meet the initial screening criteria. In addition to point by point comparisons of site data to screening levels, spatial trends will be reviewed graphically (Box 6).

Spatial trends will be evaluated both laterally and vertically. For lateral delineation for samples potentially containing elevated levels of COPCs, concentration trends toward the perimeter of the unit will be reviewed to ensure that concentrations are generally decreasing toward the perimeter. Vertical concentration trends will also be reviewed for each boring showing elevated concentrations of COPCs. Potential hot spots will be identified through the presence of clusters of elevated concentrations of COPCs. Evaluation of spatial trends will include the following:

- Lateral concentration trends toward the edge of a unit or affected area (i.e., potential hot spot) within a unit
- Vertical concentration trends in each boring and throughout a given unit or area
- Distribution of detections and non-detections of each constituent within a unit
- Where applicable, concentrations trends at an upgradient unit

For ease of evaluation, COPC concentrations exceeding the screening criteria will be presented in different colors on the figures, according to the lowest concentration screening criterion exceeded.

The spatial trends analysis will be used to make the decision identified in Box 7:

> *Are lateral and vertical boundaries of COPCs including hot spots, if applicable, defined?*

The possible outcomes of Box 7 are:

> ***Yes:*** *the lateral and vertical extent of COPCs including any hot spots are defined.*
> ***No:*** *the lateral and vertical extent of COPCs including any hot spots are not fully defined.*

This evaluation will be conducted for each compound and may indicate that the boundaries of some, but not all, compounds at a given unit are adequately defined. If all boundaries are defined for a given unit, no further data are required to resolve Decision 1 (Box 8). The determination that COPC boundaries have been adequately defined at a specific unit will then be made. Once a determination has been made that no further data are required to resolve Decision 1, the data evaluation proceeds with Decisions 2 through 5 (Boxes 16A – 16D), as described in Sections 2.7.2 through 2.7.5.

2.7.1.3 Boxes 9 through 15

If the determination is made that the boundaries of elevated concentrations of COPCs have not been adequately defined, additional sampling of specific compounds may be required to complete the delineation of the lateral and vertical extents of contamination and/or hot spots. The specific areas where COPC boundaries are not adequately defined will provide the basis for further sampling recommendations (Box 10). The information developed pursuant to Box 9 will be used to define the additional sampling needed to delineate a chemical boundary or to define potential hot spots in each area identified as needing further delineation. The extent of additional sampling recommended will then be defined. Once the additional sampling necessary to create a complete delineation has been defined (Box 10), Box 11 requires the following decision:

> *Would additional sampling significantly improve data quality or risk assessment and/or site remediation or interim measure decisions?*

The possible outcomes for the decision in Box 11 are as follows:

> ***Yes**: Additional data would significantly improve data quality or risk assessments and/or site remediation/interim measure decisions.*
>
> ***No:** The additional data would not significantly improve data quality and/or risk assessments and/or site remediation/interim measure decisions and is therefore not necessary.*

Data quality may be improved if existing sample results for the COPC in question at a given area are for older samples that may no longer represent current conditions or have data flags that could limit the reliability of the data.

The risk assessment team will review the value of the additional sampling for improving the risk characterization for the specific COPC for a specific exposure area. Risk characterization may be improved by additional sampling if (1) the existing number of samples for an exposure area or designated hot spot is low; (2) the detection limits did not achieve adequate concentrations for risk assessment purposes; (3) the total number of samples in a given exposure depth interval is low; or (4) the lateral or vertical distribution is uncertain at a level significant to the risk decisions.

Potential site remediation/interim measure decision making may be improved if the area or volume of potentially impacted soil could be defined more precisely. Thus, additional sampling in areas where samples are spaced relatively far apart and/or where vertical characterization is limited might be considered to improve decision making regarding the potential for migration. If uncertainties remain regarding soil physical properties in areas where site remediation or interim measures may be required, decision making regarding potentially required measures could also be improved through the collection of additional data pertaining to the physical characteristics of interest.

If it is concluded in Box 11 that additional sampling is not warranted, then no further sampling is required at this time, and no further sampling is required to resolve Decision 1

(Box 8). The agencies will have to concur that additional sampling is not feasible or warranted. However, PG&E will retain the right to make the final determination regarding the safety of the proposed sampling. If some sampling cannot be performed in a manner that is deemed safe by PG&E, that sampling will be considered infeasible.

If additional data collection is desirable, the feasibility of collecting the additional samples under current operating conditions will be evaluated (Box 12). The decision to be made following this evaluation is shown in Box 13:

> *Is additional data collection feasible under current operating conditions?*

The possible outcomes are:

> ***Yes**: Additional data collection is feasible under current operating conditions.*
>
> ***No:** Additional data is not feasible under current operating conditions, due to physical or institutional constraints.*

Institutional constraints may include safety requirements and the need to maintain operations at the compressor station. If additional data collection is desirable and feasible, then the sampling will be conducted and the new data will be validated (Box 14). After the data are validated, the flow chart leads back to Box 3 to reinitiate the data evaluation process. If the additional data collection is not feasible, then the uncertainties will be addressed in the risk assessment and/or CMS/FS or interim measures (Box 15).

2.7.1.4 Box 16

Once it has been determined that the nature and extent of contamination have been adequately defined and no further data collection is necessary to resolve Decision 1, the flow chart leads to Boxes 16A through 16D, which refer to the decision rules for Decisions 2, 3, 4, and 5. Those decision rules (Figures 3, 4, 5, and 6) address data sufficiency for estimating EPCs, data sufficiency for assessment of threat to groundwater, evaluation of the potential for offsite migration, and data sufficiency to support evaluation of CMS/FS, remedial design, and interim measures.

2.7.2 Decision 2 – Data to Support Calculation of EPCs – Decision Rules and Decision Process

Refer to Figure 3 for the following discussion of the decision rule for Decision 2. This decision rule follows from the decision rule for Decision 1.

2.7.2.1 Boxes 1 through 3

The first steps in addressing Decision 2 are to collect and validate Part B soil samples, validate the newly collected data, and group all Part B soil investigation and Category 1 historic RFI/RI soil data by exposure area and depth category defined in the RAWP (ARCADIS, 2008a), as discussed below.

2.7.2.2 Boxes 4 through 6

Boxes 4 through 6 consist of the evaluation of data adequacy and additional data needs, if warranted. Box 4 addresses the following decision:

> *Are sufficient Category 1 data available to calculate/determine a representative EPC for each applicable depth interval (as defined in the Risk Assessment Work Plan)?*

The outcomes of the decision in Box 4 are:

> ***Yes**: Sufficient data are available to calculate representative EPCs for each applicable depth interval.* If sufficient Category 1 data exist to calculate representative EPCs for each depth interval, then the flow chart leads to Box 5, which concludes that no further data collection is necessary to resolve Decision 2; the flow chart also leads to Box 13 to calculate the representative EPCs and to conduct the risk assessment (see discussion of Box 13, below). The RAWP defines the process to be used to calculate EPCs, assess risk, and determine whether chemicals present within the fence line of the compressor station potentially pose an unacceptable risk. The risk assessment will recommend which chemicals for which areas may require risk management until that time when full site characterization and evaluation of remedial technologies and alternatives will be conducted.
>
> ***No**: Sufficient data to calculate representative EPCs for each applicable depth interval are not available.* If the available Category 1 data are not sufficient to calculate representative EPCs for each depth interval, the flow chart leads to Box 6 to determine what additional samples are necessary to allow calculation of representative EPCs. In this step, specific sampling necessary to allow calculation of representative EPCs will be defined.

The Box 4 decision will be resolved by comparing the existing medium-specific data for each depth interval with the data requirements specified in the RAWP (ARCADIS, 2008a), coupled with professional judgment from the risk assessment experts.

2.7.2.3 Boxes 7 through 12

Box 7 addresses the feasibility of collecting the additional samples identified as desirable in Box 6. As discussed for Decision 1, there may be significant physical and other practical limitations on sampling in areas of the operating facility. The proposed additional sampling effort will be evaluated to determine whether implementation of the sampling effort is feasible. Box 7 addresses the following decision:

Is additional sampling feasible under current operating conditions?

The outcomes of Box 7 are:

> ***No**: Further sampling is not feasible.* The flow chart leads to Boxes 10 through 12, in which PG&E would document the impediments to additional data collection (Box 10) and address EPC uncertainties in the risk assessment (Box 12). No further sampling is necessary to resolve Decision 2 (Box 11).
>
> ***Yes**: Further sampling is feasible.* The flow chart leads to Box 8, in which additional sample collection is conducted and the data are validated. The flow chart then leads to Box 9 to combine the newly collected data with the previous Category 1 and Part B Phase 1 data set; the flow chart then leads back to Box 3 to restart the decision rule with the expanded data set.

The agencies will have to concur that additional sampling is not feasible or warranted. However, PG&E will retain the right to make the final determination regarding the safety of the proposed sampling. If some sampling cannot be performed in a manner that is deemed safe by PG&E, that sampling will be considered infeasible.

2.7.2.4 Box 13

The risk assessment work plan for the soil investigation program has been developed (ARCADIS, 2008a). Once sufficient data are available to calculate representative EPCs, the risk assessment can commence. It should be noted that adequate data to calculate representative EPCs may be available while uncertainty remains with regard to Decision 1, 3, and/or 5. For example, vertical extent may not be defined at a particular boring, but a representative EPC can be calculated for the exposure intervals identified in the RAWP.

2.7.3 Decision 3 – Potential Threat to Groundwater – Decision Rules and Decision Process

Refer to Figure 4 for the following discussion of the decision rule for Decision 3. This decision rule follows from the decision rule for Decision 1.

2.7.3.1 Boxes 1 through 6

The same data set used for Decision 1 will be used for Decision 3 (Boxes 1 through 3). The combined data set will be compared against background concentrations (Box 4). The decision to be made (Box 5) is:

> *Do COPCs in any area exceed background?*

The possible outcomes from Box 5 are:

> ***No**: No COPCs exceed background concentrations.* The flow chart leads to Box 10, and no further sampling is necessary to resolve Decision 3.
>
> ***Yes**: Some COPCs exceed background concentrations.* The flow chart leads to Box 6.

In Box 6, any COPCs exceeding background concentrations will be compared with soil screening levels for migration to groundwater. The combined data tables will flag each occurrence of a COPC exceeding the relevant SSL.

2.7.3.2 Boxes 7 through 10

Box 7 addresses whether the screening level assessment based on SSLs indicates a threat to groundwater. Box 7 addresses the following decision:

> *Do COPCs in any area exceed SSLs (do data indicate a potential threat to groundwater)?*

The potential outcomes of Box 7 are:

> ***Yes**: A potential threat to groundwater exists from residual soil contamination at this unit based on the screening level assessment.* Additional assessment is warranted. The flow chart leads to Box 8 to assess whether data indicate that a potential current threat to groundwater exists.
>
> ***No**: No threat to groundwater is indicated by the screening level assessment for this unit.* The flow chart leads to Box 10; no further sampling is required to resolve Decision 3.

The decision criteria used for this decision are the SSLs. The development of SSLs is described in the *Calculation of Soil Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station Technical Memorandum* dated August 1, 2008 (CH2M HILL, 2008d). SSLs will be calculated for each unit. COPC concentrations within each unit will first be compared with the SSLs developed for that unit. If COPC concentrations are all below SSLs, then soil within that unit does not pose a potential threat to groundwater.

SSLs are highly conservative screening concentrations; SSLs were chosen as the first step in evaluating the potential threat of leaching to groundwater because they are a simple, conservative screening tool. The calculation process for SSLs does not take into consideration changes in concentration with depth. However, the calculation process assumes that the maximum concentration detected at any point in the soil column is present at the groundwater interface and that all constituents are completely leachable. If SSLs are exceeded for any COPC at any unit, it does not mean that that particular COPC in soil in that particular unit necessarily poses a potential threat of leaching to groundwater; rather, it is an indication of a potential threat. More site-specific and detailed evaluation (modeling) may be appropriate to better assess the potential threat of leaching to groundwater for that specific compound at that unit.

Box 8 addresses whether data indicating a potential current threat to groundwater exists, as follows:

> *Do data indicate a potential current groundwater impact?*

Potential outcomes of Box 8 are:

> ***Yes**: Soil data indicate a potential current groundwater impact.* The flow chart leads to Box 9, which requires the development of a plan for a unit-specific groundwater assessment.
>
> ***No**: Only a potential future threat to groundwater from residual soil contamination exists at this unit based on the screening level assessment.* Additional assessment is warranted. The flow chart leads to Box 11 to conduct vadose zone modeling to further assess the potential impact.

In order to assess whether a threat to groundwater currently exists, COPC concentrations are needed throughout the entire soil column down to the water table. Therefore, the criteria for resolving this decision are vertical concentration trends of compounds in each boring and throughout a given unit or area location. If the data indicate increasing COPC concentrations with soil depth, or if elevated COPC concentrations do not decrease with depth, and there are no monitoring wells located in the vicinity of the area, deeper samples would be collected. If soil data indicate elevated concentrations of compounds (as compared with screening criteria) in samples throughout the boring and at the soil/groundwater interface, a potential for a current impact to groundwater exists. If COPC concentrations decrease with depth and are not elevated at the water table, then no current threat exists.

2.7.3.3 Boxes 11 through 13

Boxes 11 and 12 address quantitative vadose zone modeling to assess whether residual soil concentrations could affect groundwater in the future even if current groundwater impacts are not indicated. The HYDRUS-1D (Simunek et al., 1998) vadose zone model will be used. HYDRUS is a finite-element model for one-dimensional solute fate and transport simulations that incorporates sorption along with dispersion in the vadose zone. Critical input to the model will be an estimate of the mass of the COPC(s) present in soil based on soil sample data. Box 12 addresses the following decision:

> *Does modeling indicate the potential for soil-related impacts to groundwater?*

Possible outcomes of Box 12 are:

> ***Yes**: Modeling indicates the potential for future impacts to groundwater from the residual soil contamination at the unit.* The flow chart leads to Box 13 to assess whether additional site-specific refinement of the model is warranted to better simulate site conditions.
>
> ***No**: Modeling does not indicate a potential future impact to groundwater.* The flow chart leads to Box 10; no further data are required to resolve Decision 3.

The criteria for resolving this decision are the simulated groundwater concentrations relative to groundwater chemical-specific applicable or relevant and appropriate requirements (ARARs) for COPCs. The target groundwater concentrations used to assess potential impacts to groundwater are the California groundwater maximum contaminant levels, both primary and secondary, and groundwater background values. The maximum contaminant levels have been defined as chemical-specific ARARs in Volume 2 of the RFI/RI Revised Final Report (CH2M HILL, 2009a).

If the outcome of Box 12 is yes, then Box 13 addresses the following decision:

> *Is further site-specific model refinement warranted to further evaluate a potential threat to groundwater?*

Possible outcomes of Box 13 are:

> ***Yes**: Further site-specific model refinement is warranted to further evaluate a potential threat to groundwater.* The flow chart leads to Box 14 to assess whether additional data collection is required to refine the model.
>
> ***No**: Further site-specific model refinement is not warranted.* The flow chart leads to Box 19; the potential future threat to groundwater will be evaluated in conjunction with the results from the Topock Compressor Station/East Ravine Groundwater Investigation (TCS/ERGI).

The primary consideration for this decision is the evaluation of the potential uncertainty in the refined model results (i.e., would the refined model be significantly more reliable?). The decision to pursue a more refined model on which to base decision making will be made based on the available data and the potential added information achievable by refining the model.

2.7.3.4 Boxes 14 through 18

If further model refinement is warranted, the next decision is a determination of whether additional data collection is required to refine the model. Refinements would not necessarily require additional sampling because refinements may also be achieved through further literature research regarding physical and chemical characteristics, more detailed modeling of the area of interest (i.e., smaller "cells") and/or use of a model more specifically targeted at the compound in question. Box 14 states:

> *Is additional data collection required to refine the model?*

The outcomes of Box 14 are:

> ***Yes**: Additional sampling is required.* The flow chart leads to Box 15 to determine additional data collection needs.
>
> ***No**: Further data collected is not required.* The flow chart leads to Box 18, and the model is refined without additional sample collection.

The need for additional data collection may be due to a variety of factors. It is likely that a number of assumptions will have had to have been made as part of the initial modeling effort; for example, site-specific leaching data (waste extraction test and/or toxicity characteristic leaching procedure data) may not be available for all compounds of interest. It may also be determined that, rather than this type of waste characterization analysis, a DI-WET or similar modified testing method would have been more appropriate to characterize the in-situ leaching potential in the areas outside the fence line.

Boxes 15 and 16 define the additional data needed and the feasibility of collecting the desired data. Following the decision in Box 14 that additional data collection is required to refine the model, the data to be collected are determined in Box 15. From Box 15, the process flows to Box 16, which addresses the following decision:

> *Is additional data collection feasible under current operating conditions?*

Considerations for this decision are the types of data that need to be collected to refine the model and the feasibility of collecting additional samples. Feasibility of sample collection may be limited by physical, cultural/historical, and/or biological factors, and the decision regarding the feasibility of additional data collection will be based on these factors.

Possible outcomes of Box 16 are:

> ***Yes**: Additional data collection is feasible.* The flow chart leads to Box 17 to collect the additional samples and to validate the newly collected data. From there, the flow chart leads to Box 18 to refine the model and then back to Box 11 to conduct the refined modeling.
>
> ***No**: Additional data collection is not feasible.* The flow chart leads to Box 19.

The agencies will have to concur that additional sampling is not feasible or warranted. However, PG&E will retain the right to make the final determination regarding the safety of the proposed sampling. If some sampling cannot be performed in a manner that is deemed safe by PG&E, that sampling will be considered infeasible.

2.7.3.5 Box 19

Once it has been determined that, while there is a potential future threat to groundwater but no further model refinement is warranted to assess this potential future threat or no further refinement of the model through data collection is feasible, the flow chart leads to Box 19. As part of this step, the results from the forthcoming TCS/ERGI investigation will be evaluated to assess groundwater conditions below the compressor station. The areas posing a potential future threat to groundwater will be evaluated in conjunction with the TCS/ERGI results to assess the need for further evaluation. The flow chart then leads to Box 9, which requires the development of a plan for a unit-specific groundwater assessment.

2.7.4 Decision 4 – Data for Evaluation of Potential Risk to Offsite Receptors in a Surface Migration Pathway – Decision Rules and Decision Process

Refer to Figure 5 for the following discussion of the decision rule for Decision 4. This decision rule follows from the decision rule for Decision 1.

2.7.4.1 Boxes 1 through 6

A portion of the same data set used for Decision 2 will be used for Decision 4. The existing and validated Part B data will be combined as described for Decision 2 (Boxes 1 through 3). The combined surface soil (0.0-to-0.5-foot-bgs interval) dataset (from unpaved areas potentially draining to offsite locations during storm events and/or potentially subject to windborne dust generation) will then be compared with the screening levels developed for the Soil Part A Program (also referred to as the Decision 4 screening levels in the context of the Soil Part B Program) (Box 4) to determine whether COPCs in soil exceed the screening levels.

Box 5 addresses the following decision:

> *Do COPCs in soil exceed the Decision 4 screening levels?*

The possible outcomes of the decision in Box 5 are:

> ***No**: No COPCs exceed Decision 4 screening levels.* The flow chart leads to Box 6, and no further sampling is necessary to resolve Decision 4.
>
> ***Yes**: Some COPCs exceed Decision 4 screening levels.* The flow chart leads to Box 7.

The purpose of this decision step is to identify areas that may pose a potential concern to offsite receptors if migration were to occur from these areas inside the fence line to areas outside the fence line. It is not necessary to evaluate the potential for offsite migration from areas where existing COPC concentrations are below the Decision 4 screening levels, because these areas would not pose a potential threat to offsite receptors.

2.7.4.2 Box 7

Once it has been determined in Box 5 that one or more areas within the fence line of the compressor station could pose a threat to offsite receptors if offsite migration were to occur, the next step is to determine whether migration from the area(s) in question could occur. The Box 7 decision is:

> *Are COPCs in shallow soil exceeding Decision 4 screening levels able to migrate offsite?*

The possible outcomes of the decision in Box 7 are:

> ***No**: COPCs exceeding Decision 4 screening levels are not able to migrate offsite.* The flow chart leads to Box 6, and no further sampling is necessary to resolve Decision 4.

> ***Yes**: Some COPCs exceeding Decision 4 screening levels may be able to migrate offsite.* The flow chart leads to Box 8.

The evaluation conducted as part of the Box 7 decision will include an assessment of potential stormwater flow pathways to assess whether contaminants in soil could be transported offsite through either sheet flow or through storm drains and the potential for windblown dust transport. If the subject area is paved (with gravel, asphalt, or concrete), contaminants would not migrate offsite via surface transport or storm drains. In unpaved areas, the topography of the potential source location with COPC concentrations above screening levels would be evaluated to determine if a path exists for surface water to flow from that area to a storm drain or if there is an unbermed edge of the compressor station or a breach in the berm. If such a pathway exists, then COPCs could potentially migrate offsite at concentrations that exceed screening levels.

2.7.4.3 Boxes 8 through 11

If some constituents exceeding Decision 4 screening levels are potentially able to migrate offsite, the next step is to determine the extent of the areas that pose a potential threat to offsite receptors. Therefore, the following decision is made in Box 8:

> *Are areas of COPCs in surface soil exceeding Decision 4 screening levels adequately defined?*

The possible outcomes of Box 8 are:

> ***Yes**: Areas of COPCs in surface soil exceeding Decision 4 screening levels are adequately defined.* The flow chart leads to Box 9, and no further sampling is necessary to resolve Decision 4. Box 9 then leads directly to Box 10, which requires evaluation of potential migration and exposure control measures for those areas with COPCs in shallow soil exceeding screening levels.
>
> ***No**: Areas of COPCs in surface soil exceeding Decision 4 screening levels are not adequately defined.* The next step in the decision process is to determine the additional sampling needed to adequately define the extent of the area(s) with COPCs in surface soil exceeding screening levels (Box 11).

Areas where COPCs in surface soil exceed Decision 4 screening levels and are able to migrate offsite are adequately defined if the lateral extent is known (i.e., if they are largely bounded by samples that have COPC concentrations below the screening levels, paved areas, buildings, and/or berms/curbs). The lateral extent would also be evaluated by considering the overall distribution of COPCs in the area of interest. Because runoff would occur from an area as opposed to a single location, the evaluation may consider an average concentration (e.g., 95 percent upper confidence limit on the mean) as well as individual point concentrations. If these areas are adequately defined, the next step is to evaluate the potential migration control measures that could be employed to control the potential threat to receptors outside the fence line (Box 10). If the areas have not been adequately defined, then additional data collection is required, if feasible, to delineate the areas. The next step is to determine additional sampling needs (Box 11).

2.7.4.4 Boxes 12 through 16

Once the additional sampling needs have been defined in Box 11, the next step is to determine whether additional sampling is feasible under current operating conditions (Box 12). Although Decision 4 is concerned only with surface soil, there could still be some physical limitations on sampling (e.g., lack of physical access to the area of interest). Sampling under pavement and structures is not required for this decision because offsite migration of surface soils is not possible from underneath these areas. The decision for Box 12 is:

> *Is additional sampling feasible under current operating conditions?*

The possible outcomes from Box 12 are:

> ***Yes**: Additional sampling is feasible under current operating conditions.* Additional sampling will be implemented and the data will be validated (Box 13).
>
> ***No**: Additional sampling is not feasible under current operating conditions.* The impediments to additional data needs will be documented for future action (Box 15).

The agencies will have to concur that additional sampling is not feasible or warranted. However, PG&E will retain the right to make the final determination regarding the safety of the proposed sampling. If some sampling cannot be performed in a manner that is deemed safe by PG&E, that sampling will be considered infeasible.

If additional sampling is feasible, it will be conducted. The validated data will be combined with the existing data set (Box 14), and the more extensive combined data set will be used to determine whether the extent of areas with COPCs above the screening levels is adequately defined (the flow chart returns to Box 8). If additional sampling is infeasible, the impediments will be documented (Box 15), the uncertainties pertaining to the potential for offsite migration will be addressed via the risk assessment, and/or potential migration and/or exposure control measures will be evaluated to prevent potential impacts to offsite receptors.

2.7.5 Decision 5 –Inputs to CMS/FS or Interim Measures– Decision Rules and Decision Process

Refer to Figure 6 for the following discussion of the decision rule for Decision 5. This decision rule follows from the decision rule for Decision 1. The goal of this decision is to ensure that sufficient data and other information have been collected to support development of the CMS/FS, remedial design and/or interim measures.

2.7.5.1 Boxes 1 through 6

The same data set used for Decision 1 will be used for Decision 5 (Boxes 1 through 3). Once the data sets have been combined, the next step is to determine whether sufficient information is available pertaining to potential migration pathways. Box 4 for Decision 5 asks the following:

> *Are sufficient soil property, transport pathway, and contamination distribution information and data available to support the CMS/FS and/or interim measures?*

The possible outcomes of Box 4 are:

> ***Yes****: Sufficient soil property, transport pathway, and contamination distribution information data are available to support the CMS/FS and/or interim measures.* The flow chart leads to Box 5, and no further sampling is necessary to resolve Decision 5. Box 5 then leads directly to Box 11, which requires evaluation of the need for potential remediation or interim measures.
>
> ***No****: There are insufficient soil property, transport pathway, and contamination distribution information and data to support the CMS/FS and/or interim measures.* The next step in the decision process is to define the additional data or other information needed to provide sufficient transport pathway information and soil property and contamination distribution data (Box 6).

Considerations for this decision are the availability of site-specific soil property data (such as grain size, organic carbon content, Atterberg limits, plasticity, washes, and chemical makeup) and transport pathway and contaminant distribution information. Decision 5 will build on the potential source locations and transport pathway information identified as part of Decision 4. This decision step would evaluate each potential source area to (1) determine whether the potential transport pathways have been adequately characterized to identify the means for controlling contaminant movement via that pathway and (2) characterize alternate pathways that may form if the primary pathway is eliminated. For example, in an area where sheet flow to the edge of the compressor station is the primary pathway for contaminant movement, offsite contaminant movement could be prevented by installing a curb. The flow diverted by the curb would then be expected to either infiltrate (if loose soil is present) or flow to another location (a storm drain or another area lacking a curb). The Box 4 evaluation would assess each area where COPC concentrations exceed screening levels to identify existing and potential migration pathways. Where the existing or potential migration pathways cannot be characterized, further assessment of site conditions may be required. In addition, this step would assess whether sufficient soil property data are available to support decisions regarding appropriate remedial technology. Decision 1 will ensure that sufficient data are available to calculate potential soil volumes/areas potentially requiring remediation.

The actual extent of required migration and/or exposure control measures, interim measures, and/or remediation will be determined based on the results of the risk assessment and other factors, such as the accessibility of the areas.

2.7.5.2 Boxes 7 through 11

Box 7 addresses the feasibility of collecting the additional samples and/or information. The proposed additional sampling effort will be evaluated to determine whether implementation of the sampling effort is feasible. Box 7 addresses the following decision:

> *Are additional soil property and/or contaminant distribution data collection feasible and/or can additional information on transport pathways be obtained?*

The outcomes of Box 7 are:

> ***No****: Further sampling and/or obtaining the additional information is not feasible.* The flow chart leads to Box 8 (document impediments to collecting the data and/or remaining uncertainties) and Box 11 (evaluate need for potential remediation or interim measures).

Yes: *Further sampling and/or information gathering is feasible.* The flow chart leads to Boxes 9 and 10. Additional data collection and/or information gathering are conducted (Box 9). The new data are validated and combined with existing data as well as additional information pertaining to potential transport pathways (Box 10). The flow chart then leads back to Box 4 to restart the decision rule with the expanded data set.

The agencies will have to concur that additional sampling is not feasible or warranted. However, PG&E will retain the right to make the final determination regarding the safety of the proposed sampling. If some sampling cannot be performed in a manner that is deemed safe by PG&E, that sampling will be considered infeasible. The final step for Decision 5 is the evaluation of the need for potential remediation or interim measures (Box 11).

2.8 Steps 6 and 7: Acceptable Limits on Decision Error and Optimize Sampling Design

Step 6 is intended to define acceptable limits on decision errors. A decision error would occur if, based on the available data, the project team chooses the wrong response action in the sense that a different response action would have been chosen if the project team had accessed "perfect data" or absolute truth.

If it is determined that data gaps exist and additional data are needed to resolve the Part B decisions, Step 7 will be conducted. The purpose of Step 7 is to *"identify a resource-effective data collection design for generating data that are expected to satisfy the DQOs"* (USEPA, 2000). Practical constraints may limit the spatial and/or temporal boundaries or regions that will be included in the study. Practical constraints associated with the Topock RCRA corrective action/CERCLA program consist primarily of access limitations (physical, cultural, historical, or biological constraints) but may also include other factors such as soil characteristics and the presence of bedrock. The output of this step will be the sampling design agreed upon by the stakeholders during the data gaps evaluation process. Following compilation of an initial data assessment, DOI, DTSC, and PG&E, in consultation with stakeholders, will reconvene to develop Steps 6 and 7 of the DQO process.

TABLE 1
Data Quality Objectives – Part B Soil Investigation
Final Data Quality Objectives Steps 1 through 5 – Part B Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California

STEP 1 Problem Statement	**STEP 2 Decision Statement**	**STEP 3 Inputs to the Decision**	**STEP 4 Study Area Boundaries**	**STEP 5 Decision Rules**
Contaminants in soil in SWMUs/AOCs inside the compressor station fence line resulting from historical compressor station practices may pose an unacceptable risk to humans or the environment, or threaten groundwater. Adequate site-specific information is needed to: • Determine the nature and extent of soil contamination • Estimate representative exposure point concentrations (EPCs) to support human health risk assessment being conducted separately from the Part B soil investigation • Determine whether residual soil concentrations inside the compressor station fence line pose a threat to groundwater • Determine whether migration of residual soil concentrations inside the compressor station fence line via a surface migration pathway pose a threat to receptors outside the compressor station fence line • Determine the site-specific soil property and contaminant distribution information necessary to support the CMS/FS, remedial design, and/or Interim Measures	**Decision 1** Determine the nature and extent of residual soil concentrations resulting from historic compressor station practices. If determination of the nature and extent of contamination based on sample data is not feasible or is not warranted, address uncertainties in the risk assessment and/or the CMS/FS or Interim Measures.	• COPCs by AOC/SWMU • Part B and representative Category 1 and 2 historic RFI/RI COPC data grouped by AOC/SWMU • Comparison/screening values (background, risk-based, and regulatory screening values) • CSMs • Geologic/hydrogeologic/hydrologic information • Topographic information • Soil physical and chemical property information • AOC/SWMU location and use history information • Cultural and historic information by AOC/SWMU • Infrastructure information by AOC/SWMU	**Lateral Extent** *For onsite units included in the Final RFI/RI:* Initially, the same as the currently defined boundaries of each SWMU and AOC: Lateral extent will be expanded if/as necessary until COPCs concentrations fall below screening values. If samples are collected outside the fenceline in areas that provide significant habitat, then data will be compared with ecological comparison values and constituents of potential ecological concern identified. The lateral extent of AOC 13 is to the fence line, where unpaved areas extend to the fence line. Onsite units included in the Final RFI/RI include SWMUs 5, 6, 8, and 9; Units 4.3, 4.4, and 4.5; and AOCs 5, 6, 7, 8, 13, 15, 16, 17, 18, 19, and 20. *For newly identified areas*: Initially, the tentative outline shown in Figure 1. Newly identified areas include SWMU 11; AOCs 21, 22, 23, 24, 25[1], and 26; the potential burn area near AOC 17; and the motor oil pit at the former Teapot Dome facility. *For the perimeter area:* initially from the facility fence line outward to the toe of the slope. Existing and former storm drain outfalls will initially be investigated during Part B investigation. *For storm drains:* Initially the lateral extent of the storm drain alignment. **Vertical Extent** Vertical study area boundaries extend from the ground surface to the water table. **Analytical Parameters** *Chemical Parameters (COPC):* • TPH, VOCs, and SVOCs (including PAHs) for SMWUs 5, 6, 8, and 9 • Title 22 metals, hexavalent chromium, and pH for SWMU 11 • Title 22 metals, VOCs, SVOCs (including PAHs), and pH for	See Figure 2 for the Decision 1 decision rule

---

[1] This unit was identified as AOC 26 in the DTSC comments; however, AOC 25 as identified in the DTSC comments is a small, rectangular area carved out of the rock face near AOC 10 (East Ravine) that may have been used for explosives storage. Because the unit is outside the TCS, it will be further evaluated as needed in coordination with the Part A soil investigation.

	Interim Measures.	• Soil physical and chemical property information • Geologic/hydrogeologic/hydrologic information • Topographic information • Location of paved/unpaved areas • AOC/SWMU location and use history information • Historic information by AOC/SWMU • Infrastructure information by AOC/SWMU	*Soil Characteristics* (to support evaluation of potential migration and/or exposure control measures): Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes. **Temporal Boundaries** Same as for Decision 1.	

The list of analytical parameters is based on CSM and will be refined after each round of investigation/data evaluation. COCs will be selected based on the risk assessment.

ARARs = applicable or relevant and appropriate requirements.
COC = constituent of concern
Cr(VI) = hexavalent chromium..
PCB = polychlorinated biphenyl.
PAH = polycyclic aromatic hydrocarbon.
SPLP = synthetic precipitation leaching procedure
STLC = soluble threshold limit concentration
SVOC = semivolatile organic compound
TCLP = toxicity characteristic leaching procedure
TPH = total petroleum hydrocarbons
TTLC = total threshold limit concentration
VOC = volatile organic compound

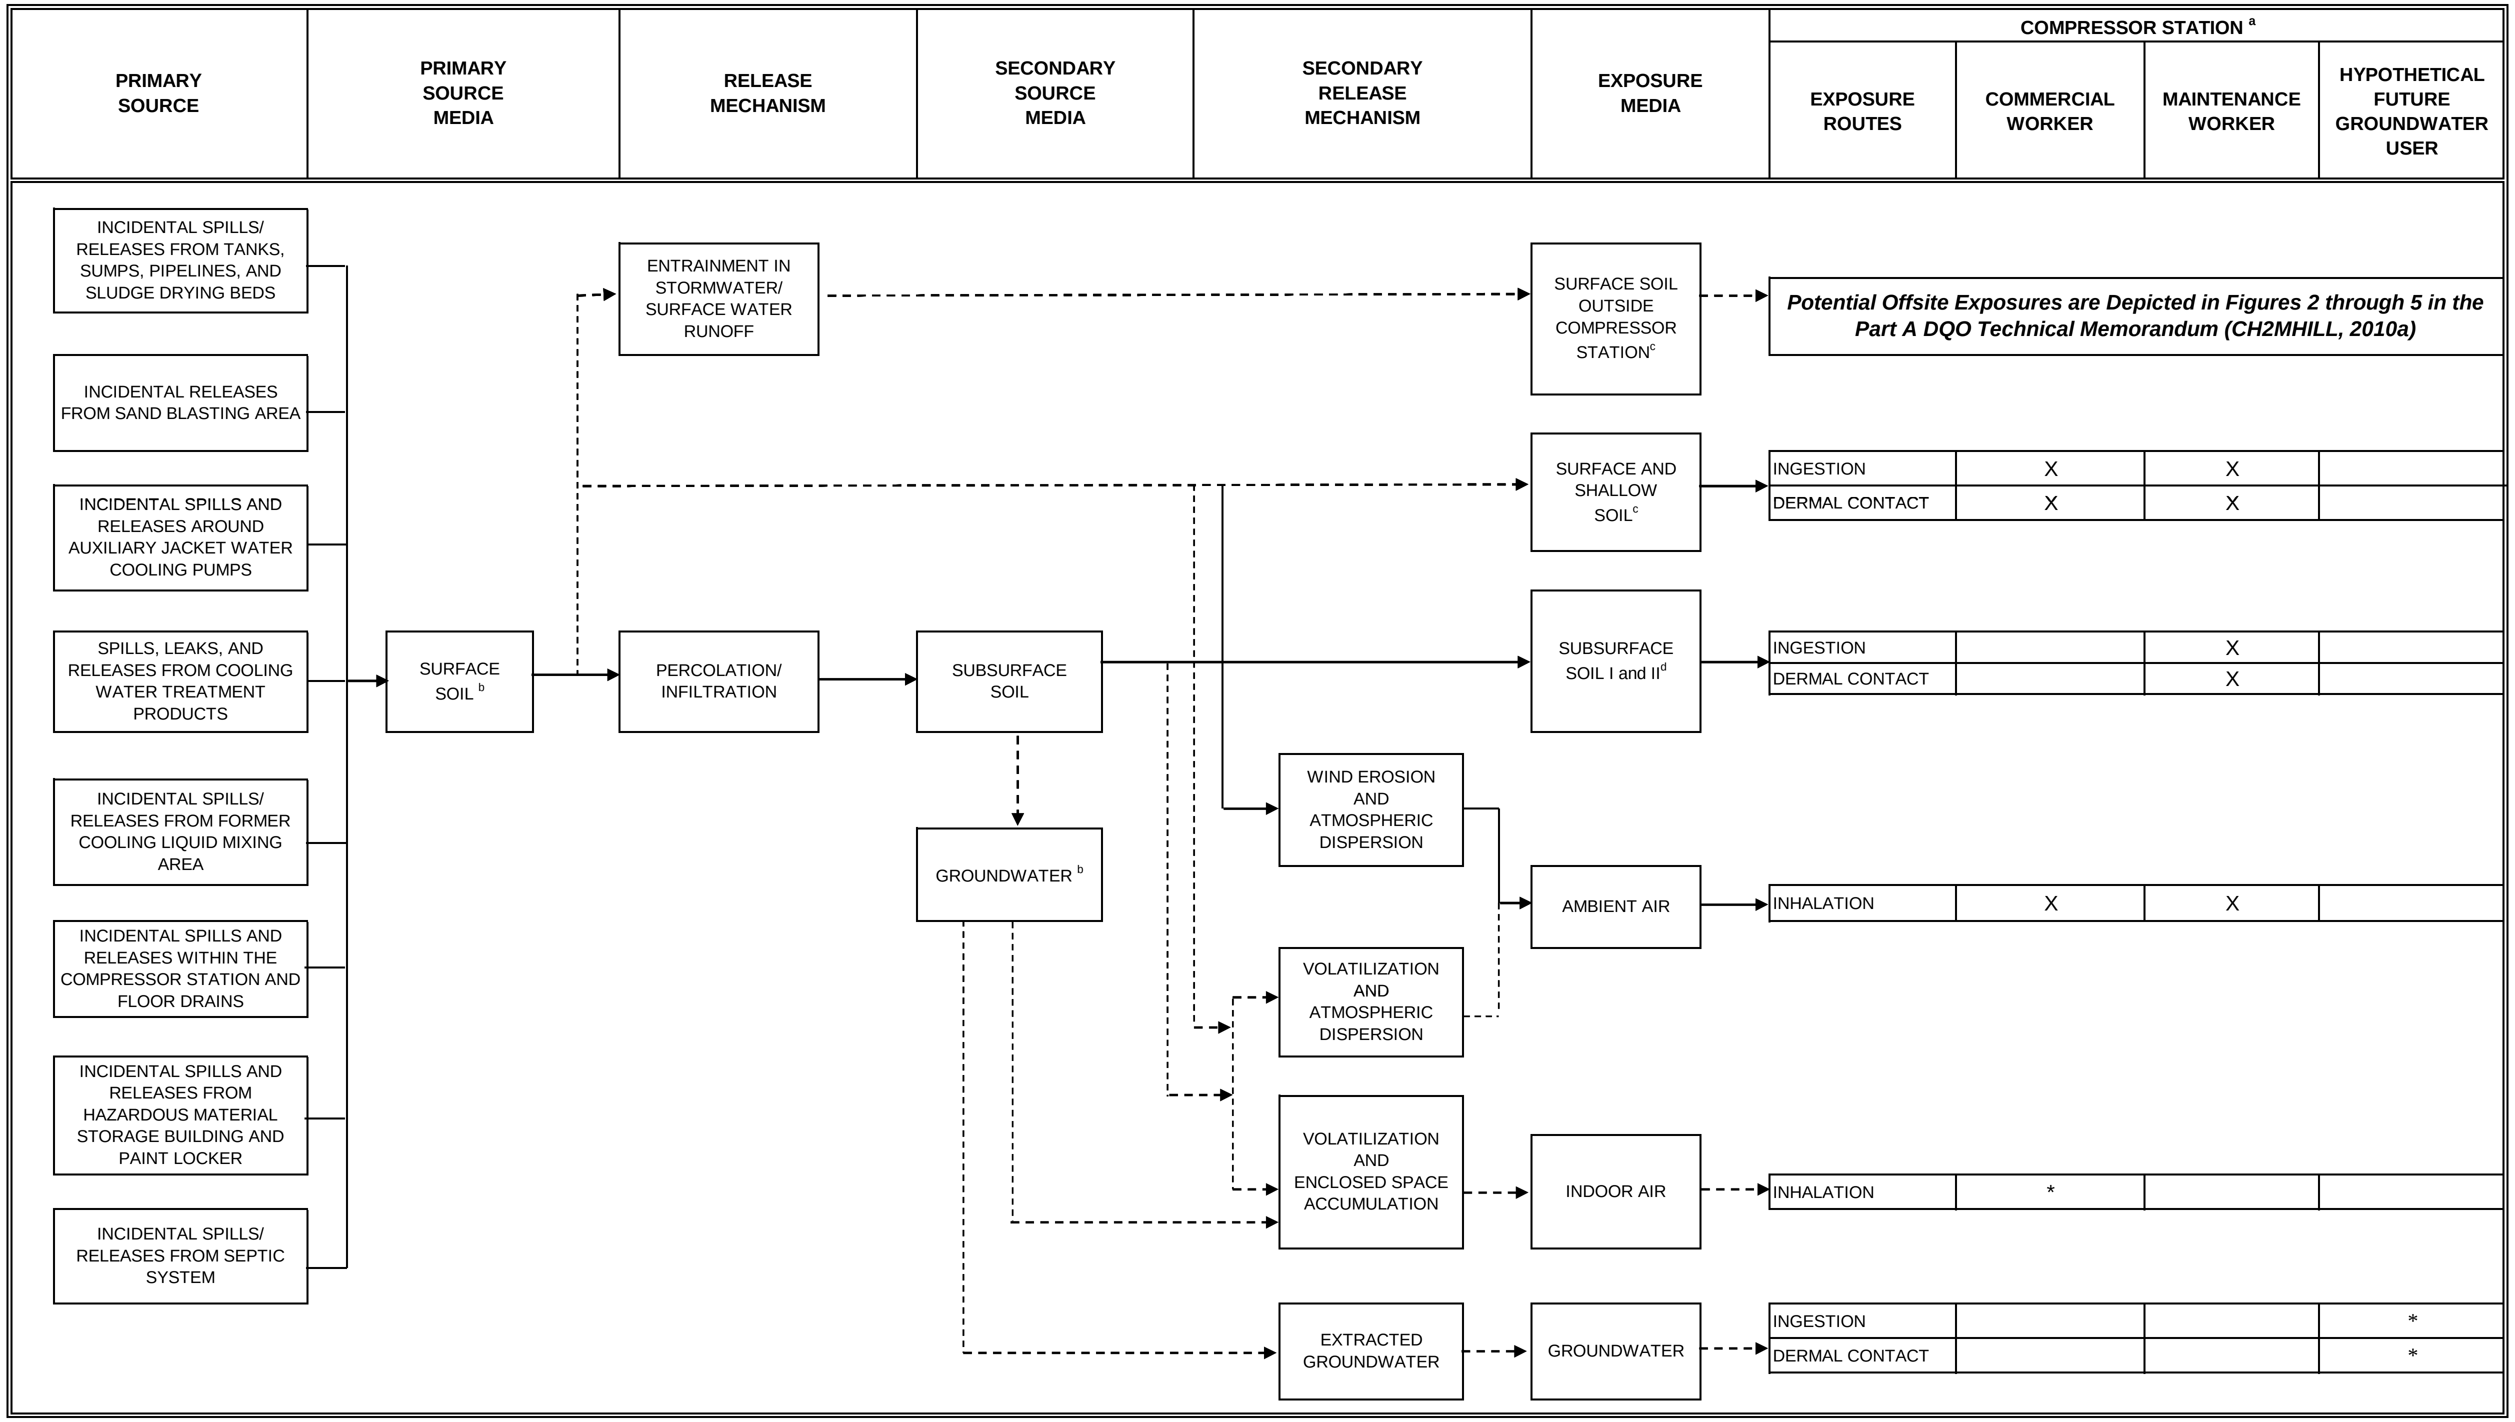
PRELIMINARY HUMAN HEALTH CSM FOR INSIDE THE COMPRESSOR STATION
PACIFIC GAS AND ELECTRIC COMPANY
DATA QUALITY OBJECTIVES - PART B SOIL INVESTIGATION



NOTES:

References are provided in the *Human Health and Ecological Risk Assessment Work Plan, Topock Compressor Station, Needles, California* (August 2008).

[a] The former sludge-drying beds, chromate reduction tank, process pump tank, transfer sump, oil holding water tank, oil/water separator, and wastewater transference pipelines inside the compressor station have already been closed (CH2MHILL, 2007i), but DTSC has requested additional investigation (CalEPA, 2007d). If complete pathways are identified based on the results, any of these areas will also be included in the HHRA.

[b] Potentially complete transport pathway from primary and secondary source media within the compressor station to exposure media outside of the compressor station and potentially complete exposure pathways will be further evaluated in the risk assessment in the context of areas outside of the compressor station (See Figures 2 through 5 of the Part A DQO Technical Memorandum; CH2MHILL, 2010a).

[c] Surface soils defined as soils collected at depths between 0 and 0.5 feet below ground surface (bgs); shallow soil defined as soil collected between 0 and 3 feet bgs. (See Figure 3-1 in the RAWP (ARCADIS, 2008a)).

[d] Subsurface soil I defined as soil collected between depths of 0 an 6 feet bgs; subsurface soil II defined as soil collected between 0 and 10 feet bgs (See Figure 3-1 in the RAWP (ARCADIS, 2008a)).

⟶	Potentially complete transport pathway to be included in the quantitative risk assessment.
- - - ➝	Potentially complete transport pathway to be further evaluated in the risk assessment.
X	Potentially complete exposure route to be included in the quantitative risk assessment.
*	Potentially complete exposure route to be further evaluated in the risk assessment.

Response to Comment Tables

DTSC Comments on the October 5, 2010 document *Draft Data Quality Objectives Steps 1 through 5 Part B Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California*

Comment Number	Section/ Page	DTSC Comment (November 1, 2010)	PG&E Response (November 30, 2010)	DTSC Response (December 23, 2010)	PG&E Response (February 4, 2011)
1.	Cover page	The draft and final Technical Memorandum must be signed by a Professional Geologist of Engineer due to the geologic interpretation process documented in the Data Quality Objective (DQO) decision rules.	The final Technical Memorandum is signed as requested. PG&E does not intend to retroactively sign the Draft Technical Memorandum.	Comment noted. In the future, PG&E should ensure draft and final technical documents are appropriately signed.	No response necessary.
2.	Section 1.0.	DTSC is still waiting for PG&E to provide the scrubber sump closure report to DTSC. As noted in DTSC comments from 2008, DTSC may also be requesting additional characterization at the former oil scrubber sump based on evaluation of the closure report.	The closure report will be provided as soon as it is obtained.	DTSC requested this report over two years ago and PG&E has had ample time to provide it to DTSC. PG&E shall provide the closure report to DTSC no later than January 7, 2011.	The report was provided to DTSC on January 18, 2011.
3.	Section 2.1.1. Page 3. Footnote.	The footnote should be modified as indicated in the revised text provided to ensure accuracy. *“[1] As discussed in the Risk Assessment Work Plan, ecological exposure inside the Topock Compressor Station is insignificant because of the industrial development of the site and the very limited habitat; therefore, constituents of potential ecological concern will not be defined for areas within the fence line except when required for Decision 4 evaluation.”*	The footnote was revised as requested.	No response necessary.	No response necessary.
4.	Section 2.1.1. Page 4. First paragraph.	The AOC/SWMU listing should call out perimeter sampling as a unique area to be investigated. See comment 8.	This area was characterized as the perimeter area, but was not added to the AOC/SWMU list. It is not an identified unit.	This section of the memorandum was changed to address the perimeter area. No further changes are requested.	No response necessary.
5.	Section 2.1.1. Page 4. Second paragraph. Last Bullet.	The bullet related to Decision 5 should be modified as follows to be consistent with the corrective action process: *Determine the site-specific soil property and contaminant distribution information necessary to support the CMS/FS, remedial design, and/or Interim ~~evaluate potential migration and exposure control m~~ Measures.* This language change should be made at all similar occurrences throughout the entire document.	The overall purpose of the Part B investigation is to support the assessment of potential migration and exposure concerns of the Compressor Station at this time, and evaluation of potentially migration and exposure control measures that may be required to address current exposure and/or migration concerns. The full investigation and remediation of the area within the fence line will not occur until after the facility has been permanently decommissioned. No change was made to the text.	DTSC wants to ensure that appropriate data are collected to allow clean up of units (e.g., dig and haul, soil washing, etc.), if necessary, utilizing data gathered as part of the associated characterization activities. The stated overall purpose in PG&E’s response is too limiting and would only require additional, unnecessary intrusions into the area at a later date, an area considered sacred by some tribes. Elimination of data collection to address the CMS/FS, remedial design, and/or Interim Measures, either short or long term, is inappropriate. DTSC does understand that full investigation/remediation of the Compressor Station Area inside the fence line is not envisioned by PG&E. However, the CMS/FS and Interim Measures process will still allow for the “potential migration and exposure control measures” identified in the Tech Memo to be addressed. Introduction of these new terms is not warranted as they are not adequately defined in the document. The RCRA and CERCLA process must not be reinvented without reason (e.g., the process flow	The text was modified as directed.

DTSC Comments on the October 5, 2010 document *Draft Data Quality Objectives Steps 1 through 5 Part B Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California*

Comment Number	Section/ Page	DTSC Comment (November 1, 2010)	PG&E Response (November 30, 2010)	DTSC Response (December 23, 2010)	PG&E Response (February 4, 2011)
				chart followed for this project and shared with the public must be utilized - see the Topock Project Executive Abstract process flow chart attached to all recent PG&E documents including this technical memorandum). Changes must be made to the document as originally requested in DTSC's comment.	
6.	Section 2.1.2. Page 5. Second paragraph.	The Part B Work Plan should provide illustrative conceptual site models for each AOC/SWMU as requested for the Part A Data Reports. The Tech. Memo states that the focus of the CSM is on evaluating potential exposure pathways to human receptors. It must also adequately address the CSM for offsite receptors. The CSM for this particular pathway should be expanded upon in the Part B Work Plan.	Based on the similar release mechanisms of the Part B AOCs and SWMUs, the physical layout of the AOCs and SWMUs across the compressor station, and the higher topographic elevation of the station to surrounding areas, a general illustrative conceptual site model will be developed for the entire compressor station, as opposed to individual CSMs for each AOC. The Part A TM addressed the potential exposure pathways for off-site receptors. The Part B CSM (Figure 7) provides the link to the Part A DQO TM.	Using the same conceptual model for all the AOCs and SWMUs is inappropriate as it ignores differences between units and will actually distract from evaluating unique issues for a particular unit. Conceptually, the units themselves and associated releases to soil are not and will not be identical. PG&E needs to address the original comment and provide illustrative conceptual models for each unit. As previously explained to PG&E in meetings, a cross-sectional conceptual figure is requested to evaluate data needs and gaps. Regarding the second DTSC comment on offsite receptors, PG&E needs to add text to the document as the existing text (page 5, second paragraph, last sentence) downplays off site migration when it is actually a separate problem statement. A single clarifying sentence added to the end of the paragraph will suffice. However, an illustrative conceptual model showing offsite migration pathways (e.g., surface water flow, storm drain flow, wind dispersal and drift) is requested as indicated above.	PG&E will prepare an individual illustrative CSM for each AOC. The text has been modified as follows: The focus of the CSM included with this Part B DQO TM is on evaluating potential exposure pathways to human receptors. A CSM addressing potential off-site migration pathways will be incorporated into the Combined Soil Workplan.
7.	Section 2.1.3. Page 5. Last paragraph.	The Tech Memo states, *"For releases from these primary sources, the primary source medium for the area within the fence line is surface soil."* Releases to concrete and buildings should also be mentioned. The Tech Memo also states that constituents known to have been released at the Topock Compressor Station consist of nonvolatile compounds. Delete this inaccurate statement from the Tech Memo as there are Topock Compressor Station releases that would have included volatile constituents (e.g., oily waste/waste water releases, gas pipeline condensate releases, fuel storage tank releases, waste solvent cleaning solutions).	The bullets above this paragraph list areas and activities that serve as primary sources for incidental spills/releases to surface soil. The second bullet already includes 'buildings and other facilities." Text changed to "consist *primarily* of…"	PG&E's first response does not address the comment. Contaminants may also be released onto concrete, buildings and other structures in addition to surface soils. To address the comment, the following sentence revision should be accepted into the final memo: *For releases from these primary sources, the primary source medium for the area within the fence line is surface soil, concrete and buildings.* No response necessary for the second comment.	PG&E concurs that contaminants may have also been released onto concrete and certain other structures in addition to surface soil. Visible staining may provide an indicator of such a case. We understand that DTSC's primary concern expressed in this comment is that potentially contaminated building materials be appropriately handled during future maintenance or demolition activities. To resolve this comment, PG&E will change the text in

DTSC Comments on the October 5, 2010 document *Draft Data Quality Objectives Steps 1 through 5 Part B Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California*

Comment Number	Section/ Page	DTSC Comment (November 1, 2010)	PG&E Response (November 30, 2010)	DTSC Response (December 23, 2010)	PG&E Response (February 4, 2011)
					Section 2.1.3 as follows: *"For releases from these primary sources, the primary source medium for the area within the fence line is surface soil. In addition, concrete or structures displaying visible staining may be a source medium to surface water runoff or a potential source to underlying soil*
8.	Section 2.1.3. Page 6. Paragraph 1 and 2.	The Tech Memo states*, "Local topography is the primary feature to consider when examining releases of constituents from the Topock Compressor Station to areas outside the fence line via surface runoff."* A more significant feature to consider appears to be storm drains that would intentionally divert facility fluids, sediments, and surface water to areas beyond the facility fence line. PG&E must identify all current and historic storm drains on a facility figure. The Part B Work Plan should sample soils offsite at the storm drain outfalls and along the drains as they are known to have leaked over time. It is recommended that this sampling be included with AOC-13 as originally envisioned. Also see comment on Figure 7 below regarding site-wide storm water sampling. The Tech Memo also states*, "However, any potential exposures to COPCs that have been transported via surface water runoff to areas outside the Topock Compressor Station will be addressed in the context of Part A soil sampling and subsequent risk assessment."* As Part A is not addressing this issue, this sentence should be deleted.	PG&E has previously provided all available information in the RFI Report (Volume 1). As previously discussed with DTSC staff, developing the type of map that DTSC is requesting would be major undertaking that would include geophysical investigation, dye testing, video investigation, and likely excavation to trace lines. No investigation of the storm drain system is proposed for the Part B investigation. For the Part B Work Plan, PG&E will review the information provided to date, and to the degree possible, correlate it with an on-the-ground review of the existing catch basins. This updated information will be provided in graphical format. The referenced Paragraph 2 was revised to specifically state that storm drains may serve as a migration pathway. To address the overall concern potentially associated with storm drains, PG&E first proposes to conduct the Part B investigation, including the perimeter sampling, The Part B investigation will include sampling at the terminus of storm drain outfalls, as well as proposed step-out sampling downslope of the outfalls. The Part B data will then be reviewed to determine which storm drain locations, if any, appear to represent a continued threat of release. Depending on the outcome of the investigation, the specific storm drains in question may be traced, sealed, or the flow to the drain rerouted to prevent potential future	PG&E has provided some additional information on storm drains since the 2007 RFI Volume 1 including adding storm drain locations on maps. PG&E has not discussed conducting a thorough investigation of historic storm drains with DTSC especially one as outlined in PG&E's response to this comment. PG&E's RFI Report (Volume 1) does document several miscellaneous releases via storm drains, but the locations of the drains are not specified in RFI figures. The information contained in the Volume 1 RFI Report does support the need to investigate storm drains. An investigation of the storm drain system is required. This includes older drains potentially no longer in service that are of greater environmental concern. Historic releases through these lines may have greater adverse impacts assuming waste management practices in the past were not as stringent as they are today. We have all learned this lesson at AOC-9 where a waste release(s) at a storm drain impacted soil and resulted in removal of the contaminated soil. A detailed drain investigation should occur at the perimeter of the site to locate potential sources that could travel further offsite. If significant contamination is eventually identified, then investigations could continue along storm drain lines on site. For instance, the storm drain on AOC-9 should be further investigated on-site if possible. DTSC concurs with the sampling approach proposed by PG&E especially for existing storm drain outfalls as well as the down slope step out plan. However, DTSC also requests that some	Per DTSC direction, PG&E will conduct an investigation of the storm drain system. The investigation will include geophysical tools, video equipment and dye tracer tests to evaluate the locations of storm drains and storm drain discharge areas, and assess storm drain conditions. In addition, soil samples will be collected and characterized in the vicinity of storm drains to the extent needed to meet DQOs and to the extent the areas are accessible and it is safe to do so. The storm drain investigation sampling approach will be incorporated into the Combined Soil Workplan. A detailed perimeter sampling effort was previously included in the Draft Part B Soil Workplan, and will be reevaluated and expanded as appropriate .

DTSC Comments on the October 5, 2010 document *Draft Data Quality Objectives Steps 1 through 5 Part B Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California*

Comment Number	Section/ Page	DTSC Comment (November 1, 2010)	PG&E Response (November 30, 2010)	DTSC Response (December 23, 2010)	PG&E Response (February 4, 2011)
			releases to the environment. It would be premature to conduct a full-scale analysis of the storm drain system at this time, and such an investigation would be very time-intensive, and potentially intrusive. Potential exposures to off-site receptors will be addressed partially in the context of the Part A investigation and partially in the context of the Part B investigation. The data collected from the perimeter sampling effort to be conducted as part of the Part B investigation will be used for both investigation programs. In the context of the Part B investigation it will be used to assess potential sources to off-site areas; in the context of the Part A investigation it will be used to determine whether further investigation, risk assessment, or remediation may be required. The Part B Work Plan will describe in detail how the two investigation programs will interface to ensure that no gaps in investigation coverage, risk evaluation, and remediation will occur.	sampling occur outside the fence line along drains prior to the outfall (see original comment). Documented, detailed discussion of the perimeter sampling program is welcome. Coordination of the Part A (off site) and Part B (on site) perimeter sampling program will hopefully become evident as the Part A and B are combined into one document. Currently, the Part A data gap evaluation and draft Part B Work Plan have not put sampling locations on a map to address this issue.	
9.	Section 2.1.7. Page 7. Paragraph 5.	The Tech Memo states, *"For evaluating the potential for offsite migration, the exposure interval of interest is surface soil (0 to 0.5 foot bgs) exposure."* The Tech Memo should acknowledge that there may be circumstances where evaluation of deeper samples might be necessary (e.g., along slopes, areas of significant erosion/potential erosion, areas that could erode over time).	The text has been modified to state that in some circumstances it may be necessary to sample more deeply to characterize the potential for off-site migration. A depth of 1.0 foot bgs is proposed for the perimeter area.	No response necessary.	No response necessary.
10.	Section 2.3. Page 8. Third paragraph.	The last paragraph of this section should be deleted. Limitations regarding possible future exposure control actions are not completely known and should not be discussed at this time.	The referenced paragraph states "The physical constraints and the types of COPCs released limit the potential migration and exposure control actions that could be employed to address constituents posing an unacceptable risk to human health and the environment or posing a threat to groundwater." This does not limit any future actions, it merely indicates that choices may be limited.	DTSC disagrees with the response. Please remove the sentence as it is predicting outcomes prior to the investigation. Currently, the COPCs released at each unit are unknown as is contaminant distribution and relation to potential physical constraints. Physical constraints at each unit have not been defined. Potential remedial actions have not been addressed at any level, yet the sentence is already limiting remedial measures before documenting what they may be, let alone knowing if they are even needed.	The sentence has been removed as directed.
11.	Section 2.4. Page 9. Item 1.	The language contained in the Tech Memo should be modified as indicated below (see comment 5): *"The alternative outcomes of this question are: (1) the nature and extent of*	Please see response to Comment 5.	Please see response to Comment 5.	The text was modified as directed.

		be clarified and examples given in the Tech Memo. A detailed list of these constraints must be included in the Part B Work Plan.	cannot be conducted in a manner that is deemed safe by PG&E, it will be considered infeasible." The text was revised to include examples of institutional constraints. A more detailed list of potential institutional constraints will be provided as part of the work plan.		
21.	Section 2.7.3.3. Page 26.	The Part B Work Plan and Report should include model runs and input parameters.	Model input parameters will be provided in the Part B Work Plan; model runs will be provided in the report for the Part B investigation.	No response necessary.	No response necessary.
22.	Section 2.7.5. Page 29.	See comment 5. Change the title of the section to the following: Decision 5 – Inputs to CMS/FS or Interim Measures – Decision Rules and Decision Process	Please see response to Comment 5.	See DTSC's response to Comment 5. Changes must be made to the document as originally requested in DTSC's comment.	The text was modified as directed.
23.	Section 2.7.5.1. Page 30.	Box 4 (Figure 6) in Decision 5 states, "*Is sufficient soil property, transport pathway, and contamination distribution information available to identify areas that may result in offsite migration concerns?"* This inappropriately limits interim or remedial measures to those onsite Part B soils that could cause an offsite problem. As onsite problems (human health risk, potential to impact groundwater) must also be addressed, the section and Figure 6 will need to be modified. Box 4 should read as follows: "*Is sufficient soil property, transport pathway, and contamination distribution ~~information~~ data available to ~~identify areas that may result in offsite migration concerns~~ support the CMS/FS or Interim Measures*?	Box 4 of Decision 5 was revised to read: "*Is sufficient soil property, transport pathway, and contamination distribution information available to identify areas that may result in offsite migration or excess onsite exposure concerns?"*	See DTSC's response to Comment 5. Changes must be made to the document as originally requested in DTSC's comment.	The text was modified as directed.
24.	Figure 7.	Releases from the cooling towers (Primary Source column) should also be documented as occurring as mists/drift that would have coated soils, concrete, and building surfaces. The figure identifies storm water/surface water runoff as a potentially complete pathway. Therefore, PG&E is directed to establish a site-wide storm water monitoring program to assess potential impacts from the facility to offsite receptors.	Release of mist/drift is an incidental spill/release from the cooling towers, and is addressed in the CSM. Other incidental spills/releases may also have contacted buildings, concrete pads or other structures in addition to soils. Any deposits on outdoor surfaces may then result in secondary release to surface soil The request for a storm water monitoring program requires further discussion between PG&E and DTSC, and is not related to the Part B DQO TM.	See DTSC's response to Comment 7 regarding releases to concrete and buildings. PG&E should add the establishment of a storm water monitoring program to the rainbow schedule. This program will ensure that current PG&E operations are not adversely affecting site conditions.	Please see PG&E's response to DTSC's Comment 7. As directed by DTSC, PGE will conduct storm drain monitoring, however, due to the location of storm drains primarily along the steep slopes of the facility perimeter, the highly sporadic nature of rainfall in this area, as well as significant safety issues, traditional storm water monitoring is anticipated to be both spatially and temporally

	Location	Type[a]	Comment	PG&E Response	Accept
1	Section 1.0, Page 2	S	The first full paragraph refers to the rock "cave" in AOC 10, noting it will be deferred to the Soil Part A investigation. Since this location is not associated with PG&E, it is recommended that deferral be eliminated and the site be absolved from further consideration.	Per email correspondence from DTSC and DOI on November 24 and 29, 2010, respectively, the text has been modified to read as follows: *DTSC also requested the addition of a small depression carved out of the rock near AOC 10, which was identified by DTSC as a potential explosives storage area, as AOC 25. This unit is not being added as a new AOC. Based on existing information, it has no known connection to the compressor station.*	
2	Section 2.1.1, Page 4, last paragraph	S	Receptors outside the compressor station should include tribal members engaged in traditional uses.	Agreed. Edits were added to this section.	
3	Section 2.1.3, Page 5, 3rd Paragraph	M	Please explain why releases from some features that are buried or extend below the surrounding ground surface (e.g., sumps) could not directly affect subsurface soil without necessarily affecting surface soil.	Edits were added to this paragraph to further clarify that features (such as the Teapot Dome Oil Pit) extending below the ground surface may result in releases to shallow soil and/or subsurface soil.	
4	Section 2.1.3, Page 6, 2nd Paragraph	M	This section states that exposure to COPCs that have been transported outside the fence line via runoff will be addressed by the Part A soil investigation. An example might be if the perimeter sampling planned for the Part B investigation identifies contamination at the fence line, with probable migration beyond the fence line. The Soil Part A sampling only addresses the	As this comment correctly notes, a third phase of investigation outside the fence line may be required if the perimeter area sampling conducted during the Part B investigation indicates that further investigation is necessary. The investigation process will be streamlined as much as possible by including potential step-out	

[a] Comment Types: M = Mandatory, S = Suggested, E = Editorial

			prescribed AOCs and SWMUs under current investigation. Perimeter sampling may indicate that other potential areas of contamination exist and require further assessment. If this is to be addressed in the Part A soil investigation, this will necessitate a third (or more) phase of Part A soil sampling.	sampling locations for the perimeter sampling detailed in the Part B Work Plan. Also, the anticipated duration of the overall investigation effort is such that it is likely that the need for follow-up sampling can be evaluated. If follow-up sampling is necessary, it can be conducted during the same mobilization. Phasing the investigation effort is critical to avoid excessive sampling. The connection between the Part A and Part B investigations will be addressed in detail in both Work Plans.	
5	Section 2.1.3, Page 6, second paragraph	M	Although off-site migration is the agencies primary concern under CERCLA, Soil Part B sampling also addresses on-site exposure to workers.	The text has been revised as requested.	
6	Section 2.1.4, Page 6, 2nd Paragraph, 3rd sentence Figure 7, Page 49	M	This paragraph characterizes the surface soil interval as deep as 3 feet; however Figure 7 and Section 2.1.7 specify that the surface interval is 0-6 inches. Soil extending from 0 to 3 feet is specified as shallow soil. Revise 3rd sentence to say "Commercial workers would be expected potentially to come into contact with surface **and shallow** soil in the 0-to-3-foot-depth interval."	The text has been revised as requested.	
7	Section 2.1.6, Page 7	S	It may be appropriate to note potential sources of recharge within the compressor station area, including meteoric water.	The text and Table 1 have been revised as requested.	
8	Section 2.1.7, Page 7	M	For clarification, distinguish the difference between subsurface soil I and subsurface soil II. Section 2.1.4 discussions do not include the 0-6' interval although all intervals are discussed in the RAWP. Please ensure consistency with the RAWP.	Comment noted. The text has been edited in Section 2.1.4 to include the 0-to-6-foot bgs interval for maintenance workers; subsurface soil I is defined as the 0-to-6-foot bgs interval, and subsurface soil II as the 0-to10-foot bgs interval.	
9	Section 2.5.2, Page 12	M	See comment on 2.1.7.	See response to Comment 8 for Section 2.1.7 and edits in Section 2.1.4	
10	Section 2.5.2, Page 12	M	This section identifies the need developing the human health risk assessment and estimating representative EPCs are specified in the RAWP	Comment noted. Clarifying edits have been added to Section 2.5.2. Data adequacy for estimating an EPC for Decision 2 is	

[a] Comment Types: M = Mandatory, S = Suggested, E = Editorial

			(ARCADIS, 2008a). The RAWP provided general information on how this will be accomplished. The Figure 3, block 4 question asks "Are sufficient Category 1 data available to calculate/ determine a representative exposure point concentration for each applicable depth interval?" The document should describe how this will be done. Please provide additional detail on the process and parameters that will be used to develop EPCs. DOI would anticipate the process to address any additional data and quality requirements, plans for integrating existing data, target sample sizes to obtain confidence levels, and spatial aggregation plans.	considered according to the RAWP (see Appendix A) independently from Decision 1 for nature and extent. However, the representativeness of the estimated EPC for each data group is dependent on whether those data considered also satisfy Decision 1 and adequately represent the nature and extent. Additional data subsequently recommended to satisfy Decision 1 and/or Decision 2 for a data group will also be used in the risk assessment to estimate the representative EPC. Spatial aggregation is not planned because the entire area within the fence line is one exposure area for human health risk evaluation, as agreed in the RAWP.	
11	Section 2.6.4.2, Page 17	M	The vertical boundary for decision 4 is suggested to be 0.5 foot bgs. Visual inspections of rills along the boundary of the TCS suggest that 1.0' bgs may be a more appropriate interval for potential offsite transport.	The text and Table 1 have been revised to reflect the fact that a deeper vertical boundary for Decision 4 may be appropriate in some locations; the vertical boundary for the perimeter area has been set at 1 foot bgs.	
12	Section 2.7.1.1, Page 18, 3rd Paragraph, 3rd sentence	M	The statement that "This data assessment process will be limited to surface and near-surface samples, as deeper samples would not be expected to be affected." is not accurate. The vertical study area, as discussed in Section 2.6.1.2, extends from the ground surface to the water table. Existing data for this interval should be included.	The data assessment referred to in this sentence is the need to evaluate whether COPC concentrations in existing samples have changed since the samples were collected. Changes in COPC concentrations could occur as a result of runoff, volatilization, and/or photodegradation, and these mechanisms are not expected to affect deeper samples.	
13	Section 2.7.1.2, Page 18, bullet list	M	As has been repeatedly commented on in the Part A DQOs, these criteria have only limited applicability because only 10 percent of the samples are being analyzed for TAL/TCL constituents.	The criteria presented are appropriate. As discussed in the context of the Part A investigation and data gaps evaluation, the purpose of analyzing 10 percent of the samples for TAL/TCL constituents is to screen the site for any new, unexpected	

[a] Comment Types: M = Mandatory, S = Suggested, E = Editorial

				compound detections that may require further investigation. The results from the Part A investigation demonstrated that only PCBs were detected at a frequency that merited further assessment and that other constituents not already identified as COPCs were detected at a low frequency and at low concentrations.	
14	Section 2.7.4.1, Page 28, last sentence	M	Regarding the sentence reading "It is not necessary to evaluate the potential for offsite migration from areas where existing COPC concentrations are below the Decision 4 screening levels, because these areas would not pose a potential threat to offsite receptors." While DOI agrees that areas with soil concentrations not exceeding SLs should not be evaluated further, it is noted that there is potential for water-borne materials eroded from such areas, or a combination of such areas, to accumulate in off-site locations (such as behind a bermed drainage like seen in AOC 11), potentially resulting in an unacceptable risk off-site. Based on the outcome of the Part A investigations, it may become necessary to control off-site migration of stormwater to prevent continued off-site degradation.	Comment noted.	
15	Table 1, Page 35	M	See applicable comments made on text.	Table 1 has been corrected to be consistent with the revised text, as noted in the various responses to comments.	
16	Table 1, Page 35 Step 5 decision rules	M	Please provide additional information describing how (e.g., information needed and interpretive rationale) PG&E anticipates answering the following questions posed in the decision diagram. Decision 2; Block 4 (See comment on Section 2.5.2) Decision 3; Block 8 Decision 4; Blocks 7 and 8 Decision 5; Block 4	For Decision 2, Block 4, please see the response to Comment 10 for Section 2.5.2. For the other blocks, the applicable subsections of Section 2.7 have been revised to provide added information regarding the referenced steps in the decision process.	

17	Figure 2, Page 44	M	The arrow from 5A connects to 5D (as it should) and also connects to the line from 5B. This is inconsistent with the if/then statements in the text. Also 5D should connect to 16A for consistency.	Box 5D should not have been shown as an endpoint. The “No” arrow from Box 5A will continue to connect to Box 5D, but will not connect directly to the “No” line between Box 5B and Box 5C. Instead, a line from Box 5D will lead to the “No” line between Box 5B and Box 5C. Box 5D is a reminder that any new COPCs without screening levels must be addressed in the RA and RFI/RI reports, and evaluation of the data set continues with Box 5C. Figure 2 for Decision 1 has been corrected as described.

APPENDIX B2

SWMU 5 Investigation Program

1.0 Introduction and Background

Solid Waste Management Unit (SWMU) 5 comprises the two former sludge-drying beds that were constructed in 1951 with the rest of the compressor station and are located within the facility fence line in the southern part of the lower yard, as shown in Figure B2-1. (All tables and figures appear at the end of this sub-appendix.) The two sludge-drying beds were located directly adjacent to one another. The closure report for this unit indicates that each bed was approximately 20 feet wide by 50 feet long. Both beds sloped longitudinally, with the upper end at grade level and the lower end about 2 feet below grade. The walls and floors of both beds were constructed of 8-inch-thick concrete and a drain line ran from the beds to the Transfer Sump (SWMU 9) to facilitate the removal of liquids (Mittelhauser, 1990).

The drying beds were used from 1951 until April 1962 to dehydrate lime sludge generated by the Permutit water softening process used to condition well water at the facility (PG&E, 1962, 1968). In historical aerial photographs from the mid-1950s, the drying beds contain whitish material. A whitish area is also present just south of the sludge-drying beds, which has been designated AOC 21, which is discussed in sub-Appendix B18.

From 1964 through 1969, a treatment pond constructed within one of the beds was used to treat chromium-bearing wastewater (PG&E, 1968). Wastewater was allowed to flow through the pond and was injected with sulfur dioxide to reduce hexavalent chromium to trivalent chromium prior to discharge to SWMU 1.

From 1969 through October 1985, the drying beds were used to dehydrate chromic hydroxide sludge generated by the two-step wastewater treatment system prior to disposal. The chromic hydroxide sludge discharged into the drying beds contained up to 37,500 milligrams per kilogram (mg/kg) total chromium and 4 mg/kg hexavalent chromium (Mittelhauser, 1986). The volume of chromic hydroxide sludge disposed of offsite was about 15,000 gallons per year (PG&E, 1984).

California Regional Water Quality Control Board Order 70-73 was issued on December 10, 1970 (Water Board, 1970), and it appears that the chromium sludge was disposed of at Needles Landfill from that time until 1983. Shipping documentation compiled by PG&E indicated that the amount of sludge disposed of each year was highly variable; it appears that the sludge-drying beds had some storage capacity. Disposal of the chromium sludge at Needles Landfill was discontinued by 1984. From January 1984 to May 1985, the dried sludge was transported offsite to an approved Class I hazardous waste facility (PG&E, 1984).

Use of both sludge-drying beds ceased in October 1985. Closure of the drying beds was initiated in December 1988, and most of the beds were removed by February 1989 (Mittelhauser, 1990). In 1995, California Environmental Protection Agency, Department of

Toxic Substances Control (DTSC) issued a closure certification acceptance letter for this unit (DTSC, 1995).

Closure of the sludge-drying beds was accomplished during Phase 1 closure activities performed from December 1988 and February 1989 (Mittelhauser, 1990). A closure certification acceptance letter for this unit was issued in 1995 (DTSC, 1995). The steps taken during closure of the sludge-drying beds included:

- Removal of a thin layer (0 to 5 millimeters) of dry solids consisting of sand and some clay and removal of a small volume of stormwater using a sorbent material; the dry solids and sorbent were placed in a roll-off bin and were transported offsite for disposal as hazardous waste.
- Hydroblasting of the concrete walls and floors to remove green deposits observed on the concrete; the hydroblast water was containerized, characterized, and properly disposed of as hazardous waste.
- Demolition, removal, and disposal of an estimated 95 cubic yards of concrete from the walls and floors of the beds; the concrete was broken up, characterized, and disposed of offsite as a Class III waste. Rebar from the concrete was transported offsite for recycling.
- Removal of the concrete footings. After determining that this concrete was not hazardous, the concrete was used as fill material onsite.
- Collection of confirmation samples.
- Final filling and grading of the area.

At the time of closure, confirmation samples were only analyzed for inorganic constituents.

Organic constituents may potentially have been present in the wastewater as a result of treated water discharge from the oily water separator. Chemicals of potential concern (COPCs) potentially associated with discharge of treated effluent from the oily water separator include total petroleum hydrocarbon (TPH) and polycyclic aromatic hydrocarbons (PAHs).

2.0 Summary of Past Soil Characterization

Following removal of the sludge-drying beds, confirmation soil samples were collected from four locations (WDB-4, WDB-5, EDB-4, and EDB-5) at an estimated depth of 2.5 to 3 feet below ground surface (bgs). The results of these samples are presented in Table B2-1 and Figure B2-1. These samples were analyzed for Title 22 metals, hexavalent chromium, fluoride, and pH. The samples were collected underneath the deeper portion of the former sludge-drying beds (i.e., in the area where releases would have been most likely, as liquids would have been present most frequently in the portion of the sludge drying beds overlying this area). Historical soil samples were analyzed for antimony, arsenic, barium, beryllium, cadmium, total chromium, hexavalent chromium, cobalt, copper, lead, mercury, molybdenum, nickel, silver, selenium, thallium, vanadium, zinc, fluoride, and pH. Laboratory analytical results for the historical soil samples are presented in Table B2-1. Data for both splits from sample WDB-4 are included in these tables. Table B2-2 presents a statistical summary of soil analytical results for COPCs and chemicals of potential ecological concern that were either detected above the laboratory reporting limits or not detected and reporting limits for one or more samples was greater than the interim screening value. All historical data are considered Category 2.

Beryllium, hexavalent chromium, selenium, silver, and thallium were not detected in soil samples collected in SMWU 5. Table B2-1 lists the 15 detected constituents. Only three of these constituents (total chromium, lead, and zinc) exceeded background threshold values (BTVs). None of constituents exceeded the applicable commercial screening values (California human health screening levels for commercial use, or United States Environmental Protection Agency Region 9 regional screening levels for commercial use). Fluoride ranged from 130 to 791 mg/kg; pH ranged from 10.21 to 11.25. Total chromium exceeded the BTV once (47 mg/kg compared to the BTV of 39.8 mg/kg), lead exceeded the BTV twice (maximum concentration of 17 mg/kg compared to the BTV of 8.39 mg/kg), and zinc exceeded the BTV once (detected concentration of 100 mg/kg compared to the BTV of 58 mg/kg). These exceedances are only marginally above the BTV, and the overall concentration and distribution of constituents in the five samples indicate that there has been no adverse impact to soil beneath the former sludge-drying beds.

This unit was closed by DTSC in 1995. Subsequent to this closure, DTSC has requested that additional analysis be conducted for volatile organic compounds (VOCs), TPH, and semivolatile organic compounds (SVOCs) in soil at SWMU 5 (DTSC, 2006). COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Section 3.0 provides the recommended sampling for this unit.

3.0 SWMU 5 Proposed Sampling

3.1 SMWU 5 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. SMWU 5 is located in Area 3 on the Topock Compressor Station Accessibility Map (Figure B-2). Twenty-three utility risers, including gas, odorant, waste water, electrical, SCADA, and an emergency shutoff device are located in Area 3. In addition, a utility trench, a cathodic protection anode, and three vaults were identified in Area 3. Photographs 60 and 61 in sub-Appendix B25 show the accessibility constraints in SMWU 5. Sample locations and depths identified for SMWU 5 reflect the identified access constraints. As described in the main text of Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

3.2 SMWU 5 Proposed Sampling

Although this unit was closed in 1995, additional sampling for organic COPCs and sampling of the fill used to backfill the excavation is proposed as required by DTSC. Table B2-3 summarizes the proposed SMWU 5 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B2-2. The figure also shows proposed samples associated with nearby SWMUs and AOCs. The proposed SMWU 5 sample locations are

Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at two locations: SWMU 5-1 and SWMU 5-2 within the footprint of the former sludge-drying beds. Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in SWMU 5; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. If the area of sampling is covered with asphalt, the surface sampling interval will begin at the bottom of the asphalt or gravel sub-base. In most cases, this first interval will be from 0.5 to 1 foot bgs. All samples will be analyzed for Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs. As required by the United States Department of Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B2-3); the specific sample to be analyzed will be confirmed in the field. Data will be reviewed and evaluated as described in the main text of this appendix. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

APPENDIX B3

Solid Waste Management Unit 6 Investigation Program

1.0 Introduction and Background

Solid Waste Management Unit (SWMU) 6 comprises the chromate reduction tank that was a component of the two-step wastewater treatment system setup at the compressor station in late 1969.[1] The two-step system consisted of the chromium reduction tank to reduce hexavalent chromium in the wastewater to trivalent chromium) (Step 1) and a precipitation tank (SWMU 7) for removing chromium from the wastewater (Step 2). Cooling-water blowdown that contained chromium was treated in the chromate reduction tank by injecting the wastewater with sulfur dioxide. The treatment reduced hexavalent chromium to trivalent chromium. The two-step treatment system remained in service from 1969 through October 1985, when the use of a chromium-based inhibitor system in the cooling water was replaced with a phosphate-based inhibitor system. The chromate reduction tank was formerly located within the facility fence line in the southern end of the lower yard, as shown in Figure B3-1. (All tables and figures appear at the end of this sub-appendix.)

The chromate reduction tank was approximately 10 feet high and 5 feet in diameter, with a capacity of 1,500 gallons (PG&E, 1982; Kearny, 1987). The tank was of steel construction and had an open top. The tank was partially set below grade within a pit that measured 10 feet wide by 10 feet long by 6 feet deep. The pit was supported on all four sides with wooden retaining walls; however, the bottom of the pit was not lined or paved (Kearny, 1987).

Cooling-water blowdown that contained chromium flowed by gravity from the cooling towers to the chromate reduction tank via a 3-inch-diameter steel pipe. A maximum combined flow of 30,000 gallons per day was discharged continuously from the cooling towers into this tank (Mittelhauser, 1986). Wastewater in the tank was injected with sulfur dioxide gas to maintain the pH between 2.9 and 3.2 units. Within this pH range, hexavalent chromium is reduced to trivalent chromium. Treated wastewater was then discharged by gravity flow through a 3-inch-diameter steel pipe into the transfer sump (SWMU 9).

Wastewater samples collected from the cooling towers contained total chromium and hexavalent chromium ranging from 2.6 to 7.8 milligrams per liter to (mg/L) and 0.62 to 6.0 mg/L, respectively (Mittelhauser, 1986). Concentrations of total chromium and hexavalent chromium in the effluent from the chromate reduction tank were found to be at 23 mg/L and 0.42 mg/L, respectively (Mittelhauser, 1986). No indications of any releases were observed during a facility inspection performed as part of the Resource Conservation and Recovery Act facility assessment (Kearny, 1987).

---

[1] Historic documents indicate that the system was installed and began operation sometime between November 1969 and March 1970.

The chromate reduction tank was removed from service when the compressor station switched to the non-hazardous phosphate-based inhibitor system in October 1985. However, starting in November 1985, the tank was reportedly used as a holding tank for an unspecified period of time (Kearny, 1987).[2] As a holding tank, it received treated effluent from the Oil/Water Separator (Unit 4.4) prior to discharge of the treated effluent to the evaporation ponds.

Closure of the chromium treatment system was completed between December 1988 and March 1990. Physical removal of the chromate reduction tank occurred during Phase 2 of the hazardous waste management facilities closure process between November 1989 and March 1990 (Mittelhauser, 1990). In 1995, the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) issued a closure certification acceptance letter for this unit (DTSC, 1995). The steps taken during closure of the chromate reduction tank included:

- Removal of sludge and water in the tank for characterization and disposal of the materials as hazardous waste.
- Hydroblasting of the steel tank; the hydroblast water was containerized and properly disposed of as hazardous waste.
- Removal of the tank from the pit; inspection revealed that all the green sludge adhering to the tank could not be removed. The tank was disposed of as hazardous waste.
- Removal of the concrete footings. After determining that this concrete was non-hazardous, the concrete was used as fill material onsite.
- Removal of approximately 1 foot of soil over the entire floor and disposal of the soil as hazardous waste.
- A shallow trench was dug across floor of excavation for collection of confirmation samples.
- Removal of the wooden shoring from the excavation, backfilling with local (non-native) fill material, and final grading.

The confirmation samples were collected from the wall of the trench at one location at 0.5, 1.0, 1.5, and 5.0 feet below the bottom of the trench. Because the tank pit was originally 6 feet deep and another 1 foot of soil was removed during closure activities, actual sample depths from the trench were 7.5, 8, 8.5, and 12 feet below ground surface (bgs). These samples were analyzed for Title 22 metals, hexavalent chromium, fluoride, specific conductance, and pH. The closure report identified oil stained soil on the south wall of the excavation; however, no analysis for organic constituents was conducted.

2.0 Summary of Past Soil Characterization

Four historical subsurface soil samples (collected approximately 7.5, 8.0, 8.5, and 12.0 feet bgs) were collected from one location in the bottom of the tank excavation (CRT-4) in

---

[2] It is possible that the tank was used as holding tank up until October 1989 when the associated transfer sump was also removed from service.

SMWU 6, as shown in Figure B3-1. Historical soil samples were analyzed for antimony, arsenic, barium, beryllium, cadmium, total chromium, trivalent chromium, hexavalent chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, zinc, fluoride, and pH. Laboratory analytical results for the historical soil samples are presented in Table B3-1. Table B3-2 presents a statistical summary of soil analytical results for chemicals of potential concern (COPCs) that were either detected above the laboratory reporting limits or not detected and reporting limits for one or more samples was greater than the interim screening value. All historical data are considered Category 2.

Antimony, mercury, selenium, silver, and thallium were not detected in soil samples collected in SMWU 6. Table B3-1 lists the sixteen detected constituents. Only three of these constituents (total chromium, hexavalent chromium, and zinc) exceeded their respective background threshold values (BTVs). None of constituents exceeded the applicable commercial screening values (California human health screening levels for commercial use or United States Environmental Protection Agency Region 9 regional screening levels for commercial use). Fluoride ranged from 380 to 650 milligrams per kilogram (mg/kg); pH ranged from 8.42 to 10.01.

Hexavalent chromium and total chromium each exceeded their respective BTVs once. Hexavalent chromium was detected in one sample at concentration of 1 mg/kg (compared to the BTV of 0.83 mg/kg). Total chromium was detected in all four samples; the maximum detected concentration of 120 mg/kg exceeded the BTV (39.8 mg/kg). Detected zinc concentrations exceeded the BTV three times (maximum detected concentration of 96 mg/kg compared to the BTV of 58 mg/kg). These exceedances are only marginally above the BTV, and the overall concentration and distribution of constituents in the four samples indicate that there has been no adverse impact to soil beneath the former tank.

This unit was closed by DTSC in 1995. Subsequent to this closure, DTSC has requested that additional analysis be conducted for volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), and semivolatile organic compounds (SVOCs) in soil at SWMU 6 (DTSC, 2006). COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Section 3.0 provides the recommended sampling for this unit.

3.0 SWMU 6 Proposed Sampling

3.1 SMWU 6 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. SMWU 6 is located in Area 3 on the Topock Compressor Station Accessibility Map (Figure B-2). Twenty-three utility risers, including gas, odorant, waste water, electrical, SCADA, and an emergency shutoff device are located in Area 3. In addition, a utility trench, a cathodic protection anode, and three vaults were identified in Area 3. Photographs 60 through 61 in sub-Appendix B25 show the accessibility constraints in SMWU 6. Sample locations and depths identified for SMWU 6 take into account the identified access constraints. As described in the main text of Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

3.2 SMWU 6 Proposed Sampling

Although this unit was closed in 1995, additional sampling for organic COPCs and sampling of the fill used to backfill the excavation is proposed as required by DTSC. Table B3-2 summarizes the proposed SMWU 6 sample locations, depths, description/rationale for each location, and analytes. Proposed sample locations are also shown in Figure B3-2. The figure also shows proposed samples associated with nearby SWMUs and AOCs. The proposed SMWU 6 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at one location (SWMU 6-1). Because of numerous subsurface utilities and pipelines in the area, only hand tools can be used to collect samples in SWMU 6; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. If the area of sampling is covered with asphalt, the surface sampling interval will begin at the bottom of the asphalt or gravel sub-base. This sample location will be placed as close as possible to the center of the area that was excavated as part of the closure activity. All samples will be analyzed for Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and polycyclic aromatic hydrocarbons. As required by United States Department of the Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

APPENDIX B4

SWMU 8 Investigation Program

1.0 Introduction and Background

Solid Waste Management Unit (SWMU) 8 comprises the process pump tank that was part of the two-step wastewater treatment system and was located within the facility fence line on the southern end of the lower yard, shown in Figure B4-1. (All tables and figures appear at the end of this sub-appendix.) The process pump tank consisted of a 1,500-gallon-capacity steel holding tank about 8 feet high and 5.5 feet in diameter (PG&E, 1982; Kearny, 1987). The tank had an open top and was situated on a concrete pad. Before being reused in the hazardous waste treatment system, this tank was used in the Permutit water-softening process that operated at the facility until 1962. The area immediately around the tank was formerly unpaved. The station road is present to the east and south of this unit, and the former Water Conditioning Building (AOC 23) is located immediately to the north. SWMU 7 was located to the west of this unit. Currently, the fire pump building is located over the area formerly occupied by this SWMU. A small strip of gravel-covered soil is present between the station road and the fire pump building, and between the fire pump building and the former Water Conditioning Building.

The process pump tank was used as a temporary holding tank for treated wastewater discharged from the precipitation tank (SWMU 7; closed). Treated wastewater from this tank was sent to the former percolation bed (SWMU 1) from late 1969 to May 1970. From May 1970 to December 1973, effluent was discharged primarily to injection well PGE-08 (SWMU 2); however, after Pond 1 (part of SWMU 10) was constructed in late 1971, it also received some of the discharged wastewater. From December 1973 to October 1985, the effluent was discharged to the old evaporation ponds (SWMU 10). Chemical analysis data for wastewater held within the process pump tank are not available. No indication of a release was observed during a facility inspection performed as part of the Resource Conservation and Recovery Act facility assessment (Kearny, 1987).

The process pump tank was removed from service, along with the remainder of the two-step treatment system, in October 1985. Closure of the process pump tank was accomplished during Phase 1 closure activities performed from December 1988 through February 1989. A closure certification acceptance letter that included this SWMU was issued by the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) on June 26, 1995 (DTSC, 1995).The steps taken during closure of the process pump tank included:

- Hydroblasting of the steel tank; the hydroblast water was containerized and disposed of as hazardous waste.
- Removal of sludge from the tank and disposal of the sludge as hazardous waste.
- Removal of the tank from its foundation; the tank was cut up and recycled.

- Removal of the concrete foundation; this concrete was combined with the concrete from the Precipitation Tank (SWMU 7), for a total of about 30 cubic yards, and was disposed of as Class III waste.
- Collection of an initial round of confirmation samples.
- Soil removal after the initial confirmation samples indicated residual contamination (the volume of soil removed is estimated to have been about 0.25 cubic yard).
- Collection of final confirmation samples.
- Backfilling of the area with local (non-native) material and final grading.

Following removal of the tank, concrete foundation, and subsoils, and approximately 1.5 feet of contaminated soil, a trench was dug and samples were collected from the wall of the trench at 2 feet and 3 feet below the bottom of the excavation (which corresponds to approximately 4 and 5 feet below ground surface [bgs]). Locations for the confirmation samples were selected based upon the DTSC-approved *Closure Plan for the Hazardous Waste Management Facilities at the Topock Compressor Station* (Mittelhauser, 1986). The samples were analyzed for Title 22 metals, hexavalent chromium, fluoride, and soil pH. Previous sampling encountered bedrock at approximately 5 to 6 feet bgs at this site (Mittelhauser, 1990).

2.0 Summary of Past Soil Characterization

Two historical confirmation subsurface soil samples (4 and 5 feet bgs) were collected from one location (PPT-4) in SMWU 8, as shown in Figure B4-1. Historical soil samples were analyzed for antimony, arsenic, barium, beryllium, cadmium, total chromium, hexavalent chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, zinc, fluoride, and pH. Laboratory analytical results for the historical soil samples are presented in Table B4-1. Table B4-2 presents a statistical summary of soil analytical results for chemicals of potential concern (COPCs) that were either detected above the laboratory reporting limits or not detected and reporting limits for one or more samples was greater than the interim screening value. All historical data are considered Category 2.

Antimony, beryllium, hexavalent chromium, molybdenum, selenium, silver, and thallium were not detected in soil samples collected in SMWU 8. Table B4-1 lists the 13 detected constituents. Only three of these constituents (cobalt, copper, and nickel) exceeded their respective background threshold values (BTVs). None of constituents exceeded the applicable commercial screening values (California human health screening levels for commercial use, or United States Environmental Protection Agency Region 9 regional screening levels for commercial use). Cobalt, copper, and nickel each exceeded their respective BTVs once. The detected cobalt concentration of 13 milligrams per kilogram (mg/kg) exceeded the BTV of 12.7 mg/kg, copper was detected at 19 mg/kg (compared to the BTV of 16.8 mg/kg), and nickel was detected at concentration of 33 mg/kg (compared to the BTV of 27.3 mg/kg). These exceedances are only very marginally above the BTV, and the overall concentration and distribution of constituents in the two samples indicate that there has been no adverse impact to soil beneath the former tank.

This unit was closed by DTSC in 1995. Subsequent to this closure, DTSC has requested that additional analysis be conducted for (VOCs), total petroleum hydrocarbons (TPH), and semivolatile organic compounds (SVOCs) in soil at SWMU 8 (DTSC, 2006). COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Section 3.0 provides the recommended sampling for this unit.

3.0 SWMU 8 Proposed Sampling

3.1 SMWU 8 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. SMWU 8 is located in Area 15 on the Topock Compressor Station Accessibility Map (Figure B-2). Thirty-five utility risers, including gas, electrical, SCADA, and water lines are located in Area 3. In addition two cathodic protection anodes, and a vault were identified in Area 15. Sample locations and depths identified for SMWU 8 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less,

3.2 SMWU 8 Proposed Sampling

Although this unit was closed in 1995, additional sampling for organic COPCs and sampling of the fill used to backfill the excavation is proposed as required by DTSC. Table B4-3 summarizes the proposed SMWU 8 sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B4-2. The proposed SMWU 8 sample locations are Pacific Gas and Electric Company’s initial assessment of candidate locations for additional characterization. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at one location (SWMU8-1). Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in SWMU 8 therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. If the area of sampling is covered with concrete or asphalt, the surface sampling interval will begin at the bottom of the concrete/asphalt or gravel sub-base. In most cases, this first interval will be from 0.5 to 1 foot bgs. All samples will be analyzed for Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and polycyclic aromatic hydrocarbons. As required by the United States Department of the Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

APPENDIX B5

SWMU 9 Investigation Program

1.0 Introduction and Background

Solid Waste Management Unit (SWMU 9) comprises the transfer sump that was part of the two-step wastewater treatment system and was located within the facility fence line in the southern end of the lower yard, shown in Figure B5-1. (All tables and figures appear at the end of this sub-appendix.) The transfer sump was a pre-fabricated concrete septic tank with a capacity of 1,500 gallons (PG&E, 1982; Mittelhauser, 1990). The sump measured about 3 feet in diameter and 20 feet deep, of which 18.5 feet was set below grade. The sump was fitted with a concrete cover.

From 1969 to October 1985, effluent containing chromium from the chromate reduction tank (SWMU 6) was routed through SWMU 9 to the precipitation tank (SWMU 7; closed). In addition, a 3-inch-diameter steel pipe ran from the sludge-drying beds (SWMU 5) to the transfer sump (SWMU 9) to facilitate the removal of liquids from the sludge-drying beds (Mittelhauser, 1990). Sometime around 1974, SWMU 9 also started to receive treated effluent water from the oily water separator (either directly or through the chromate reduction tank) (Kearny, 1987). From November 1985 to October 1989, the transfer sump received non-hazardous (i.e., phosphate-based) cooling-water blowdown, and the effluent from the transfer sump was discharged directly to the old evaporation ponds (SWMU 10). Oily sludges and solids that accumulated in the transfer sump were periodically removed and transported to an offsite disposal facility (Kearny, 1987).

The transfer sump was removed from service in October 1989. Physical removal of the transfer sump occurred during Phase 2 of the hazardous waste management facilities closure process between November 1989 and March 1990 (Mittelhauser, 1990). In 1995, the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) issued a closure certification acceptance letter for this unit (DTSC, 1995).

The steps taken during closure of the transfer sump included:

- Removal of surface soil around the manhole of the sump that was visibly stained with oil; approximately 2 cubic feet of stained soil were removed and disposed of as hazardous waste.
- Removal of sludge and water in the sump followed by hydroblasting of the concrete sump; the sludge and hydroblast water was containerized and disposed of as a hazardous waste.
- Demolition of the sump in place; the concrete rubble was found to be non-hazardous and was used as fill onsite.

- Collection of a confirmation sample underneath the former tank location.
- Backfilling of the approximately 18.5-foot excavation with local material and final grading.

The confirmation sample was collected from the base of the excavation.

2.0 Summary of Past Soil Characterization

One historical subsurface soil sample, TS-3, was collected from one location directly beneath the former sump, as shown in Figure B5-1. The historical soil sample was collected at approximately 19 feet below ground surface (bgs) and was analyzed for antimony, arsenic, barium, beryllium, cadmium, total chromium, hexavalent chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, zinc, fluoride, and pH. Laboratory analytical results for the historical soil samples are presented in Table B5-1. Antimony, hexavalent cadmium, chromium, mercury, molybdenum, selenium, silver, and thallium were not detected in the sample. Beryllium was the only constituent detected at a concentration exceeding its background threshold value (BTV); the detected concentration of 1 mg/kg exceeds the BTV (0.672 milligrams per kilogram [mg/kg]). Fluoride was detected at 400 mg/kg, and the pH of the sample was 9.05. Based on the available information, no release occurred from the bottom of the tank. The historical data are considered Category 2.

This unit was closed by DTSC in 1995. Subsequent to the closure, DTSC has requested that additional analysis be conducted for volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), and semivolatile organic compounds (SVOCs) in soil at SWMU9 (DTSC, 2006). COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Section 3.0 provides the recommended sampling for this unit.

3.0 SMWU 9 Proposed Sampling

3.1 SMWU 9 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. SMWU 9 is located in Area 3 on the Topock Compressor Station Accessibility Map (Figure B-2). Twenty-three utility risers, including gas, odorant, waste water, electrical, SCADA, and an emergency shut-off device, are located in Area 3. In addition, a utility trench, a cathodic protection anode, and three vaults were identified in Area 3. Photograph 61 in sub-Appendix B25 show the accessibility constraints in SMWU 9. Sample locations and depths identified for SMWU 9 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils, which apply to depths easily sample using small hand tools. Generally, this infers a depth of 1 foot bgs or less

3.2 SMWU 9 Proposed Sampling

Although this unit was closed in 1995, additional sampling for organic COPCs and sampling of the fill used to backfill the excavation, is proposed as required by DTSC.

Table B5-2 summarizes the proposed SMWU 9 sample locations, depths, description/ rationale for each location, and analytes. Proposed sample locations are also shown in Figure B5-2. The proposed SMWU 9 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at one location (SWMU9-1). Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in SWMU 5; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. If the area of sampling is covered with asphalt, the surface sampling interval will begin at the bottom of the asphalt or gravel sub-base. This sample location will be placed as close as possible to the center of the area that was excavated as part of the closure activity. All samples will be analyzed for Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and polycyclic aromatic hydrocarbons. As required by the United States Department of the Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

APPENDIX B6

SWMU 11 Investigation Program

1.0 Introduction and Background

1.1 Background

Solid Waste Management Unit (SWMU) 11 consists of two 400-gallon sulfuric acid tanks, one tank is located at Cooling Tower A in Area of Concern (AOC) 5 and the other tank is located at Cooling Tower B in AOC 6. SWMU11 was incorporated into this Work Plan at the request of California Environmental Protection Agency, Department of Toxic Substances Control (DTSC, 2010). Sulfuric acid is and was used to control pH and minimize scaling in the cooling towers. The composition of the cooling water must be carefully maintained at optimal conditions to minimize the potential for scale, corrosion, and biological growth. As needed, an automatic controller adds sulfuric acid and other chemicals to maintain the proper conditions in the cooling water.

When the station first began operations, sulfuric acid was delivered to the facility in drums and pumped or dumped directly into the basins at the bottoms of the old cooling towers. The original tanks were unlined steel aboveground storage tanks with a capacity of 2,600 gallons each and were located within concrete secondary containment areas. The steel tanks were replaced with polyethylene-lined 400-gallon tanks in 1984. These tanks were located within the original epoxy-coated concrete contaminated structures.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for SMWU 11 based on the above site history and background, as shown in Figure B6-1. (All tables and figures appear at the end of this sub-appendix.) Table B6-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for SMWU 11. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011). The primary sources of contamination at SMWU 11 are likely to be historical incidental spills of sulfuric acid during transfer. The quantity of acid released, if any, is unknown but is expected to be relatively small, as any spills or incidental leaks would have quickly been addressed due to the inherent hazards of the acid. If a large release from the tank occurred, it could have resulted in acid reaching the storm drain system. Releases via the storm drain system are addressed by the storm drain investigation program described in Appendix D of the main report.

The primary source medium at SMWU 11 is surface soil. Because the majority of the area around the tanks is covered with gravel, liquids released in SMWU 11 would have been released to surface soil and would have infiltrated shallow soil. Acid released to soils could have solubilized metals in the soil matrix. Liquids released to shallow soils and metals solubilized from surface and shallow soils could also have infiltrated to deeper soils.

Because the entire SWMU is covered with gravel or pavement, runoff of contaminated surface soil in rainwater is not considered a potential migration pathway.

2.0 Summary of Past Soil Characterization

No data have been collected specifically to evaluate potential concerns associate with the sulfuric acid tanks; however, one surface soil sample (2 B-Tower) was collected in AOC 6 at 0 feet below ground surface (bgs) in the immediate vicinity of the sulfuric acid tank. This sample was analyzed for hexavalent chromium, total chromium, copper, nickel, and zinc. Hexavalent chromium was not detected, and nickel was only detected a concentration below its background threshold value (BTV). Total chromium, copper, and zinc were each detected at concentrations exceeding their BTVs. The detected total chromium concentration of 78 milligrams per kilogram (mg/kg) exceeds the BTV of 39.8 mg/kg, the detected copper concentration of 41 mg/kg exceeds the BTV of 16.8 mg/kg, and the detected zinc concentration (120 mg/kg) exceeds the BTV for zinc (58 mg/kg). All constituent concentrations are well below the applicable commercial screening levels (California human health screening levels for commercial use or United States Environmental Protection Agency Region 9 regional screening levels for commercial use).

3.0 SWMU 11 Data Gaps and Proposed Sampling

3.1 SMWU 11 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gaps identified for Decision 1 include:

1. Data Gap #1 – Lateral and vertical extent of contamination in area around the sulfuric acid tank in AOC 5.
2. Data Gap #2 – Lateral and vertical extent of contamination in area around the sulfuric acid tank in AOC 6.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include the following:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes polycyclic aromatic hydrocarbons, has been added to most soil samples collected within the fence line, this data gap has been addressed.
- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data

are required to characterize surface soils in unpaved areas to define locations with chemical of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data, and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 SMWU 11 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. SMWU 11 is located in Areas 6 and 9 on the Topock Compressor Station Accessibility Map (Figure B-2). Ninety-one utility risers, including main gas, cooling water, sulfuric acid, telecommunications, plant air, instrument air, water, and electrical lines, were identified in Area 6. Eighty-two utility risers, including main gas, gas, cooling water, sulfuric acid, electrical, and plant air lines, seven vaults, a SCADA cabinet, and two anodes were identified in Area 9. Photographs 4, 10, and 11 in sub-Appendix B25 show the accessibility constraints in SMWU 11. Sample locations and depths identified for SMWU 11 reflect the identified access constraints. As described in the main text of Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less

3.3 SMWU 11 Proposed Sampling

Table B6-2 summarizes the proposed SMWU 11 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figures B6-2 and B6-3. The figure also shows proposed sample locations for nearby AOCs. The proposed SMWU 11 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at seven locations: SWMU 11-1 through SWMU 11-7. Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. All samples will be analyzed for Title 22 metals, hexavalent chromium, and pH. As required by the United States Department of the Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite. In addition, soil samples collected for AOCs 5 and 6 will be used to assess this SWMU.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B6-2); the specific sample to be analyzed will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

APPENDIX B7

AOC 5 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of concern (AOC) 5 consists of the area surrounding original Cooling Tower A, as shown in Figure B7-1. (All tables and figures appear at the end of this sub-appendix.) The new Cooling Tower A is in the same location as the original Cooling Tower A. AOC 5 encompasses the cooling tower, the location of the former chemical shed, the sulfuric acid tank (now addressed separately as part of Solid Waste Management Unit 11 [SWMU 11]; further discussed in Appendix B6), and the current cooling water treatment chemical tanks, as well as the unpaved areas around the cooling tower. The majority of AOC 5 is unpaved (covered with gravel), but the area is bounded on all sides by pavement.

Operations in this area consist of the storage, handling, and use of cooling water additives. From 1951 to 1985, chromium-based corrosion inhibitors were used to treat the cooling water. From 1985 to the present, non-hazardous, phosphate-based inhibitors, scale control agents, and biocides have been used. The closed-loop systems were converted to a molybdenum-based corrosion protection system at about the same time. Sulfuric acid has been used from 1951 to the present to control the pH of the cooling water. The major features located in this AOC are discussed below.

Original Cooling Tower A: The original Cooling Tower A was a coil shed tower constructed along with the rest of the compressor station in 1951. The original tower was replaced with a new tower in 2001. The cooling tower is used to cool compressed natural gas and lubricating-oil cooling water. The original tower was located within a concrete water basin that held heated cooling water (a hotwell). The original basin still exists and was used as a foundation for the new tower, but the hotwell basin is no longer used for cooling water; the new tower is closed system. Wastewater samples collected from the cooling towers contained total chromium and hexavalent chromium ranging from 2.6 to 7.8 and 0.62 to 6.0 milligrams per liter, respectively (Mittelhauser, 1986).

Former Chemical Shed: The former chemical shed was located about 15 feet east of Cooling Tower A. The shed was used to store chromium-based cooling water additives used in the cooling tower from 1951 to 1985. The shed was demolished in the summer of 2000 as part of the replacement of Cooling Tower A. Stained soils beneath the former chemical storage shed were observed after its demolition (PG&E, 2000). The stained soils were reportedly limited to a small area of about 4 feet by 4 feet. The stained soil was excavated by the construction crew and hauled offsite. Confirmation soil samples were not collected. After removal, the area was backfilled with clean fill. As part of the new cooling tower construction, a reinforced concrete pad was built adjacent to the removal area, and a small portion of the area is covered with this pad.

Chemical Storage Tanks: There are three aboveground storage tanks at the southern end of the cooling tower that are used for the storage of the currently used cooling water treatment products. Two of the tanks are constructed of polyethylene and one is a stainless-steel tank; all tanks have secondary containment.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 5 based on the above site history and background, as shown in Figure B7-2. Table B7-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 5. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 5 are likely to be potential historical liquid discharges (spills) from the cooling tower hotwell (i.e., while the old cooling tower was in operation) and potentially incidental spills of cooling system additives during storage and/or transfer of the additive chemicals. The quantity of liquid released from the hotwell is unknown; however, periodic overflows are known to have occurred. The potential quantity of chemicals released in the vicinity of the storage shed is also unknown; however, is expected to be relatively small, as any spills or incidental leaks would have been small. If a large release from the hotwell occurred, it could have resulted in cooling water reaching the storm drain system and being discharged outside the fence line. Potential releases via the storm drain system are addressed by the storm drain investigation program described in Appendix D of this Work Plan.

Until 1985, cooling water blowdown containing hazardous constituents was discharged to the hazardous waste treatment system as part of routine operations. Potential leaks from the hazardous waste transference piping are addressed by the AOC 18 investigation program, and effects outside the fence line due to routine cooling water blowdown discharge are evaluated in AOC 1 and SWMU 1. Finally, while there is no information indicating that the concrete hotwells have lacked integrity in the past, it is possible that potential cracks are present and that small quantities of cooling water may have been released to shallow soil directly beneath the hotwell.

The primary source medium at AOC 5 is surface soil. Because the majority of the area around the cooling tower and former chemical shed is covered with gravel, liquids released in AOC 5 would have been released to surface soil and infiltrated shallow soil. Liquids released to shallow soils could have infiltrated to deeper soils. If present, organic constituents in surface soils could have been degraded by heat and light. Because the entire AOC is covered with gravel or pavement, runoff of contaminated surface soil in rainwater is not considered a potential migration pathway. Stained concrete has not been identified at this unit.

The normal operation of the cooling towers also included some loss of cooling water through evaporation and/or mist from the top of the tower; this phenomenon is known as drift. As discussed in the *Revised Final RCRA Investigation/Remedial Investigation Report, Volume 1 - Site Background and History, PG&E Topock Compressor Station, Needles, California*, drift accounts for an estimated 1 percent of total cooling water losses from a cooling tower. Chemicals released in drift could have affected concrete surfaces and surface soils in unpaved areas. In paved areas, any chemicals deposited from drift would ultimately have been discharged to storm drains via surface water runoff.

2.0 Summary of Past Soil Characterization

Five historical surface and shallow soil samples (0 and 3 feet below ground surface [bgs]) were collected from four locations (PS-13, PS-14, PS-15, and PS-16) in AOC 5, as shown in Figure B7-1. Historical soil samples were analyzed for five constituents: total chromium, hexavalent chromium, copper, nickel, and zinc. One sample (PS-16) was also analyzed for iron, manganese, and sulfates. Laboratory analytical results for the historical soil samples are presented in Tables B7-2 and B7-3. Table B7-4 presents a statistical summary of soil analytical results for chemicals of potential concern (COPCs) that were either detected above the laboratory reporting limits or not detected but where the reporting limits for one or more samples was greater than the interim screening value.

All historical data are considered Category 1 and were used as inputs to the five data quality objective decisions for AOC 5. As described in the main text of Appendix B, there is insufficient information to conduct a data gaps analysis for Decisions 3 and 4. Because the risk assessment will be conducted for the entire area within the fence line, the data gaps evaluation for Decision 2 was conducted for the entire area within the fence line as a whole. Decision 5 data gaps analysis was also conducted for the entire area within the fence line. The data gaps evaluation for Decision 2 through 5 is presented in the main text of this appendix, and additional sampling for these decisions, if necessary, are included in this sub-appendix.

All five constituents analyzed were detected in soil samples collected in AOC 5. Table B7-2 lists the five detected constituents. Iron, manganese, and sulfate were detected above laboratory reporting limits in the one sample (surface soil sample collected at PS-16) analyzed for these constituents. California human health screening levels (CHHSLs) for commercial use or United States Environmental Protection Agency Region 9 regional screening levels (RSLs) for soil have not been developed for sulfates. In addition, a Topock-specific background threshold value has not been developed for iron; however, the one detected concentration of iron was below the commercial screening level. Two of the remaining six constituents (manganese and nickel) were only detected at concentrations below their respective background threshold value (BTV). Four of these constituents (total chromium, hexavalent chromium, copper, and zinc) exceeded their respective backgrounds in at least one sample; however, all detected concentrations were below the respective CHHSLs for commercial use or RSLs for commercial use (collectively referred to as the commercial screening levels). The four constituents with concentrations above the BTVs are discussed below. In all cases, the lowest concentrations of detected constituents were found in the shallow soil sample.

3.0 AOC 5 Nature and Extent Data Gaps Evaluation

The following subsection discusses the nature and extent of detected COPCs detected above BTVs at AOC 5. As discussed in the main text of Appendix B, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Constituents that may require further evaluation are summarized in Section 3.5, and Section 4.0 of this sub-appendix provides the recommended sampling for this unit.

3.1 Total Chromium

Total chromium was detected in five of five soil samples collected at AOC 5. None of the detected concentrations of total chromium exceeded the commercial screening level (1,400 milligrams per kilogram [mg/kg]) (RSL), as shown in Tables B7-2 and B7-4 and Figure B7-1. Detected concentrations ranged from 8.4 mg/kg to 535 mg/kg. Concentrations in three of five samples exceeded the background concentration (39.8 mg/kg). The highest concentration was detected in a surface soil sample collected in the vicinity of the former chemical storage area at location PS-15; however, a concentration of 505 mg/kg was also detected at the northeast corner of the AOC at location PS-16. The total chromium concentration in the soil sample collected at 3 feet bgs at location PS-13 was well below background. The lateral extent of contamination has not been adequately delineated in the unpaved areas to the east, north, and west of the cooling tower and associated equipment, and the vertical extent of contamination has not been has not been defined.

3.2 Hexavalent Chromium

Hexavalent chromium was detected in four of five soil samples collected at AOC 5. It was not detected in the soil sample collected at 3 feet bgs. None of the detected concentrations of hexavalent chromium exceeded the commercial screening level (37 mg/kg) (CHHSL), as shown in Tables B7-2 and B7-4 and Figure B7-1. Three of the detected concentrations exceeded the background concentration (0.83 mg/kg). Detected concentrations ranged from 0.7 to 9.8 mg/kg. The lateral extent of contamination has not been adequately delineated in the unpaved areas to the east, north, and west of the cooling tower and associated equipment, and the vertical extent of contamination has not been has not been defined.

3.3 Copper

Copper was detected in five of five soil samples collected at AOC 5. None of the detected concentrations of copper exceeded the commercial screening level (38,000 mg/kg) (CHHSL), as shown in B7-2 and B7-4 and Figure B7-1. Three of the detected concentrations exceeded the background concentration (16.8 mg/kg). Detected concentrations ranged from 6.7 to 95.6 mg/kg. The lateral extent of contamination has not been fully delineated in the unpaved areas to the east, north, and west of the cooling tower and associated equipment, and the vertical extent of contamination has not been has not been defined.

3.4 Zinc

Zinc was detected in five of five soil samples collected at AOC 5. None of the detected concentrations of copper exceeded the commercial screening level (100,000 mg/kg)

(CHHSL), as shown in B7-2 and B7-4 and Figure B7-1. All five samples exceeded the background concentration (58 mg/kg). Detected concentrations ranged from 70.4 to 1,250 mg/kg. The lateral extent of contamination has not been fully delineated in the unpaved areas to the east, north, and west of the cooling tower and associated equipment, and the vertical extent of contamination has not been has not been defined.

3.5 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, a qualitative review of the historical data indicates that metals are present above background levels but are well below commercial screening levels in surface soil. No data have been collected for organic constituents. The number of samples and depths of samples collected to date are insufficient to adequately delineate the vertical and lateral extent of COPCs in this AOC.

4.0 AOC 5 Data Gaps and Proposed Sampling

Based on the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California*, data gaps were identified for Decision 1 include:

- Data Gap #1 – Lateral and vertical extent of contamination in the unpaved areas to the north, east, and west of the cooling tower.
- Data Gap #2 – Lateral and vertical extent of contamination near previous samples PS-13, PS-15, and PS-16.
- Data Gap #3 – Assess former chemical storage shed.
- Data Gap #4 – Vertical extent of contamination (if any) underneath the cooling towers.

Data gaps for Decisions 2 through 5 are discussed in the main text of Appendix B and include the following:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes polycyclic aromatic hydrocarbons, has been added to most soil samples collected within the fence line, this data gap has been addressed.
- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas and to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening

levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

4.1 AOC 5 Access Constraints

As discussed in Section 3.0 of the main text of Appendix B, there are substantial access constraints within the compressor station. AOC 5 is located in Area 9 (see Figure B-2). Eighty-two utility risers, including main gas, gas, cooling water, sulfuric acid, electrical, and plant air lines, seven vaults, a SCADA cabinet, and two anodes were identified in Area 9. Photographs 1 through 6 in sub-Appendix B25 show the accessibility constraints in AOC 5. The area beneath the cooling tower and portions of the area immediately adjacent to the cooling tower are considered inaccessible. Proposed sample locations and depths identified for AOC 5 reflect the identified access constraints. As described in the main text of Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

4.2 AOC 5 Proposed Sampling

Table B7-5 summarizes the proposed AOC 5 sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B7-3. The figure also shows proposed sample locations for surrounding SWMUs and AOCs. The proposed AOC 5 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for risk management and soil remediation.

Samples will be collected at six locations: AOC 5-1 through AOC 5-6. Because of limited access, only hand tools can be used to collect samples in AOC 5. Therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. All samples will be analyzed for Title 22 metals, hexavalent chromium, and pH. Ten percent of all samples collected during the investigation will also be analyzed for the full suite of United States Environmental Protection Agency Contract Laboratory Program Target Analyte List/Target Compound List. In addition, soil samples collected for SWMU 11 will be used to assess this AOC.

To address the data needs associated with Decision 5, two samples will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The samples have been tentatively identified (see Table B7-5); the specific samples to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in the main text of Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

AOC 6 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 6 includes the entire area surrounding Cooling Tower B, as shown in Figure B8-1. (All tables and figures appear at the end of this sub-appendix.) The new Cooling Tower B is in the same location as the original Cooling Tower B. The area encompasses the cooling tower, the location of the former chemical shed, the sulfuric acid tank (now addressed as part of Solid Waste Management Unit 11 (SWMU) 11, discussed further in sub-Appendix B6), and the current cooling water treatment chemical tanks. AOC 6 is largely unpaved (covered with gravel) but is bounded on all sides by pavement. A former employee stated that he had once observed cooling water from Cooling Tower B overflowing and discharging into the Northeast Ravine upstream of AOC 11 (Russell, 2006a).

Operations in this area consist of the storage, handling, and use of cooling water additives. Operations in this area began in 1954 with the construction of a two-cell cooling tower. From 1954 to 1985, chromium-based corrosion inhibitors were used to treat the cooling water. From 1985 to the present, non-hazardous, phosphate-based inhibitors, scale control agents, and biocides have been used. The closed-loop systems were converted to a molybdenum-based corrosion protection system at about the same time. Sulfuric acid has been used from 1954 to the present to control the pH of the cooling water. The major features located in this AOC are discussed below.

Original Cooling Tower B: The original Cooling Tower B was a coil shed tower constructed as a two-cell unit in 1954 to support the expansion of the compressor station. Cooling Tower B was subsequently expanded to a four-cell tower in 1958. The original tower was replaced with a new tower in 2002. The cooling tower is used to cool compressed natural gas and lubricating-oil cooling water. The original tower was located within a concrete water basin that held heated cooling water (i.e., a hotwell). The original hotwell basin still exists and is used as a foundation for the new tower, but the hotwell is no longer used for cooling water; the new tower operates as a closed system. Wastewater samples collected from the cooling towers contained total chromium and hexavalent chromium ranging from 2.6 to 7.8 and 0.62 to 6.0 milligrams per liter, respectively (Mittelhauser, 1986).

Former Chemical Shed: The former chemical shed was located approximately 15 feet east of Cooling Tower B. The shed was used to store the chromium-based cooling water additives used in the cooling tower from 1954 to 1985. The shed was demolished in the winter of 2001 in conjunction with the installation of the new cooling tower. Stained soil was observed beneath the shed following its removal. The stained soil was removed, generating five drums of material that were shipped offsite for disposal. The excavation was backfilled with clean soil. No confirmation samples were collected. As part of the new cooling tower construction, a reinforced concrete pad was built adjacent to the removal area, and a small portion of the area is covered with this pad.

Chemical Storage Tanks: There are currently three aboveground storage tanks located just east of the cooling tower that are used for the storage of cooling water treatment products. Two of the tanks are constructed of polyethylene; one is a stainless-steel tank; and all tanks have secondary containment.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 6 based on the above site history and background, as shown in Figure B8-2. Table B8-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 6. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 6 are likely to be potential historical liquid discharges (spills) from the cooling tower hotwell (i.e., while the old cooling tower was in operation) and potential incidental spills of cooling system additives during storage and/or transfer of the additive chemicals. The quantity of liquid released from the hotwell is unknown; however, periodic overflows are known to have occurred. The quantity of chemicals released in the vicinity of the storage shed is also unknown; however, is expected to be relatively small, as any spills or incidental leaks would have been small. If a large release from the hotwell occurred, it could have resulted in cooling water reaching the storm drain system and being discharged outside the fence line, most likely to AOC 11. In addition, if large quantities of cooling water overflowed, they also could have migrated to the west to the station road and potentially down the station road to the lower yard. Potential releases via the storm drain system are addressed by the storm drain investigation program described in Appendix D of this Work Plan. Downslope impacts to the east are addressed by the investigation being conducted for AOC 11, and potential impacts to the lower yard are being addressed in AOC 13.

Until 1985, cooling water blowdown containing hazardous constituents was discharged to the hazardous waste treatment system as part of routine operations. Potential leaks from the hazardous waste transference piping are addressed by the AOC 18 investigation program, and effects outside the fence line due to routine cooling water blowdown discharge are evaluated in AOC 1 and SWMU 1. Finally, while there is no information indicating that the concrete hotwell lacked integrity in the past, it is possible that small fractures are present and that small quantities of cooling water may have been released to shallow soil directly beneath the hotwell.

The primary source medium at AOC 6 is surface soil. Because the majority of the area around the cooling tower and former chemical shed is covered with gravel, liquids released in AOC 6 would have been released to surface soil and would have infiltrated shallow soil. Liquids released to shallow soils could have infiltrated to deeper soils. If present, organic constituents in surface soils could have been degraded by heat and light. Because the entire AOC 6 is covered with gravel or pavement, runoff of contaminated surface soil in rainwater is not considered a potential migration pathway. Stained concrete has not been identified at this unit.

The normal operation of the cooling towers also included some loss of cooling water through evaporation and/or mist from the top of the tower; this phenomenon is known as drift. As discussed in the *Revised Final RCRA Investigation/Remedial Investigation Report, Volume 1 - Site Background and History, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2007), drift accounts for an estimated 1 percent of total cooling water losses from a cooling tower. Chemicals released in drift could have affected concrete surfaces and surface soils in unpaved areas. In paved areas, any chemicals deposited from drift would ultimately have been discharged to storm drains via surface water runoff.

2.0 Summary of Past Soil Characterization

Thirteen historical surface and shallow soil samples (10 surficial samples from 0 feet below ground surface [bgs], one sample from 1 foot bgs, and two samples from 3 feet bgs) were collected from 10 locations (2 B-Tower, 3 B-Tower, B-Tower SE standpipe, and PS-1 through PS-7) in AOC 6, as shown in Figure B8-1. Historical soil samples were analyzed for five constituents: total chromium, hexavalent chromium, copper, nickel, and zinc. Laboratory analytical results for the historical soil samples are presented in Table B8-2. Table B8-3 presents a statistical summary of soil analytical results for chemical of potential concern (COPCs) that were either detected above the laboratory reporting limits or not detected but where the reporting limits for one or more samples were greater than the interim screening value.

All historical data are considered Category 1 and were used as inputs to the five data quality objective decisions for AOC 6. As described in the main text of Appendix B, there is insufficient information to conduct a data gaps analysis for Decisions 3 and 4. Because the risk assessment will be conducted for the entire area within the fence line, the data gaps evaluation for Decision 2 was conducted for the entire area within the fence line as a whole. Decision 5 data gaps analysis was also conducted for the entire area within the fence line. The data gaps evaluation for Decision 2 through 5 is presented in the main text of Appendix B, and additional sampling for these decisions, if necessary, are included in this sub-appendix.

All five constituents analyzed were detected in soil samples collected in AOC 6. One constituent (nickel) was only detected at concentrations at or below its background concentration. The four remaining constituents detected at AOC 6 (chromium, hexavalent chromium, copper, and zinc) were detected at concentrations above the below their applicable commercial screening values (California human health screening levels [CHHSLs] for commercial use or United States Environmental Protection Agency Region 9 regional screening levels [RSLs] for commercial use).

Samples were collected around the perimeter of the cooling tower and associated equipment. Two locations were sampled in the area of the former chemical shed.

3.0 AOC 6 Nature and Extent Data Gaps Evaluation

The following subsection discusses the nature and extent of detected COPCs detected above interim screening levels at AOC 6. As discussed in the main text of Appendix B, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Constituents that may require further evaluation are summarized in Section 3.5, and Section 4.0 of this sub-appendix provides the recommended sampling for this unit.

3.1 Total Chromium

Total chromium was detected in 13 of 13 soil samples collected at AOC 6. None of the detected concentrations of total chromium exceeded the commercial screening level (1,400 milligrams per kilogram [mg/kg]) (RSL), as shown in Table B8-2 and Figure B8-1. Detected concentrations ranged from 4.9 mg/kg to 459 mg/kg. Concentrations in 12 of 13 samples exceeded the background concentration (39.8 mg/kg). The highest concentration was detected in the vicinity of the former chemical storage area; however, a concentration of 386 mg/kg was also detected on the west side of cooling tower at location PS-5. The total chromium concentration in the soil samples collected at 3 feet bgs was much lower than the surface soil sample from the same location. The lateral extent of contamination has not been adequately delineated in the unpaved areas to the east, west, and south of the cooling tower and associated equipment, and the vertical extent of contamination has not been has not been defined.

3.2 Hexavalent Chromium

Hexavalent chromium was detected in 8 of 13 soil samples collected at AOC 6. It was not detected in soil samples collected at 1 foot bgs. None of the detected concentrations of hexavalent chromium exceeded the commercial screening level (37 mg/kg) (CHHSL), as shown in Table B8-2 and Figure B8-1. All eight detected concentrations exceeded the background concentration (0.83 mg/kg). Detected concentrations ranged from 1.3 to 15.3 mg/kg (at PS-6 in the area of the former chemical storage shed). The lateral extent of contamination has not been adequately delineated in the unpaved areas to the west and south of the cooling tower and associated equipment, and the vertical extent of contamination has not been has not been defined.

3.3 Copper

Copper was detected in 13 of 13 soil samples collected at AOC 6. None of the detected concentrations of copper exceeded the commercial screening level (38,000 mg/kg) (CHHSL), as shown in Table B8-2 and Figure B8-1. Eleven of the detected concentrations exceeded the background concentration (16.8 mg/kg). Detected concentrations ranged from 9 to 211 mg/kg. The lateral extent of contamination has not been fully delineated in the unpaved areas to the east, west, and south of the cooling tower and associated equipment. While the near surface and shallow soil samples all contained lower concentrations of copper than the overlying surface soil samples, the vertical extent of contamination has not been has not been adequately defined.

3.4 Zinc

Zinc was detected in 13 of 13 soil samples collected at AOC 6. None of the detected concentrations of copper exceeded the commercial screening level (100,000 mg/kg) (CHHSL), as shown in Table B8-2 and Figure B8-1. Eleven of the detected concentrations exceeded the background concentration (58 mg/kg). Detected concentrations ranged from 31 to 1,130 mg/kg. The lateral extent of contamination has not been fully delineated in the unpaved areas to the east, west, and south of the cooling tower and associated equipment. While the near surface and shallow soil samples all contained lower concentrations of zinc than the overlying surface soil samples, the vertical extent of contamination has not been has not been adequately defined.

3.5 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review of the historical data indicates that metals are present above background levels but are well below commercial screening levels in surface soil. No data have been collected for organic constituents. The number of samples and depths of samples collected to date are insufficient to adequately delineate the vertical and lateral extent of COPCs in this AOC.

4.0 AOC 6 Data Gaps and Proposed Sampling

Based on the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California*, data gaps were identified for Decision 1 including:

- Data Gap #1 - Lateral and vertical extent of contamination in the unpaved area to the north, east, west, and south of the cooling tower.
- Data Gap #2 - Lateral and vertical extent of contamination near existing sample locations PS-1 and PS-4.
- Data Gap #3 – Assess soil in vicinity of former chemical storage shed.
- Data Gap #4 - Vertical extent of contamination (if any) underneath the cooling tower.

Data gaps for Decisions 2 through 5 are discussed in the main text of Appendix B and include the following:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes polycyclic aromatic hydrocarbons, has been added to most soil samples collected within the fence line, this data gap has been addressed.
- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas and to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.
- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data, and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

4.1 AOC 6 Access Constraints

As discussed in Section 3.0 of the main text of Appendix B, there are substantial access constraints within the compressor station. AOC 6 is located in Area 6 (see Figure B-2). Ninety-one utility risers, including main gas, cooling water, sulfuric acid, telecommunications, plant air, instrument air, water, and electrical lines were identified in Area 6. Photographs 7 through 11 in sub-Appendix B25 show the accessibility constraints in AOC 6. The area beneath the cooling tower and portions of the area immediately adjacent to the cooling tower are considered inaccessible. Proposed sample locations and depths identified for AOC 6 reflect the identified access constraints. As described in the main text of Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

4.2 AOC 6 Proposed Sampling

Table B8-4 summarizes the proposed AOC 6 sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B8-3. The figure also shows proposed sample locations for surrounding SWMUs and AOCs. The proposed AOC 6 sample locations are Pacific Gas and Electric's initial assessment of accessible, candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for risk management and soil remediation.

Samples will be collected at six locations: AOC 6-1 through AOC 6-6. Because of limited access, only hand tools can be used to collect samples in AOC 6. Therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. All samples will be analyzed for Title 22 metals, hexavalent chromium, and pH. Ten percent of all samples collected during this investigation will also be analyzed for the full suite of the United States Environmental Protection Agency Contract Laboratory

Program Target Analyte List/Target Compound List. In addition, soil samples collected for SWMU 11 will be used to assess this AOC.

To address the data needs associated with Decision 5, two samples will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The samples have been tentatively identified (see Table B8-4); the specific samples to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in the main text of Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

AOC 7 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 7 consists of a hazardous materials storage building and loading dock located in the southeastern portion of the facility, inside the facility fence line, as shown in Figure B9-1. (All tables and figures appear at the end of this sub-appendix.) At the request of California Environmental Protection Agency, Department of Toxic Substances Control (DTSC, 2010), the footprint of this AOC was expanded to include the adjacent building (the Carpenter Shop). The building currently used as the Carpenter Shop is visible in the 1955 aerial photographs of the facility provided in the *Revised Final RCRA Investigation/Remedial Investigation Report, Volume 1 - Site Background and History, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2007). Materials appear to be stored immediately in front of this building in areas that were then unpaved (these areas are now paved). Currently, pavement is present to the west of AOC 7. Other maintenance shops are present to the north. The area to the north was historically open and unpaved. The area to east (behind AOC 7 and the facility fence line) is unpaved and may have been periodically used for storage. To the south, AOC 7 abuts a retaining wall; the soil surface is approximately 0.5 foot higher than the floor of the hazardous materials storage area.

A portion of the hazardous materials storage area is concrete-lined and is equipped with secondary containment walls. It serves as the storage area for hazardous wastes generated at the facility (e.g., oily rags, used oil filters, etc.). The hazardous materials storage area has been used for the collection and storage of hazardous materials since at least the early to mid 1980s (Riddle, 2004). The area is also used to store chemical products used at the compressor station (e.g., lubricants, parts-cleaning compounds, and small quantities of solvents). The largest typical container size is a 55-gallon drum. This area has apparently always been used for chemical storage (Riddle, 2004), although the types of chemicals stored are unknown. A roof was installed over the storage area during in the 1980s (Russell, 2006). Review of aerial photographs suggests that this area was open and unpaved until at least the mid-1950s.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 7 based on the above site history and background, as shown in Figure B9-2. Table B9-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 7. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2010).

The primary sources of contamination at AOC 7 are likely to be incidental spills of hazardous materials and/or waste during storage and/or transfer of the materials. The specific compounds released, if any, are unknown. The potential quantity of any chemicals released in AOC 7 are also unknown; however, is expected to be relatively small because the containers stored in this area are 55 gallons in capacity or smaller. Due to small quantity of materials that would have been released at any one time, it is not expected that the material would have migrated to any nearby storm drains; however, this potential migration pathway is included for completeness. Releases via the storm drain system are addressed by the storm drain investigation program described in Appendix D to the main report.

The primary source media at AOC 7 are pavement and surface soil. The majority of the area around AOC 7 is asphalt-paved or covered by concrete foundations; however, unpaved soils are present immediately to the east of this unit. Liquids released in AOC 7 would either have been released to pavement or to surface soil. From surface soils, materials could have infiltrated to shallow soil and subsurface soil. Some materials could potentially also have penetrated the asphalt paving. The concrete foundations in this area are quite thick, and it is unlikely that any materials migrated through the concrete. If any materials did penetrate either asphalt or concrete and reach surface soil, they could also have migrated into shallow soil. In the paved area, movement of contaminants with rainwater (i.e., infiltration) is not considered an existing pathway and any liquids released are unlikely to have migrated to subsurface soils. If present, organic constituents in surface soil or on pavement could have been degraded by heat and light. Runoff of contaminated surface soil in rainwater is a potential migration pathway from the eastern side of this AOC.

2.0 Summary of Past Soil Characterization

This AOC has not been previously sampled.

3.0 Area of Concern 7 Data Gaps and Proposed Sampling

3.1 AOC 7 Data Gaps

Based on the site conceptual model and Part B DQOs, the following data gap was identified for Decision 1, as follows:

1. Data Gap #1 – Lateral and vertical extent of contamination in the unpaved area to the east of this AOC and the asphalt paved area to the west of the AOC.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include the following:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound (SVOC) analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with chemical of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.
- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 AOC 7 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 7 is located in Area 16 on the Topock Compressor Station Accessibility Map (Figure B-2). Thirty-six utility risers, consisting of various water and electrical lines are present in this area. Photographs 12 and 13 in sub-Appendix B25 show the accessibility constraints in the AOC 7 and AOC 8 area. Sample locations and depths identified for AOC 7 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils depth of 1 foot below ground surface (bgs) or less.

3.3 AOC 7 Proposed Sampling

Table B9-2 summarizes the proposed AOC 7 sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B9-1. The figure also shows proposed sample locations for surrounding Solid Waste Management Units and AOCs. The proposed AOC 7 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization to fill the data gaps. The figure is provided to facilitate planning for additional sampling that may be needed to address data gaps, meet agency requirements, and define the need for soil remediation, if any.

The precise chemicals and hazardous wastes historically stored at this unit are unknown; however, it is likely that they were similar to the types of chemicals stored today (new and spent lubricants and other maintenance materials). Based on interviews with station personnel, weed and insect control is conducted by a contractor, so these materials are not stored onsite. Chemicals used in the cooling towers were stored in the chemical storage sheds by the cooling towers, and are currently stored in tanks located near the cooling towers. COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Samples from this area will be analyzed for Title 22 metals, hexavalent chromium, total petroleum hydrocarbons (TPH), SVOCs including PAHs, polychlorinated biphenyls (PCBs), volatile organic compounds (VOCs), and pH. Sampling for AOC 8 will also be used to assess AOC 7 since this unit is immediately adjacent. Ten percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List suite, as required by the United States Department of the Interior.

Samples will be collected at five locations: AOC 7-1 through AOC 7-5. Because of limited access and numerous subsurface utilities, only hand tools can be used to collect samples in AOC 7; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Where the area of sampling is covered with concrete or asphalt, the surface sampling interval will begin at the bottom of the concrete/asphalt or gravel sub-base. In most cases, this first interval will be from 0.5 to 1 foot below the pavement.

To address the data needs associated with Decision 5, one of the samples will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B9-2); the specific sample to be analyzed for these parameters will be confirmed in the field.

APPENDIX B10

AOC 8 Investigation Program

1.0 Introduction and Background

1.1 Background

A small storage locker used for paint storage is located in the southeastern portion of the facility, shown in Figure B10-1. (All tables and figures appear at the end of this sub-appendix.) The paint locker measures about 5 feet wide by 5 feet long and is set back into a niche constructed into the southern retaining wall in this portion of the compressor station. It is constructed of steel and is located on pavement. The area in front of the paint locker is also paved, and a small retaining wall is present on the sides and behind the paint locker because the ground surface around the locker rises approximately 2 to 3 feet. The locker has tight-fitting doors and was designed for fire-safe storage of flammable materials. Sub-Appendix B25 presents photos of Area of Concern (AOC) 8. AOC 7, the Hazardous Materials Storage Area, is located immediately to the east of AOC 8.

Large-scale painting activities at the compressor station are handled by subcontractors (Riddle, 2004). Therefore, only small quantities of paint and thinners used for minor touch-up work are stored in this shed. Paint is stored in both spray cans and in 1- to 5-gallon cans. Non-chlorinated paint thinners are also stored in 1-gallon cans. Approximately 100 gallons of paint and thinners can be stored in this shed, but the quantity is typically far less than 100-gallons. No evidence of any release is present in or around the shed.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 8 based on the above site history and background, as shown in Figure B10-2. Table B10-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 8. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

If contamination is found at AOC 8, the likely source would be incidental spills of paints and paint thinners (solvents) to pavement. There is no information indicating that any spills have occurred, and the maximum quantity likely to be released at any one time would be small (i.e., 5 gallons or less of paint; 1 gallon or less of thinners). Due to small quantity of materials that would have been released at any one time, it is highly unlikely that material would have migrated to any nearby storm drains; however, this potential migration pathway is included for completeness. Releases via the storm drain system are addressed by the storm drain investigation program described in Appendix D of the main report.

The primary source medium at AOC 8 is pavement. Because the majority of the area around the paint locker is asphalt-paved, liquids released in AOC 8 would have been released to pavement and potentially from there to surface soil. If any materials did penetrate the pavement and reach surface soil, they could also have migrated into shallow soil. Because the area is paved, movement of contaminants with rainwater (i.e., infiltration) is not considered an existing pathway, and any liquids released are unlikely to have migrated to deeper soils. If present, organic constituents in pavement could have been degraded by heat and light. Because the entire AOC likely to have been affected by spills is covered with pavement, runoff of contaminated surface soil in rainwater is not considered a potential migration pathway.

2.0 Summary of Past Soil Characterization

This AOC has not been previously sampled.

3.0 AOC 8 Data Gaps and Proposed Sampling

3.1 AOC 8 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gap was identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination north and northwest of the paint locker.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound (SVOC) analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with chemical of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 AOC 8 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 8 is located in Area 16 on the Topock Compressor Station Accessibility Map (Figure B-2). Thirty-six utility risers, consisting of various water and electrical lines are present in this area. Photograph 14 in sub-Appendix B25 show the accessibility constraints in AOC 8. Sample locations and depths identified for AOC 8 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot below ground surface (bgs) or less.

3.3 AOC 8 Proposed Sampling

Table B10-2 summarizes the proposed AOC 8 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B10-1. The proposed AOC 8 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization to fill the data gaps. The figure is provided to facilitate planning for additional sampling that may be needed to address data gaps, meet agency requirements, and define the need for soil remediation, if any.

It is likely that paints contained within the locker have consisted of oil-based and water-based paints. Thinners are believed to have consisted of non-chlorinated thinners. Based on this information, COPCs for soil associated with AOC 8 consist of volatile organic compounds (VOCs) and total petroleum hydrocarbons (TPH). COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Samples from this area will be analyzed for Title 22 metals, TPH, and VOCs. Sampling for AOC 7 will also be used to assess AOC 8 since this unit is immediately adjacent. Ten percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List suite, as required by the United States Department of the Interior.

Samples will be collected at two locations: AOC 8-1 and AOC 8-2. Because of limited access and numerous subsurface utilities, only hand tools can be used to collect samples in AOC 8; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Where the area of sampling is covered with concrete or asphalt, the surface sampling interval will begin at the bottom of the concrete/ asphalt or gravel sub-base. In most cases, this first interval will be from 0.5 to 1 foot below the pavement.

To address the data needs associated with Decision 5, one of the samples will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B10-2); the specific sample to be analyzed for these parameters will be confirmed in the field.

APPENDIX B11

AOC 13 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 13 consists of current and formerly unpaved areas within the fence line of the compressor station. These areas may have been impacted incidentally as a result of facility activities. In addition, former employees have reported, and existing documentation suggests, that pipeline liquids and/or waste oil were sprayed on station roads for dust control (PG&E, 1980; Russell, 2006). Some dark staining is visible in the May 1955 aerial photographs (CH2M HILL, 2007). In addition, incidental staining is visible in the lower yard in construction photographs taken in the early 1950s. Currently, the unpaved areas are located in various strips and patches among buildings and structures on this active facility. The majority of the unpaved areas within the fence line lie within the lower yard on the west side of the facility, shown in Figure B11-1. (All tables and figures appear at the end of this sub-appendix.) Formerly unpaved areas that are now paved or covered by buildings include much of the upper yard, including most of the area east of the main station buildings (i.e., east of the Compressor and Auxiliary Buildings). Ecology and Environment, Inc. identified numerous subareas within AOC 13; however, given that stormwater runoff is likely to have traversed various areas, pipeline liquids could have been sprayed in various areas, and potential spills of cooling water could have occurred in various areas, AOC 13 will be addressed as one unit across the entire station.

Eight spills that have occurred at the Topock facility are associated with AOC 13. Confirmation sample results from these spills are included in Tables B11-1 through B11-7. All spill sample results contain the word 'spill' and the date of the spill in the location column of the associated tables. Detailed information regarding each of these spills is presented in the *Revised Final RCRA Investigation/Remedial Investigation Report, Volume 1 - Site Background and History, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2007).

1.2 Conceptual Site Model

Table B11-8 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 13. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 13 are likely to be historical incidental spills of lubricants and pipeline liquids, cooling water, and wastewater. The quantity of liquid released to unpaved areas of the compressor station is unknown; however, overflows from some of the equipment on the station are known to have occurred in past. While spills that occurred in recent years have been cleaned up; no information is available regarding the cleanups of any historical spills.

The primary source medium at AOC 13 is surface soil. Because areas comprising AOC 13 either are or historically were unpaved, liquids released in AOC 13 would have been released to surface soil and would have infiltrated shallow soil. Liquids released to shallow soils could have infiltrated to deeper soils. If present, organic constituents in surface soils could have been degraded by heat and light. During high rainfall events, chemicals contained in currently unpaved portions of AOC 13 could also reach the storm drain system and/or runoff in sheet flow. Releases to areas outside the fence line via the storm drain system are addressed by the storm drain investigation program described in Appendix D of the main report.

2.0 Summary of Past Soil Characterization

AOC 13 comprises a large area, and multiple investigations have occurred within the unit. Investigations include samples designed to help establish background concentrations (Mittelhauser, 1986),[1] spill cleanup confirmation samples, sampling to evaluate potential petroleum releases from the former oil bath filters, and samples collected during the installation of various utility trenches. Some past sampling has been within the unpaved areas adjacent to the industrial buildings and equipment where the greatest potential for contamination exists; however, the majority of these data are considered data quality Category 3. One hundred fifty-five historical soil samples, ranging in depth from 0 to 13 feet below ground surface (bgs), were collected from 124 locations in AOC 13, as shown in Figures B11-1 through B11-4.. Historical soil samples were analyzed for Title 22 metals, hexavalent chromium, volatile organic compounds (VOCs); benzene, toluene, etheylbenzene, and xylene (BTEX); polycyclic aromatic hydrocarbons (PAHs); polychlorinated biphenyls (PCBs); total petroleum hydrocarbons (TPH); total recoverable petroleum hydrocarbons; oil and grease; chloride; fluoride; sulfate; and pH.

Forty-nine constituents, including one calculated quantity (benzo(a)pyrene equivalents), were detected in AOC 13. The detected constituents included:

- Twenty-one metals (antimony, arsenic, barium, beryllium, cadmium, total chromium, hexavalent chromium, cobalt, copper, iron, lead, manganese, total mercury, dissolved mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, and zinc)
- Fluoride
- Chloride
- Sulfates
- Fourteen PAHs (acenaphthene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene,

---

[1] Because these samples were collected within the fence line of the compressor station, they were removed from the background data set used for the Part A and B soil investigations.

dibenz(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, pyrene, and benzo(a)pyrene equivalent)

- Five VOCs (acetone, chloroform, methylene chloride, toluene, and total xylenes)Six TPH-range compounds (TPH-gasoline, TPH-diesel, TPH-motor-oil, total recoverable hydrocarbons, oil and grease, and heavy oil [>C_{34}])
- Benzo(a)pyrene equivalents

Laboratory analytical results for the historical soil samples are presented in Tables B11-1 through B11-7. Table B11-9 presents a statistical summary of soil analytical results for chemicals of potential concern (COPCs) that were either detected above the laboratory reporting limits or not detected and reporting limits for one or more samples was greater than the interim screening value.

Historical data Category 1 and 2 data were used as inputs to Decision 1; only Category 1 data were used as inputs for Decision 2. As described in Appendix B, there is insufficient information to conduct a data gaps analysis for Decisions 3 and 4. Because the risk assessment will be conducted for the entire area within the fence line, the data gaps evaluation for Decision 2 was conducted for the entire area within the fence line as a whole. Decision 5 data gaps analysis was also conducted for the entire area within the fence line. The data gaps evaluation for Decision 2 through 5 is presented in the main text of this sub-appendix, and additional sampling for these decisions, if necessary, are included in this sub-appendix. Section 3.0 presents the Decision 1 data gaps evaluation for AOC 13.

Eleven metals (beryllium, cadmium, total chromium, hexavalent chromium, cobalt, copper, lead, molybdenum, nickel, selenium, and zinc) were detected at concentrations exceeding their respective background threshold values (BTV). Lead was the only metal detected at a concentration that exceeded the respective California human health screening level for commercial use or United States Environmental Protection Agency Region 9 regional screening levels for commercial use (collectively referred to as the commercial screening levels). With the exception of lead, all metals data are Category 1 or 2.

Benzo(a)pyrene exceeded its commercial screening level of 130 micrograms per kilogram (µg/kg) in one sample (210 µg/kg); consequently, benzo(a)pyrene equivalents also exceeded the screening level in two samples. All PAH data are Category 1. Finally, three TPH compounds (TPH-gasoline, TPH-diesel, and TPH-motor-oil) were detected at concentrations exceeding their respective California Regional Water Quality Control Board environmental screening level (ESLs). These TPH data include Category 1 through 3 data.

Some of the data collected for other units at the compressor station are also pertinent to AOC 13, including data from Solid Waste Management Unit (SWMU) 5 (EDB-4, EDB-5, WDB-4, and WDB-5 samples; Table B2-1),[2] Unit 4.3 through Unit 4.5 (all five samples; Table B24-1), AOC 16 (two samples; Table B13-2), and AOC 18 (all samples; Table B15-2).

---

[2] Although the data associated with SWMUs 6 and 9 were also collected from unpaved areas, they were collected at depth (approximately 7 feet bgs and 18.5 feet bgs, respectively) and are thus not representative of the general conditions associated with AOC 13. Impacts to AOC 13 would have been associated with releases to the surface of the compressor station. The samples associated with these two SWMUs evaluated concentrations associated with releases at depth.

3.0 AOC 13 Nature and Extent Data Gaps Evaluation

The following subsection discusses the nature and extent of detected COPCs and chemicals of potential ecological concern detected above interim screening levels at AOC 13. As discussed in Appendix B, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Constituents that may require further evaluation are summarized in Section 3.16, and Section 4.0 of this sub-appendix provides the recommended sampling for this unit.

3.1 Beryllium

Beryllium was detected in one of 24 Category 1 samples and eight of 25 Category 2 samples. Detected concentrations of beryllium in soil ranged from 0.5 to 1 milligrams per kilograms (mg/kg), as shown in Table B11-1. The concentrations of beryllium in three samples were above the BTV (0.672 mg/kg), but all concentrations were below commercial screening levels.

While the total number of samples with beryllium data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of beryllium concentrations exceeding the screening level have not been defined.

3.2 Cadmium

Cadmium was detected in four of 24 Category 1 samples and 10 of 25 Category 2 samples. Detected concentrations of cadmium in soil ranged from 0.5 to 14 mg/kg, as shown in Table B11-1. The concentrations of cadmium in two samples were above the BTV (1.1 mg/kg).

While the total number of samples with cadmium data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of cadmium concentrations exceeding the screening level have not been defined.

3.3 Hexavalent Chromium

Hexavalent chromium was detected in 11 of 35 Category 1 samples and 0 of 17 Category 2 samples. Detected concentrations of hexavalent chromium in soil ranged from 0.48 to 12.2 mg/kg, as shown in Table B11-1 and Figures B11-1 and B11-2. The concentrations of hexavalent chromium in seven samples were above the BTV (0.83 mg/kg), but all concentrations were below commercial screening levels.

While the total number of samples with hexavalent chromium data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of hexavalent chromium concentrations exceeding the screening level have not been defined.

3.4 Total Chromium

Total chromium was detected in 35 of 35 Category 1 samples and 24 of 25 Category 2 samples. Detected concentrations of total chromium in soil ranged from 3.1 to 743 mg/kg, as shown in Table B11-1 and Figures B11-1 and B11-2. The concentrations of total chromium in nine samples were above the BTV (39.8 mg/kg), but all concentrations were below commercial screening levels.

While the total number of samples with total chromium data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of total chromium concentrations exceeding the screening level have not been defined.

3.5 Cobalt

Cobalt was detected in 20 of 24 Category 1 samples and 25 of 25 Category 2 samples. Detected concentrations of cobalt in soil ranged from 1.2 to 18 mg/kg, as shown in Table B11-1. The concentrations of cobalt in three samples were above the BTV (12.7 mg/kg), but all concentrations were below commercial screening levels.

While the total number of samples with cobalt data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of cobalt concentrations exceeding the screening level have not been defined.

3.6 Copper

Copper was detected in 35 of 35 Category 1 samples and 10 of 25 Category 2 samples. Detected concentrations of copper in soil ranged from 1.7 to 760 mg/kg, as shown in Table B11-1and Figures B11-1 and B11-2. The concentrations of copper in 25 samples were above the BTV (16.8 mg/kg), but all concentrations were below commercial screening levels.

While the total number of samples with copper data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of copper concentrations exceeding the screening level have not been defined.

3.7 Lead

Lead was detected in 24 of 24 Category 1 samples and 25 of 25 Category 2 samples. Detected concentrations of lead in soil ranged from 2.2 to 330 mg/kg, as shown in Table B11-1 and Figures B11-1 and B11-2. The concentrations of lead in 17 Category 1 and 2 samples combined were above the BTV (8.39 mg/kg); one sample was detected at a concentration above the commercial screening level (320 mg/kg).

While the total number of samples with lead data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of lead concentrations exceeding the screening level have not been defined.

3.8 Mercury

Mercury was detected in two of 24 Category 1 samples and 42 of 42 Category 2 samples. Detected concentrations of mercury in soil ranged from 0.008 to 3.4 mg/kg, as shown in Table B11-1. No BTV is available for mercury; however, the concentrations of mercury were below the commercial screening levels.

While the total number of samples with mercury data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of mercury concentrations exceeding the screening level have not been defined.

3.9 Molybdenum

Molybdenum was detected in seven of 24 Category 1 samples and nine of 25 Category 2 samples. Detected concentrations of molybdenum in soil ranged from 0.6 to 16 mg/kg, as shown in Table B11-1. The concentrations of molybdenum in 13 samples were above the BTV (1.37 mg/kg), but all concentrations were below commercial screening levels.

While the total number of samples with molybdenum data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of molybdenum concentrations exceeding the screening level have not been defined.

3.10 Nickel

Nickel was detected in 35 of 35 Category 1 samples and 25 of 25 Category 2 samples. Detected concentrations of nickel in soil ranged from 2.1 to 56 mg/kg, as shown in Table B11-1 and Figures B11-1 and B11-2. The concentrations of nickel in five samples were above the BTV (27.3 mg/kg), but all concentrations were below the commercial screening levels.

While the total number of samples with nickel data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of nickel concentrations exceeding the screening level have not been defined.

3.11 Selenium

Selenium was detected in 6 of 24 Category 1 samples and 9 of 25 Category 2 samples. Detected concentrations of zinc in soil ranged from 0.5 to 3 mg/kg, as shown in Table B11-1 and Figures B11-1 and B11-2. The concentrations of selenium in four samples were above the BTV (1.47 mg/kg), but all concentrations were below commercial screening levels.

While the total number of samples with zinc data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of zinc concentrations exceeding the screening level have not been defined.

3.12 Zinc

Zinc was detected in 35 of 35 Category 1 samples and 25 of 25 Category 2 samples. Detected concentrations of zinc in soil ranged from 3.4 to 315 mg/kg, as shown in Table B11-1 and Figures B11-1 and B11-2. The concentrations of zinc in 22 samples were above the BTV (58 mg/kg), but all concentrations were below commercial screening levels.

While the total number of samples with zinc data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of zinc concentrations exceeding the screening level have not been defined.

3.13 Benzo(a)pyrene

Benzo(a)pyrene was detected in six of 24 Category 1 samples. Detected concentrations of benzo(a)pyrene in soil ranged from 28 to 210 µg/kg, and detected concentrations of benzo(a)pyrene equivalents in soil ranged from 5.0 to 320 µg/kg, as shown in Table B11-3 and Figure B11-3. The concentration of benzo(a)pyrene in one surface soil sample collected at PGE-LT8 was above the commercial California human health screening level (130 µg/kg).

The concentration of calculated benzo(a)pyrene equivalents in two surface soil samples (Grab1 and PGE-LT8) was above the commercial California human health screening level (130 µg/kg).

The total number of samples with PAH data is relatively limited. The lateral and vertical extent of benzo(a)pyrene and benzo(a)pyrene equivalents concentrations exceeding the screening levels have not been defined.

3.14 TPH-diesel

TPH-diesel was detected in seven of 24 Category 1 samples and 0 of 12 Category 2 samples. Detected concentrations of TPH-diesel in soil ranged from 13 to 120 mg/kg, as shown in Table B11-4 and Figures B11-3 and B11-4. None of the concentrations of TPH-diesel were above the ESL (540 mg/kg).

While the total number of samples with TPH-diesel data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of TPH-diesel concentrations exceeding the screening level have not been defined.

3.15 TPH-motor-oil and Heavier Hydrocarbons

TPH-motor oil was detected in 12 of 24 Category 1 samples and 11 of 12 Category 2 samples. Detected concentrations of TPH-motor-oil in soil ranged from 14 to 240,000 mg/kg, as shown in Table B11-4 and Figures B11-3 and B11-4. The concentrations of TPH-motor-oil in 10 samples were above the ESL (1,800 mg/kg).

While the total number of samples with TPH-motor-oil data is extensive, the distribution of sample points is relatively localized. The lateral and vertical extents of TPH-motor-oil concentrations exceeding the screening level have not been defined.

Oil and grease by United States Environmental Protection Agency Method 418.1 was also analyzed for 18 Category 2 samples. However, there are no screening levels for oil and grease.

3.16 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review of the historical data indicates that the lateral and vertical extents of the 10 metals discussed above, benzo(a)pyrene, and TPH (gasoline, diesel, and motor oil) have not been defined. In addition, PCB data are limited, and the majority of the samples collected have high detection limits. Although there are no known current exposure pathways for the formerly unpaved areas that are now covered by buildings and pavement, the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) has requested that these areas also be investigated as part of the current sampling program.

4.0 AOC 13 Data Gaps and Proposed Sampling

4.1 AOC 13 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gaps were identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of COPCs.
2. Data Gap #2 – Potential impacts associated with surface soil discoloration in historical aerial photographs.
3. Data Gap #3 – Potential impacts from potential burn area near AOC 17.

DTSC has also requested that soil at select locations around the perimeter of the compressor station be characterized to assess if COPCs may have migrated offsite. Appendix C describes the Perimeter Area monitoring program. Perimeter sample locations were identified during the October 18, 2007 agency site reconnaissance walk. Perimeter samples were located based on visual observations of potential impacts on slopes around the station and also in areas where surface or storm water discharged.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of PAHs in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound (SVOC) analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.
- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.
- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

4.2 AOC 13 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. Portions of AOC 13 are located in most areas of the compressor station (Figure B-2), and access constraints are present throughout most of these areas. Photographs 15 and 16 sub-Appendix B25 show the accessibility constraints in AOC 13. Sample locations and depths identified for AOC 13 reflect the identified access constraints and will be modified. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

4.3 AOC 13 Proposed Sampling

Table B11-10 summarizes the proposed AOC 13 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B11-5. The proposed sample locations for all SWMUs, AOCs, and units within the fence line, Perimeter Area, Storm Drain Investigation, and Part A Phase 2 Investigation have also been included on the figure. The proposed AOC 13 sample locations are Pacific Gas and Electric Company’s initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Soil samples will be collected at the locations shown on Figure B11-5 and are summarized on Table B11-10. Sampling will be in both the currently paved (formerly unpaved) and currently unpaved areas. Sample locations were initially identified using an approximate grid spacing of 100 feet. Samples locations were added or adjusted to address specific concerns identified in the unpaved areas of the compressor, including historical staining identified in photographs, and the potential burn area. Samples were located to ensure adequate coverage of the paved and unpaved areas.

Samples will be collected at 34 locations (AOC 13-1 through AOC 13-34), including two former Perimeter Area sample locations actually located on the slope between the upper and lower yards (former samples AOC13-39 and AOC13-40) that were added and integrated into the overall AOC 13 sampling program. Because of limited access, numerous subsurface utilities and pipelines, and proximity to operational structures, only hand tools can be used to collect samples in AOC 13. Therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Where the area of sampling is covered with concrete or asphalt, the surface sampling interval will begin 6 inches below the bottom of the concrete/asphalt or gravel sub-base. All samples will be analyzed for Title 22 metals, hexavalent chromium, TPH, VOCs, SVOCs, including PAHs, PCBs, and asbestos. Dioxin and furan analysis will be added to proposed sample location near the potential burn area (AOC13-17). As required by United States Department of the Interior, 10 percent of all samples collected during this investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite. In addition, data from various other AOCs, including AOCs 17, 18, 20, 21, 22, and 24 will be used to assess AOC 13.

To address the data needs associated with Decision 5, two samples will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The samples have been tentatively identified (see Table B11-10); the specific samples to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

Notes:

1 Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used.
2 RWQCB. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.
3 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.
4 Commercial screening level is below background value; therefore, arsenic results are only screened against the background value.
Results greater than or equal to the Background value are bolded. Results greater than or equal to the Commercial Screening level or RWQCB ESL are circled.
NE = not established
USEPA = United States Environmental Protection Agency
DTSC = California Department of Toxic Substances Control
RWQCB = California Regional Water Quality Control Board
CHHSL = California human health screening levels
-- = not analyzed
FD = Field Duplicate
ft bgs = feet below ground surface
J = concentration or reporting limit estimated by laboratory or data validation
mg/kg = milligrams per kilogram
N = Primary Sample
ND = not detected at the listed reporting limit

TABLE B11-3

Sample Results: Polycyclic Aromatic Hydrocarbons
Area of Concern 13 - Unpaved Areas within the Compressor Station Investigation Program
Soil Investigation Part B Phase 1 Work Plan
Pacific Gas and Electric Company Topock Compressor Station Needles, California

Notes:

1 Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used.
2 RWQCB. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.
3 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

Results greater than or equal to the Background value are bolded. Results greater than or equal to the Commercial Screening level or RWQCB ESL are circled.

NE = not established
USEPA = United States Environmental Protection Agency
DTSC = California Department of Toxic Substances Control
RWQCB = California Regional Water Quality Control Board
CHHSL = California human health screening levels

Calculations:

BaP equivalent = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all PAHs are nondetect, the final qualifier code is U.
PAHLow = Sum of Result of low molecular weight PAHs, zero is used for nondetect values.
PAHHigh= Sum of Result of high molecular weight PAHs, zero is used for nondetect values.
-- = not analyzed
µg/kg = micrograms per kilogram
FD = Field Duplicate
ft bgs = feet below ground surface
J = concentration or reporting limit estimated by laboratory or data validation
N = Primary Sample
ND = not detected at the listed reporting limit

TABLE B11-5

Sample Results: General Chemistry Parameters

Area of Concern 13 - Unpaved Areas within the Compressor Station Investigation Program

Soil Investigation Part B Phase 1 Work Plan

Pacific Gas and Electric Company Topock Compressor Station Needles, California

Notes:

1 Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used.

2 RWQCB. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

3 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

Results greater than or equal to the Background value are bolded. Results greater than or equal to the Commercial Screening level or RWQCB ESL are circled.

NE = not established

USEPA = United States Environmental Protection Agency

DTSC = California Department of Toxic Substances Control

RWQCB = California Regional Water Quality Control Board

CHHSL = California human health screening levels

-- = not analyzed

FD = Field Duplicate

ft bgs = feet below ground surface

J = concentration or reporting limit estimated by laboratory or data validation

mg/kg = milligrams per kilogram

N = Primary Sample

µS/cm = micro siemens per centimeter

ND = not detected at the listed reporting limit

pH is reported in pH units.

Specific conductance is reported in micro siemens per centimeter.

TABLE B11-6

Sample Results: Volatile Organic Compounds

Area of Concern 13 - Unpaved Areas within the Compressor Station Investigation Program

Soil Investigation Part B Phase 1 Work Plan

TABLE B11-8
Conceptual Site Model, AOC 13– Unpaved Areas within the Compressor Station
Soil Investigation Part B Phase 1 Work Plan
PG&E Topock Compressor Station, Needles, California

Primary Source	**Primary Source Media**	**Potential Release Mechanism**	**Secondary Source Media**	**Potential Secondary Release Mechanism**
Incidental spills of lubricants and pipeline liquids, and cooling and wastewater	Surface Soil	Percolation and/or infiltration Potential entrainment in stormwater/ surface water runoff	Subsurface Soil Potential Groundwater	Wind erosion and atmospheric dispersion of surface soil Potential volatilization and atmospheric dispersion Potential extracted groundwater[a]

Notes:

[a] Quantitative evaluation of the groundwater pathway completed in the Groundwater Risk Assessment (ARCADIS, 2009); Part B Phase 1 data will be reviewed in the data gaps assessment to evaluate potential fate impacts or current localized impacts to groundwater from soil.

[2] RWQCB. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[3] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[5] Number of exceedences are the number of detections that are equal to or exceeds the screening level (commercial screening level or RWQCB Environmental Screening Levels)

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the Background value.

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

mg/kg	miligrams per kilogram
µg/kg	micrograms per kilogram
ng/kg	nanograms per kilogram
NA	not applicable
ND	not detected in any of the samples
NE	not established
SL	screening level

USEPA	United States Environmental Protection Agency
DTSC	California Department of Toxic Substances Control
CHHSL	California human health screening levels
RWQCB	Regional Water Quality Control Board

TABLE B11-10
Proposed Sampling Plan - AOC 13 – Unpaved Areas within the Compressor Station
Soil Investigation Part B Phase 1 Work Plan,
PG&E Topock Compressor Station, Needles, California

Location	Depths (feet)	Description/Rationale	Analytes
AOC 13-13	0-0.5 and 3, if feasible	Visitor Parking Area, east of new oil aboveground storage tanks; to resolve Data Gap #1 and #2 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-14	0-0.5 and 3, if feasible	Southeast of Lower Yard Scrubbers; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-15	0-0.5 and 3, if feasible	Southwest corner of Compressor Building; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-16	0-0.5, 3, 6, and 10	Southeast side of Compressor Building, adjacent to Aqua Tower; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-17	0-0.5 and 3, if feasible	Visitor parking area, east of wash rack sump; to resolve Data Gaps #1, #2, and #3 – Lateral and vertical extent of COPCs and potential impacts from potential burn area near AOC 17	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, asbestos, and dioxin and furans
AOC 13-18	0-0.5 and 3, if feasible	South of Cooling Tower A, within historical cooling water release area; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-19	0-0.5 and 3, if feasible	East of Welding Shop; to resolve Data Gap #1 and #2 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-20	0-0.5 and 3, if feasible	East of Maintenance Shop; to resolve Data Gap #1 and #2 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-21	0-0.5 and 3, if feasible	West of storage trailer; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-22	0-0.5 and 3, if feasible	Northwest of northern scrubbers; to resolve Data Gaps #1 and #2 – Lateral and vertical extent of COPCs and potential impacts associated with surface soil discoloration in historical aerial photographs.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-23	0-0.5 and 3, if feasible	Northeast of northern scrubbers; to resolve Data Gaps #1 and #2 – Lateral and vertical extent of COPCs and potential impacts associated with surface soil discoloration in historical aerial photographs.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-24	0-0.5 and 3, if feasible	West of northern scrubbers; to resolve Data Gaps #1 and #2 – Lateral and vertical extent of COPCs and potential impacts associated with surface soil discoloration in historical aerial photographs.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos

TABLE B11-10
Proposed Sampling Plan - AOC 13 – Unpaved Areas within the Compressor Station
Soil Investigation Part B Phase 1 Work Plan,
PG&E Topock Compressor Station, Needles, California

Location	Depths (feet)	Description/Rationale	Analytes
AOC 13-25	0-0.5 and 3, if feasible	Southeast of northern scrubbers; to resolve Data Gaps #1 and #2 – Lateral and vertical extent of COPCs and potential impacts associated with surface soil discoloration in historical aerial photographs.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-26	0-0.5 and 3, if feasible	West of Meter Building, within the 2004 Scrubber Release Area; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-27	0-0.5 and 3, if feasible	East of Meter Building, within the 2004 Scrubber Release Area; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-28	0-0.5 and 3, if feasible	West of Lower Yard Scrubbers, within the 2001 Oil Water Release Area; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-29	0-0.5 and 3, if feasible	West of Sludge Drying Beds, adjacent to transfer piping; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-30	0-0.5 and 3, if feasible	Lower Yard east of Waste Oil Holding Tank and west of Cooling Tower A, bottom of slope; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-31	0-0.5 and 3, if feasible	Northwest edge of “A” Valve Nest Area; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-32	0-0.5 and 3, if feasible	Lower Yard west of Cooling Tower A, along wastewater transfer pipeline; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-33	0-0.5 and 3, if feasible	Sample west of Cooling Tower B on slope above Lower Yard; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos; also will be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation.
AOC 13-34	0-0.5 and 3, if feasible	Sample west of Cooling Tower B on slope above Lower Yard; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos

Notes:

Ten percent of samples collected during the investigation will be analyzed for Target Analyte List/Target Compound List constituents.VOC analysis will not be conducted on surface soil samples (0 to 0.5 feet bgs).

TABLE B11-10
Proposed Sampling Plan - AOC 13 – Unpaved Areas within the Compressor Station
Soil Investigation Part B Phase 1 Work Plan,
PG&E Topock Compressor Station, Needles, California

Location	Depths (feet)	Description/Rationale	Analytes
AOC 13-1	0-0.5 and 3, if feasible	North of Cooling Tower B; to resolve Data Gaps #1 and #2 – Lateral and vertical extent of COPCs and potential impacts associated with surface soil discoloration in historical aerial photographs.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-2	0-0.5 and 3, if feasible	North of Cooling Tower B on paved road; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-3	0-0.5 and 3, if feasible	East of Cooling Tower B; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-4	0-0.5 and 3, if feasible	South of Cooling Tower B; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-5	0-0.5 and 3, if feasible	Northwest side of Compressor Building; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-6	0-0.5 and 3, if feasible	Northeast side of Compressor Building; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-7	0-0.5 and 3, if feasible	West side of Compressor Building, adjacent to Aqua Tower; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-8	0-0.5 and 3, if feasible	East side of Compressor Building, adjacent to Aqua Tower; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-9	0-0.5 and 3, if feasible	Jacket Water Cooling Pumps surface water runoff area; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-10	0-0.5 and 3, if feasible	Between Compressor Building and Lower Yard Scrubbers; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 13-11	0-0.5 and 3, if feasible	West of Compressor Building; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos; also will be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation
AOC 13-12	0-0.5 and 3, if feasible	East of Compressor Building, adjacent to Aqua Tower; to resolve Data Gap #1 – Lateral and vertical extent of COPCs	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos

APPENDIX B12

AOC 15 Investigation Program

1.0 Introduction and Background

1.1 Background

The auxiliary jacket cooling water (AJCW) pumps are part of the AJCW system and are located within the facility fence line north of the Auxiliary Building, as shown in Figure B15-1. (All tables and figures appear at the end of this sub-appendix). The AJCW system is a closed-loop cooling water system for the generator engines. The pumps are used to circulate the cooling water through the system. The AJCW system was subject to occasional leaks due to failure of pump and valve seals.

The ground surface in the immediate vicinity of the pumps is unpaved but covered with gravel; the area outside the raised area where the pumps are located is paved. The area around the pumps is currently covered with gravel. Chromium-based cooling water additives were used in ACJW system from 1951 through 1985. In 1985, the system was converted to using non-hazardous, molybdate-based cooling water additives. Incidental leaks and spills have occurred and may have resulted in impacts to the soil beneath the pumps. Historical information indicates that cooling water concentrations of molybdenum as molybdate (MoO_4) typically ranged from 300 to 800 parts per million (Betz, 1987, 1989, 1990, 1991); cooling water concentrations of chromium as chromate ranged from several hundred to over 1,000 parts per million (concentrations decreased with time).

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for Area of Concern (AOC) 15 based on the above site history and background, as shown in Figure B12-2. Table B12-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 15. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 15 are likely to be historical liquid discharges (leaks) from the pumps and valves. The quantity of liquid released from the pumps and associated valves are unknown; however, periodic leaks are known to have occurred. If a large release from the pumps or valves occurred, it could have resulted in AJCW reaching the storm drain system. Releases via the storm drain system are addressed by the storm drain investigation program described in Appendix D of this of the main report.

The primary source medium at AOC 15 is surface soil. Because the area around the pumps is covered with gravel, liquids released in AOC 15 would have been released to surface soil and would have infiltrated shallow soil. Liquids released to shallow soils could have infiltrated to deeper soils. Because the entire AOC is covered with gravel or concrete pavement, runoff of contaminated surface soil in rainwater is not considered a potential migration pathway.

2.0 Summary of Past Soil Characterization

Seventeen historical surface and shallow soil samples (sample depths of 0, 3, and 4.5 feet below ground surface [bgs]) were collected from 10 locations (JP-1 through JP-10) in AOC 15, as shown in Figure B12-1. Historical soil samples were analyzed for seven constituents: hexavalent chromium, total chromium, copper, lead, molybdenum, nickel, and zinc. Two rounds of sampling were conducted. Locations JP-1 through JP-7 were installed in April 1997, and locations JP-8 through JP-10 were installed in November 1998. Surface soil samples were collected from all April 1997 locations. In addition, three subsurface samples were collected in April 1997. At location JP-1, samples were collected at 3 feet bgs and 4.5 feet bgs. At location JP-2, a sample was collected at 3 feet bgs. The November 1998 samples were collected from the ground surface and at 3 feet bgs at all three locations and also at 2 feet bgs JP-10. Samples from the initial round were not analyzed for copper and nickel; samples from the second round were not analyzed for lead and molybdenum. Laboratory analytical results for the historical soil samples are presented in Table B12-2. Table B12-3 presents a statistical summary of soil analytical results for chemicals of potential concern (COPCs) and chemical of potential ecological concern (COPECs) that were either detected above the laboratory reporting limits or not detected and reporting limits for one or more samples was greater than the interim screening value.

All historical data are considered Category 1 and were used as inputs to the five data quality objective decisions for AOC 15. As described in Appendix B, there is insufficient information to conduct a data gaps analysis for Decisions 3 and 4. Because the risk assessment will be conducted for the entire area within the fence line, the data gaps evaluation for Decision 2 was conducted for the entire area within the fence line as a whole. Decision 5 data gaps analysis was also conducted for the entire area within the fence line. The data gaps evaluation for Decision 2 through 5 is presented in Appendix B, and additional sampling for these decisions, if necessary, is included in this sub-appendix.

All constituents analyzed were detected in every soil samples in which they were analyzed. Table B12-2 lists the seven detected constituents. Nickel was the only constituent that did not exceed its background threshold value (BTV). Three of the constituents, total chromium, hexavalent chromium, and lead, each exceeded the applicable commercial screening values (California human health screening levels [CHHSLs] for commercial use or the United States Environmental Protection Agency Region 9 regional screening levels [RSLs] for commercial use) one time.

3.0 AOC 15 Nature and Extent Data Gaps Evaluation

The following subsection discusses the nature and extent of detected COPCs detected above screening levels at AOC 15. As discussed in Appendix B, multiple factors were considered to assess whether the nature and extent of a specific constituent have been adequately delineated. Constituents that may require further evaluation are summarized in Section 3.1

through 3.6, and Section 4.0 of this sub-appendix provides the recommended sampling for this unit.

3.1 Total Chromium

Total chromium was detected in 17 of 17 soil samples collected at AOC 15. Detected concentrations of total chromium in these samples ranged from 25.7 to 2,100 milligrams per kilogram (mg/kg). Detected concentrations in 15 of the samples exceeded the BTV (39.8 mg/kg). Detected concentrations of total chromium exceeded the commercial screening level (1,400 mg/kg) (RSL) one time (detected concentration of 2,100 mg/kg at JP-2-S at 0 feet bgs), as shown in Table B12-2 and Figure B12-1. Detected concentrations at the surface ranged from 81 to 2,100 mg/kg; detected concentrations in shallow soils (1 to 3 feet bgs) ranged from 25.7 to 135 mg/kg; and the deepest sample, collected at 4.5 feet bgs, contained 35 mg/kg total chromium. The lateral and vertical extents of concentrations exceeding the screening level have not been fully delineated.

3.2 Hexavalent Chromium

Hexavalent chromium was detected in 17 of 17 soil samples collected at AOC 15. Detected concentrations of hexavalent chromium ranged from 0.47 to 53 mg/kg. Detected concentrations in 15 of the samples exceeded the BTV (0.83 mg/kg). The commercial screening level (37 mg/kg) (CHHSL) was exceeded in one sample (detected concentration of 53 mg/kg at JP-2 at 0 feet bgs), as shown in Table B12-2 and Figure B12-1. Detected concentrations at the surface ranged from 0.47 to 53 mg/kg; detected concentrations in shallow soils (1 to 3 feet bgs) ranged from 0.8 to 8.3 mg/kg; and the deepest sample, collected at 4.5 feet bgs, had a reported hexavalent chromium concentration of 3.4 mg/kg. One of the deeper soil samples had an estimated (J-flagged) concentration. The lateral and vertical extents of hexavalent chromium concentrations exceeding the screening level have not been fully delineated.

3.3 Copper

Copper was detected in seven of seven soil samples collected at AOC 15. Detected concentrations of copper ranged from 7.6 to 316 mg/kg. Detected concentrations in five of the samples exceeded the BTV (16.8 mg/kg). None of the detected concentrations exceeded the commercial screening level (38,000 mg/kg) (CHHSL), as shown in Table B12-2 and Figure B12-1. Detected concentrations in the three surface soil samples ranged from 33.5 to 316 mg/kg; detected concentrations in the four shallow soil samples (1 to 3 feet bgs) ranged from 7.6 to 27.1 mg/kg. The lateral and vertical extents of copper concentrations exceeding the screening level have not been fully delineated.

3.4 Lead

Lead was detected in 10 of 10 soil samples collected at AOC 15. Detected concentrations of lead ranged from 5.4 to 820 mg/kg. Detected concentrations in seven of the samples exceeded the BTV (8.39 mg/kg). The commercial screening level (320 mg/kg) (CHHSL) was exceeded in one sample (detected concentration of 820 mg/kg at JP-2 at 0 feet bgs), as shown in Table B12-2 and Figure B12-1. Detected concentrations in the seven surface soil samples ranged from 28 to 820 mg/kg; detected concentrations in the two shallow soil samples (1 to 3 feet bgs) and the subsurface soil sample (collected at 4.5 feet bgs) were all well below the BTV. The lateral extent of lead concentrations exceeding the screening level has not been fully delineated. The vertical extent of lead concentrations exceeding the screening level has been delineated.

3.5 Molybdenum

Molybdenum was detected in 10 of 10 soil samples collected at AOC 15. Detected concentrations of molybdenum ranged from 24 to 720 mg/kg. Detected concentrations in all 10 samples exceeded the BTV (1.37 mg/kg). None of the detected concentrations exceeded the commercial screening level (4,800 mg/kg) (CHHSL), as shown in Table B12-2 and Figure B12-1. Detected concentrations in the seven surface soil samples ranged from 25 to 720 mg/kg; detected concentrations in the two shallow soil samples (1 to 3 feet bgs) were 24 and 310 mg/kg, respectively, and the concentration in the subsurface soil sample (collected at 4.5 feet bgs) was 52 mg/kg. The lateral and vertical extents of molybdenum concentrations exceeding the screening level have not been fully delineated.

3.6 Zinc

Zinc was detected in 17 of 17 soil samples collected at AOC 15. Detected concentrations of zinc ranged from 20 to 57 mg/kg. Detected zinc concentrations did not exceed the BTV (58 mg/kg). Detected concentrations of zinc also did not exceed the commercial screening level (100,000 mg/kg) (CHHSL), as shown in Table B12-2 and Figure B12-1. The lateral and vertical extents of zinc concentrations exceeding the screening level have been defined.

3.7 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review of the historical data indicates that lateral delineation of all metals analyzed is incomplete, and that the vertical delineation of total chromium, hexavalent chromium, copper, and molybdenum is also incomplete. Data gaps remain with regard to other metals.

4.0 AOC 15 Data Gaps and Proposed Sampling

4.1 AOC 15 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gaps were identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination of Title 22 metals.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes polycyclic aromatic hydrocarbons, has been added to all soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.
- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

4.2 AOC 15 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 15 is located in Area 13 on the Topock Compressor Station Accessibility Map (Figure B-2). Sixty-three utility risers, consisting of auxiliary cooling water and electrical lines, were identified in Area 13. In addition, this area contains two large vaults, a cathodic protection anode, and a bank of SCADA cabinets. Photographs 17 through 24 in sub-Appendix B25 show the accessibility constraints in AOC 15. As can be seen in the photos, the AOC is completely blocked to equipment access. The eastern portion of the unit is raised approximately 3 feet above grade, and major aboveground utilities are present in front of the area. The control building is present to the north, jacket coolers are present to the south, and extensive control panel cabinets (SCADA cabinets) are present to the west. Only hand sampling is feasible in this unit. Sample locations and depths identified for AOC 15 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

4.3 AOC 15 Proposed Sampling

Table B12-4 summarizes the proposed AOC 15 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B12-3. The proposed AOC 15 sample locations are Pacific Gas and Electric Company’s initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Based on the historical use of chromium-based cooling water additives in this system and California Environmental Protection Agency, Department of Substances Control requirements, the COPCs associated with AOC 15 are Title 22 metals, hexavalent chromium, and pH as the COPCs for soil associated with AOC 15. COPCs are anticipated to be limited to soil only (CH2M HILL, 2007).

Samples will be collected at six locations: AOC 15-1 through AOC 15-6. Because of limited access, numerous subsurface utilities and pipelines, and proximity to operational structures, only hand tools can be used to collect samples in AOC 15; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. All samples will be analyzed for Title 22 metals, hexavalent chromium, and pH. As required by the United States Department of the Interior, 10 percent of all samples collected during this investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

To address the data needs associated with Decision 5, one samples will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B12-4); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

APPENDIX B13

AOC 16 Investigation Program

1.0 Introduction and Background

1.1 Background

The sand blast shelter is located in the lower yard near injection well PGE-08 (Solid Waste Management Unit 2), as shown in Figure B13-1. (All tables and figures appear at the end of this sub-appendix.) The area immediately surrounding the shelter is currently and historically has been unpaved, except for the concrete driveway between the eastern edge of the shelter and the paved roadway. The sandblast shelter was installed in the early 1990s. The sand blast shelter is used to prepare metal items at the facility for protective coating. The shelter is constructed of four supports and a roof with open sides. The sandblasting operations were conducted by off-site personnel who followed the applicable air quality standards and BMPs of the time, including the use of tenting, drop cloths, and post-sandblasting cleaning to minimize the spreading of material during and after sandblasting operations.

During site walks with California Environmental Protection Agency, Department of Substances Control, two different colors of abrasive material were noted on the ground in the immediate vicinity of the sand blast shelter. The abrasive materials were brought onsite by the sandblasting operators and were specified to meet standards associated with the air permit for sandblast activities. Two types of sand blast material were typically been used in the past several years: KleenBlast® and Monterey 30 Mesh sand. KleenBlast is comprised mostly of iron oxide, silicon dioxide, silica, alumina, calcium, and 5.9 percent of other trace metals and oxides. Monterey sand is primarily (99%) silica (quartz) sand. Historically, lead-based paint and/or paint containing higher levels of other heavy metals may have been used at the facility and may be present in sand blast residue.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for Area of Concern (AOC) 16 based on the above site history and background, as shown in Figure B13-2. Table B13-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 16. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 16 are likely to be used sand blast grit, incidental spills of sand blasting materials, and potentially lead-based paint resulting from sand-blasting activities. The quantity of any used sand blast grit released in the area is unknown; however, as noted above, sand blast grit was noted on the ground in the vicinity of the structure.

The primary source medium at AOC 16 is surface soil. The area around the structure is unpaved. Any contaminated sand blast grit spilled from the shelter would have been released to surface soil. Contaminants could have leached from surface soils into underlying soils. Contaminated sand blast grit could also have been carried off the station in sheet flow during high rainfall events. Windblown dust contamination from small particles of sand blast grit or contaminated surface soil around AOC 16 is a potential secondary release mechanism. Windblown contamination, if any, is expected to be limited to surface soils. Surface runoff from AOC 16 to Bat Cave Wash could also have transported chemicals of potential concern/chemicals of potential ecological concern (COPCs/COPECs) in surface soil from AOC 16 to Bat Cave Wash.

2.0 Summary of Past Soil Characterization

Soil within AOC 16 has not been previously sampled. However, two soil samples associated with AOC 2 are located in proximity to AOC 16. These two historical surface soil samples (collected at 3 to 5 inches below ground surface [bgs]) were collected from two locations (AOC2A and AOC2B) in proximity to AOC 16. For the purpose of this work plan, these two samples have been included on Table B13-2 and Figure B13-1 for AOC 16. Historical soil samples were analyzed for total chromium, hexavalent chromium, copper, nickel, and zinc. Laboratory analytical results for the historical soil samples are presented in Table1 B13-2. Table B13-3 presents a statistical summary of soil analytical results for COPCs and COPECs that were either detected above the laboratory reporting limits or not detected but where the reporting limits for one or more samples was greater than the interim screening value.

All historical data are considered Category 1 and were used as inputs to the five data quality objective decisions for AOC 16. As described in Appendix B, there is insufficient information to conduct a data gaps analysis for Decisions 3 and 4. Because the risk assessment will be conducted for the entire area within the fence line, the data gaps evaluation for Decision 2 was conducted for the entire area within the fence line as a whole. Decision 5 data gaps analysis was also conducted for the entire area within the fence line. The data gaps evaluation for Decision 2 through 5 is presented in Appendix B, and additional sampling for these decisions, if necessary, are included in this sub-appendix.

Four of the five constituents (total chromium, copper, nickel, and zinc) analyzed were detected in soil samples collected near AOC 16. Table B13-2 lists the four detected constituents. All four constituents were only detected at concentrations at or below their respective background threshold values. All detections were well below their applicable commercial screening values (California human health screening level for commercial use or United States Environmental Protection Agency Region 9 regional screening levels for commercial use).

3.0 AOC 16 Nature and Extent Data Gaps Evaluation

This section discusses the nature and extent of detected COPCs detected above interim screening levels at AOC 16. As discussed in Appendix B, multiple factors were considered to assess whether the nature and extent of a specific constituent have been adequately delineated. Section 4.0 of this sub-appendix provides the recommended sampling for this unit.

Based on the site history, background, and conceptual site model, qualitative review of the historical data indicates that the lateral and/or vertical extent of potential contamination to the east, north, and west of this unit has not been defined, and the nature of the sand blast grit noted in the vicinity of the unit has not been evaluated.

4.0 Area of Concern 16 Data Gaps and Proposed Sampling

4.1 AOC 16 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gaps were identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination east, north and west of the structure.
2. Data Gap #2 – Nature of sandblast grit in the vicinity of the structure.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.
- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.
- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

4.2 AOC 16 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 16 is located in Area 4 on the Topock Compressor Station Accessibility Map (Figure B-2). Twenty-three utility risers, including water, electrical, telecommunications, and cooling water lines, were identified in Area 4. In addition, the area contains an active and an abandoned cathodic protection anode. Photograph 26in sub-Appendix B25 show the accessibility constraints in AOC 16. Sample locations and depths identified for AOC 16 reflect the identified access constraints, and will be modified. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less

4.3 AOC 16 Proposed Sampling

Table B13-4 summarizes the proposed AOC 16 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B13-3. The figure also shows proposed sample locations for surrounding solid waste management units and AOCs. The proposed AOC 16 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at four locations: AOC 16-1 through AOC 16-4. Because of limited access and numerous subsurface utilities and pipes, only hand tools can be used to collect samples in AOC 16; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs from locations AOC16-1 through AOC 16-3. Based on the available information, COPCs for soil associated with AOC 16 consist of some metals (e.g., lead from lead-based paint). COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). All samples will be analyzed for Title 22 metals. Prior investigation in the area outside the fence line and available information regarding the site history indicate that volatile organic compounds and semivolatile organic compound other than PAHs should not be considered COPCs for this unit. As required by the United States Department of the Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

To address the data needs associated with Decision 5, one samples will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B13-4); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

APPENDIX B14

AOC 17 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 17 consists of the onsite septic system that serves the Auxiliary Building and other nearby buildings (the Technical Maintenance Building, Weld Shop, Garage, and Maintenance Shop), as shown in Figure B14-1(All tables and figures appear at the end of this sub-appendix.) The Auxiliary Building includes the electricity generator engines (P-Units), air compressors, electric switchgear, battery room, laboratory, mechanics' office, machine shop, locker room, and crew lunchroom.

One of the sources of waste water received by this septic system is the facility laboratory located in the Auxiliary Building. The plant cooling water was routinely sampled to monitor its chemical content and pH. Test chemicals consisted of indicator reagents, which were supplied by the cooling water treatment chemical company. Once the cooling water was tested, the laboratory waste (testing solutions and small amounts of cooling water) was discharged into the septic system. Approximately 1 pint per day of testing solutions and cooling water was disposed of into the septic system connected to the facility laboratory. This practice ended approximately five years ago. Incidental releases of maintenance-type chemicals could also have entered the septic system.

The septic system consists of a septic tank and associated leachfield. A plaque mounted on the wall of the Air Dryer Building indicates that the southwest corner of the septic tank associated with the laboratory is located 4 feet northeast of the Air Drying Building and is buried 4 feet deep (Russell, 2006). An undated hand sketch shows the approximate location of the leachfield in the location shown in Figure B14-1. Aerial photos from 1967 and earlier indicate that the area around the septic tank and leachfield was unpaved. While review of the aerial photograph from 2004 shows that the area was paved, aerial photographs between 1967 and 2004 do not have sufficient resolution to determine at what point the area was paved.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 17 based on the above site history and background, as shown in Figure B14-2. Table B14-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 17. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 17 are likely to be historical liquid discharges from the laboratory. The quantity of liquid released to the septic system is unknown.

Weekly testing of plant cooling water would have resulted in the disposal of approximately 6.5 gallons of liquid per year, whereas daily testing would have resulting in the disposal of approximately 45.5 gallons of liquid per year (assuming approximately one pint of liquid waste per test event). In addition to the laboratory waste, the septic system received, and continues to receive, sanitary waste from the Auxiliary Building.

The primary source medium at AOC 17 is subsurface soil. Although the exact depth of the leach lines is unknown, they would be located below the top elevation of the septic tank (i.e., more than 4 feet bgs). The continuous release of liquids in AOC 17 would have served as a possible driver for wastes to infiltrate to deeper soils. Because the liquids were discharged below the ground surface and the entire area is currently paved, there are no surface migration pathways for this AOC.

2.0 Summary of Past Soil Characterization

This AOC has not been previously sampled.

3.0 AOC 17 Data Gaps and Proposed Sampling

3.1 AOC 17 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gaps were identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination in the vicinity of the leach field.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound (SVOC) analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.
- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with chemical of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data, and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 AOC 17 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 17 is located in Area 11 on the Topock Compressor Station Accessibility Map (Figure B-2). Thirty-two utility risers, consisting of wastewater, water and electrical lines, were identified in Area 11. Photograph 7in sub-Appendix B25 show the accessibility constraints in AOC 17. The primary access constraint for AOC 17 is the need to preserve the integrity of the septic system, which is currently operational. Sample locations and depths identified for AOC 17 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

3.3 AOC 17 Proposed Sampling

Table B14-2 summarizes the proposed AOC 17 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B14-1. A geophysical survey will be performed to attempt to locate the exact location of the leachfield to assist with sample location placement. The figure also shows proposed sample locations for surrounding solid waste management units and AOCs. The proposed sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation

Sampling is required near the septic tank and in the general vicinity of the leachfield. If feasible, without endangering the integrity of the septic system, samples will be collected from within the leachfield. Based on operational history and California Environmental Protection Agency, Department of Substances Control requirements, the COPCs associated with AOC 17 are Title 22 metals, hexavalent chromium, volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), and semivolatile organic compounds (SVOCs), including PAHs. COPCs are anticipated to be limited to soil only (CH2M HILL, 2007).

Samples will be collected at five locations: AOC 17-1 through AOC 17-5. Because of the active leachfield and numerous subsurface utilities, only hand tools can be used to collect samples in AOC 17; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, deeper samples will be collected at 2 to 3 and 5 to 6 feet bgs. Because the area to be sampled is covered with asphalt, the surface sampling interval will begin 6 inches below of the asphalt or gravel sub-base. All samples will be analyzed for Title 22 metals, hexavalent chromium, VOCs, TPH, and SVOCs, including PAHs. As required by the United States Department of the Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B14-2); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

PAH	polycyclic aromatic hydrocarbon
SVOC	semivolatile organic compound
SWMU	Solid Waste Management Unit
TPH	total petroleum hydrocarbons
VOC	volatile organic compound

APPENDIX B15

AOC 18 Investigation Program

1.0 Introduction and Background

Area of Concern (AOC) 18 consists of the pipelines that were used to connect the cooling towers to the wastewater system including Solid Waste Management Unit (SWMU) 1 (Former Percolation Bed), SWMU 2 (Inactive Injection Well PGE-08), SWMU 5 (Sludge-drying Beds), SWMU 6 (Chromate Reduction Tank), SWMU 7 (Precipitation Tank), SWMU 8 (Process Pump Tank), SWMU 9 (Transfer Sump), SWMU 10 (Old Evaporation Ponds), and Units 4.3 (Oil/Water Holding Tank), 4.4 (Oil/Water Separator), and 4.5 (Portable Waste Oil Storage Tank). The hazardous waste management system and the related piping were closed, and piping was pressure tested for leaks as part of the closure process, as described in the *Phase 1 and 2 Closure Certification Report Hazardous Waste Management Facilities* (Mittelhauser, 1990).

The majority of the pipelines were removed at the time of the closure of the hazardous waste management system, inaccessible portions of the pipelines that were no longer needed were abandoned in place, and some lines were (and continue to be) in active use. There is limited information regarding these pipelines. No as-built drawings have been located. Wastewater pipelines at the site were made of polyethylene, polyvinyl chloride, aluminum, cast iron, and vitrified clay (Mittelhauser, 1986). These pipelines were used only to convey wastewater. Pipelines for stormwater and septic waste are separate systems.

The pipelines were removed in accordance with the hazardous waste treatment system closure plan (Mittelhauser, 1986). The closure plan designated each pipeline segment by letter; during the actual closure process, the segments were further subdivided where needed based upon length and other considerations. To accomplish the closure, the pipelines were uncovered, pressure tested, and inspected for visible leakage. Table B15-1 lists the pipeline segments, the pressure test results, and associated sample points, including the rational for sampling the specified locations. These segments are shown on Figure B15-1. (All tables and figures appear at the end of this sub-appendix.)

Pressure testing consisted of two static pressure tests. The pipes were filled with water, pressurized and maintained at pressure for a minimum of two 15-minute intervals, and the volume loss from the pipeline was measured in 0.001-gallon increments (approximately 4 milliliters). Due to air pockets and other difficulties, volume loss could not be measured at some locations. These locations were inspected visually for evidence of water release. Pipe segments in level areas were tested a pressure between 15 and 21 pounds per square inch, and pipe segments on slopes were pressure tested at pressures between 24 and 28 pounds per square inch to evaluate the higher pressure head these pipes would experience. One pipeline segment (F-3) failed the pressure test, one segment (F-4) could not be tested because it was damaged by a backhoe during work on another pipeline, and Segment H was not pressure tested because it was constructed of vitrified clay. Pipeline segments G-2 and G-3, which led from the compressor station to the former evaporation ponds, were partially aboveground and very long and were therefore air-tested.

Visibly contaminated soil was removed, confirmation samples were collected, the pipeline trench and any excavation area was then covered with plastic, and the pipeline trench was backfilled with clean backfill. Confirmation sample results for six areas indicated that metals were present above background levels as defined at the time, and additional excavation was conducted below the backfill (the clean fill was removed down to the level of the plastic, additional excavation was conducted, the plastic was replaced, and the trench backfilled again). Confirmation samples from all six locations showed that adequate soil had been removed during the second round of excavation.

During the closure process, Mittelhauser Corporation confirmed that some pipeline sections had already been removed during extensive excavation of the area associated with repairs of the underlying high pressure gas lines. Portions of lines D, F, and H had already been removed.

The wastewater from the pressure test was also analyzed. The wastewater samples were analyzed for Title 22 metals, pH, and fluoride, shown in Table B15-2. The interior of most of the pipelines had a visible green sludge and they were disposed of as hazardous waste. Portions of pipeline sections D-3, F-5, G-1, G-2, G-3, and all of A-3 were not removed because they were inaccessible, sufficiently decontaminated, and still active, or they were long and difficult to remove. The remaining portions of sections D-3 and F-5 were capped in place, and the remaining section of G-1 was encased in concrete. Sections G-2 and G-3 were closed in place without removal; these sections consisted of two long sections (approximately 1,500 feet) of 3-inch polyvinyl chloride and polyethylene piping that served to connect the former evaporation ponds with the compressor station. The piping passed the pressure test. The portion of the piping that crossed Bat Cave Wash on a high pipeline bridge was removed in 2007. Pipelines A-3, G-2, and G-3 have been extensively flushed extensively since 1985 when cooling water treatment with chromate ceased. Segment A-3 remains in use.

Because pipeline segment H, the vitrified clay pipeline, could not be pressured tested additional sampling was conducted to evaluate this segment. After contaminated soils (visible green and white soils) identified in the vicinity of the pipeline were removed, a second round of soil sampling was conducted for each section of the pipeline to confirm that the area was clean. A sample was also taken where a portion of the pipeline had been removed a few years earlier.

The original oil/water separator system (OWS) (Units 4.3 through 4.5) was closed around 1990 (Mittelhauser, 1990), and there was some characterization of leaks near the pipelines associated with the OWS system. The OWS system 3-inch-diameter underground piping was removed as part of the closure. Water from the OWS system flowed into this pipe and discharged into the Chromate Reduction Tank (this pipeline segment is referred to as segment I-2 in the closure report for the OWS). During the closure, leaks in the OWS system appeared to have occurred. Piping was removed where accessible, but some sections of the pipe were capped and left in place.

2.0 Summary of Past Soil Characterization

Eighteen historical soil samples were collected from 18 locations in AOC 18 (PA-3, PC-1, PF-6, PF-8, PG-2, and PH-1 through PH-13) at depths between 1 and 6 feet below ground surface (bgs), as shown in Figure B15-2. Historical soil samples were analyzed for antimony, arsenic, barium beryllium, cadmium, total chromium, trivalent chromium, hexavalent chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, and zinc. Laboratory analytical results for the historical soil samples are presented in Table B15-2. Table B15-3 presents a statistical summary of soil analytical results for chemicals of potential concern (COPCs) that were either detected above the laboratory reporting limits or not detected and reporting limits for one or more samples was greater than the interim screening value.

All but one of the 19 constituents (thallium) analyzed were detected in soil samples collected in AOC 18. Table B15-2 lists the 18 detected constituents. Seven of these constituents (beryllium, total chromium, hexavalent chromium, lead, molybdenum, nickel, and zinc) were detected at concentrations exceeding their respective background threshold values. All 18 constituents were detected at concentrations below their respective California human health screening level for commercial use or United States Environmental Protection Agency Region 9 regional screening levels for commercial use (collectively referred to as the commercial screening levels).

Based on the confirmation soil sampling, the former treatment system piping was considered clean-closed (Mittelhauser, 1990). A closure certification acceptance letter dated June 26, 1995 was issued and included this portion of the former hazardous waste management facility (California Environmental Protection Agency, Department of Toxic Substances Control [DTSC] 1995). Although this unit was closed by DTSC in 1995 as part of the overall closure of the hazardous waste treatment system, DTSC subsequently requested that additional analysis be conducted for volatile organic compounds (VOCs), total petroleum hydrocarbon (TPH), and semivolatile organic compounds (SVOCs) in soil at AOC 18 (DTSC, 2006). COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Section 4.0 provides the recommended sampling for this unit.

3.0 AOC 18 Data Gaps and Proposed Sampling

Based upon DTSC’s request, the following data gaps have been identified for Decision 1:

1. Data Gap #1 – Collect additional soil samples to analyze for organics.
2. Data Gap #2 – Define lateral and vertical extent of detected metals at historical sample location PH-2.
3. Data Gap #3 – Assess waste water transference piping near fence line.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values.

However, since SVOC analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) for additional analytes must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.
- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

4.0 AOC 18 Proposed Sampling

4.1 AOC 18 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 18 is located in multiple Areas: 3, 4, 6, 8, 9, and 15 (Figure B-2). Some of these areas have extensive utilities. In addition, a portion of the AOC (along the alignment of pipeline segments A-3 and alignments of former pipeline segments D-2, F-3, and H-2) is on the slope between the upper and lower yards. Sample locations and depths identified for AOC 18 reflect the identified access constraints, and will be modified. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

4.2 AOC 18 Proposed Sampling

Table B15-4 summarizes the proposed AOC 18 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B15-3. The figure also shows proposed sample locations for surrounding SWMUs and AOCs. The proposed AOC 18 sample locations are Pacific Gas and Electric Company’s initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at twelve locations: AC 18-1 through AOC 18-12. Because of limited access and extensive subsurface features, only hand tools can be used to collect samples in AOC 18; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, deeper samples will be collected at 2 to 3 and 5 to 6 feet bgs. Where the area to be sampled is covered with concrete or asphalt, the surface sampling interval will begin 6 inches below the bottom of the concrete/asphalt or gravel sub-base.

All samples will be analyzed for Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, and PAHs. As required by United States Department of the Interior, 10 percent of all samples collected from the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

To address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

TABLE B15-1
Wastewater Pipelines Status Summary
AOC 18 – Combined Waste Water Transference Pipelines
Soil Investigation Part B Phase 1 Work Plan,
PG&E Topock Compressor Station, Needles, California

Sub-segment	Connection	Diameter (inches)	Material	Length (feet)	Pressure Test Results	Associated Samples	Sample Rationale	Segment Status
Pipeline Segment A								
	Cooling Towers to Chromate Reduction Tank	3	PVC	1,500 (750 feet per tower)				
A-1	Chromate Reduction Tank to east bend at former Oily Water Holding Tank				Pass			Not removed; active pipeline; wastewater had acceptable concentrations of chromium
A-2	End of A1 to east of new oily water treatment system				Pass			Removed; clean-closed
A-3	End of A2 to junction of Cooling Tower A and B wastewater lines					PA-3 (1042-S1-10)	Operating pipeline, sampled below joint (same sample as for F-3)	Active line; wastewater had acceptable concentrations of chromium; ample flushing has occurred; clean-closed for contamination.
Pipeline Segment B								
B-1	Chromate Reduction Tank to Transfer Sump	3	PVC	30	Pass			Removed; clean-closed
Pipeline Segment C								
C-1	Transfer Sump to transfer pumps	3	PVC	15	Pass, slight leak at gate valve	PC-1 (1042-51-03)	Sampled beneath slight leak at valve	Removed; clean-closed
Pipeline Segment D								
	Process Pump Tank to transfer pumps	3	PVC	500				
D-1[a]	Transfer pumps to east bend at former Oily Water Holding Tank				Pass			Removed; clean-closed
D-2	End of D1 to east of new oily water treatment system				Pass			Removed; clean-closed
D-3	End of D2 to Process Pump Tank				Pass			Portion not removed; clean-closed
Pipeline Segment E								
E-1	Precipitation Tank to Process Pump Tank	3	Steel	15	Short aboveground pipe, not tested, visual inspection			Removed; clean-closed
Pipeline Segment F								
	Transfer pumps to Precipitation Tank	4	PVC	500				
F-1[b]	to east bend at former Oily Water Holding Tank				Pass			Removed; clean-closed
F-2	End of F1 to east of new oily water treatment system				Pass			Removed; clean-closed
F-3	End of F2 to				Fail	PA-3 (1042-S1-10)	Section failed pressure test (same sample as for A-3)	Most of pipe and underlying soil removed; clean-closed.
F-4	10- to 15-foot section damaged by backhoe				Not tested; damaged by backhoe			Removed; clean-closed
F-5					Pass, slight seepage at coupling	PF-6 (1042-43-11 and duplicate sample 1042-43-12)	Sampled beneath slight leak at PVC slip joint	Portion of pipe removed; remainder abandoned in place (capped); clean-closed

Soil Investigation Part B Phase 1 Work Plan,
PG&E Topock Compressor Station, Needles, California

Sub-segment	Connection	Diameter (inches)	Material	Length (feet)	Pressure Test Results	Associated Samples	Sample Rationale	Segment Status
H-3[c]	East of new oily water treatment system				Not tested, visual inspection for leaks and contamination	PH-4 (1042-43-04) PH-5 (1042-43-105)	Sampled off end of previous break in pipe; no visible evidence of leakage Sampled 65 feet off end of previous break in pipe at probably location of former pipe	Removed; clean-closed
H-4[c]	West of new oily water treatment system to Sludge-drying Beds				Not tested, visual inspection for leaks and contamination	PH-1 (1042-43-01)1 PH-2 (1042-43-02) PH-2 (1042-43-30) PH-3 (1042-43-03) PH-3 (1042-43-31)	Sampled 3 inches below gate valve after removal of soil contaminated with green sludge Sampled below gate valve, no visible evidence of leakage Second confirmation sample following additional excavation Sampled beneath joint in clay pipe, no visible evidence of leakage Second confirmation sample following additional excavation	Removed; clean-closed
Pipeline Segment I[d]								
		NA	NA	NA	NA			
I-1	Oily Water Treatment System Influent from Valve Box east of New Oily Water Treatment System to former Oily Water Holding Tank			NA	NA	OWS-PI-1 (1042-55-4); OWS-Valve-PI-1 (1042-55-6)	Stained soil by valve	NA
I-2	Oil/Water Separator to Chromate Reduction Tank			Approx. same length as A-1	NA	NA	NA	Removed
Pipeline Segment J[e]								
J-2	Sludge-drying Beds to Transfer Sump	NA	NA	Est. 30 feet	NA	NA	NA	Removed

[a] This pipeline is shown as terminating just north of the Chromate Reduction Tank; the missing partial segment is interpreted as removed.

[b] This pipeline is shown as terminating just north of the Chromate Reduction Tank; the missing partial segment is interpreted as removed.

[c] Long section of pipe between H-2 and H-3 not shown in Mittelhauser drawing, interpreted as previously removed; similarly, a section of pipelines is shown as missing between H3 and H4, in the area where the new oily water treatment system was installed, this unit was also interpreted as removed.

[d] Pipeline segments listed in oily water treatment system closure report (Mittelhauser, 1990); see discussion for Units 4.3 to 4.5 in Appendix B24.

[e] Pipeline segment shown in figure in closure report, but not listed in tables.

NA = Not available.

Notes:

1 Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used.

2 RWQCB. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

3 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

4 Commercial screening level is below background value; therefore, arsenic results are only screened against the background value.

5 Samples were collected beneath pipelines located at varying depths. Confirmation samples were collected after excavation of contaminated soil surrounding the pipelines.

Results greater than or equal to the Background value are bolded. Results greater than or equal to the Commercial Screening level or RWQCB ESL are circled.

NE = not established

USEPA = United States Environmental Protection Agency

DTSC = California Department of Toxic Substances Control

RWQCB = California Regional Water Quality Control Board

CHHSL = California human health screening levels

-- = not analyzed

FD = Field Duplicate

ft bgs = feet below ground surface

J = concentration or reporting limit estimated by laboratory or data validation

mg/kg = milligrams per kilogram

N = Primary Sample

ND = not detected at the listed reporting limit

pH is reported in pH units.

Specific conductance is reported in micro siemens per centimeter.

APPENDIX B16

AOC 19 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 19 is the Former Cooling Liquid Mixing Area located directly east of the Compressor Building (Figure B16-1). (All tables and figures appear at the end of this sub-appendix.) AOC 19 was initially defined as the concrete pad area associated with the former cooling additive mixing shed, however, subsequent information regarding potential leaks from the Jacket Cooling Water (JCW) system (Russell, 2006a) led to the inclusion of the adjacent pumps and tank area in AOC 19. The pad from the former shed currently exists and is located adjacent to a smaller concrete pad that presently serves as a base for an exterior employee emergency safety shower.

AOC 19 was identified by routine inspection in January 2006. During a test of the eyewash shower located in this area in January 2006, droplets of green liquid were observed on the concrete pad below the eyewash shower (PG&E, 2006). A sample of the greenish water droplets was analyzed for Title 22 metals on January 20, 2006. Results showed a total chromium concentration of 770 milligrams per liter (mg/L).

The JCW system was originally designed with a hotwell (a large rectangular concrete structure, partially below grade) that acted as a surge tank for the JCW system. Cooling water additives for this system were chromium-based until October 1985; since 1985, the additive has been molybdenum-based. Historic records (Betz, 1987, 1989, 1990, 1991) indicate that concentrations of molybdenum as molybdate typically ranged from 300 to 800 parts per million. The water was pumped from the hotwell into the heat exchangers. There was no control system to adequately prevent overflow on the hotwell, and employees stated that the hotwell periodically overflowed. The hotwell was approximately 10 feet deep, with about 5 feet above ground. The area covered by the hotwell was about twice the area covered by the current concrete containment area for the aboveground temporary compressor engine oil holding tanks. The hotwell was abandoned in place and replaced with JCW tanks (which still exist) prior to 1990. The JCW tanks are located immediately to the south of the former hotwell location. In the early 1990s, a construction project began to provide secondary containment for the temporary compressor engine oil storage tanks in the area. During the construction, remnants of the old hotwell were discovered.

A cleanup project was conducted to remove the hotwell remnants. The remaining concrete and the soil contained in the former hotwell were removed, and the concrete debris and soil were sampled (Technical and Ecological Services, 1994). Total chromium and hexavalent chromium were detected in all soil and concrete samples and the concrete was characterized as hazardous waste. No soil samples were collected underneath the footprint of the former hotwell, nor were any soil samples collected from soils adjoining the former hotwell.

The JCW system was also subject to occasional leaks from pump and valve seal failure. The cooling water would flow onto the graveled area near the hotwell and pumps. Larger leaks from the hotwell or pumps could sometimes result in releases onto the paved area between the JCW system and the visitor parking lot/warehouse and potentially down the main entrance road leading to the station (Russell, 2006). The area around the former hotwell and the JCW pumps is unpaved but covered with gravel. The area of the former hotwell is elevated approximately 3 feet above grade (and above the pumps and JCW surge tanks) on east side of the AOC; the former cooling additive mixing shed is located at the same grade as the pumps and surge tanks.

The chemical additive shed was located south of the JCW pumps and southeast of the former hotwell. At some time in the past, powdered coolant chemicals were mixed here and reportedly hand-added to the hotwell (Russell, 2006). The pad from the shed remains; it is adjacent to an eyewash station/emergency shower. Upon discovery of the droplets of green-colored water, sampling was conducted in the area. The affected area was covered with visqueen to minimize employee contact, and a wooden pad was installed over the concrete pad to minimize human exposure and to allow the safety shower to remain in operation. The area around the former shed/concrete pad is unpaved. The former shed/concrete pad will be removed and properly disposed to facility soil sampling beneath this former structure.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 19 based on the above site history and background, as shown in Figure B16-2. Table B16-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 19. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 19 are likely to be historic liquid discharges (spills) from the former JCW hotwell and leaks from the JCW pumps. In addition, incidental spills during the mixing of the chemicals, and potentially during the manual addition of the chemicals, could have impacted the soil in this area. The quantity of liquid released from the hotwell and pumps is unknown; however, periodic overflows and leaks are known to have occurred. The integrity of the concrete from former hotwell is also unknown; it is possible that small quantities of JCW could have been released directly to subsurface soil through small cracks in the concrete. The potential quantity of chemicals released in the vicinity of the former cooling additive mixing shed is also unknown; however, is expected to be relatively small, as any spills would have been small. If a large release from the hotwell occurred, it could have resulted in cooling water reaching the storm drain system and/or station access road and being discharged outside the fence line. Releases via the storm drain system are addressed by the storm drain investigation program described in Appendix D of this work plan.

The primary source medium at AOC 19 is surface soil. Because the majority of the area around the former hotwell and former cooling additive mixing shed is covered with gravel, liquids released in AOC 19 would have been released to surface soil and would have infiltrated shallow soil. Liquids released to shallow soils could have infiltrated to deeper soils. If the concrete of the former hotwell lacked integrity, subsurface soil may be a secondary source medium. Because the entire AOC is covered with gravel or pavement, runoff of contaminated surface soil in rainwater is not considered a potential migration pathway.

2.0 Summary of Past Soil Characterization

Seven historical surface soil samples (SS#1 to SS#7) were collected from six locations in AOC 19, as shown in Figure B16-3. SS#1 through SS#6 were collected at 0 feet below ground surface (bgs); SS#7 was collected at 4 inches bgs). The samples were collected along the edge of the concrete pad. Soil samples SS#2, SS#3, and SS#4 were collected along the north side of the pad, and samples SS#1 and SS#5 were collected along the southwest and southeast corners, respectively. Soil samples SS#6 and SS#7 were collected from the same location along the west side of the pad. A small section of the darkly stained concrete pad along the southwest corner was also removed and submitted for analysis. All samples were tested for Title 22 metals. Waste Extraction Tests (WETs) for total chromium and hexavalent chromium were also performed for all the samples. In addition, the concrete sample was tested for soluble chromium using the toxicity characteristic leaching procedure (TCLP).

Samples have not been collected in the immediate vicinity of the former hotwell. Laboratory analytical results for the historical samples are presented in Tables B16-2 and B16-3. Table B16-4 presents a statistical summary of soil analytical results for chemicals of potential concern (COPCs) that were either detected above the laboratory reporting limits or not detected and reporting limits for one or more samples was greater than the interim screening value.

The samples were analyzed for antimony, arsenic, barium beryllium, cadmium, total chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, and zinc (the samples were not analyzed for hexavalent chromium). All 17 constituents were detected in soil samples collected in AOC 19. Table B16-2 lists the 17 detected constituents. Six of these constituents (cadmium, chromium, copper, lead, molybdenum, and zinc) were detected at concentrations exceeding their respective background threshold values (BTVs) in all seven samples. Selenium was the only other compound detected above its BTV; it was detected at a concentration of 2 milligrams per kilogram (mg/kg) in one sample (compared to the BTV of 1.47 mg/kg).

Total chromium and lead were also detected at concentrations exceeding their respective commercial screening levels (California human health screening levels [CHHSLs] for commercial use or United States Environmental Protection Agency Region 9 regional screening levels [RSLs] for commercial use).

The concrete debris from the former hotwell and the soil contained in the hotwell were sampled and analyzed for total chromium and hexavalent chromium. Five concrete samples were analyzed. The two concrete samples with the highest total chromium concentrations were analyzed for soluble total chromium and hexavalent chromium using the WET, as well as soluble total chromium using the TCLP. Since the concrete debris and soil samples collected from the former hotwell have been removed and are not representative of current site conditions, these data are not presented on tables and figures in this sub-appendix, but are discussed in the following nature and extent discussion for context.

All historical data are considered Category 2 and were used as inputs to Decision 1 for AOC 19. The data are not suitable for use for the remaining decisions, which require Category 1 data.

3.0 2011 Trench Sampling Results

In January 2011, a utility trench was dug across the asphalt-covered compressor station entryway between AOC 19 and the compressor station office. Eight opportunistic soil samples were collected from four locations (AOC19-1 through AOC 19-4) within the trench located along the northern boundary of AOC 19 and to the northeast of the AOC. The samples were collected at 0.5 and 2 feet bgs, and soil samples were analyzed for Title 22 metals, hexavalent chromium, polycyclic aromatic hydrocarbons (PAH), and pH. Laboratory analytical results for the historical samples are presented in Table B16-2. Table B16-4 presents a statistical summary of soil analytical results for COPCs that were either detected above the laboratory reporting limits or not detected and reporting limits for one or more samples was greater than the interim screening value.

Eleven metals (arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, and zinc), 12 PAHs (2-methylnaphthalene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, and pyrene), and one calculated value (benzo(a)pyrene equivalent) were detected in the trench soil samples collected near AOC 19. Table B16-2 lists the detected constituents. Hexavalent chromium, lead, and molybdenum were the only metals detected at concentrations exceeding their respective BTVs, but none of the metals concentrations was detected above respective commercial screening levels.

None of the detected concentrations of PAHs or the calculated values of benzo(a)pyrene equivalent was above respective commercial screening levels.

All 2011 trench sampling data are considered Category 1 and were used as inputs to the five data quality objective decisions for AOC 19. As described in Appendix B, there is insufficient information to conduct a data gaps analysis for Decisions 3 and 4. Because the risk assessment will be conducted for the entire area within the fence line, the data gaps evaluation for Decision 2 was conducted for the entire area within the fence line as a whole. Decision 5 data gaps analysis was also conducted for the entire area within the fence line. The data gaps evaluation for Decision 2 through 5 is presented in Appendix B, and additional sampling for these decisions, if necessary, are included in this sub-appendix.

4.0 AOC 19 Nature and Extent Data Gaps Evaluation

The following subsection discusses the nature and extent of detected COPCs detected above interim screening levels at AOC 19. As discussed in Appendix B, multiple factors were considered to assess whether the nature and extent of a specific constituent have been adequately delineated. Constituents that may require further evaluation are summarized in

Section 4.8, and Section 5.0 of this sub-appendix provides the recommended sampling for this unit.

4.1 Total Chromium

Total chromium was detected in eight of eight Category 1 samples and seven of seven Category 2 samples. Detected concentrations of total chromium in soil ranged from 6.8 to 4,300 mg/kg, as shown in Table B16-2 and Figures B16-3. The concentrations of total chromium in seven samples were above the BTV (39.8 mg/kg), but all concentrations were below commercial screening levels, and concentrations in six samples exceeded the commercial RSL (1,400 mg/kg).

All seven of the soil samples exceeded the Title 22 WET soluble threshold limit concentration (STLC) limit for chromium and/or trivalent chromium compounds (5 mg/L). The removed concrete sample did not exceed the total threshold limit concentration limit for chromium and other Title 22 metals. However the STLC and TCLP limits were exceeded, again for chromium and/or trivalent chromium compounds.

The two removed hotwell soil samples contained total chromium at 280 and 220 mg/kg, respectively. The removed five hotwell concrete samples contained total chromium at concentrations ranging from 530 to 2,300 mg/kg. All samples exceed STLC criterion of 5 mg/L. The TCLP analysis showed soluble total chromium at 40 mg/L and 68 mg/L, respectively, while the WET indicated soluble total chromium at 78 mg/L and 110 mg/L, respectively.

The lateral and vertical extents of total chromium concentrations exceeding the screening have not been defined.

4.2 Hexavalent Chromium

Hexavalent chromium was detected in four of eight Category 1 samples. Detected concentrations of hexavalent chromium in soil ranged from 0.91 to 1.1 mg/kg, as shown in Table B16-2 and Figure B16-3. The concentrations of hexavalent chromium in five samples were above the BTV (0.83 mg/kg), but all concentrations were below commercial screening levels.

Hexavalent chromium in historical soil samples SS#1 through SS#7 was only analyzed to determine its soluble concentrations. Soluble hexavalent chromium concentrations in all soil samples were below the STLC limit of 5 mg/L. The concrete sample from the former cooling additive mixing shed also contained soluble hexavalent chromium but again below the STLC limit.

The two removed hotwell soil samples contained hexavalent chromium at 4 and 3.6 mg/kg, respectively. The five hotwell concrete samples contained hexavalent chromium at concentrations ranging from 37 to 330 mg/kg. The soluble hexavalent chromium concentrations in the hotwell concrete samples determined using the WET were 64 mg/L and 80 mg/L, respectively.

The lateral and vertical extents of hexavalent concentrations exceeding the screening level have not been defined.

4.3 Cadmium

Cadmium was detected in 0 of eight Category 1 samples and seven of seven Category 2 samples. Detected concentrations of cadmium in soil ranged from 1.5 to 4.5 mg/kg, as shown in Table B16-2 and Figure B16-3. The concentrations of cadmium in all seven samples were above the BTV (1.1 mg/kg). None of the detected concentrations exceeded the commercial CHHSL (500 mg/kg). The lateral and vertical extents of cadmium concentrations exceeding the screening level have been defined.

4.4 Copper

Copper was detected in seven of eight Category 1 samples and seven of seven Category 2 samples. Detected concentrations of copper in soil ranged from 2.9 to 84 mg/kg, as shown in Table B16-2 and Figure B16-3. The concentrations of copper in seven samples were above the BTV (16.8 mg/kg). None of the detected copper concentrations exceeded the commercial CHHSL (3,800 mg/kg). The lateral and vertical extents of copper concentrations exceeding the screening level have been defined.

4.5 Lead

Lead was detected in eight of eight Category 1 samples and seven of seven Category 2 samples. Detected concentrations of lead in soil ranged from 3.7 to 890 mg/kg, as shown in Table B16-2 and Figure B16-3. The concentrations of lead in eight samples were above the BTV (8.39 mg/kg). In addition, five of the detected lead concentrations exceeded the commercial CHHSL (320 mg/kg). The lateral and vertical extents of copper concentrations exceeding the screening level have not been defined.

4.6 Molybdenum

Molybdenum was detected in four of eight Category 1 samples and seven of seven Category 2 samples. Detected concentrations of molybdenum in soil ranged from 8.8 to 300 mg/kg, as shown in Table B16-2 and Figure B16-3. The concentrations of molybdenum in 11 samples were above the BTV (1.37 mg/kg). None of the detected copper concentrations exceeded the commercial CHHSL (4,800 mg/kg). The lateral and vertical extents of copper concentrations exceeding the screening level have been defined.

4.7 Zinc

Zinc was detected in eight of eight Category 1 samples and seven of seven Category 2 samples. Detected concentrations of zinc in soil ranged from 16 to 480 mg/kg, as shown in Table B16-2 and Figure B16-3. The concentrations of zinc in seven samples were above the BTV (58 mg/kg). None of the detected copper concentrations exceeded the commercial CHHSL (100,000 mg/kg). The lateral and vertical extents of copper concentrations exceeding the screening level have been defined.

4.8 Benzo(a)pyrene

Benzo(a)pyrene was detected in three of eight Category 1 samples. Detected concentrations of benzo(a)pyrene in soil ranged from 12 to 50 micrograms per kilogram (µg/kg), and detected concentrations of benzo(a)pyrene equivalents in soil ranged from 4.5 to 84 µg/kg as shown in Table B16-3. The concentration of benzo(a)pyrene and calculated benzo(a)pyrene equivalent are below the commercial CHHSL (130 µg/kg).

The total number of samples with PAH data is relatively limited. The lateral and vertical extents of benzo(a)pyrene and benzo(a)pyrene equivalents concentrations exceeding the screening levels have not been defined.

4.9 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review of the historical data indicates that the lateral and vertical extents of total and hexavalent chromium (both total and soluble forms), lead, benzo(a)pyrene, and benzo(a)pyrene equivalents have not been defined.

5.0 AOC 19 Data Gaps and Proposed Sampling

5.1 AOC 19 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gaps were identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination at AOC 19.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of PAHs in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data, and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

5.2 AOC 19 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 19 is located in Area 12 on the Topock Compressor Station Accessibility Map (see Figure B-2). Ninety-one utility risers, including cooling water, air, water, and electrical lines, were identified in Area 12. SCADA cabinets and three vaults were also identified in this area. Photographs 28 through 43 in sub-Appendix B25 show the accessibility constraints in AOC 19. As can be seen in the photos, the AOC is completely blocked to equipment access. The eastern portion of the unit is raised approximately 3 feet above grade, and major aboveground utilities, as well as the JCW pumps and the JCW surge tanks, are present in front of the area. Jacket coolers are present to the north and south, and the temporary compressor engine oil holding tanks and further utilities are present to the west. Only hand sampling is feasible in this unit. Sample locations and depths identified for AOC 19 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools).

5.3 AOC 19 Proposed Sampling

Table B16-5 summarizes the proposed AOC 19 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B16-4. The figure also shows proposed sample locations for surrounding solid waste management units and AOCs. The proposed AOC 19 sample locations are Pacific Gas and Electric Company’s initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at five locations (AOC19-5 through AOC19-9). Because of limited access and numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in AOC 19; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Where the area of sampling is covered with asphalt, the surface sampling interval will begin at the bottom of the asphalt or gravel sub-base. Based on the operations history, available data, and California Environmental Protection Agency, Department of Toxic Substances Control requirements, the COPCs associated with AOC 19 consist of Title 22 metals, hexavalent chromium, and pH. COPCs are anticipated to be limited to soil (CH2M HILL, 2007).

All samples will be analyzed for Title 22 metals, hexavalent chromium, and pH. As required by the United States Department of the Interior, 10 percent of all samples collected will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B16-5); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

Notes:

1 Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used.

2 RWQCB. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

3 CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

Results greater than or equal to the Background value are bolded. Results greater than or equal to the Commercial Screening level or RWQCB ESL are circled.

NE = not established

USEPA = United States Environmental Protection Agency

DTSC = California Department of Toxic Substances Control

RWQCB = California Regional Water Quality Control Board

CHHSL = California human health screening levels

Calculations:

BaP equivalent = Sum of Result x TEF, 1/2 reporting limit used for nondetects. If all PAHs are nondetect, the final qualifier code is U.

-- = not analyzed

µg/kg = micrograms per kilogram

FD = Field Duplicate

ft bgs = feet below ground surface

J = concentration or reporting limit estimated by laboratory or data validation

N = Primary Sample

ND = not detected at the listed reporting limit

APPENDIX B17

AOC 20 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 20 consists of the industrial floor drains within the compressor station buildings and other industrial structures and facilities within the upper yard of the compressor station that are routed to the oily water treatment system (Units 4.3, 4.4, and 4.5). AOC 20 was incorporated in the *Revised Final RCRA Investigation/Remedial Investigation Report, Volume 1 - Site Background and History, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2007) at the request of California Environmental Protection Agency, Department of Toxic Substances Control (DTSC, 2007). AOC 20 does not include the miscellaneous floor drains in areas such as lavatories that drain to one of the three septic systems on the station.

Several of the industrial buildings within the compressor station are equipped with floor drains that capture liquids released to the floor of the building and convey the liquid to Units 4.3, 4.4, and 4.5. In addition, other industrial facilities, such as the steam-cleaning area and the main jacket water surge tanks, are equipped with drains that capture overflow and spills. A pipe trench that extends from the sump next to the steam-cleaning area to the east side of the compressor building also drains to the Units 4.3, 4.4, and 4.5 and has been included in AOC 20. Collectively, these drains are referred to as industrial drains to distinguish their use and intent from the storm drains that are also present at the facility. As shown in Figure B17-1, industrial drains are found in the following buildings and facilities: Compressor Building, Auxiliary Building, Jacket Cooling Water Pumps, Oil Storage Tank Area, Steam Rack (steam-cleaning area), Fire Water Pump Building, and Former Water Softener Building (AOC 23).

Pipelines that are connected to the Units 4.3, 4.4, and 4.5 historically were made primarily of vitrified clay. Currently, the system contains a variety of pipe materials including reinforced fiberglass, polyvinyl chloride, cast iron, and acrylonitrile-butadiene-styrene. The aboveground lines are all welded carbon steel pipe (Pacific Gas and Electric Company [PG&E], 1991). No sampling of the industrial floor drains has been conducted; however, two samples located on piping segment I-1 were collected during closure of the former Units 4.3, 4.4, and 4.5 in 1989. Many of the pipes leading from the industrial floor drains to the Units 4.3, 4.4, and 4.5 system are located under building floors and machinery and/or are buried below ground and are largely inaccessible. Piping segment I-1 conveyed influent to Units 4.3, 4.4, and 4.5. Pressure testing conducted during closure of Units 4.3, 4.4, and 4.5 suggested that pipe segment I-1 may have been leaking. Because pressure testing suggested that this pipe may have leaked, accessible portions were exposed and visually inspected and then removed. Visibly stained soil from around the piping was also excavated and disposed of. Inaccessible piping was capped and left in place. One sample was collected underneath the piping and one sample was collected underneath a valve.

The liquids potentially discharged to the industrial drains would consist of liquids present within the industrial buildings and facilities. Liquids used in industrial buildings operations included lubricating oil, oily water from the steam-cleaning area and compressor and generator engine cleaning, jacket cooling water, and lubricating-oil cooling water. Drainage from the various cooling water systems would have contained chromium compounds and, later, molybdenum. No records exist of any specific releases to the industrial drains; however, the drains are expected to have captured incidental drips and spills during plant operations, as well as occasional washing liquid from floor cleaning within the buildings. Information collected during the facility assessment indicated that the oil/water holding tank (Unit 4.3) collected approximately 220,000 gallons of oily water per year from the compressor floor drainage (about 200,000 gallons per year), compressor engine cleaning operations (about 10,000 gallons per year), and steam-cleaning operations (about 10,000 gallons per year) (Kearny, 1987). In general, all oily water was discharged to the oily water system, as it is today.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 20 based on the above site history and background, as shown in Figure B17-1. (All tables and figures appear at the end of this sub-appendix.) Table B17-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 20. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 20 are likely to be incidental spills and leaks from the industrial drain system of lubricants and cooling water generated during plant operations. The quantity of liquid released from the industrial floor drains to the environment is unknown.

The primary source media at AOC 20 are shallow and/or subsurface soil, as the system consists primarily of underground piping. Short runs of aboveground piping overlying unpaved (gravel covered) soil are also part of this unit. In the gravel-covered areas with aboveground piping, liquids released in AOC 20 would have been released to surface soil and could have infiltrated shallow soil. Liquids released to shallow soils either directly from underground piping or through infiltration from the surface could have infiltrated to deeper soils. If present, organic constituents in surface soils could have been degraded by heat and light. Because the entire AOC is covered with gravel or pavement, runoff of contaminated surface soil in rainwater is not considered a potential migration pathway.

2.0 Summary of Past Soil Characterization

As noted above, two samples were collected from the I-1 piping segment during the closure of the former Units 4.3, 4.4, and 4.5. The two I-1 pipelines segment samples were analyzed for total petroleum hydrocarbons as gasoline, diesel, motor oil, and jet fuel (TPH-gasoline, TPH-diesel, TPH-motor-oil, and TPH-jet-fuel). TPH-motor-oil was the only TPH constituent detected. This constituent was detected at concentrations of 850 and 1,200 milligrams per kilogram (mg/kg), respectively, in the two samples. These concentrations are below the applicable environmental screening level of 1,800 mg/kg promulgated by the California Regional Water Quality Control Board.

3.0 AOC 20 Data Gaps and Proposed Sampling

3.1 AOC 20 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gap was identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination underneath the piping conveying discharge from the industrial floor drains.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.
- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.
- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with chemicals of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.
- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 AOC 20 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 20 itself contributes to the access constraints within the compressor station, as a large portion of the piping associated with this unit is located underground. The only areas within the station that do not have any identified piping associated with AOC 20 are Areas 4, 5, 10, and 16 on the Topock Compressor Station

Accessibility Map (see Figure B-2). Access constraints for AOC 20 include numerous buildings and other utilities. Sampling may be feasible underneath aboveground portions of the system; no attempt will be made to locate and uncover underground piping as—it is operational equipment. Sample locations and depths identified for AOC 20 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

3.3 AOC 20 Proposed Sampling

Table B17-2 summarizes the proposed AOC 20 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B17-2. The proposed AOC 20 sample locations are PG&E's initial assessment of candidate locations for additional characterization. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Based on operational history and DTSC requirements, the COPCs associated with AOC 20 are Title 22 metals, hexavalent chromium, volatile organic compounds (VOCs), TPH, polychlorinated biphenyls (PCBs), and PAHs. COPCs are anticipated to be limited to soil (CH2M HILL, 2007).

Samples will be collected at eight locations: AOC 20-1 through AOC 20-8. Because of limited access, numerous subsurface utilities and pipelines, and operational features, only hand tools can be used to collect samples in AOC 20. Therefore, samples will only be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Where the area of sampling is covered with concrete or asphalt, the surface sampling interval will begin 6 inches below the bottom of the concrete/asphalt or gravel sub-base. All samples will be analyzed for Title 22 metals, hexavalent chromium, VOCs, TPH, PCBs, and PAHs. As required by the United States Department of the Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B17-2); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

APPENDIX B18

AOC 21 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 21 is a former round structure partially filled with white material adjacent to the sludge drying beds (Solid Waste Management Unit 5) that is visible in the May 19, 1955 aerial photographs. AOC 21 was incorporated into this Work Plan at the request of California Environmental Protection Agency, Department of Toxic Substances Control based on a review of historical aerial photographs (DTSC, 2010). No interview or written information has been identified related to this structure. The structure appears to contain material of the same color as the material in the Sludge Drying Beds, and may have served as an overflow and/or storage area for the Sludge Drying Beds. During the 1950s and early 1960s, the sludge drying beds (Solid Waste Management Unit 5) were used to dry lime treatment sludge from the Permutit® water softening system. The available information indicates that at least a portion of the dried or partially dried sludge was transported to the Railroad Debris Site (AOC 14) (Russell 2006 a). Some apparent spillage of the white material is visible between the Sludge Drying Beds and the round structure.

The structure appears to consist of a circular earthen berm. No information is available regarding the materials of construction. The sludge drying beds were constructed to a depth of 2 feet below ground surface (bgs) (CH2M HILL 2007a), and from the aerial photos the structure appears to be similar in elevation to the deeper portions of the Sludge Drying Beds. The sludge drying beds were approximately 20 feet wide by 50 feet long; the round structure appears to have a diameter slightly greater than the width of the Sludge Drying Beds.

No samples have been collected in this area. The Permutit water softening system used a combination of lime and soda ash to remove excess minerals from Topock well water. Based on data from the white powdery material in AOC 14, it is possible that the material contains low levels of total and hexavalent chromium

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 21 based on the above site history and background, as shown in Figure B18-1. (All tables and figure appear at the end of this sub-appendix.) Table B18-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 21. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 21 are likely to be incidental spills of water-softener sludge during transfer of material from the sludge-drying beds to AOC 21 and/or during loading of material onto trucks to haul it to AOC 14. Some incidental spills apparently occurred, as there is some white coloration present between AOC 21 and the sludge-drying beds. The water-softener sludge likely contained some liquid, as former employees reported that it was sprayed onto the ground at AOC 14 (CH2M HILL, 2007). The potential quantity of solids sludge and/or associated liquid released in the vicinity AOC 21 is unknown. It is possible that the bottom of the structure consisted solely of soil, and that softened water may have been released to shallow soil directly beneath the structure.

The primary source media at AOC 21 are surface and shallow soil. Because the area around AOC 21 was unpaved, spilled sludge would have been released directly to surface soil and any associated liquids could have infiltrated shallow soil. Liquids released inside the round structure AOC 21 would have been released to directly to shallow soil. Liquids released to shallow soils could have infiltrated to deeper soils. Runoff of contaminated surface soil in rainwater is a potential migration pathway for soils located outside the structure.

2.0 Summary of Past Soil Characterization

This AOC has not been previously sampled.

3.0 AOC 21 Data Gaps and Proposed Sampling

3.1 AOC 21 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gap was identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination underneath and immediately adjacent to the round structure.

Data gaps for Decisions 2 through 5 are discussed in the main text of this appendix, and include the following:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes polycyclic aromatic hydrocarbons, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with chemicals of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data, and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 AOC 21 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 21 is located in Area 3 (Figure B-2). Twenty-three utility risers, including gas, odorant, waste water, electrical, SCADA, and an emergency shutoff device, are located in Area 3 on the Topock Compressor Station Accessibility Map (see Figure B-2). In addition, a utility trench, an anode, and three vaults were identified in Area 3. Sample locations and depths identified for AOC 21 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot below ground surface (bgs) or less.

3.3 AOC 21 Proposed Sampling

Table B18-2 summarizes the proposed AOC 21 sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B18-2. The proposed AOC 21 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Based on the available information, COPCs for this unit consist of metals, potentially including hexavalent chromium. COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Samples from this area will be analyzed for Title 22 metals, hexavalent chromium, calcium, sodium, and pH. Samples will be collected at two locations: AOC 21-1 and AOC 21-2. Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in AOC 21; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Ten percent of all samples collected during the investigation will also be analyzed for the full suite of Target Analyte List/Target Compound List constituents.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B18-2); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

APPENDIX B19

AOC 22 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 22, which is visible in the May 19, 1955 aerial photographs (CH2M HILL, 2007), consists of a three-sided structure located in the upper yard, along what is now the compressor station fence line. AOC 22 was incorporated into this Work Plan at the request of California Environmental Protection Agency, Department of Toxic Substances Control (DTSC, 2010). The northern end of the structure was slightly north of what is now the Tech Maintenance Shop (the Tech Maintenance Shop did not exist in the aerials that show the three-sided structure). Based on the aerial photo, it appears that the footprint of the structure would have been located within the current unpaved area adjacent to the fence line.

In the aerial photo, a container that appears to be a drum is located near this structure. There is no available information on the use of this structure or any materials that may have been stored at this structure or in its vicinity. The area around the structure is unpaved.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 22 based on the above site history and background, as shown in Figure B19-1. (All tables and figures appear at the end of this sub-appendix.) Table B19-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 22. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 22 are likely to be incidental spills of any materials stored in this area. The potential type and quantity any materials released in the vicinity this structure are unknown. The primary source medium at AOC 22 is surface soil. Because the area around AOC 22 is unpaved, liquids released in AOC 22 would have been released to surface soil and could have infiltrated shallow soil. Liquids released to shallow soils could have infiltrated to deeper soils. If present, organic constituents in surface soils could have been degraded by heat and light. In addition, contaminated surface soil runoff would have been a potential migration pathway to the east to the area outside the fence line.

2.0 Summary of Past Soil Characterization

There is no information regarding the purpose of this structure, and there are no current data in the immediate vicinity of the structure; however, several samples associate with AOC 9 (Southeast Fence Line) are located downslope from this structure. Sample locations AOC9-5 and AOC9-10 are immediately downslope from where the three-sided structure was located. Sample locations AOC9-6, AOC9-11, AOC9-13, and AOC9-14 are located further downslope (i.e., downslope from locations AOC9-5 and AOC9-10).

The six soil samples collected immediately downslope of this structure indicate that total chromium, hexavalent chromium, copper, lead, mercury, zinc, and benzo(a)pyrene exceeded the Part A screening values for areas outside the fence line one or more times in these samples. Detectable concentrations of mercury were found in four of the six samples.

3.0 AOC 22 Nature and Extent Data Gaps Evaluation

This AOC has not been previously sampled.

4.0 AOC 22 Data Gaps and Proposed Sampling

4.1 AOC 22 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gap was identified for Decision 1, as follows:

1. Data Gap #1 – Lateral and vertical extent of contamination underneath and immediately adjacent to former three-sided structure.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include the following:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound (SVOC) analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with chemicals of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

4.2 AOC 22 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 22 is located in Area 16 on the Topock Accessibility Map (Figure B-2). Thirty-six utility risers, consisting of various water and electrical lines, are present in this area. Photograph 44 in sub-Appendix B25 show the accessibility constraints in AOC 22. Sample locations and depths identified for AOC 22 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot below ground surface (bgs) or less.

4.3 AOC 22 Proposed Sampling

Table B19-2 summarizes the proposed AOC 22 sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B19-2. The figure also shows proposed sample locations for surrounding SWMUs and AOCs. The proposed AOC 22 sample locations are Pacific Gas and Electric Company’s initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Samples will be collected at two locations: AOC 22-1 and AOC 22-2. Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in AOC 22; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. COPCs have not been defined for this unit. COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Samples from this area will be analyzed for Title 22 metals, hexavalent chromium, pH, volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), SVOCs, PCBs, and PAHs. Ten percent of all samples collected during the investigation will also be analyzed for the full suite of Target Analyte List/Target Compound List constituents.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B19-2); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

Area of Concern 23 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 23 is the former water conditioning building which is located in the southern portion of the upper yard. AOC 23 was incorporated into this Work Plan at the request of California Environmental Protection Agency, Department of Toxic Substances Control (DTSC, 2010). Two solid waste management units (SWMUs)—SWMU 7 Precipitation Tank (closed), and SWMU 8 Process Pump Tank—are located immediately south of this building (the area occupied by the two former tanks is now covered by the Fire Pump Building). The tanks associated with these two units were removed in 1990 as part of the closure of the former hazardous waste treatment system. The Former Water Conditioning Building has also previously been identified as the “Water-Softening Building” and is currently identified as the “Storage Building.” AOC 23 is currently used for storage of dry materials; no hazardous materials are stored here.

Available information indicates that the Former Water Conditioning Building was used for dry storage of the chemicals used in the Permutit water-softening process used at the compressor station until approximately 1962 and also contained the treatment plant (water-softening process). The treatment plant consisted of one to two tanks that were used to handle a mixture of soda ash, lime, and sodium aluminate. Raw (incoming) well water was pumped through the plant to remove excess minerals and thereby soften the water. Minerals were removed from the raw well water to reduce the amount of cooling tower blowdown generated during plant operations. Since the Former Water Conditioning Building was part of the water softening system, it would have most likely contained pertinent structures to get chemicals into the system, which may have included hoppers and aboveground tanks.

From 1969 to 1985, the tanks formerly located outside the building (then called the Precipitation Tank [SWMU 7], and the Process Pump Tank [SWMU 8]) were used as part of the hazardous waste treatment system. Therefore, it is also possible that this building may have been used to store chemicals or house incidental equipment associated with the hazardous waste treatment system. The chemicals used in the hazardous waste treatment system at this location consisted of sodium hydroxide, Poly Floc II, and ferric sulfate in the Precipitation Tank. No chemical were known to have been added to the Process Pump Tank.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 23 based on the above site history and background, as shown in Figure B20-1. (All tables and figure appear at the end of this sub-appendix.) Table B20-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 23. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 23 are likely to be historical incidental spills of dry soda ash or lime, and/or water-softening sludge. If sodium hydroxide, Poly Floc II and ferric sulfate were stored in the building, incidental spills of these chemicals could also have occurred at AOC 23. The quantity any materials released is unknown; however, is expected to be relatively small, as spills of dry material would most likely have been contained in the building or cleaned up if needed, and spills of water softening sludge in the building would similarly have been cleaned up. Sodium hydroxide spills would have been cleaned up quickly due to the acute danger posed by the chemical. Any releases of sodium hydroxide to soil would have raised the pH of the soil and thereby reduced the solubility of metals in the soil. If a large release of water-softening sludge occurred, it could have resulted in water potentially containing some sludge reaching the storm drain system and being discharged outside the fence line. Because the area around the AOC was unpaved, dry chemicals deposited on the soil could also have been entrained in stormwater runoff and being discharged outside the fence line. Releases via the storm drain system are addressed by the storm drain investigation program described in Appendix D of this work plan. Finally, while there is no information indicating that the concrete floor in the building lacked integrity in the past, it is possible that small cracks are present and that small quantities of dissolved lime or soda ash may have been released to shallow soil directly beneath the building.

The primary source medium at AOC 23 is concrete within the building (the building floor). Secondary source media include surface soil adjacent to the building, and shallow soil underneath the building. If any liquids were released in AOC 23, they would have been released to surface soil and could have infiltrated shallow soil or been released to shallow soil directly. Liquids released to shallow soils could have infiltrated to deeper soils. Due to the high pH of the main chemicals used in the water softening process, release of the chemicals or sludge would have helped to fix any metals contained in the material, and prevent migration. No organic compounds were used in the water-softening process.

2.0 Summary of Past Soil Characterization

There are no current data in the immediate vicinity of AOC 23; however, inorganic compound data from the adjacent SWMUs 7 and 8 were collected during the closure of the SWMUs. Both tanks were open top tanks located on concrete pads. Confirmation samples were collected following removal of the tanks, concrete foundations, sub-soils, and approximately 1 foot of contaminated soils. A sample trench was excavated, and confirmation samples were collected from two locations in the wall of the trench for SWMU 7 and one location for SWMU 8. At location PT-3, samples were collected at approximately 4 and 6 feet below ground surface (bgs). At location PT-4, samples were collected at 3.5 feet bgs. At location PPT-4, samples were collected at 4 and 5 feet bgs. The samples were analyzed for Title 22 metals, hexavalent chromium, fluoride, and pH.

The results of the final confirmation samples (PT-3_2, PT-3_4, and PT-4_1.5, PPT4_2, and PPT 4_3) indicated that all chemicals of potential concern (COPCs) were at levels below cleanup objectives (i.e., established background concentrations at the time). Five constituents were detected above their respective background threshold values in these five samples and mercury was detected at a concentration of 0.015 mg/kg. A background concentration for mercury has not been established; however, the detected concentration is below the commercial screening level. Cobalt, copper, lead, nickel, and zinc samples each exceeded their respective background threshold values once. None of these concentrations exceeded respective commercial screening levels. The overall concentration and distribution of constituents in the five samples indicate that there has been no adverse impact to soil beneath the former tanks. Additional data will be collected at SWMU 8 in accordance with requirements defined by the California Environmental Protection Agency, Department of Toxic Substances Control (2006).

This AOC has not been previously sampled.

3.0 AOC 23 Data Gaps and Proposed Sampling

3.1 AOC 23 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gap was identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination underneath and immediately adjacent to the Water Conditioning Building.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound (SVOC) analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 AOC 23 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 23 is located in Area 15 on the Topock Compressor Accessibility Map (Figure B-2). Thirty-five utility risers, including gas, electrical, SCADA, and water lines, are located in Area 3. In addition two anodes and a vault were identified in Area 15. Photographs 45 through 49 in sub-Appendix B25 show the accessibility constraints in AOC 23. The building has a two-level foundation: the western portion of the building has a foundation that is approximately 2 to 3 feet thick, and the eastern portion is approximately 1 foot thick. Sample locations and depths identified for AOC 23 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

Due to the active use of the building and difficult access into the building, no sampling is proposed within the building.

3.3 AOC 23 Proposed Sampling

Table B20-2 summarizes the proposed AOC 23 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B20-2. The figure also shows proposed sample locations for nearby SWMUs and AOCs. The proposed AOC 23 sample locations are Pacific Gas and Electric's initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Based on the available information, COPCs for this unit consist of metals, potentially including hexavalent chromium. COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Samples from this area will be analyzed for Title 22 metals, hexavalent chromium, volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), SVOCs, PAHs, polychlorinated biphenyls (PCBs), and pH. Samples will be collected at three locations: AOC 23-1 through AOC 23-3. Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in AOC 23; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Ten percent of all samples from the investigation will also be analyzed for the full suite of Target Analyte List/Target Compound List constituents.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B20-2); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

APPENDIX B21

AOC 24 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 24 is the stained area near the former structure found on the northern edge of the lower yard, and also includes the footprint of this former structure. AOC 24 was incorporated into this Work Plan at the request of California Environmental Protection Agency, Department of Toxic Substances Control (DTSC, 2010). The May 19, 1955 aerial photographs show a narrow, elongated area of dark staining near a structure located on the northeast side of the lower yard. This structure is located near where the oily water treatment system piping currently exits (near the grit tank) and may have been an American Petroleum Institute (API) oil/water separator that preceded the installation of the oil/water separator in the southern portion of the lower yard. Subsequent to the 1955 aerial photo, additional grading was performed in the lower yard, and the northern portion of the lower yard was expanded. The unit is also visible in a January 26, 1954 photograph documenting the construction of the first three northern scrubbers, and a subsequent (May 27, 1954) photo showing the completed scrubbers (California Environmental Protection Agency, Department of Toxic Substances Control, 2008). No staining is visible in either of these photos. However, staining is visible in a June 25, 1954 photo. It appears that the staining is due to a discharge emanating from the potential former API separator. No written or interview information about this staining or the potential former API separator has been identified, and no other information is available.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 24 based on the above site history and background, as shown in Figure B21-1. (All tables and figures appear at the end of this sub-appendix.) Table B21-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 24. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2010).

The primary sources of contamination at AOC 24 are likely to be historical liquid discharges from the former structure. The quantity of liquid released from the structure is unknown. There is a potential for the discharge to have migrated past what was then the northern boundary of the lower yard; however, with the expansion of the compressor station, the affected area would now be covered by several feet of additional soil.

The primary source medium at AOC 24 was surface soil and may now be shallow or subsurface soil. Because the entire AOC is covered with additional soil, runoff of contaminated surface soil in rainwater is not considered a potential migration pathway.

2.0 Summary of Past Soil Characterization

No data have been collected in the vicinity of the stained soil or the potential former API separator.

3.0 AOC 24 Data Gaps and Proposed Sampling

3.1 AOC 24 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gap was identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination near the stained soil.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound (SVOC) analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with chemicals of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 AOC 24 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 24 is located in Area 1 on the Topock Compressor Accessibility Map (see Figure B-2). Eighty-eight utility risers, including main gas, gas, odorant, waste water, and electrical lines, are located in Area 1. Photograph 50 in sub-Appendix B25 show the accessibility constraints in AOC 24. Sample locations and depths identified for AOC 24 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot below ground surface (bgs) or less.

3.3 AOC 24 Proposed Sampling

Table B21-2 summarizes the proposed AOC 24 sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B21-2. The figure also shows proposed sample locations for nearby solid waste management units and AOCs. The proposed AOC 24 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Based on the available information, COPCs for this unit consist of metals, total petroleum hydrocarbons (TPH), and PAHs. COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Samples from this area will be analyzed for Title 22 metals, hexavalent chromium, volatile organic compounds (VOCs), TPH, SVOCs, PAHs, polychlorinated biphenyls (PCBs), and pH. Samples will be collected at two locations: AOC 24-1 and AOC24-2. Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in AOC 24; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Ten percent of all samples collected during the investigation will also be analyzed for the full suite of Target Analyte List/Target Compound List constituents.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B21-2); the specific sample to be analyzed for these parameters will be confirmed in the field. -Data will be reviewed and evaluated as described in the main text of this appendix. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

AOC 25 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 25 is the compressor station engines and associated basements and the auxiliary (generator) engines and associated basements. AOC 25 was incorporated into this Work Plan at the request of California Environmental Protection Agency, Department of Toxic Substances Control (DTSC, 2010). The Topock Compressor Station contains 10 compressor engines; nine of these engines are currently active. The Auxiliary Building houses four generators that provide electricity to the station. The compressors and generators are fueled by natural gas and are housed inside the Compressor Building in the upper yard, respectively.

Each compressor engine is mounted on a concrete block; the top of the concrete pedestal is level with the floor of the building. Each concrete pedestal is surrounded by an open concrete trench. This open area is referred to as the compressor engine basement. The basements for each unit extend across the entire width of the Compressor Building, and have small openings (open air windows) on each side of the building to allow pipes to enter the basement. The lower edge of the openings is approximately 36 inches above the floor of the basement. Each compressor basement is also equipped with two drains that are connected to the oily water treatment system. The basements provide access to piping leading to and from the compressor engines, as well as to the lower portions of the compressor engines themselves. During normal operation, the basements are covered with solid trench plates. Incidental drips and leaks from the compressor engines would enter the basements and would be discharged to the drains connected to the oily water treatment system.

The generators are equipped with basements somewhat similar to the compressors. The generator basements are shallower, have only one drain, and only have an open air window on the east side of the Auxiliary Building. The bottom of the window opening is level with the basement floor. Incidental drips and leaks from the generator engines that collect in the basements would be discharged to drains connected to the oily water treatment system, and could also leak out through the basement window.

The basements were not intended or designed to serve as holding areas for large quantities of liquids. The two types of liquids present in the compressor and generator engines are lubricating oil and cooling water. When the lubricating oil is drained from the compressor or generator engines during engine maintenance, it is (and has historically) been drained directly to a holding tank via piping specifically installed for that purpose. Cooling water was contained in a closed-loop system. When this system was drained the water was combined with the oily water, and was routed to the oil/water separator. The oil/separator effluent was then combined with the cooling tower blowdown. Currently, the cooling water is still drained to the oil/water separator through the industrial drains. The engine basements are cleaned periodically to remove surface coatings of oil; the cleaning water is allowed to drain to the oily water treatment system.

Some site investigation and soil removal has been conducted adjacent to the east side of the Auxiliary Building in AOC 13. This area was formerly unpaved and is now covered with concrete. Prior to the installation of the concrete apron, visibly stained soil was removed, and 18 soil samples were collected and analyzed for TPH constituents (TPH-gasoline, TPH-diesel, TPH-motor oil, TPH-heavy oil); of these eight samples were also analyzed for lead. Samples were collected at depths ranging from 0 to 2.5 feet below ground surface (bgs). Five samples were analyzed for TRPH; these samples were collected at depths ranging from 1 to 3 feet bgs. All sample data are data quality Category 3, and are located in areas now covered by the concrete apron.

Lead was detected in all eight samples analyzed, at concentrations ranging from 8 to 31 mg/kg. None of these concentrations exceed the commercial screening value (California Human Health Screening Level for commercial use). TPH-motor oil and TRPH were the only TPH constituents detected. TPH-motor oil was detected in 13 of 17 samples analyzed for this constituent, and TRPH was detected in all five samples analyzed for this constituent. Detected concentration of TPH-motor oil ranged from 24 to 46,900 mg/kg; three samples exceeded the RWQCB Environmental Screening Level (ESL) of 1,800 mg/kg. TRPH was detected a concentrations ranging from 10,100 to 85,000 mg/kg; no screening level exists for this compound.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for Area of Concern (AOC) 25 based on the above site history and background, as shown in Figure B22-1. (All tables and figures appear at the end of this sub-appendix.) Table B22-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 25. A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 25 are likely to be small-scale historic liquid discharges from the compressor and generator engines, including small quantities of lubricating oil, cleaning fluids, and coolant. The estimated annual flow of oily waste water is 220,000 gallons (CH2M HILL 2007); a portion of this total derives from the drains in the Compressor and Auxiliary Buildings. The construction of the compressor basements largely precludes releases of fluids from the basements to the soil adjacent to the buildings. Only if there had been massive failure of an engine or a cooling water line would large quantities of liquids have been generated and had any potential to overflow out of the compressor basement to areas adjacent to the buildings. There are no records of any such events.

Unlike the compressor basements, the generator engine basements would have been more likely to have leaked oily water and cooling liquid to the area immediately outside the building, because the bottoms of the windows were at the same level as the basement floors. As discussed above, stained soil was removed from this area and the area was subsequently paved with concrete.

The primary source media at AOC 25 are surface soil, shallow soil and concrete. Liquids released to the drains could have entered shallow soils at breaks in the oily water system pipelines, and from shallow soil the liquid could have infiltrated to deeper soils. Leaks to surface soil outside the generator engine basements could have infiltrated to shallow soil, and from shallow soil the liquid could have infiltrated to deeper soils. Liquids released to the basements could also have impacted the concrete. However, the concrete is steam-cleaned periodically, and concrete is not considered a major source. Because the entire potential surface soil source area is covered by concrete or asphalt, runoff of contaminated surface soil is not considered a potential migration pathway.

2.0 AOC 25 Nature and Extent Data Gaps Evaluation

No data have been collected from the compressor engine or generator engine basements. Surface soil data are available for the areas immediately adjacent to the compressor and auxiliary buildings; however, these data address potential leaks and drips from the pipes and other equipment adjacent to the buildings, and are not related to the basements. These data are evaluated as part of AOC 13 in sub-Appendix B11.

3.0 AOC 25 Data Gaps and Proposed Sampling

3.1 AOC 25 Data Gaps

Based on the site conceptual model and Part B data quality objectives, the following data gap was identified for Decision 1:

1. Data Gap #1 – Lateral and vertical extent of contamination underneath the Compressor and Auxiliary Buildings and the associated basements.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound analysis, which includes polycyclic aromatic hydrocarbons, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with chemicals of potential concern (COPCs) and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

3.2 AOC 25 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 25 is located in Area 8 (Compressor Building) and 14 (Auxiliary Building), on the Topock Compressor Station Accessibility Map (see Figure B-2 of Appendix B). Eighty-nine utility risers, including main gas, gas, electrical, air, lubricating oil, lubricating oil cooling water, and jacket cooling water lines, are located in Area 8. Twenty-six utility risers, including main gas, gas, electrical, air, auxiliary lubricating oil cooling water, and water lines, are located in Area 14. In addition, a pipe trench and five vaults were identified in Area 14. Photographs 51 through 56 in sub-Appendix B25 show the accessibility constraints in AOC 25. The Compressor Building has a thick concrete foundation and use of equipment that may generate sparks is not permitted in the building. The Auxiliary Building also has a thick concrete foundation. Due to the active use of the buildings and physical danger associated with working in the buildings, no sampling is proposed within the buildings. Soil samples have been collected around the Compressor and Auxiliary Buildings (these samples are located in AOC 13; see sub-Appendix B11), and several more are proposed to be collected for AOC 13. These proposed and existing sample locations are shown on Figure B22-2. Detailed discussions of the existing and proposed sample locations are provided in sub-Appendix B11.

APPENDIX B23

AOC 26 Investigation Program

1.0 Introduction and Background

1.1 Background

Area of Concern (AOC) 26, The Scrubber Oil Sump (Scrubber Sump) was located in the lower yard south of the South Scrubbers and was removed May 15, 1996. AOC 26 was incorporated into this Work Plan at the request of California Environmental Protection Agency, Department of Toxic Substances Control (DTSC, 2010). It was removed as part of an upgrade of the waste oil system and was replaced with a pipeline liquids collection point. The Scrubber Sump consisted of an underground concrete structure with three compartments, each measuring 5 feet wide by 5 feet long by 4 feet deep. The Scrubber Sump received pipeline liquids removed from two banks of natural gas scrubbers. When the northern compartment of the scrubber sump filled up, the pipeline liquids were either transferred to one of the other two compartments or was pumped directly to the Dirty Oil Sump (Trident, 1996a).

Closure of the sump consisted of the following steps:

- Piping was emptied, disconnected, and capped at abandoned ends.
- Residual liquid was removed from the sump by vacuum.
- Oily sludge in the sump was removed, placed into 55-gallon drums, and disposed of at a Class I landfill as non-RCRA hazardous waste.
- The sump was steam-cleaned after removal of the liquids and sludge and was completely removed from the site.
- Discolored soil was excavated and stockpiled.
- Stockpiled soils were analyzed for California Assessment Manual (CAM) 17 metals; total petroleum hydrocarbons (TPH) by United States Environmental Protection Agency (USEPA) Method 418.1; and benzene, toluene, ethylbenzene, and xylene (BTEX) by USEPA Method 5030/8020
- The sludge within the sump was also analyzed for polychlorinated biphenyls (PCBs).
- Additional soil excavation was performed, and four initial confirmation samples were collected at 6 feet below ground surface (bgs) and were analyzed for TPH by USEPA Method 418.1
- Supplemental excavation was conducted to 10 bgs, and four additional soil samples were collected.

Although TPH was present in the bottom of the excavation, safety considerations precluded further extending or deepening the excavation. High-pressure pipelines are present to the south and west of the excavation area, and the scrubber oil pump foundation and enclosed electrical conduits are present to the north. The electrical conduits prevented removal of the pump foundation. Upon receipt of the closure certification report, the County of San Bernardino requested further delineation of the residual contamination (sidewall samples) and additional data for metals. The results of the additional sampling were submitted in an addendum to the closure certification report (Trident, 1996b).

To further assess the extent of the remaining contamination, platforms were constructed at the corners of the excavation to allow use of a hand sampling tool without having workers enter the excavation. The success of the hand sampling was limited by the very rocky soil encountered in the bottom of the excavation; soil samples were successfully obtained from four locations at depths ranging from 10.4 to 11 feet bgs; at two locations, two soil samples were collected (Trident, 1996b). Although there was residual contamination, closure of the tank was proposed based on leaking underground fuel tank manual criteria, including low rainfall and depths to groundwater exceeding 100 feet, which lead to the conclusion that the residual contamination did not pose a threat. The conclusions presented in the closure certification report remained the same (Trident, 1996b). No information is available regarding the backfill used to fill the excavation.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for Area of Concern (AOC) 26 based on the above site history and background, as shown in Figure B23-1. Table B23-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 26. (All tables and figures appear at the end of this attachment.) A detailed discussion of the migration pathways, exposure media, exposure routes, and receptors is included in the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (CH2M HILL, 2011).

The primary sources of contamination at AOC 26 are likely to be incidental spills or leakage at fittings during transfer of the accumulated pipeline liquids, as well as potential leaks through the bottom of the sump. The quantity of pipeline liquids released from the scrubber sump is unknown; however, as documented in the Trident report, some releases known to have occurred because contamination was present in the excavation.

The primary source medium at AOC 26 is subsurface soil. While there is residual contamination, it is present at approximately 10 to 11 feet bgs, as discussed in Section 2.0.

2.0 Summary of Past Soil Characterization

As described in Section 1.1, sampling at AOC 26 included the soil stockpiled from the excavation and the sludge in the bottom of the sump, two sets of confirmation samples, and a final round of sampling designed to further characterize residual contamination. The stockpile samples were analyzed for CAM 17 metals; TPH by USEPA Method 418.1; benzene, ethylbenzene, toluene, and xylene. In addition to these parameters, the sludge sample was also analyzed for PCBs. Neither tabulated data nor laboratory data reports are included in the available copy of the closure report. The following information was provided in the text:

- Metals concentrations in the stockpile soil samples are near background.
- Benzene, ethylbenzene, toluene, and xylene test results were less than 1 milligram per kilogram (mg/kg).
- PCBs in the sludge sample were non-detect.
- TPH is the only chemical of concern.

Although the metals results were described as being near background, the maximum concentration of chromium detected was 139 mg/kg, and the maximum concentration of lead detected was 89 mg/kg (Trident, 2006b).

Based on the results of the soil stockpile and sludge testing, which concluded that “oil” (i.e., TPH) was the only constituent of concern, confirmation samples were consequently analyzed for TPH only. The test results from the initial round of confirmation sampling indicated that TPH concentrations in the four samples ranged from 8,400 mg/kg to 15,000 mg/kg, and additional excavation was performed to 10 feet bgs. Four additional confirmation samples were collected; TPH concentrations ranged from 2,000 mg/kg to 12,000 mg/kg.

As discussed in Section 1.1, because further excavation would not have been safe, an attempt was then made to characterize the remaining contamination; however, the rocky soil greatly limited the depth that could be achieved for these supplemental samples. Samples from the southern portion of the excavation were collected at 10.5 (two locations), 10.8, and 11.0 feet bgs and contained TPH at 1,300 mg/kg, 780 mg/kg, 570 mg/kg, and 400 mg/kg, respectively. Only two samples were obtained from the northern side of the excavation at 10.4 and 10.5 feet bgs. These two samples contained TPH concentrations of 3,700 mg/kg (“North” sample) and 15,000 mg/kg (“Northeast” sample). There was no visible discoloration of the soil.

At the request of San Bernardino County, additional metals analyses were performed on the stockpiled soil and high-TPH concentration samples from the bottom of the excavation. Sidewall samples were analyzed for TPH; however, the analytical results are not provided in the available copy of the report (Trident, 2006b). The testing of the stockpiled soil consisted of analysis for hexavalent chromium, waste extraction tests for total chromium and lead, and a fish bioassay to determine toxicity. Hexavalent chromium was non-detect, and waste extraction test results for both total chromium (1.9 milligram per liter [mg/L]) and lead (0.63 mg/L) were well below the soluble threshold limit concentrations (560 mg/L and 5 mg/L, respectively). The soil sample also passed the fish bioassay. In addition, three high-TPH concentration excavation bottom and sidewall samples (with TPH concentrations ranging from 6,700 mg/kg to 15,000 mg/kg) were analyzed for total chromium, lead, and hexavalent chromium. Hexavalent chromium was non-detect in all three samples, total chromium concentrations ranged from 14 to 22 mg/kg, and the samples with the highest detected TPH concentration (SS-NE-10.5) also contained a detectable concentration of lead (12 mg/kg). The detected lead concentration slightly exceeds the background threshold value for lead (8.39 mg/kg). Although the specific date of the additional metals analysis for the stockpile sample is uncertain, it is likely that the holding time for hexavalent chromium was exceeded.

3.0 AOC 26 Nature and Extent Data Gaps Evaluation

The following subsection discusses the nature and extent of detected chemicals of potential concern (COPCs) and chemicals of potential ecological concern detected above interim screening levels at AOC 26. As discussed in Appendix B, multiple factors were considered to assess whether the nature and extent of a specific chemical has been adequately delineated. Section 4.0 of this sub-appendix provides the recommended sampling for this unit.

Based on the site history, background, and conceptual site model, qualitative review of the historical data indicates that slightly elevated levels of metals and slightly to moderately elevated levels of TPH may be present in the subsurface below depths of approximately 10 feet bgs. In addition, the source of the backfill for the excavation is unknown.

4.0 AOC 26 Data Gaps and Proposed Sampling

4.1 AOC 26 Data Gaps

Based on the Part B data quality objectives, data gaps were identified for Decision 1:

1. Data Gap #1 - Vertical and lateral extent of contamination beneath and immediately adjacent to the former excavation.
2. Data Gap #2 – Quality of the backfill in the former excavation.

Data gaps for Decisions 2 through 5 are discussed in Appendix B and include:

- **Decision 2:** In general, with the exception of polycyclic aromatic hydrocarbons (PAHs) in shallow soil, existing data are adequate to support exposure point concentration development for detected chemicals that exceeded one or more comparison values. However, since semivolatile organic compound (SVOC) analysis, which includes PAHs, has been added to most soil samples collected within the fence line, this data gap has been addressed.

- **Decision 3:** Nature and extent (Decision 1) must be defined to fully assess Decision 3. Insufficient information is available to calculate soil screening levels protective of groundwater and to support screening-level groundwater modeling results, where necessary.

- **Decision 4:** Insufficient information is available to characterize the potential migration pathways from areas within the fence line to areas outside the fence line. An evaluation of the storm drain system and sheet flow runoff pathways is required. In addition, data are required to characterize surface soils in unpaved areas, to define locations with COPCs and chemicals of potential ecological concern above Part A interim screening levels that could become potential sources of COPCs and chemicals of potential ecological concern to areas outside the fence line.

- **Decision 5:** Various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study and potential interim measures, including soil physical parameters, constituent leachability data and, if remediation is required, waste characterization information and more detailed information on subsurface obstructions.

The proposed sample design is discussed below.

4.2 AOC 26 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. AOC 26 is located in Area 2 on the Topock Compressor Station Accessibility Map (Figure B-2). One hundred and thirty-four utility risers, including main gas, gas, electrical, odorant and water line, were identified in Area 2. In addition, this area contains an emergency shutoff device, five vaults, a control panel, a utility trench, and a pipe coming from the upper yard. Photographs 57 through 59 in sub-Appendix B25 show the accessibility constraints in AOC 26. Sample locations and depths identified for AOC 26 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

4.3 AOC 26 Proposed Sampling

Table B23-2 summarizes the proposed AOC 26 sample locations, depths, description/ rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B23-2. The proposed AOC 26 sample locations are Pacific Gas and Electric Company’s initial assessment of candidate locations for additional characterization to fill the data gaps. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

Based on the available information, COPCs for this unit associated with releases from the scrubber sump consist of metals and TPH; the quality of backfill is unknown. COPCs are anticipated to be limited to soil only (CH2M HILL, 2007). Samples from this area will be analyzed for Title 22 metals, hexavalent chromium, volatile organic compounds (VOCs), TPH, SVOCs, PAHs, PCBs, and pH. Samples will be collected at one location: AOC 26-1. Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in AOC 23; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. Ten percent of all samples from the investigation will also be analyzed for the full suite of Target Analyte List/Target Compound List constituents.

To address the data needs associated with Decision 5, one sample will also be analyzed for soil characteristics, including grain size, washes (P200 sieve), Atterberg limits, and gradation. The sample has been tentatively identified (see Table B23-2); the specific sample to be analyzed for these parameters will be confirmed in the field. Data will be reviewed and evaluated as described in Appendix B. In addition, to address potential concerns associated with leaching of COPCs to groundwater, select samples may be analyzed for soluble total chromium and hexavalent chromium using the SW1312 synthetic precipitation leaching procedure. Samples will be analyzed by synthetic precipitation leaching procedure only after initial sample results have been received, evaluated, and compared against the soil screening levels developed for Decision 3.

Units 4.3, 4.4, and 4.5 Investigation Program

1.0 Introduction and Background

The former oily water treatment system consisted of the oil/water holding tank (Unit 4.3), the oil/water separator (OWS) (Unit 4.4), the portable waste oil storage tank (Unit 4.5), and the interconnecting piping, located in the southern portion of the lower yard, as shown in Figures B24-1, and B24-2. Closure of these facilities was performed between November 1989 through March 1990 in general accordance with the *Work Plan for Removal of the Oil Water Separator System, Topock Compressor Station* (Mittelhauser, 1989). The former oil/water separator was located slightly further west than the current system, shown on Figure B24-1. (All tables and figures appear at the end of this sub-appendix.)

1.1 Unit 4.3 Former Oil/Water Holding Tank

The oil/water holding tank was identified by the United States Environmental Protection Agency (USEPA) in the *RCRA Facility Assessment, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California* (RFA) (Kearny, 1987) but was not subsequently designated as a Solid Waste Management Unit (SWMU) or Area of Concern (AOC) by the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC). The oil/water holding tank was reported to have been installed in 1970 (Kearny, 1987).[1] It consisted of a cylindrical steel tank about 15 feet long and 5 feet in diameter with a capacity of 3,000 gallons. The tank was mounted horizontally on two concrete supports; the area beneath the tank and around the OWS was unpaved.

The oil/water holding tank was used to collect oily water from the compressor floor drainage (about 200,000 gallons per year), compressor engine cleaning operations (about 10,000 gallons per year), and steam-cleaning operations (about 10,000 gallons per year) (Kearny, 1987). In general, all oily water was discharged to the oily water system, as is the case today (Russell, 2006). Wastewater that was collected in this tank was discharged by gravity flow via an aboveground 3-inch-diameter steel pipe to the adjacent Unit 4.4.

Chemical analysis data for wastewater processed through the oil/water holding tank indicate that the wastewater contained up to 48 milligrams per liter oil and grease (Brown and Caldwell, 1986). Detectable concentrations of some metals, including total chromium, were also present in the wastewater. No indication of a release was observed during a facility inspection performed as part of the RFA (Kearny, 1987).

---

[1] The RFA (Kearny, 1987) indicates that the oil/water holding tank in place at the time of the RCRA facility investigation was installed in 1970. It is unknown whether the RFA information is correct, when the oily water treatment system may first have been installed in this area of the facility, whether another oil/water holding tank was in place prior to 1970, or whether prior to 1970, oily water flowed directly to an OWS. It appears that the oily water treatment system was not yet in place in 1955, although some type of equipment is discernable to the north of the eventual location in the May 1955 aerial photographs (CH2M HILL 2007).

The oil/water holding tank was removed in conjunction with the sludge-drying beds (SWMU 5) between November 1988 and February 1989 (Mittelhauser, 1990a). The steps taken during closure of the oil/water holding tank included:

- Hydroblasting of the steel tank; the hydroblast water was containerized and disposed of as hazardous waste.
- Removal of the tank from its foundation.
- The tank was cut up; due to the presence of oily sludge deposits in the tank that could not be removed, the tank was disposed of as hazardous waste.
- Removal of the concrete foundation; the tank foundation was not visibly contaminated and was therefore used as fill at the station.

Soils beneath the tank and concrete foundation were inspected and found not to be visibly contaminated; therefore, no confirmation samples were collected from this area.

1.2 Unit 4.4 Former Oil Water Separator

The former OWS (it was replaced with a new system) was identified by the USEPA in the RFA (Kearny, 1987) but was not subsequently designated as a SWMU or AOC by DTSC. The former OWS was part of the original oily water treatment system and was located adjacent to the oil/water holding tank (Unit 4.3) in the southern portion of the lower yard, as shown on Figure B24-1.

The former OWS was approximately 4.5 feet deep, 15 feet long, and 6 feet wide, and it was constructed of 6-inch-thick concrete (Kearny, 1987). The unit was set below grade (i.e., the top of the unit was at grade). The exact installation date for this unit is unknown. It received oily water from Unit 4.3 (Kearny, 1987). The unit was equipped with an underflow weir to control discharges and a suction pump on the effluent end to collect and remove floating oil. The floating oil was transferred by flexible hose to a portable waste oil storage tank (Unit 4.5). Prior to 1964, treated water from the OWS was directed to the transfer sump (SWMU 9) prior to discharge to Bat Cave Wash. From 1964 to 1969, effluent from the OWS may have been directed to the former sludge-drying beds and processed along with the cooling-water blowdown through the single-step chromium treatment system prior to discharge. From 1969 through October 1985, effluent from the OWS was routed to the chromate reduction tank and was processed along with the cooling-water blowdown through the two-step chromium treatment system prior to being discharged. In November 1985, the chromate reduction tank was converted into a holding tank (Kearny, 1987), and the discharge from the OWS was routed to either the holding tank or the transfer sump prior to discharge.

Chemical analysis data for wastewater processed through the OWS indicate that the wastewater contained up to 60 milligrams per liter oil and grease (Brown and Caldwell, 1986). Detectable concentrations of some metals, including total chromium, copper, and zinc, were also present in the wastewater. No indication of a release was observed during a facility inspection performed as part of the RFA (Kearny, 1987).

The OWS was closed and removed between November 1989 and March 1990 (Mittelhauser, 1990b). The steps taken during closure of the OWS included:

- Hydroblasting the concrete OWS was performed. The hydroblast water was containerized and disposed of as hazardous waste.
- Breaking up the concrete OWS. Due to oily sludge that could not be adequately removed, a majority of the concrete was disposed of as hazardous waste.
- Excavating approximately 14 cubic yards of visibly-stained soil. The soil was removed from the area around the former OWS and was disposed of as hazardous waste.
- Collecting three initial confirmation samples (OWS-10, OWS-11, and OWS-12).
- Removing another 5 cubic yards of soil in the vicinity of former sample 1042-55-12; the soil was disposed of as a hazardous waste.
- Collecting another confirmation sample (OWS-12-Deeper).
- Backfilling the pit with local material and performing final grading

After removal of the OWS and visibly-stained soil, three soil samples were collected from the excavation (OWS-10, OWS-11, and OWS-12) and were analyzed for total petroleum hydrocarbons (TPH) using USEPA Method 8015. Based on the work plan (Mittelhauser, 1989), the cleanup criterion for soil was established at 10,000 milligrams per kilogram (mg/kg) TPH. Sample 1042-55-12 contained TPH at a concentration exceeding the cleanup criterion, so an additional 5 cubic yards of soil were excavated from that area. A fourth confirmation sample (OWS-12-Deeper) was then collected. The locations of the samples are depicted in Figure B24-1.

1.3 Unit 4.5 Former Waste Oil Storage Tank

The portable waste oil storage tank was identified by the USEPA in the RFA (Kearny, 1987) but was not subsequently designated as a SWMU or AOC by DTSC. The portable waste oil storage tank was located in the southern portion of the lower yard adjacent to the OWS (Unit 4.4), as depicted in Figure B24-1.

The portable waste oil storage tanks consisted of an enclosed steel tank about 6 feet long and 2 feet in diameter, mounted horizontally on a trailer (Kearny, 1987). The tank was connected to a suction pump within the OWS with a flexible hose. The portable tank was stationed on a concrete pad that was bermed on three sides with a 6-inch-high curb. The fourth side of the pad was left open to allow removal of the unit.

The tank was used to collect floating oil from the OWS. When the tank was full, it was transported to the east side of the facility and placed next to the stationary waste oil storage tank (Unit 4.6). Oil within the portable tank was then transferred to the stationary tank. Starting in 1975, oil within the stationary tank was periodically removed, initially sold for reuse, and later transported offsite for recycling (Pacific Gas and Electric Company, 1980; Riddle, 2004).

The portable waste oil storage tank was removed from service in 1989. During the removal of the transfer sump (SWMU 9) and the OWS (Unit 4.4), the portable tank was used to temporarily hold waste oil removed from the sump and OWS. The waste oil was subsequently removed from the portable tank, and the tank was then transported offsite to

Chemical Transportation in Wilmington (Mittelhauser, 1990a). No indication of a release associated with the portable waste oil storage tank was observed during a facility inspection performed as part of the RFA (Kearny, 1987).

The steps taken during closure of the portable waste oil storage tank included:

- Waste oil in the tank was transferred to the waste oil storage tank (Unit 4.6) and was ultimately transported offsite for recycling.
- The empty tank was then transported offsite to Chemical Transportation for disposal or recycling.
- The concrete pad was demolished and disposed of along with the concrete from the OWS.

In addition to the OWS itself, the associated influent piping was closed. Pressure testing suggested that pipe segment I-1 may have been leaking. Complete details regarding the closure of this system are presented in the *Closure Activity Report, Oil Water Separator System, Topock Compressor Station* (Mittelhauser, 1990b). This report includes a description of the closure activities and contains the data from disposal characterization sampling, disposal manifesting information, and ultimate disposal locations. Soil sampling results are provided in Table B24-1.

2.0 Summary of Past Soil Characterization

Three historical subsurface soil samples were collected from three locations (OWS-10, OWS-11, and OWS-12-deeper) in Unit 4.4, as shown in Figure B24-1. The precise depth of the samples is not known; however they were collected below 4.5 feet below ground surface (bgs), as they were collected from the excavation below the former OWS. The former OWS was set 4.5 feet below grade, and approximately 19 cubic yards of soil were also removed from the excavation. Historical soil samples were analyzed for TPH- extractables only.

In addition to the samples collected from the excavation beneath the former OWS, two samples were collected underneath piping (I-1 segment) and a valve on the I-1 segment, respectively (OWS PI-1 and OWS Valve PI-1). The I-1 pipe segment was the pipe segment that carried the influent to the oil/water holding tank. Because pressure testing suggested that this pipe may have leaked, accessible portions were exposed and visually inspected, and then removed. Visibly stained soil from around the piping was also excavated and disposed of. Inaccessible piping was capped and left in place. The two I-1 pipelines segment samples were analyzed for TPH-gasoline, TPH-diesel, TPH-motor-oil, and TPH-jet-fuel. TPH-motor-oil was the only TPH constituent detected. This constituent was detected at concentrations of 850 and 1,200 mg/kg, respectively, in the two samples. These concentrations are below the applicable California Regional Water Quality Control Board environmental screening level of 1,800 mg/kg.

Laboratory analytical results for the historical soil samples are presented in Table B24-1. The historical data are considered Category 2.

This unit was closed by DTSC in 1995. Subsequent to this closure, DTSC requested that additional analysis be conducted for Title 22 metals, hexavalent chromium, pH, volatile organic compounds (VOCs), TPH, and semivolatile organic compounds (SVOCs) in soil at Units 4.3. 4.4, and 4.5 (DTSC, 2006). Chemicals of potential concern are anticipated to be limited to soil only (CH2M HILL, 2007). Section 3.0 provides the recommended sampling for this unit.

3.0 Units 4.3, 4.4, and 4.5 Proposed Sampling

3.1 Units 4.3, 4.4, and 4.5 Access Constraints

As discussed in Section 3.0 of Appendix B, there are substantial access constraints within the compressor station. Units 4.3, 4.4, and 4.5 are located in Area 3 on the Topock Compressor Station Accessibility Map (Figure B-2). Twenty-three utility risers, including gas, odorant, wastewater, electrical, SCADA, and an emergency shutoff device, are located in Area 3. In addition, a utility trench, a cathodic protection anode, and three vaults were identified in Area 3. Photographs 60 and 61 in sub-Appendix B25 show the accessibility constraints in Units 4.3, 4.4, and 4.5. Sample locations and depths identified for Units 4.3, 4.4, and 4.5 reflect the identified access constraints. As described in Appendix B, all sample locations in this area are limited to surface/shallow soils (depths that can be sampled using small hand tools). Generally, sampling using hand tools is limited to a depth of 1 foot bgs or less.

3.2 Units 4.3, 4.4, and 4.5 Proposed Sampling

Although this unit was closed in 1995, additional sampling for organic chemicals of potential concern and sampling of the fill used to backfill the excavation is proposed, as required by DTSC. Table B24-1 summarizes the proposed Units 4.3, 4.4, and 4.5 sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure B24-1. The proposed Units 4.3, 4.4, and 4.5 sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for additional characterization. The figures are provided to facilitate planning for additional sampling that may be needed to meet agency requirements and further progress toward decision-making for soil remediation.

Samples will be collected at two locations (Unit 4.3-1 and Units 4.3-2). Because of numerous subsurface utilities and pipelines, only hand tools can be used to collect samples in Units 4.3, 4.4, and 4.5; therefore, samples will be collected at the surface (0 to 0.5 foot bgs). If possible, a deeper sample will be collected at 2 to 3 feet bgs. If the area of sampling is covered with asphalt (i.e., in the station road), the surface sampling interval will begin at the bottom of the asphalt or gravel sub-base. All samples will be analyzed for Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, and polycyclic aromatic hydrocarbon (PAHs). As required by the United States Department of the Interior, 10 percent of all samples collected during the investigation will be analyzed for the full Target Analyte List/Target Compound List constituent suite.

DTSC GSU COMMENTS ON "RCRA FACILITY INVESTIGATION/REMEDIAL INVESTIGATION, SOIL INVESTIGATION WORK PLAN PART B, PG&E TOPOCK COMPRESSOR STATION, NEEDLES, CALIFORNIA" dated 3/25/08

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
General 1	The Department of Toxic Substances Control (DTSC) has conducted an evaluation of historic site related photographs provided subsequent to the RFI Part B Work Plan and provided comments in a GSU memorandum dated February 12, 2008. Areas identified in the review memo which occur within the facility fence line should be evaluated as part of the Part B work plan. Please provide a response to address those concerns and revise the workplan accordingly.	Comment acknowledged. Responses to these comments have been included with this comment response document.	No response necessary.	No response necessary.
General 2	The (DTSC) understands the limitations of investigating operating industrial facilities. However, an identification, rationale and discussion of units which cannot be adequately investigated and characterized while the facility is in operation is required. Please provide an evaluation of adequacy of investigation for each Solid Waste Management Unit (SWMU) and Area of Concern (AOC) including the proposed investigation and historical investigation. Additionally, provide a discussion of areas which cannot be characterized under normal operation, but where investigation might be undertaken if operations are offline for maintenance, etc. Additionally, please discuss additional sampling that can be conducted currently at Compressor Number 1. It is understood that this unit no longer operates and will remain offline as it has been used for parts.	The requested information will be provided in the revised Part B Workplan. A map will be developed and included in the Revised Part B Work Plan that will identify various access limitations within the Compressor Station. PG&E recommends a site visit to review proposed sampling locations to understand safety and access limitations to sampling within the Compressor Station. With respect to investigation at Unit 1, the gas compression process was thoroughly evaluated in the Final RFI/RI Volume 1. This included documenting the chemical use and waste generation and management. The compressors were not identified as a SWMU or AOC in the RFI/RI.	Field observations have identified the Compressor Engines as an AOC and shall therefore be designated as AOC 26, Compressor Engines. Large oily sump reservoirs were noted below the engines that were not described in the RFI Volume 1. A field visit is requested to assist in better understanding the unit. PG&E's proposed site visit to address access limitations must be conducted early in the process to assist in developing the work plan.	The Compressor Engines were designated AOC 25.
General 3	Background upper threshold limits (UTLs) for soils are yet to be determined for this project. Prior to any comparisons of site investigation data to background thresholds, an agreement must be achieved on the background dataset and the resultant statistical evaluations. The existing background dataset is useful in assessing the relative concentrations of constituents of potential concern (COPCs) at the site and DTSC acknowledges that additional background investigation is proposed as part of the November 2006 RFI Part A Workplan, however, the timing relationship of the background investigation and the on site Part A investigation should be stated to provide assurance that	The additional background investigation has been completed. The revised final technical memorandum was submitted and accepted by DTSC (*Revised Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California*; CH2M HILL, May 2009).	DTSC acknowledges receipt of the 2009 background soil technical memorandum.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	the background evaluation will be conducted first and soil data will be compared with the agreed upon background values.			
General 4	Sample depths proposed in the text of the document should be considered default values; however, significant lithologic changes, evidence of impact or other conditions warrant additional samples in place of or in addition to the defined depths.	During sampling if field conditions indicate that a greater sample depth is needed, PG&E will sample to a deeper depth as long as this meets the objectives of the work plan and the deeper samples can be collected safely. The maximum vertical sampling depth may be adjusted (up or down) based on field conditions.	Please note that the original DTSC comment is potentially requiring additional samples as well as potential adjustment of default sample depths. PG&E must ensure that this issue is documented in the text of the revised work plan.	A detailed accessibility evaluation was conducted as part of the work plan preparation process and is documented in Appendix B. Proposed sample locations and depths were determined based on the Part B DQOs evaluation and accessibility constraints.
General 5	If the results of the investigation indicate that contamination is present at any location in the deepest sample collected, additional sampling may be required by DTSC. The investigation will not be complete until the extent of contamination is adequately defined. Please provide a plan to address any areas in which the initial phase of sampling does not define the extent of contamination.	The data evaluation process illustrated in the draft Part B DQO decision flow charts (included in this comment response document) is designed to identify data gaps, if any, after the investigation described in the workplan is completed. Further sampling to fill the data gaps will be determined following the Part B data gaps evaluation and completion of DQO steps 6 and 7.	No response necessary.	No response necessary.
General 6	Each of the tables describing the proposed sampling programs (e.g., 5-3, 5-5, 5-7…) should include the rationale for each proposed boring, not just a description of the location. Please revise the applicable tables to include sampling rationale.	An additional column describing the rationale will be provided.	No response necessary.	No response necessary.
General 7	The work plan states that sampling for individual AOCs will be conducted to the currently defined boundary of the AOC. Any impacts beyond the boundary will be addressed as part of AOC 13. Characterization of AOCs and SWMUs should be completed specific to each unit. Sampling should continue in each area until the limits of impact are defined. The boundary can then be refined to include areas affected by the operation of the unit.	Comment noted. DTSC's proposed approach was agreed to by PG&E and DTSC during our discussion of the work plan assumptions in July 2007.	DTSC reiterates the original comment, characterization of AOCs and SWMUs should be completed specific to each unit. Sampling should continue for each unit, regardless of the current unit boundary, until the limits of impact are defined. The unit boundary can then be refined to include areas affected by the operation of the unit. Please revise the text of the work plan to ensure that the DTSC comment is addressed.	This text was removed from the work plan.
General 8	Uncertainty remains as to the usability of the historic data for characterization or risk assessment purposes. Evaluation of the Data Usability Assessment is ongoing and should be considered in the proposed sampling	Comment acknowledged. The Data Usability Assessment (DUA) has now been completed and accepted by DTSC and DOI (*Final Soil and Sediment Data Usability Assessment Technical Memorandum,*	No response necessary.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	program to ensure that all data are sufficient and adequate for risk assessment purposes. Currently, Category 2 data are not being considered eligible for risk assessment purposes unless the nature of any data deficiencies is clearly specified. A separate table should be included in the work plan to summarize the categories of the historic data. The table will illustrate that Category 2 or 3 data exits for some AOCs (i.e., AOCs 13 and 19) not identified in previous data usability assessments. The work plan should explicitly identify why each data set is assigned to a specific category (this should also be added to the summary table).	*PG&E Topock Compressor Station*; CH2M HILL, 2008). The DUA provides the basis for assigning each historic data point to a specific category (Categories 1, 2, 3). PG&E will provide the data quality categories for the historic data in table format in the workplan. Over 70% of the data within the compressor station fenceline are Category 2 or 3. Only Category 1 will be used for risk assessment, and Category 1 and 2 data will be used for site characterization. Category 3 data will provide additional insights regarding the potential extent of COPCs, but will not be relied upon to define the boundaries of contamination. (See the August 29, 2008 *Final Soil and Sediment Data Usability Assessment Technical Memorandum, PG&E Topock Compressor Station).*		
General 9	Several units that were formerly closed for inorganic constituents are currently being investigated since organic constituents were not included in the original investigation. It is recommended that metals analyses be included along with the organics as part of the scope of the proposed investigation for those closures with existing Category 2 metals data. The Category 2 metals data may be problematic as it may be inappropriate to use those data to assess cumulative risk. Collecting Category 1 metals data for these units will ensure that a risk assessment can be conducted if necessary.	As part of the DQO process (included in this comment response document), a data sufficiency evaluation will be performed to determine if there is adequate Category 1 data to address the various DQO decision statements.	Please revise the text of the work plan to ensure that the DTSC comment is addressed.	Inorganics analysis has been added to the closed SWMUs.
General 10	Field techniques, including x-ray fluorescence (XRF) should be tested at the site to determine if they can assist in locating conventional borings. The Fort Mojave Indian Tribe has specifically requested that field techniques of this nature be considered for Part A soil sampling programs. Conceptually, XRF surface sample data would provide information to place borings to collect conventional samples at proposed depths. Further, a phased approach to sampling could be utilized to limit the number of samples collected as well. Once data are obtained that shows the relative concentrations of COPCs, boring locations can be	The use of various non-invasive field techniques including XRF, will be evaluated for its use to help guide the Part B sampling program and if viable, will be included in the Revised Part B Work Plan.	Please revise the text of the workplan accordingly. Please note that XRF is being used extensively for field screening soils associated with the AOC 4 removal action.	Use of XRF was added as a field investigation methodology for debris in AOCs 10 and 14, and for soil in MW-24.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	modified to ensure that additional samples obtain the data necessary for the investigation.			
General 11	Statements are provided that only one drill rig will likely be working within the facility fence line at any one time. The total amount of time for the investigation would be significantly reduced if additional drilling crews worked concurrently. Although drilling crew costs may be higher, savings may be realized for other factors related to the project including regulatory oversight costs. The DTSC recommends not limiting the workforce as part of the workplan process, but rather basing the number of crews on the needs of the investigation.	Due to the high risk posed by subsurface investigations within the boundaries of the compressor station, PG&E requires that 2 monitors be present at each subsurface investigation location. One monitor oversees the overall effort, the other monitor specifically evaluates the progress of the subsurface investigation effort. All boring locations must be hand-dug to 3 or more feet bgs to avoid potential damage to subsurface utilities. The Topock Compressor Station does not have sufficient available personnel or emergency response capability to support more than one investigation location at a time. Further, many of the proposed sample locations will require traffic to be restricted from various areas of the compressor stations and will require re-routing of traffic. Having two rigs working at the same time will not be possible due to internal compressor station traffic and access needs. The primary factor controlling the rate and progress of the investigation will be the need to hand dig every boring to a minimum of 3 feet bgs.	In an effort to increase drilling efficiency, an area can be pre-"cleared" by hand digging to clear an area prior to the arrival of a drill rig (a steel plate could be placed over open holes for safety). Additionally, DTSC notes that PG&E recently had several major pipeline retrofit excavations in 2008 occurring simultaneously onsite and assumes that they where completed safely. Multiple drill rigs on the site is certainly possible, but DTSC understands that one rig at a critical location can be problematic. DTSC again recommends not limiting the workforce as part of the work plan process, but rather basing the number of crews on the needs of the investigation. Please revise the text of the workplan accordingly.	The text was removed from the work plan. Field work will be scheduled as feasible based on PG&E staff resources.
General 12	The presence of above ground and below ground utilities in the vicinity of a proposed boring location may complicate the investigation, but will not automatically result in boring elimination. Relocating specific borings from proposed locations should only be conducted after DTSC approval. PG&E should have identified likely obstructions as part of the work plan preparation process and located proposed borings utilizing this information.	PG&E agrees that the presence of utilities will not necessarily result in boring elimination. PG&E is committed to obtaining DTSC approval to relocate borings, provided however, that such approval does not delay the progress of the field investigation. As described in General Comment 2, a map will be developed and included in the Revised Part B Work Plan that will identify various access limitations within the Compressor Station. Visible obstructions were located during an extensive site walk, and some proposed Part B areas were determined to be inaccessible. Many potential subsurface obstructions/utilities cannot be located via a utility or geophysical survey, therefore cannot be identified in advance and can only be identified during investigation implementation. Further, all boring locations will be hand-excavated to at least 3 feet bgs	DTSC staff will be accessible throughout the work plan implementation process. While DTSC may not be available onsite at all times throughout the implementation, communication via telephone and email will be available. DTSC disagrees that approval to relocate borings may cause a delay. It should be noted that the DQOs will address sample locations prior to mobilization. Unfortunately, if PG&E moves forward without DTSC concurrence, and the action is not consistent with the DQOs, then PG&E may be required to perform additional follow up investigations.	While DQOs were utilized to define proposed sample locations, and known accessibility constraints are also reflected in the proposed sample locations, subsurface obstructions may still be encountered. PG&E will work with DTSC to minimize any potential delays associated with the need to relocate sample locations.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
		for safety reasons, regardless of the results of a utility survey (see response to General Comment 11, above).		
General 13	Please ensure that the laboratory detection limits for polycyclic aromatic hydrocarbons allow for detection in the range of site specific risk assessment goals.	The laboratory reporting limits for PAHS are below all screening levels. Reporting limits and minimum detection limits may increase for certain samples due to potential of matrix interference and/or lack of resolution due to the presence of other organic compounds.	Please ensure that the revised work plan includes language stating that detection limits will strive to the meet the DQOs.	The proposed methods are the same as for the Part A investigation, and detection limits will be similar. Detection limits achieved for the Part A investigations resulted in usable data.
General 14	Based on a review of historical photographs, an additional AOC has been identified in the lower yard near SWMU 5. An apparent round impoundment area with white material is located to the south of the sludge drying beds. The use of this area is not documented. However, oblique aerial photos from 1955 appear to indicate the area was depressed with berms around the edges. This new AOC will be identified as AOC 21 and should be included in the sampling program within the revised work plan. The COPCs are the same as for SWMU 5.	PG&E proposes to investigate this as a newly identified area. Designation of this area as a new AOC will be evaluated once the sampling data are available (during the data evaluation phase).	Designation as an AOC is not contingent upon the findings of the investigation. Please include this area into the workplan, identified as AOC 21, Unidentified Round Impoundment Area, provide historical information and a proposed investigation specific to historic uses in a revised Part B Work Plan. Also see DTSC 2010 Response for DTSC GSU Comment 3 on the 1950s photographs.	This area was added as AOC 21.
General 15	Based on a review of historical information, an additional AOC has been identified in the upper yard east of the Auxiliary Building. A three sided building type structure with no roof appears in historic aerial photographs. Information is required as to the use of this structure to assess the potential effect on the environment. This AOC will be identified as AOC 22, Unidentified Building. Based on the current unknown historic use, the COPCs will include metals, pH, volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), and semi-volatile organic hydrocarbons (SVOCs).	PG&E proposes to investigate this as a newly identified area. Designation of this area as a new AOC will be evaluated once the sampling data are available (during the data evaluation phase).	Designation as an AOC is not contingent upon the findings of the investigation. Please include this area into the workplan, identified as AOC 22, Unidentified Building, provide historical information and a proposed investigation specific to historic uses in a revised Part B Work Plan. Also see DTSC Response for DTSC GSU Comment 12 on the 1950s photographs.	This area was added as AOC 22.
General 16	Based on a review of historical information, an additional SWMU in need of closure has been identified in the upper yard near the cooling towers. The former bulk sulfuric acid tanks at each of the cooling towers (A and B) will be added as one SWMU (two tanks at 2,600 gallons each). This SWMU will be identified as SWMU 11, Former Bulk Sulfuric Acid Tanks, and should be included in the sampling program within the revised work	These tanks are included within AOCs 5 and 6. Potential metals contamination resulting from sulfuric acid leaks will be evaluated as part of the overall sampling approach for AOCs 5 and 6.	SWMUs and AOCs are not handled the same from a regulatory perspective and will have to undergo a formal regulatory closure process. The former bulk sulfuric acid tanks are considered a SWMU due to their known historic hazardous material handling activities. Please include this new SWMU 11, Former Bulk Sulfuric Acid Tanks, into the work plan and	The sulfuric acid tanks were added as SWMU 11.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	plan. The COPCs will include metals and pH.		provide a proposed investigation specific to current and historic uses.	
General 17	More information is requested regarding past operations at the former Water Conditioning Building (currently identified as the "Storage Building") to determine if environmental samples should be collected from this area. Based on current information, sampling is suggested at this building as it is associated with the white powders at the site that can exhibit elevated chromium concentrations. The building was also adjacent and potentially connected to the Process Pump and Precipitation Tanks that yielded green sludge with high metals content during closure. The building has also treated water used in the closed-loop cooling systems.	PG&E does not have any additional information regarding the operations at this building. Water conditioning operations ceased in 1962, and hazardous waste treatment operations began in late 1968 or early 1969, and ceased in 1986. The available information pertaining to the operations that occurred in this building is discussed in the Final RFI/RI Volume 1. This included available information on chemical use and waste generation and management in the water conditioning process. PG&E has no knowledge that the building specifically treated water used in the closed-loop cooling system. Also, based on data collected from Soil Part A, the white powdery material associated with the water conditioning process (lime sludge) contains only low concentrations of metals (i.e., any metals in this material would be due to metals contained in the incoming well water).	PG&E does have knowledge that the building specifically treated water used in the closed-loop cooling system (see page 3-3 of the RFI/RI Volume 1). Based on PG&E's response, significant uncertainty exists regarding the operations at this building. Therefore, characterization of this area is requested to be included in the revised work plan. This area shall be designated as AOC 23, Former Water Conditioning Building. Also see DTSC Response for DTSC GSU Comment 3 on the 1950s photographs.	This area was added as AOC 23.
Specific 1	Section 1.1 – Background The section indicates that the 2007 RFI Volume 1 identifies all areas AOCs and SWMUs. The section should be revised to acknowledge additional units will be identified in a Volume 1 addendum.	Comment noted. The text will be revised to reflect that additional units will be identified in a Volume 1 RFI/RI addendum.	No response necessary.	No response necessary.
Specific 2	Section 3.5 – Step 4 – Study Boundaries When discussing the boundaries of the investigation, the workplan states "… in areas where bedrock is encountered at depths above 10 feet bgs and/or where subsurface utilities are generally absent below 6 feet bgs, the vertical study boundary will be shallower…". The DTSC is unclear as to the rationale for limiting the depth of investigation based on the current absence of deeper utilities in a particular area or due to the occurrence of bedrock. The drilling program should stay focused on the DQO objectives (e.g., nature and extent of contamination, satisfy risk assessment protocol).	Per DTSC request (via an email dated March 22, 2010), all comments pertaining to DQOs and the associated data evaluation (decision) process have been set aside, and no response is required. The Soil Part B DQOs will be redeveloped and presented to Agencies in a Soil Part B DQO Technical Memorandum similar to the Soil Part A Phase 1 DQO TM. A draft of the DQO table and associated decision flowcharts are included with this response to comments.	Revision of the work plan is still necessary to address and clarify this issue. Ultimately, DTSC expects the workplan to be revised in accordance with the DQOs.	The work plan has been prepared in accordance with the DQOs presented in the Soil Part B DQO Technical Memorandum.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	Revision of the work plan is requested to address this issue.			
Specific 3	Section 3.6 – Step 5 – Decision Rule The intent of the first complete paragraph on page 3-5 of the work plan is unclear and needs to be revised. The paragraph states that upper confidence (95 percent) limits of the mean for each unit of interest will be compared to risk-based thresholds (i.e., CHHSLs/PRGs). The work plan should clearly state that discrete sample data from individual locations will be compared to risk based comparison values and/or background soil concentrations to assess if sufficient data points have been collected to characterize risk and the extent of contamination.	See Response to DTSC Specific Comment 2	DTSC expects the workplan to be revised in accordance with the DQOs.	The work plan has been prepared in accordance with the DQOs; the data evaluation process is described in the Soil Part B DQO Technical Memorandum.
Specific 4	Table 3-1: Summary of Data Quality Objectives • AOC 5 should also be included with AOCs 6, 15, 17, and 19 for deeper sampling due to site history and similarity with AOC 6. • Clarification is requested regarding the intent of the Step 3 comment on cultural resource impacts associated with each remedial technology. It seems that this comment should be dismissed since a remedy has not yet been selected. • Problem 3, Step 4: Target analytes should also highlight and include soil constituents that have potential to impact groundwater. Step 5 should also consider potential for soil to impact groundwater. • Problem 5, Step 5, Decision Rule 5B and 5C: These decision rules imply that if migration pathway can be stopped, then there is no need to assess the extent of contamination from historic migration. This is contrary to Problem 6: Delineation to Characterize the Nature and Extent of COPCs. In practice, PG&E must identify the extent of contamination, define the current risk, then conclude if additional action is warranted, which includes evaluation of possible means of control.	See Response to DTSC Specific Comment 2.	DTSC expects the workplan to be revised in accordance with the DQOs.	The work plan has been prepared in accordance with the DQOs presented in the Soil Part B DQO Technical Memorandum.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	Under the RFI, PG&E can not and should not limit its investigation because the “migration pathways can be controlled by approved means.” The objective of an RFI is to define the nature and extent of contamination, not remedy. • Problem 6, Characterization of the Nature and Extent of COPCs: As identified in previous DTSC comments on Part B DQOs, characterization may require evaluating trends in data (e.g., three samples in linear array) especially where the source of a release is uncertain. The workplan should address this issue.			
Specific 5	Section 4.2.2 – Decision Process for Problem Statement 2 The groundwater recharge rate quoted in the text (<0.1 millimeters per year) does not agree with the findings of the United States Geological Survey (USGS) Water Resources Investigation Report 03-4090 of 2.8 millimeters per year. The sample calculation on page 4-5 does utilize an appropriate conversion (0.1 inches per year). Please ensure that the appropriate value is utilized in presentation of this data. Also, please note that this groundwater recharge rate has not been agreed upon by the DTSC. While the value provides an acceptable starting point, DTSC and other interested parties have not evaluated the USGS report and its applicability to the subject study area.	See Response to DTSC Specific Comment 2.	Response noted; DTSC expects the workplan to be revised in accordance with the DQOs; however, part of the original DTSC comment refers to an error in the units, please ensure that the appropriate value is utilized.	The work plan has been prepared in accordance with the DQOs presented in the Soil Part B DQO Technical Memorandum. The appropriate value will be used in the evaluation.
Specific 6	Section 4.2.6 – Decision Process for Problem Statement 6 Determinations of the adequacy of delineation will be made in concert with DTSC. The DTSC will evaluate the dataset and determine if it is sufficient to adequately demonstrate decreasing concentrations in soil. Further, DTSC and the federal agencies will ultimately determine if data collected as part of any additional soil investigation will affect decisions for the risk assessment or Corrective Measures Study/Feasibility Study.	See Response to DTSC Specific Comment 2.	DTSC expects the workplan to be revised in accordance with the DQOs	The work plan has been prepared in accordance with the DQOs presented in the Soil Part B DQO Technical Memorandum.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
Specific 7	Section 5.3.2 – SWMU 5 – Sludge Drying Beds Review of historical site photos and aerial photos identifies the presence of white material extending beyond the boundaries of SWMU 5. Sampling programs for SWMUs and AOCs adjacent to this SWMU (SWMUs 5 and 9 and Units 4.3, 4.4 and 4.5) should include all of the same COPCs. This is to ensure that releases attributable to SWMU 5 that extended beyond its current boundary are evaluated.	SWMU 5 and units adjacent to this SWMU (SWMU 9, Units 4.3, 4.4, and 4.5) have been previously closed based on inorganic data. Sampling to further evaluate inorganic COPCs at SWMU 5 and units adjacent to it are not warranted. The approved RFI/RI Volume 1 documents the organic COPCs identified by PG&E and the additional COPCs identified by DTSC for these units.	As cited in the original comment, the additional information reviewed by DTSC as part of the Part B work plan evaluation indicates that additional investigation is warranted. Please include the additional COPCs for the SWMU and AOCs identified.	Inorganics analysis has been added to the closed SWMUs.
Specific 8	Section 5.3.2 – SWMU 5 – Sludge Drying Beds Per DTSC's March 29, 2006 letter, the COPCs for this unit shall include Title 22 metals, hexavalent chromium and pH in addition to total petroleum hydrocarbons (TPH), volatile organic compounds (VOCs) and semi-volatile organic compounds SVOCs.	The referenced letter distinguishes between COPCs and constituents requiring further evaluation. The Final Soil Investigation Part B Workplan will be revised to more clearly describe this distinction. Furthermore, the approved RFI/RI Volume 1 documents the organic COPCs identified by PG&E and the additional COPCs identified by DTSC for these units.	The list of COPCs is the inclusive list of constituents expected to be potentially present in each SWMU or AOC. The constituents requiring further evaluation were generated based upon review of existing data. At this point, following the DQO process should yield the same list of compounds (identified in this DTSC comment) which require further evaluation.	Inorganics analysis has been added to the closed SWMUs.
Specific 9	Section 5.3.5 – SWMU 5 – Sludge Drying Beds The proposed boring locations do not adequately characterize the elevated historic COPC concentrations. PG&E should include additional borings to properly characterize the area.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs, once approved by the agencies.	DTSC will review proposed boring locations in a revised workplan to ensure historically elevated concentrations are evaluated.	Per DTSC direction, both organic and inorganic analysis has been proposed in the work plan. However, based on the conceptual site model, historical samples were collected in the appropriate locations and depth. No further sampling for inorganic constituents is merited.
Specific 10	Section 5.4.4 – SWMU 6 – Chromate Reduction Tank Per DTSC's March 29, 2006 letter, the COPCs for this unit shall include Title 22 metals, hexavalent chromium and pH in addition to TPH, VOCs and SVOCs.	See response to Specific Comment 8.	See DTSC's response to Specific Comment 8.	Per DTSC direction, both organic and inorganic analysis has been proposed in the work plan. However, based on the conceptual site model, historical samples were collected in the appropriate locations and depths. The lateral and vertical extents of inorganic constituents have been adequately defined. No further sampling for inorganic constituents is merited.
Specific 11	Section 5.5.4 – SWMU 8 (Unit 4.10) – Process Pump Tank Per DTSC's March 29, 2006 letter, the COPCs for this	See response to Specific Comment 8.	See DTSC's response to Specific Comment 8.	Per DTSC direction, both organic and inorganic analysis has been proposed in the work plan. However, based on the conceptual site model,

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	unit shall include Title 22 metals, hexavalent chromium and pH in addition to TPH, VOCs and SVOCs.			historical samples were collected in the appropriate locations and depths. The lateral and vertical extents of inorganic constituents have been adequately defined. No further sampling for inorganic constituents is merited.
Specific 12	Table 5-7 – SWMU 8 (Unit 4.10) – Process Pump Tank Footnote number 3 states that samples will not be collected at 0.5 to 1 foot bgs due to the previous excavation activities. This statement does not agree with the text in section 5.5.5 regarding sample collection. Due to unknown sources of backfill material during historic remediation activities, samples should be collected at 0.5 to 1 foot bgs related to SWMU 8 and analyzed per the text in section 5.5.5.	The text will be revised as requested by this comment.	No response necessary.	No response necessary.
Specific 13	Section 5.6.1 – SWMU 9 (Unit 4.8) – Transfer Sump The physical description of the tank appears inconsistent with the closure plan, which contains photographs depicting the tank as a box shape rather than the cylinder describe in the text. Please confirm the construction and assess the sampling program to ensure that the existing data and proposed sampling program are adequate.	This unit is closed, and any further sampling will be limited to organic constituents only. Available information regarding tank construction will be rechecked and verified in the Final Part B Work Plan to evaluate whether additional sampling is appropriate.	Limiting the proposed sampling based upon whether the unit was previously closed is not appropriate. Use of the DQO process is necessary to assess the adequacy of the investigation program. Based on the uncertainty in the description of the unit, additional sampling is necessary, including analysis of inorganic constituents. Include additional sampling for this unit.	Per DTSC direction, both organic and inorganic analysis has been proposed in the work plan. However, based on the conceptual site model, the historical sample was collected at the appropriate location and depth (immediately beneath the bottom of the former tank), and the lateral and vertical extents of inorganic constituents have been adequately defined. No further sampling for inorganic constituents is considered merited.
Specific 14	Section 5.6.4 – SWMU 9 (Unit 4.8) – Transfer Sump Per DTSC's March 29, 2006 letter, the COPCs for this unit shall include Title 22 metals, hexavalent chromium and pH in addition to TPH, VOCs and SVOCs.	See response to Specific Comment 8.	See DTSC's response to Specific Comment 8.	See response to Specific Comment 13.
Specific 15	Section 5.7.3 – AOC 5 – Cooling Tower A The proposed boring locations do not adequately characterize the elevated historic COPC concentrations. PG&E should include additional borings to provide proper lateral and vertical characterization of the area. Additionally, potential contaminant source material may exist below the cooling tower structures and will not be	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs. . All proposed locations will be evaluated based on access limitations and safety concerns. An assessment of conditions beneath the cooling towers will be	Include an evaluation of areas where limited or no sampling can be performed in the revised Part B work plan.	A detailed accessibility evaluation was conducted as part of the work plan preparation process and is documented in Appendix B. Proposed sample locations were determined based on the Part B DQOs evaluation and accessibility constraints.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	evaluated based on the proposed sampling program. PG&E should evaluate methodologies, including angle borings, to assess beneath the cooling towers.	attempted only if it is feasible and safe.		
Specific 16	Figures 5-5 and 5-6 – AOC 5 – Cooling Tower A • The figures should be revised to depict: • location of the historic chemical storage shed • location of the identified stained soil • identify current and historic unpaved areas	The document will be revised to reflect this comment.	No response necessary.	No response necessary.
Specific 17	Figure 5-6 – AOC 5 Cooling Tower A Additional soil boring locations are required to more adequately characterize this area. The previously identified elevated chromium concentrations should be defined in both lateral and vertical directions. Please revise the proposed sampling program for AOC 5 to provide adequate lateral coverage.	See response to Specific Comment 15.	The work plan should be revised to address the DTSC Comment. Also see DTSC's response to Specific Comment 15	See response to Specific Comment 15.
Specific 18	Section 5.8.4 – AOC 6 – Cooling Tower B The proposed boring locations do not adequately characterize the elevated historic COPC concentrations. PG&E should include additional borings to properly characterize the area. Additional lateral coverage is warranted surrounding the tower. Potential source material may exist below the cooling tower structures and will not be evaluated based on the proposed samples. PG&E should also evaluate methodologies, including angle borings, to assess beneath the cooling towers.	See response to Specific Comment 15.	The work plan should be revised to address the DTSC Comment. Also see DTSC's response to Specific Comment 15.	See response to Specific Comment 15.
Specific 19	Figures 5-7 and 5-8 – AOC 6 – Cooling Tower B • The figures should be revised to depict: • location of the historic chemical storage shed • identify current and historic unpaved areas	The document will be revised to reflect this comment.	No response necessary.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
Specific 20	Section 5.9.7 – AOC 7 and AOC 8 – Hazardous Materials Storage Area and Paint Locker Based on historical data, the current maintenance building was formerly used as the chemical storage building. This area should be investigated as part of AOC 7. Please include borings inside and around the maintenance building to address the historic chemical materials storage use.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	This is a known data gap that should be addressed as part of the revised Part B work plan.	The footprint of AOC 7 was expanded as requested. See also response to Specific Comment 15.
Specific 21	Section 5.9.7 – AOC 7 and AOC 8 – Hazardous Materials Storage Area and Paint Locker Although the alluvium/bedrock contact is anticipated to be shallow (less than 10 feet) in this area, the collection of a soil sample at 10 feet bgs should be included in the sampling program. The soil sampling program should not be limited prior to field mobilization based on expectations. If the actual depth to bedrock precludes collection of a soil sample at 10 feet bgs, comments should be included in the RFI Report. However, if sampling is possible, the data should be collected and reported in the report. Also see General Comment 4.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	This is a known data gap that should be addressed as part of the revised Part B work plan.	See response to Specific Comment 15.
Specific 22	Table 5-16 - AOC 13 – Unpaved Areas within the Fence Line The data category of the historic data should be confirmed. Some of the samples appear to indicate inconsistent notes (i.e., BGCS-2 at 0.5 feet is identified as Category 2, but BGCS-2 at 1 foot is identified as Category 1). Please confirm the sample data category and revise the table as necessary. Pages 5, 6, and 7 of Table 5-16 list samples, but the associated data have not been presented on the table. The table should be revised to address this issue. Text on page 5-28 indicates that two spill samples detected polychlorinated biphenyls (PCBs), yet the data contained Table 5-17 does not support this statement. Appropriate revisions should be made to the work plan to reconcile this discrepancy.	The data categories will be confirmed and the table revised as necessary.	No response necessary.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
Specific 23	Figure 5-14 – AOC 13 – Unpaved Areas Within the Fence Line Additional rationale should be provided in the text and tables for the proposed sampling program. DTSC acknowledges the grid type sampling proposed (particularly in the lower yard), however, historic leaks, spills, drainages, low points, etc., should be preferentially sampled as well.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	This comment requested sampling rationale for samples to be collected within AOC 13 which should be provided as part of a revised Part B work plan.	Comment noted.
Specific 24	Section 5.11 – AOC 15 – Auxiliary Jacket Cooling Water Pumps In order for DTSC to fully assess the proposed sampling program, AOC 15 should be better described, including photographs, to illustrate unit configuration (e.g., illustrate pump and valve seals that have leaked in the past), surface drainage directions/low points, and relationships to trenches, storm drains, and historic data. Formerly unpaved areas mentioned in Section 5.11.1 should also be delineated on figures and samples should be proposed in the unpaved areas where releases from the unit would have traveled.	PG&E will redraw this figure to more clearly show the locations of pipelines and other nearby obstructions. PG&E will identify accessible and inaccessible areas on the figure for this AOC and provide the requested photographs. Specific information regarding which pump seals leaked is not available. The entire site, except the roads, was previously unpaved. All pumps are located within a small, contiguous area on an elevated pad. The area underneath pumps is covered by gravel as are the adjacent areas to the east and west.	No response necessary.	No response necessary.
Specific 25	Figure 5-15 and 5-16 – AOC 15 - Auxiliary Jacket Cooling Water Pumps The historic sample locations identified with green dots on Figures 5-15 and 5-16 are not plotted in the same locations on each figure and require confirmation of the true sample location. Additionally, the pipe trench and storm drain identified in Section 5.11.1 are not identified on either figure and should be added. The figures will need to be revised to properly address these issues.	To the degree this information is available, the figures will be revised to address these issues.	Ensure that various figures depicting the same boring location agree in location in figures submitted as part of the revised Part B work plan.	The figures have been made consistent.
Specific 26	Figure 5-16 – AOC 15 - Auxiliary Jacket Cooling Water Pumps Additional sample locations appear warranted based on the existing information presented in the text. The five historic samples with chromium exceeding industrial screening criteria are not adequately bounded with step out borings. Sampling along the pipe trench and storm	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	This is a known data gap that should be addressed as part of the revised Part B work plan.	AOC 15 is in a different location than the actual auxiliary jacket water coolers which were reported to have leaked. The auxiliary jacket water coolers are adjacent to the Auxiliary Building. The pipe trench and drain will be evaluated as part of the storm drain investigation program. See also response to

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	drain appears warranted, as leaks from AOC 15 have been documented to have entered these structures. The proposed sampling plan should be revised to address these issues			Specific Comment 15.
Specific 27	Section 5.12.1 – AOC 16 – Sandblast Shelter Additional information is required related to the age of the sandblast shelter. Please provide an approximate date when the feature was installed. Further, discuss where similar operations were conducted prior to construction of the sandblast shelter.	The sandblast shelter was installed in about 1995. Some sandblasting activity had occurred in this area in the past. As described in the RFI/RI, however, sandblasting also occurred in situ, as much of the painted equipment at Topock cannot be moved. The age of the sandblast shelter will be added to description of this unit in the workplan.	Include COCs associated with sandblasting activity to all AOCs/SWMUs in which the activity was conducted as part of the revised Part B work plan. Please identify where similar operations were conducted prior to construction of the 1995 sandblast shelter, and evaluate these areas for characterization.	Title 22 metals are the COPCs associated with sandblasting and are included in all sample analyses proposed for the Part B investigation. Prior to 1995, ex situ sand blast activities occurred in the same area as the sand blast shelter.
Specific 28	Section 5.12.1 – AOC 16 – Sandblast Shelter Additional information is required as to the abrasive materials used at the sandblast shelter. During recent site visits to the area, at least two distinct materials were present. One light colored and one dark colored. The composition of each and potential effect on the environment should be presented in the background information for this unit.	These questions will be researched and if this information is available in existing reports, it will be added to the revised work plan.	DTSC awaits PG&E's response.	Two types of sand blast material have typically been used in the past several years: KleenBlast and Monterey 30 Mesh. , PG&E has not found any historical Topock-specific records regarding the use of sand blast grit. Information regarding the two types of sand blast grit has been included in the work plan.
Specific 29	Section 5.12.4 – AOC 16 – Sandblast Shelter The actual soil surface with sandblast grit should be sampled. For this AOC, the 0.5 to 1 foot samples proposed should be revised to true surface samples collected from the soil sandblast grit mixture on the surface. This is requested to address potential risk associated with loose surface material that may be more accessible and more easily transported via wind or storm events.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	This is a known data gap that should be addressed as part of the revised Part B work plan.	Four surface soil samples total will be collected from the areas with apparent sand blast grit. Three of the samples will be collected from the 0.0 to 0.5-foot interval in association with the previously proposed sample locations; a fourth surface (0.0 – 0.5 foot bgs) sample was added to further assess the constituents potentially present in the sand blast grit.
Specific 30	Section 5.13.1 – AOC 17 – Onsite Septic System A geophysical survey or other technique should be conducted to establish the actual location of the subsurface leach lines. A single historic source of a hand drawn sketch does not provide the certainty necessary to conduct a useful investigation. Please	Comment noted. A geophysical survey will be performed in an attempt to more precisely locate the septic system leach field.	No response necessary.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	provide for the more precise location of the septic system leach field.			
Specific 31	Section 5.14.1 – AOC 18 - Combined Wastewater Transference Pipeline Additional information is required to describe the pathway of the waste water pipelines related to Cooling Towers A and B. The wastewater pipelines from the towers do not appear to be described in the text or identified on figures. Please provide a discussion and route of the pipelines. Additional piping layout from the 1990 Closure Plan and 2004 RFI Report should be incorporated into the work plan.	This information will be provided where available but available pipeline information is limited and schematic.	In the absence of a known location of piping, an expanded investigation program may be necessary to properly evaluate this AOC. A pipeline location survey may also need to be conducted.	Additional information regarding the pipelines was added to the work plan.
Specific 32	Section 5.14.1 – AOC 18 - Combined Wastewater Transference Pipeline Pages 5-35 and 5-36 of the work plan discussing the letter / number designation of pipelines (pipe sections A to H) are confusing. A figure similar to that presented in the 1990 Closure Plan or 2007 RFI, Volume 1 should be used to link the pipeline designations to site locations. Pages 5-35 and 5-36 indicate that Pipeline H is vitrified clay pipe, yet Table 5-28 indicates that it is cast iron. This discrepancy should be resolved.	A figure equivalent to those referenced will be included in the workplan. The discrepancy in pipe materials will be researched, and any additional or more definitive information found will be added to the revised work plan.	DTSC awaits PG&E's response.	A figure similar to the 2007 RFI has been added to the work plan. In addition, most of pipeline H was vitrified clay; the first 60 feet of H-1 were cast iron. The information about pipeline H has been added to the work plan.
Specific 33	Section 5.14.1 – AOC 18 - Combined Wastewater Transference Pipeline The original rationale for sample collection during closure should be evaluated. That evaluation should be taken into account when proposing additional investigation to ensure that the AOC is properly characterized. Additionally, elevated concentrations at PH-2 should be further characterized to determine the extent of contamination.	The rationale for sampling during closure is discussed in Section 5.14.3. The sample locations targeted points along the pipelines with the highest likelihood of a release based on results of pressure testing, locations of valves and joints, and visual evidence of leaking (e.g., visibly stained soils). Soil found during the closure activities to be impacted was removed during the pipeline closure work, as documented in the closure report, the 2005 RFI/RI and the Final RFI/RI Volume 1. This information was taken into account in the work plan.	This is a known data gap that should be addressed as part of the revised Part B work plan.	All samples associated with AOC 18 were collected from beneath pipelines. The majority of the pipelines were uncovered and removed. Impacted soils were then removed, and confirmation samples were collected after removal of impacted soil. Another location has been added in the vicinity of AOC18-2 to address this request. Samples associated with Units 4.3 – 4.5, SWMU 5, and AOC 21 will also provide information on the possible nature and extent of contamination associated with location PH-2.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
Specific 34	Section 5.14.1 – AOC 18 - Combined Wastewater Transference Pipeline Sampling should be conducted on the "outlet" side of the wastewater treatment system. Historic sampling has all occurred on the "inlet" side of the units. For the purposes of the Part B Workplan, samples should be collected from the units to the fence line.	The outlet side of the wastewater treatment system was Bat Cave Wash (i.e., a pipeline discharged directly to Bat Cave Wash, as is visible in Figure 3-14 of the Final Volume 1 RFI). The area in Bat Cave Wash beneath the discharge pipe location is within the boundary of SWMU1, and has been extensively sampled. The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	PG&E needs to adequately respond to the comment. The area between the wastewater treatment system and the fenceline is a known data gap that should be addressed as part of the revised Part B work plan.	Three sample locations AOC 13-29, AOC18-10, and AOC18-11 are proposed in the area between the waste water treatment system and the fence line.
Specific 35	Figure 5-20 and 5-21 – AOC 18 - Combined Wastewater Transference Pipeline The method of differentiation between removed pipelines and in place pipelines should be revised. The text provides discussion of the pipe removal and sampling program; however, for ease of evaluation, distinction should be made visually as well on the figures.	The figures will be revised.	No response necessary.	No response necessary.
Specific 36	Section 5.14.4 – AOC 18 - Combined Wastewater Transference Pipeline An effort should be made to ensure existing sample data is adequate in areas where previous pipe removal operations identified stained soil or soil was removed. Some data does exist for these pipelines, however, it is not clear if an evaluation has been made on the adequacy of the dataset. Please provide detailed justification for omitting specific samples in areas previously identified as impacted.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	Please note that additional boring locations may be necessary.	Comment noted.
Specific 37	Section 5.14.4 – AOC 18 - Combined Wastewater Transference Pipeline The section indicates that the pipelines were below-grade structures. The depths of the lines will need to be disclosed to ensure appropriate sample horizons are selected for characterization. If the depths or locations of the pipelines are uncertain, then trenching should be considered to adequately locate sample points relative to a pipeline.	The closure reports indicate that sampling occurred below some pipes and joints. Some (but not all) depths are provided in the reports and will be included in a table in the workplan. This available information was considered when establishing proposed sampling depths. Additional assessment of pipeline depths will be evaluated and if feasible, will be proposed in the revised work plan.	Manual excavation of pipelines may be necessary to uncover pipelines and ensure that samples are collected at appropriate depths.	All samples associated with AOC 18 were collected from beneath pipelines or were confirmation samples collected after removal of impacted soil. Depths are shown on Table B15-2. None of the samples were collected beneath 6 feet bgs, indicating all pipelines and subsequent excavations were in the top 6 feet. Based on the information in the transference pipeline closure report (Mittlehauser, 1990), all pipes were installed above – 6 feet. A detailed

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
				accessibility evaluation was conducted as part of the work plan preparation process and is documented in Appendix B. Proposed sample locations were determined based on the Part B DQOs evaluation and accessibility constraints. Manual excavation of the pipelines was not proposed in the work pan.
Specific 38	Table 5-27 – AOC 18 - Combined Wastewater Transference Pipeline It is unclear whether the single asterisk referring to sample collection after soil removal applies to this table. Please confirm the applicability of the single asterisk for this table.	This information will be revised in the work plan.	No response necessary.	No response necessary.
Specific 39	Table 5-30 – AOC 19 - Former Cooling Liquid Area Page 5-40 and Table 5-30 of the work plan indicate that all seven AOC 19 samples are Category 2. Specific deficiencies and limitations of the seven Category 2 samples should be stated in this section of the work plan to allow assessment on how the data can be used. In general, additional samples would be warranted if the existing Category 2 data have significant deficiencies.	To avoid redundancy, PG&E chose to not restate the limitations on data use for each investigation area. PG&E will prepare a table with this information per the response to General Comment #8.	No response necessary.	No response necessary.
Specific 40	Figures 5-22 and 5-23 – AOC 19 - Former Cooling Liquid Area The proposed sampling plan cannot be adequately evaluated without an accurate depiction of the AOC. Revised or additional figures are requested at appropriate scales so that site features and sample locations can be accurately depicted (e.g., at a scale similar to Figure 5-15). Currently, site features are not illustrated and historic boring locations overlap one another. At a minimum, the figure(s) should identify: the former Hot Well; Jacket Cooling Water (JCW) tanks; JCW pumps and valves (especially ones that have leaked); the former cooling additive mixing shed/current pad; unpaved areas; the two current 1,426 gallon above ground reusable engine oil tanks; the three existing	PG&E will provide a more detailed figure to show placement of pipelines and other obstructions, and include available information regarding the former locations of various features. Known underground piping will be shown in the figure, however, other underground piping may be present as well. Photographs will also be included in the workplan..	No response necessary.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	above ground chemical storage tanks (one 200 gallons and two 400 gallons); underground and aboveground piping; surface drainage directions and depressions; and potential or known routes of former releases and leaks especially ones that would travel to the visitors parking lot/warehouse and down the main entrance road. Photographs of the AOC are also suggested.			
Specific 41	AOC 19 - Former Cooling Liquid Area The proposed sampling plan appears focused on the eyewash pad (see the “Description” column on Table 5-31) and not the other units within the area (see comment above). Certainly, samples from around and beneath the Hot Well and around leak areas are warranted. Based on evaluation of Figure 5-22 and 5-23, additional samples east of the AOC appear warranted to bound eastward contamination and to characterize documented releases towards the visitors parking lot, warehouse, and entrance road.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	This is a known data gap which should be addressed as part of the revised Part B work plan.	Samples have been added in the vicinity of the hot well. See also response to Specific Comment 15.
Specific 42	AOC 19 - Former Cooling Liquid Area Section 5.15.2 - Summary of Soil Characterization: The first paragraph discusses results of a Hot Well cleanup project. The work plan should include a table of all Hot Well cleanup sampling data from this particular project including the Title 22 metals for the greenish liquid sample discussed in the second paragraph of section 5.15.2. If a Hot Well cleanup document exists, it should be provided to DTSC. The first paragraph of section 5.15.2 also inappropriately refers to Figure 5-22 regarding the Hot Well cleanup data. This should be corrected in the revised work plan.	The hotwell closure report will be provided to DTSC. Most of the hot well cleanup data pertain to disposal characterization. The hot wells were removed and the sampling and clean up were focused on remnants of the hot well that were to be disposed of, i.e., concrete from the former hot well and sediments contained within the remnant hot well. No data were collected outside of the hot well footprint. It should be noted that most of the requested information is provided in the Final RFI/RI Volume 1. The text will be corrected.	DTSC awaits PG&E’s submittal of the closure report.	The Hotwell Closure Report was submitted to DTSC on May 3, 2011
Specific 43	AOC 19 - Former Cooling Liquid Area The section mentions darkly stained concrete and concrete with elevated chromium that has exceeded hazardous waste criteria. PG&E should indicate how stained concrete and asphalt will be managed and if it plans to characterize the stained materials during this investigation. If so, the work plan should be modified	To prevent access to the affected area, PG&E has covered the stained concrete as described in the workplan. There is no asphalt located in the AOC 19 footprint; asphalt is present in plant roads east and west of AOC 19. There is no visible staining emanating from AOC 19 onto this asphalt. PG&E is planning to conduct additional characterization	No response necessary.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	accordingly.	to determine whether the remainder of the concrete exceeds hazardous waste criteria, and is currently evaluating the feasibility of removing the pad. If feasible, PG&E will seek DTSC's permission to remove the pad.		
Specific 44	Section 5.16.1 – AOC 20 - Industrial Floor Drains The last paragraph of this section should indicate that approximately 220,000 gallons a year of oily waste water is transmitted through the floor drain system. The section could be misread to suggest the floor drains only collect incidental drips and spills and occasional floor washing liquids.	The work plan will be revised to clarify this information. It should be noted that this equates to a very low flow system (220,000 gallons per year implies an average flow of 0.4 gpm from all sources combined).	No additional response necessary. It should be noted that 220,000 gallons per year is substantial and over the course of several years the cumulative total would be in the millions of gallons.	No response necessary.
Specific 45	Section 5.16.3 – AOC 20 - Industrial Floor Drains Per DTSC's May 9, 2007 letter, the COPCs for this unit shall include PCBs in addition to Title 22 metals, hexavalent chromium, TPH, VOCs and polycyclic aromatic hydrocarbons.	Comment Noted, PCBs will be added to the analyte list for AOC 20.	No response necessary.	No response necessary.
Specific 46	Section 5.16.3 – AOC 20 - Industrial Floor Drains The section indicates that the floor drains are primarily below-grade structures located at varying depths. The depths of the drain lines will need to be disclosed to ensure appropriate sample horizons are selected for characterization.	The depths of most of the oily water lines are not known. Because sampling will be occurring in the immediate vicinity of a subsurface utility, hand excavation will be required until the lines are physically encountered, to ensure that the lines are not damaged by the sampling effort. Thus, although the general requirement is to hand excavate to a minimum depth of 3 feet bgs, hand-digging will be required to the oily water line depth(s) at AOC 20.	No response necessary.	No response necessary.
Specific 47	Figure 5-24 – AOC 20 – Industrial Floor Drains To ensure appropriate sample coverage for this feature, soil boring locations should be placed at approximately 100 foot centers along pipe runs and at each angle joint. Please revise the proposed boring locations to adequately address lateral coverage.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs.	The work plan should be revised to address the DTSC Comment.	See response to Specific Comment 15.
Specific 48	Section 5.18 – Monitoring Well Installation Area 1: If unsaturated alluvial conditions are encountered in the first borehole proposed in the area,	Per DOI and DTSC's direction on February 24, 2010 (*PG&E Topock Compressor Station Remediation Site – Groundwater Characterization Requirements for the East Ravine and Compressor Station Areas*),	The proposed groundwater monitoring investigation is no longer contained within the Part B soils investigation work plan and is being addressed as a separate groundwater	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	then PG&E should contact DTSC for direction on whether a new borehole should be drilled to the north/northwest. DTSC may direct PG&E to complete the well in the shallow portion of the conglomerate in lieu of drilling an additional borehole depending on the proximity to the water table and the character of the conglomerate. While unlikely, if the alluvial sequence is much larger than anticipated, DTSC may require a shallow and deep well be completed in this area. Area 2: If the alluvial sequence is larger than anticipated, DTSC may require a shallow and deep well be completed in this area. While unlikely, if significant saturated alluvial materials are encountered in Area 2, DTSC may direct PG&E to install a well further south closer to potential source areas (e.g., AOC 19). Area 3: To be consistent with the hydrogeologic characterization methodology used over the entire site, a shallow, middle, and lower well is requested for this area provided that the anticipated thickness of the saturated alluvial material is encountered in Area 3. Additionally, the work plan should include soil sample collection and analyses (for both COPCs and various soil parameters) from the deeper zones during borehole drilling for these wells.	groundwater investigation inside the compressor station will be combined with additional characterization at the East Ravine area. Therefore, no response to this comment will be provided in the Part B Soil Investigation Work Plan.	investigation.	
Specific 49	Section 6.3.1 – Monitoring Well Installation, Drilling requirements Borehole diameters should not be limited to eight inches in diameter. Nested wells will require, at a minimum, a 10-inch diameter borehole to allow emplacement of sufficiently thick annular seals. The text should be revised accordingly.	See response to Specific Comment 48.	See DTSC's response to Specific Comment 48.	No response necessary.
Specific 50	Section 6.3.3 – Depth-specific Groundwater Sampling When running chromium confirmation samples on Isoflow® samples at certified laboratories, hexavalent chromium should also be conducted as the 24-hour holding time should no longer be an issue due to	See response to Specific Comment 48.	See DTSC's response to Specific Comment 48.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	updated analytical methodologies.			
Specific 51	Section 6.3.4.1 – Monitoring Well Specifications Although the text specifies 2-inch Schedule 40 polyvinyl chloride (PVC) casing for wells less than 300 feet, DTSC may require alternative well construction materials based on site specific conditions.	See response to Specific Comment 48.	See DTSC's response to Specific Comment 48.	No response necessary.
Specific 52	Section 6.3.4.5 – Casing Grout Specifications As indicated in previous DTSC correspondence, Type I Portland cement is not recommended due to elevated sulfate concentrations on site. A Type II or V cement is necessary.	See response to Specific Comment 48.	See DTSC's response to Specific Comment 48.	No response necessary.
Specific 53	Section 6.3.6 – Well Completion Diagrams Please also include the borehole diameter on well completion diagrams.	See response to Specific Comment 48.	See DTSC's response to Specific Comment 48.	No response necessary.
Specific 54	Figure 6-3 The figure should be revised to incorporate the minimum 10-inch diameter borehole requirement previously discussed for nested wells.	See response to Specific Comment 48.	See DTSC's response to Specific Comment 48.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
1	Photographs identified as PG 153, PG 154, PG 160, and PG 161 from the Photo File reveal what the GSU presumes is an aboveground wastewater clarifier within the lower yard of the compressor station. The figure below (PG 153) illustrates the clarifier within the northern scrubber area. This figure shows dark staining on the sides of the clarifier and in soils down slope of the unit. Figure 3-15 from RFI – Volume 1 (attached) illustrates prominent soil staining associated with this unit at least 40 to 50 feet in length. PG&E will need to identify the unit, and discuss its operation and closure as it is not described in the RFI – Volume 1 (CH2M HILL, 2007). Soil sampling below and around this unit is recommended due to observed releases.	This unit is most likely an API Oil/Water separator. The pipe exiting the bottom of the hill lines up with the routing of the current and historic oily water piping. It is possible that this OWS location preceded the known (current) OWS location. In 1958 or 1959, the three scrubbers shown in the photo were expanded to a bank of six scrubbers. The northern-most current scrubber appears to be located approximately where this OWS was formerly located. The existing workplan calls for two samples in this area. PG&E will increase the AOC 13 sample density by two sample locations in this area to address this concern.	PG&E has failed to properly identify this unit that has obviously released wastes to the environment. DTSC must now direct PG&E to include this unit as a separate AOC – AOC 24, Former Oil/Water Separator. Based on the limited input from PG&E, this AOC shall be identified as the “Former Oil/Water Separator” and will require evaluation and sampling as a unique AOC. It is not to be included as part of AOC-13 (Unpaved Areas at the Compressor Station) as it is a unique unit with documented releases. PG&E is again directed to gather more information on this unit and submit it to agencies as soon as possible including its operation and closure. Description of AOC 24, Former Oil/Water Separator shall also be included in the RFI – Volume 1 Addendum. PG&E needs to accurately locate and map the former OWS as well as the documented releases that emanated from the unit. Photograph PG 160-4 illustrates that the unit was located just north of the trench for the “scrubber inlet header”. PG&E must note that the unit is located some distance away from the bank of scrubbers. All six scrubber header lines (including the stubs of yet to be installed scrubbers) can be seen in PG 154. Figure 3-15 from the RFI – Volume 1 also illustrates the relative location of the unit and associated soil staining. The total number of samples needed for this unit will be based upon locating the unit with certainty. Trenching / potholing is also requested to find and track soil staining away from the unit. Additional sample locations and trenching are needed based on the minimal information provided by PG&E.	This unit and the associated staining were added as AOC 24. Available information was included in the work plan. Given the available photographic information PG&E does not believe that trenching or potholing is required to accurately locate potential sampling points.
2	The Photo File contains photographs (PG 154 – Photos 4 and 5) that exhibit discolored soil in the lower yard northern scrubber area. Photo 4 (PG 154) exhibits dark stained soil in a small area just north of the scrubbers (see red oval on the next page). This same area still exhibits stained soil one year later as illustrated in Figures 3-14 and 3-15 from RFI – Volume 1 (CH2M HILL, 2007). Photo 5 (PG 154) exhibits darkened soil around the northern scrubber unit with the majority of the darkened area south of the unit (see photo on next page).	The staining by the pole mentioned in this comment is apparent in Photo 4 and the 1995 aerial photos, but does not appear in Photo 5. The bigger staining is apparent only in Photo 5. This indicates that the “staining” in Photo 5 was of very short duration. It also appears that significant grading has occurred between the times associated with Photos 4 and 5; it is likely that the larger “staining” is water used to condition the soil and control dust during grading and/or aid in compaction of the soils. The smaller stain may be associated with the oil bath filters that were formerly part of the scrubbers. The proposed boring locations and sample depths	PG&E needs to describe the oil bath filter process that is suggested for causing the smaller soil staining noted in the comment. Samples will need to occur at this area (Photo 154-4) after an understanding of the process is documented by PG&E. No samples are currently proposed for this area. This stained area should be accurately located on a map/figure to aid in site characterization. Characterization is warranted as the staining noted in this area persisted for at least a years time and can be noted from aerial observations. Samples of the darkened soils from the groomed area in Photo 154-5 area are requested to ensure waste oil or other similar fluid was not used to prepare the site. No	Samples have been added in AOC 13 to address the larger discolored area, and the smaller stained area.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	Soil sampling within the areas of discolored or darkened soil is recommended due to potential contamination associated with the discolored soils.	will be reviewed and adjusted as needed for consistency with the Part B DQOs.	samples are currently proposed for this area. PG&E should document that a portion of the darkened soil is still visible a year later in 1955 aerial photographs (Figure 5-13 and 5-14). Please note that photographs on the adjacent oil/water separator indicate that waste oil is being collected in a container and, therefore, could have been utilized for preparing or maintaining site soils.	
3	Photo 5 (PG 154) also pictures the white colored sludge drying beds in the background. Another white area and probable impoundment is located beyond the sludge drying bed in Photo 5 (PG 154). Figures 3-14 and 3-15 from RFI – Volume 1 (CH2M HILL, 2007) also illustrate this second white area. Soil sampling within the second white area is recommended due to potential contamination associated with the white material. PG&E should document the operation and any closure associated with this unit adjacent to the sludge drying beds.	This white area is described in Volume 1 of the RFI/RI. At the time of the aerial photo review for the RFI/RI, it was interpreted to be a mound of white material. It is important to distinguish between the two types of sludge that were dried in the sludge drying beds: lime softener sludge and hazardous waste treatment system sludge. The material in this area is most likely lime softener sludge from the plant water conditioning system. Until 1962, Topock used the Permutit® system to remove excess minerals from the plant water, and dried the sludge associated with this process in the sludge drying beds. As shown from the sampling conducted in AOC 14 (which received lime softener sludge), concentrations of Cr(T) and Cr(VI) in the softener sludge are low (well below industrial CHHSLs/PRGs). Because 2-phase treatment of the chromium-containing waste water did not begin until late 1968 or early 1969, it is not possible for the material in the photographs to be hazardous waste treatment system sludge. As reported in the RFI/RI Volume 1, lime softener sludge from the water conditioning system was transported to AOC 14 and sprayed on the ground for disposal. It is likely that the round area served as an interim storage area for the sludge. There is no record of any “secondary storage” associated with the hazardous waste treatment system. Because of the site history information described above, this area was not identified in the Final RFI/RI Volume 1 as a unit specifically requiring investigation.	PG&E cannot say with any certainty if the white sludge formerly located south of SWMU 5: Former Sludge Drying Beds is not contaminated. Please note that white powder sampled from AOC 14: Railroad Debris Site does contain elevated concentrations of hexavalent chromium. In fact, it exhibits the highest hexavalent chromium of all the 2008 AOC 14 soil samples. Additionally, other white powders sampled from both Bat Cave Wash and the East Ravine contain significantly elevated chromium concentrations. Therefore, soil sampling within this white area is warranted (see General Comment 14). The Final RFI/RI Volume 1 only briefly discusses this white area. Figure 3-14 from RFI – Volume 1 (CH2M HILL, 2007) clearly shows that the unit is a bermed, bowl-like, impoundment. PG&E should respond to the original comment and document the operation and any closure associated with this former unit.	This area was added as AOC 21. Available information was incorporated into the work plan.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
4	The Photo File contains two photographs (PG 40 – Photo 5 and PG 41 – Photo 1) that are titled "Cleaning interior of engine with solvent spray." As illustrated below, the photos show the large compressor engines being cleaned with a jet spray system. PG&E should attempt to determine how often this cleaning was performed and what type of solvent was used. These photographs appear to contradict the RFI – Volume 1 (CH2M HILL, 2007) which indicates that solvent use was only incidental and used in small quantities.	The standard practice during operations was to steam clean the exterior of the compressor engines. The referenced activity is part of the construction effort to remove a protective coating. The compressor engines typically were shipped to the station with a protective coating to prevent damage during transport after manufacture and before operation. There is no information from any former employees indicating that solvent spraying was a standard means of cleaning the compressor engines when the plant was in operation, and actually was prohibited by PG&E safety rules. Thus, this solvent cleaning was likely a one-time occurrence following the original installation of the compressor engines.	DTSC requests that PG&E fully respond to the comment by indicating what type of solvent was used and an estimate of the total volume that would have been used to clean one engine. Also describe how the solvents were disposed (e.g., Did they flow to the sump below the engine?).	There are no records regarding the precise type or volume of solvent used. Collection or management of solvents after spraying/use is unknown. VOC analysis is proposed at SWMUs 5, 6, 8, and 9, and AOCs 7, 8, 13, 17, 18, 20, 22, 23, 24, and 26, and Units 4.3. In addition, 10 percent of all samples on the station are being analyzed for TAL/TCL compounds, which includes VOCs; thus if any VOCs were released during this activity, they will be identified through the sampling program.
5	The Photo File contains several photographs (PG 110, 111, 164, 165, and 167) of gas headers being forcefully purged as illustrated below in PG 165 – Photo 1. PG&E should describe the purging operation including why and how the purging is conducted, how often it was/is done, and what fluids were injected/ejected during the process.	The purging of the lines depicted in this photo was done to remove all air and water from the lines prior to moving natural gas through the lines. Pipes were tested for leaks by filling them with water and pressurizing them. This was and continues to be the standard practice every time modifications are made to piping. The reason that the purging appears to discharge a waste material is because the high pressure and velocity during the purging aerosolize any water released, and the moisture contained in air purged from the pipelines is frozen due to the sudden decompression as it exits the pipeline. The purged material is always forced upward, because it is highly pressurized. Due to the high pressure and speed of the purged material, it would represent a significant danger to people if it where to hit somebody. If the line being purged was previously in use, the purged material could have contained small amounts of pipeline liquids. Although any associated impacts to the Topock Compressor Station are unlikely, they would be addressed by the sampling already proposed for AOC 13.	To complete the response, PG&E should indicate how often this practice is conducted and if it is done in specific areas.	This practice is infrequent during new construction to remove all air and water from the lines prior to moving natural gas through the lines. This type of purging has occurred an estimated five to 10 times since the start of station operations. Exact locations of these purges are unknown, but would be unique to each time a section of pipeline was repaired or constructed. In addition, pipeline purging or "blowing down" is also done as part of the compressor station operation and maintenance. These blow-downs occur several times a year at fixed stack-pipes for plant safety and maintenance.
6	The Photo File contains several photographs of transformers mounted to twin telephone poles (PG 18, 19, 126, 156, 157, and 163). It is assumed that these transformers would have used polychlorinated biphenyls (PCBs).	PCBs will be added to the analyte list for those AOCs where used transformers or used oil may have been stored or in exposed areas where oil may have been applied to the ground surface. As previously documented in the March 1, 2006 memorandum to DTSC (entitled *Background*	PG&E should document where PCB use and disposal occurred on the site in light of detecting PCBs in AOC 4: Debris Ravine and other AOCs. Documentation of the use of PCBs should be included as an Addendum to RFI/RI Volume 1 to appropriately update the PCB discussion currently contained in the RFI/RI Volume 1 document.	Documentation of the use of PCBs will be included as an Addendum to the RF/RI Volume 1. The reference to UA-1 should be to UA-2 (the Former 300B Pipeline Liquids Tank). The pipeline drip legs are simply valves with an unusual name, and there is no evidence of any leakage (e.g., staining) at the two drip

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	Additionally, and more importantly, PCB occurrence in natural gas pipelines and pipeline condensate is well documented (USEPA, 2004; Kennedy, 1993). In the past, PCBs were used in oils for some compressor lubricants, as valve sealants, and used in a pipeline process known as “oil fogging” during the 1940s through the 1960s (USEPA, 2004). Therefore, PG&E should include PCBs as a constituent of potential concern (COPC) and include soil samples for PCB analyses in the following areas: former transformer area; chemical storage areas; used oil storage areas; pipeline drip legs/tanks, and areas where used oil may have been applied to the ground surface.	*Information Concerning PCBs and Naturally-Occurring Radioactive Materials at PG&E’s Topock Compressor Station*), PCBs related to natural gas pipelines and pipeline condensate are not expected to be of concern at the Topock Compressor Station. DTSC has previously concurred with these findings. Therefore, PCB sampling is not proposed for areas associated with pipeline drip legs or tanks	New information cited in DTSC Comment 6 and the widespread detection of PCBs in AOC 4 warrant that sampling for PCBs occur at pipeline drip legs and tanks. UA-1 has already been sampled for PCBs in 2008 and in the 1990s.	legs that are within the area of potential effects (APE). PCB analysis has been proposed in applicable Part A and Part B SWMUs and AOCs.
7	The Photo File contains photographs of blasting that occurred during construction of the site (PG 2, 4, 80). PG&E should determine if explosives were stored in a designated area at the station for lengthy periods of time. If an explosives storage area is identified, PG&E should include explosives as a COPC for the storage unit and have soil samples collected from the area.	There is no record of any storage of explosives at the Topock Compressor Station, nor did any former employees mention any such practice during any of the interviews. Furthermore, blasting was not required during the operation of the station. Blasting would simply pose too much of a risk at an active gas compression facility.	Comment noted.	No response necessary.
8	The Photo File contains a photograph, dated April 16, 1951 (see Photo 4 - PG 86), of excavation activities for the waste oil sump that is located south of the tank farm. The RFI – Volume 1 describes this sump as measuring approximately 15 to 20 feet deep and 6 feet square. It was originally constructed as a concrete sump, but is now equipped with an inner steel liner and the original concrete structure acts as secondary containment (CH2M HILL, 2007). As this large waste sump has been in operation for over 50 years, it is recommended that environmental samples (soil matrix and/or soil gas) be collected to assess potential releases to the environment.	The tank farm and waste oil sump are active units, and therefore not part of the Corrective Action program. This request is similar to the inclusion of the Waste Oil Storage Tank in the RFA (it was identified as Unit 4.6). As documented in the Final RFI/RI Volume 1, the Waste Oil Storage Tank was removed from the Corrective Action program because it is an active unit. Neither the waste oil sump nor the tank farm were ever identified as SWMUs or AOCs. Furthermore, there is no exposed soil in these areas, groundwater is at a depth of 200 feet or more, the constituents in this area have low mobility, and bedrock may be present above first encountered groundwater. The tank farm currently has full containment and the tanks are fully above ground. There are no records of leaks from the tank farm; however, no records are kept to track inventory.	Based on PG&E’s response environmental samples are warranted for both the tank farm and waste sump. Both units have the potential for releases. DTSC will determine if the operation of a particular unit makes it problematic to characterize soils. Just because a unit is active, does not necessarily eliminate it from being investigated and characterized in a timely manner. As requested, PG&E should provide the scrubber sump closure report to DTSC as soon as possible.	A detailed accessibility evaluation was conducted as part of the work plan preparation process and is documented in Appendix B. The tank farm and waste sump area is identified as unsafe for collection of surface and subsurface soil samples, see Topock Compressor Station Accessibility Map Figure B-2. However, proposed soil sample locations are located to the east and north of this area as part of the AOC 13 and AOC 19 investigation. Additionally, a monitoring well is being installed downgradient of this area (Site 3 in the East Ravine/TCS monitoring well installation investigation) to assess groundwater conditions in this area. The scrubber sump closure report was provided to DTSC on January 18, 2011.At the direction of DTSC, the Scrubber Sump was added to the work plan as AOC 26.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	Additionally, environmental sampling of the adjacent tank farm may be warranted as it has also been in operation for over 50 years. PG&E should provide information to DTSC regarding the tank farm (e.g., documents of tank conditions, inspections, replacement, releases) to properly assess the need to characterize potential releases from the unit. The complete closure report is also requested for the former scrubber sump to ensure an appropriate analytical suite was used during its closure. PG&E should consider investigation of this area absent information regarding its closure.	As DTSC is aware, the scrubber sump was located in the lower yard. The only potential COPCs associated with the scrubber sump were pipeline liquids drained from the scrubbers. Information on the scrubber sump was included in the 2005 Draft RFI and the Final RFI/RI Volume 1, and DTSC has previously received a copy of the closure report. Another copy of the closure report will be provided to DTSC.		
9	The Photo File contains photographs of a “Lube Oil Drain Tank” as it is being readied for underground installation (Photo 2, PG 39 - see next page). PG&E should determine if this tank has been accounted for in the RFI Volume 1 (CH2M HILL, 2007). If it hasn’t, then environmental sampling should be conducted for the unit. Photo File 95 (Photo 5) shows an emergency gasoline driven fire pump. PG&E should determine if the source of gasoline came from an underground storage tank that has not been previously identified.	The “Lube Oil Drain Tank” is one of the USTs referred to as the Reusable Engine Oil USTs in the RFI/RI Volume 1 (Section 3.1.5.1). These tanks were removed, closed, and replaced by ASTs. No further action is necessary. The emergency fire pump is incorrectly identified as a gasoline driven pump. The pump was a natural gas fueled pump that was decommissioned in the 1990’s	Based on review of section 3.1.5.1 of RFI/RI Volume 1, it is not clear if the “Lube Oil Drain Tank” is one of the three former oil USTs located adjacent to the compressor and auxiliary buildings. Clarification is requested. Closure reports for these former tanks should be provided. PG&E should double check if the fire pump was always powered by natural gas. In an emergency, it would seem that an alternate fuel source would be desired. The radiator cowling pictured on Photo File 95 (Photo 5) suggests that the engine is a “Buda” which certainly could have run on gasoline or diesel.	The Topock compressor station contained four fuel USTs as well as three below ground lube oil drain tanks. All seven USTs have been removed and replaced with ASTs. PG&E is unable to find the closure reports for the former USTs, and a record search at the San Bernardino County Fire Department also failed to turn up the files. The Buda fire pump used natural gas as its primary fuel source. The backup fuel source was a propane gas cylinder located along the north outside wall of the fire pump building.
10	The Photo File contains a photograph (see Photo 4 from PG 115 on the following page) describing a view of the “acid house” as it is being erected. This building appears to be located at the southern end of the southern cooling tower in 1955 Figures 3-14 and 3-15 of the RFI Volume 1 (CH2M HILL, 2007). A similar structure is noted in Figure 3-15 for the northern cooling tower. Page 3-23 of the RFI Volume 1 refers to chemical storage sheds located near the cooling towers which may be equivalent to the “acid house” noted on PG115. PG&E should ensure environmental samples are collected from the footprint of both “acid houses”.	These “acid houses” are the chemical sheds located in AOCs 5 and 6 and are included in the sampling plans for these units.	Comment noted.	No response necessary.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
11	The Photo File contains several 1953 photographs of the "chemical storage building" (PG 122, 123, 124, 125, and 126). The "chemical storage building" is visible in the 1955 Figures 3-14 and 3-15 of the RFI Volume 1 (CH2M HILL, 2007). It is the most southeasterly building in the 1955 photographs. Very close examination of Figure 3-15 illustrates storage, possibly drum storage, along a fence to the north of the "chemical storage building". Currently, the "chemical storage building" is identified as the "Maintenance Shop" in Figure 3-1 of the RFI Volume 1. Environmental samples in and around the "chemical storage building"/"Maintenance Shop" is warranted based on the findings discussed above. Area of Concern 7 - Hazardous Materials Storage Area identified in RFI Volume 1 is located adjacent and south of the "chemical storage building"/"Maintenance Shop".	The characterization approach to this building will be reviewed and adjusted as needed for consistency with the Part B DQOs.	Characterization of the chemical storage building and surrounding area is obviously required. The Work Plan must ensure appropriate samples are collected from this unit.	This area was added as AOC 23. Proposed sampling described for this unit is described in the work plan.
12	The 1955 Figures 3-14 and 3-15 of the RFI Volume 1 (CH2M HILL, 2007) illustrate an unknown structure northeast of the chemical storage building. The structure had three wooden walls and the soils associated with the unit were lighter in color than surrounding soils. PG&E staff have indicated that they are uncertain what operations occurred at the structure. Without further information, it is recommended that environmental samples be collected from this former unit.	The characterization approach to this building will be reviewed and adjusted as needed for consistency with the Part B DQOs	The location of this building should be accurately located in figures to ensure soil samples are appropriately collected from this AOC.	This structure was added as AOC 22. Proposed sampling to evaluate potential impacts associated with this structure is described in the work plan.
13	The Photo File includes photographs of the "Hot Well" including the one pictured on the next page that shows the concrete Hot Well structure (circled in red) to the right of the main jacket water cooling tower. As it has been documented that the Hot Well was constructed 5 feet below grade and periodically overflowed (CH2M HILL, 2007), PG&E should ensure that the unit is appropriately characterized.	The hot well is included in the description of AOC 19. The characterization of AOC 19 will be reviewed and adjusted as needed for consistency with the Part B DQOs.	The location of the former Hot Well should be accurately plotted on AOC 19 figures so that soil samples are appropriately collected for this unit.	The location of the hot well was added to the figure for AOC 19. Access for sampling in this area is extremely limited.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
14	The Photo File includes two photographs (PG 110 and PG165) of a lube oil flushing system. PG&E should describe the operation of this unit and indicate if it had potential to release COPCs to the environment.	The lube oil flushing system was an ad hoc system used during construction to flush out the lube oil transfer lines prior to operation. The photo on Pg 110 shows the system used for flushing the lube oil system for Units K-1 through K-6 in 1951. The flushing system was located next to the lube oil sump in the tank farm area. The photo on Pg 165 shows a similar ad hoc system used to flush the lube oil system for Units K-7 through K-9 a few years later. It was located in the access road area between K-8 and the fin fan coolers. PG&E does not have detailed information about the use of both of these temporary systems but believes that the basic mode of operation would be to discharge the waste oil collected into the readily available waste oil sump. PG&E has no reason to believe that any releases to the environment occurred during this short-term operation more than fifty years ago. In fact, this system is designed to prevent releases and capture the oil in the waste oil system.	Comment noted.	No response necessary.
15	The Photo File includes several photographs related to installation of transite siding, roofing, and pipe conduit during construction of compressor station buildings and pipe galleys. Transite is identified in the following photographs in the Photo File: pages PG 41, PG 56, PG 91/92, PG 99, and PG 102. This comment supplements the RFI – Volume 1 (CH2M HILL, 2007) which discusses asbestos and transite noted in debris around the facility, but makes no mention as to where this material originated. PG&E should evaluate all Areas of Concern (AOC) and Solid Waste Management Units and determine if asbestos should be included as a COPC. For example, it is recommended that AOC 13 include asbestos analyses as transite debris has been noted in the lower yard and site fill. Future RFI reports discussing transite should identify that the compressor station was constructed with transite and is a probable source.	ACM has been included as a COPC in areas with transite (e.g., AOC 4). The transite material can be easily identified when it is encountered in the field and it is generally in good condition (not friable). Sampling for asbestos in the lower yard in areas where transite has been observed will be added to the AOC 13 sampling plan.	Comment noted. PG&E should also include analyses for asbestos in other areas when transite is identified in the field (e.g., Bat Cave Wash, AOC 14).	Seventy-two samples from AOC 14, which is the most likely area to have received wastes containing ACM, were analyzed for ACM. Only 2 samples were confirmed to have ACM, both at trace levels (less than 0.1%). Further general sampling for ACM is not warranted; however, samples from the mouth of Bat Cave Wash will be analyzed for ACM.

Comment No.	2008 DTSC Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
16	The following photographs have been repeated in the Photo File: pages PG 18/19, PG 23/24, PG 91/92, PG 98/100, and PG 99/101. It is assumed that one of the pages from each preceding pair has not been scanned and included in the Photo File. Therefore, PG&E should include the omitted pages in a revised Photo File to be submitted to DTSC.	PG&E has reviewed the Photo file and found that no photos were omitted from the historic photo binder at TCS. Apparently the individual who scanned the photos duplicated a few of the pages.	Comment noted.	No response necessary.
17	The Photo File does not contain pages PG 140, PG 143, and PG 151. PG&E should clarify if this was intentional and if any photographs were omitted. If photos were omitted, they should be included in the revised Photo File to be provided to DTSC.	PG&E has reviewed the Photo file and found that no photos were omitted from the historic photo binder at TCS. Apparently the individual who scanned the photos did not number all of the pages in sequence.	Comment noted.	No response necessary.
18	PG&E's cover letter to the Photo File, dated August 22, 2007, indicates that some of the photographs came from the draft Route 66 National Register of Historic Places nomination report. It is not apparent if any of the photos came from this source. PG&E should clarify, in the revised Photo File itself and/or the associated cover letter, the source of each photograph.	PG&E will provide the requested information.	DTSC awaits PG&E's response.	No response necessary.
19	Photographs A and B on the next page are included in this memorandum in hope of identifying the nature of the earthen structure DTSC staff observed on June 19, 2007. The structure is located along a wash that connects to the East Ravine. The East Ravine parallels the main access road leading up to the Topock Compressor Station. Some staining was noted inside the structure and a layer of asphalt occurs in front of the earthen hollow, but the asphalt is not visible in the photos. In June 2007, DTSC questioned both PG&E and federal agency representatives if they knew what the earthen structure might be. Formal responses are still pending. PG&E should determine if the structure was used as part of site operations to assist in determining if environmental analyses are now warranted.	No information is available about this structure, which is not on PG&E property and does not appear to have any connection to PG&E. A speculative theory for this structure is that it was for dynamite storage for Route 66 construction in 1931, Arch Bridge construction in 1931, or Red Rock Bridge construction in 1889. This structure had only been discovered by PG&E personnel a few weeks prior to DTSC's site visit.	Based on PG&E's response, the structure could also have been used to store explosives during the construction of the compressor station. Therefore, it is requested that this unit be characterized and include sampling for explosives and TPH. The unit shall be designated AOC 25, Potential Explosives Storage Area. This AOC shall be described in the RFI Volume 1 Addendum.	Per recent discussion DTSC and DOI, this unit will not be designated as an AOC. No further investigation is required.

Comment No.	2008 HERD Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
General	Overall, the development of the DQOs shows a significant improvement compared to the DQOs that were developed in the Soil Investigation Workplan, Part A.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.
Specific 1	**Section 2.2.2, Potentially Exposed Receptors** As stated in Section 2.2.1, chemicals of potential concern (COPCs) could potentially move outside the fence line via sheet flow. Therefore HERD recommends that potential exposures of ecological receptors outside the fence line be evaluated if it is determined that COPCs that this transport mechanism did occur. Table 3-1, Problem 1 should be modified to incorporate this comment.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.
Specific 2	**Section 2.2.3, Potential Exposure Depth Intervals** HERD recommends that the depth interval for surface soil exposures be from 0 to 0.5 foot below ground surface (bgs), rather than 0 to three feet bgs. If the site-specific potential exposures of the construction and maintenance workers would not be more than six feet bgs, then inclusion of chemical concentrations at depths deeper than six feet bgs could dilute the exposure point concentrations for subsurface depths. HERD recommends that potential exposures to soils at depths deeper than six feet bgs be included only if the chemical concentrations are higher than those detected from 0 to 3 feet bgs. By doing so, occasional exposures to soil at depths to 10 feet bgs are also addressed.	PG&E agrees with this recommendation, and it was incorporated into the Risk Assessment Workplan, which was approved by both DTSC and DOI	No response necessary.	No response necessary.
Specific 3	**Comments on Table 3-1** The following comments on Table 3-1 should be addressed and incorporated into the discussion in the text, wherever it is appropriate.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.

Comment No.	2008 HERD Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	Problem 1, Inputs to Decisions Cultural resources impacts associated with each remedial technology are not inputs to deciding whether sufficient data had been collected to evaluate human health risk within the fence line. This information is more relevant during the feasibility study, as stated in Section 3.4, and should be deleted from this section of Table 3-1.			
	Problem 1, Study Boundaries HERD defers to the Geological Services Unit (GSU) on how the lateral delineation will be determined. However, should industrial CHHSLs/PRGs be considered potential criteria for lateral delineation, HERD had previously indicated that the CHHSL/PRG for each individual constituent should be adjusted to account for cumulative risk/hazard index. **Problem 1, Decision Rule** Another option for Decision 1b is to use the maximum concentration, rather than additional data collection, if the number of samples is inadequate for calculating a statistically-based exposure point concentration. This comment is consistent with the statement in the first paragraph of Step 6. **Problem 2 Inputs to Decision** Since beneficial use of groundwater is the stated problem whereas human health risk and/or hazard associated with groundwater use is not, the contribution to carcinogenic and noncarcinogenic risk is not an appropriate input to the decision. The lateral and vertical extent of COPCs that contribute to an excess risk would be relevant if one of the stated problems is the unknown risk associated with a specific use of groundwater. HERD recommends that this specific input to decision be deleted.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.

Comment No.	2008 HERD Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	Problem 4, Stated Problem The stated problem indicates that the standard for clean closure had not been defined. If so, PG&E should clarify whether the assumption that clean closure of SWMUS 5, 6, 8, or 9 will be based on industrial use standards (Step 2, Identify the Decisions) is being proposed for consideration by DTSC.			
	Problem 4, Inputs to the Decision Although one of the assumptions in Problem 1 implies that risk may be one of the factors in the RCRA closure of SWMUS 5, 6, 8, and 9 (Problem 4), this was not stated in Problem 4. Consequently, all inputs pertaining to risk should be deleted if health risk is not one of the decision criteria for RCRA Closure of SWMUs 5-9.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.
	Problem 6, Study Boundaries HERD does not agree with the statement that target analytes will be determined by the risk assessment. Target analytes are analytes that were detected in previous investigations. The risk assessment cannot identify COPCs that are significant contributors to risk unless the GSU has agreed that the characterization is adequate. In addition, the discussion on target analytes should be in “Inputs to the Decision” rather than in “Study Boundaries.”	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.
Specific 4	**Section 4.2** As indicated in the preceding comments, the CHHSLs/PRGs should be adjusted in order to account for cumulative risk and/or hazard index.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.
Specific 5	**Figure 4-3 and Section 4.2.2** Step 13B states that if there is a potential risk of leaching to groundwater, this pathway will be addressed through the risk assessment and/or remedial action. One of the Inputs to Decision	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.

Comment No.	2008 HERD Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	shown in Table 3-1, Problem 2, is "Beneficial Uses of Groundwater," which is usually the maximum contaminant level (MCL) in drinking water. Clarification should be provided whether addressing through risk assessment means that alternative use of groundwater will be proposed for concurrence and that risk-based concentrations based on this alternative use will be developed.			
Specific 6	**Figure 4-4A** It is HERD's understanding that each of the decision boxes (shaded in gray) indicates that the data set from each SWMU will be evaluated separately from the entire data set inside the fenceline. Clarification should be provided because the magnitude of the remediation, if any, to support closure of each RCRA SWMU could be different from the remediation required for the entire area inside the fenceline.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.
Specific 7	**Figure 4-5, Table 3-1, Problem 4, and Section 4.2.4** If the lateral study boundaries for SWMUs 5, 6, 8, 9 consist of the footprint of each SWMU, it would be more straightforward to evaluate the risk for each SWMUs rather than for the entire area within the fenceline, as shown in Step 3. Therefore, Steps 3 and 4, and the relevant discussion in Section 4.2.4 should be modified accordingly.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.

Comment No.	2008 HERD Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	The described approach is confusing. If the number and the locations of the samples to be collected in order to address Problem 4 were truly premised on the DQO process, the decision rule should specify whether the maximum concentration or a statistically-based concentration within the boundaries of each SWMU will be applied. Consequently, Steps 5 and 6 in Figure 4-5 can be eliminated. The discussion in Section 4.2.4 should be modified for consistency with the revisions to Figure 4-5 based on HERD's comments.			
Specific 8	**Figure 4-6, Problem Statement 5** Step 4 indicates that potential leaching to groundwater will be evaluated if there is a potentially complete migration pathway to areas outside the fenceline. However, this is not stated in the decision rule for Problem 5 and not clearly explained in Section 4.2.5. Additional discussion should be provided for clarification. It should also be explained whether the action to go to Figure 4-3A refers to Figure 4-3 or to Step 3A in Figure 4-3.	See Response to DTSC Specific Comment 2	No response necessary.	No response necessary.

Comment No.	2007 FMIT Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
1 (General)	Primarily, the Tribe wishes to express its concern over this incremental disturbance to sacred grounds. The Tribe has repeatedly provided comments relating to the offensiveness of the many, many intrusions, disturbances, and violations of the sacred grounds that have accrued to date. Indeed, this workplan represents yet another significant level of disturbance. In commenting on the Part A Soils Workplan, the Tribe strongly petitioned for the DTSC to apply an alternative approach to minimize sampling and to try in every way possible to minimize the number of samples to be collected.[1] In response, DTSC indicated that it did not understand why the Tribe would consider the number of samples proposed as excessive. DTSC pointed to the large number of non-contiguous sites covering “vast acreages” that were impacted historically by discharges.[2] Indeed, this characterization highlights the basis of the Tribe’s concern: that there seems to be no degree of characterization that the DTSC considers to be enough or excessive. Indeed, the Tribe is aware that “DTSC is mandated to evaluate any such potentially impacted areas to ensure protection of human health and the environment through reasonable science.” At the same time, the Tribe questions whether “reasonable science” is so prescriptive as to necessitate such a degree of inflexibility in DTSC’s approach to assessment. The DTSC further points out that it cannot “predetermine” a remedy without such information, yet the Tribe notes that the U.S. Environmental Protection Agency (EPA) has embraced the concept of presumptive remedies “… to streamline site investigations and accelerate the selection of cleanup actions….”[3] A presumptive remedy is defined as “… a technology that EPA believes, based upon its past experience, generally will be the most appropriate remedy for a specified type	The FMIT perspective expressed in this comment is that the work plan is too extensive and includes too many samples. This perspective is in conflict with the comments received from the other parties. Clarification was requested in an April 21, 2008 email from PG&E to DTSC and DOI. The following response was provided in the DTSC’s response dated March 10, 2010 (*Part B Soil Investigation Clarification Comments and Additional Direction, Pacific Gas and Electric Compressor Station Needles, California (EPA ID No. CAT080011729*):  <u>DTSC Response:</u> PG&E should first address all comments based on the technical needs of the project. DTSC is open to approaches that can minimize impacts to the area caused by the characterization activities. However, the initial characterization proposal must be based on sound science. Tribes and stakeholders will have the opportunity to provide input regarding the proposed plan and discuss all of their concerns with the agencies and PG&E. Additional revisions to the proposal are anticipated and will be needed to address comments obtained from the stakeholders. If applicable, DTSC recommends that PG&E reconsider using XRF and other screening techniques to potentially reduce investigation impacts and hopefully also expedite certain phases of the investigation. DTSC understands that PG&E is currently utilizing the XRF for the AOC-4 removal activities.	DTSC recognizes and respects the Tribe’s views regarding the sacredness of the area. DTSC understands the Tribe’s concern regarding the potential physical and cultural disturbance from the proposed sampling and will continue to work actively with all the tribes and stakeholders to minimize potential disturbances. DTSC notes that changes have occurred in the general approach for the soils investigation since the submittal of the draft 2007 Part B RFI Workplan. More emphasis will be given to the use of data quality objectives (DQOs) to guide the investigation. A DQO’s technical memorandum will be developed to help guide the formulation of a revised draft Part B RFI Workplan. DTSC believes that the DQO’s that are currently being developed, along with the comments on the draft 2007 Part B Workplan, will result in a revised workplan that may be substantially different from the draft 2007 Part B RFI Workplan. Regardless of the changes to the next version of the draft workplan, it will be distributed to all stakeholders to solicit additional comments. It is DTSC’s hope that the discussions with the tribes and stakeholders will result in a final workplan that will present a streamlined approach and minimize potential physical and cultural impacts.	No additional response necessary.

Comment No.	2007 FMIT Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	of site."4 If the concept of presumptive remedies can be used to facilitate remedy selection based on site to-site similarities at geographically different facilities, why can't the same concept be applied to the "non-contiguous" areas with similar operational histories across the Topock Site? It seems that this may lessen sampling requirements. With full recognition of the value of data abundance in decision making, the Tribe understands that there will be residual uncertainty with any level of characterization sampling. In its comments, the DTSC also stated that it "… must balance the need to properly define the nature and extent of contamination with minimal site disturbance." The Tribe is wondering how the DTSC in fact achieves this "balance," moreover how it views its performance along this line. As pointed out in EPA's principles for Superfund reauthorization: "The Administration's goals for Superfund reauthorization continue to be to: protect human health, welfare and the environment; maximize participation by responsible parties in the performance of cleanups; ensure effective State, Tribal and community involvement in decision making; and promote economic redevelopment or other beneficial reuse of sites, all in a manner that increases the pace of cleanups, improves program efficiency and decreases litigation and transaction costs, and which does not disrupt or delay ongoing progress." [emphasis added]5 From this policy, it would seem that human health, welfare, and the environment are all factors that must be appropriately weighed in the decision process. At this point, other than DTSC's claim, the Tribe does not understand how or at what point the DTSC exercises the balance between that it claims to be achieving. It seems that DTSC is not recognizing that the			

Comment No.	2007 FMIT Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
	issue that the Tribe is raising relates to the disruption of cultural values of the Tribe, not merely to "site disturbance." 1. Hargis + Associates, Inc., 2007. 2	In addition to the issues raised above regarding the number of samples, the Tribe is wondering if there is any estimate of the total number of soil characterization samples collected to date. Also, has there been any quantification with regard to the volume of soils removed and disturbed historically and with respect to this proposal? Finally, is there any plan to repatriate these soils?	An estimate of the total number of historic soil samples can be developed and will be included in the workplan; however repatriation of soils removed during historic sampling is not feasible. For soil removed from borings in the future, consistent with current practice, PG&E will collect the soil and stockpile it until the sample collection is completed and borings will be grouted. After the collected soil has been evaluated, PG&E will work with the Tribe to determine if another appropriate re-use of the soil is feasible.	DTSC defers to PG&E regarding the specific number and volume of samples collected. For future sampling, DTSC agrees with the proposal to potentially re-use soils to the extent possible.	An estimated 1,002 soil samples from 480 locations have been collected in and around the compressor station to date. This estimate does not include recent samples collected pursuant to maintenance activities within the fence line of the compressor station. The volume of samples collected and soil removed cannot be quantified. Quantities of investigation-derived waste have not been recorded during prior investigations.

Comment No.	2007 FMIT Comment	2010 PG&E Response	2010 DTSC Response	2011 PG&E Response
3	It is unclear from Figure 6-1 whether the alternative staging areas are on already disturbed areas and if so, what the prior disturbances are. In any case, those staging areas seem to be larger than need be and may unnecessarily disturb additional land.	All staging areas were selected because they are already disturbed ground. The size of the areas was defined to ensure that all equipment that may be required (e.g., a long-reach excavator) could be located entirely within the staging area/on previously disturbed ground.	The Tribe's comment is noted. As indicated above, due to the anticipated substantial revision in the revised workplan, all issues, including staging areas, will be re-evaluated.	No additional response necessary.
4	As you are aware, the Tribe has already commented on the December 11, 2007, PG&E Work Plan for the East Ravine Groundwater Investigation. Comments were transmitted to you on December 28, 2008. Within those comments, the Tribe asserted its opposition to the proposal to drill new monitoring wells in the East Ravine area based on the violation that they represent to its sacred grounds. Specifically, the Tribe's comments indicated that "…the need to do further characterization at this time (as opposed to some time in the future that may indicate the need for a separate remedy component) is not fully justifiable." Noting that this work plan also includes a proposal to construct up to three additional monitor wells for investigating groundwater within the fenced area, the Tribe reasserts its opposition to the proposed additional wells on the same grounds as previously stated for the East Ravine area.	This comment is in conflict with the direction received from the agencies. Specifically, DTSC provided the following response in DTSC's response letter dated March 10, 2010 (*Part B Soil Investigation Clarification Comments and Additional Direction, Pacific Gas and Electric Compressor Station Needles, California (EPA ID No. CAT080011729*):  DTSC Response: PG&E should first address all comments based on the technical needs of the project. DTSC is open to approaches that can minimize impacts to the area caused by the characterization activities. However, the initial characterization proposal must be based on sound science. Tribes and stakeholders will have the opportunity to provide input regarding the proposed plan and discuss all of their concerns with the agencies and PG&E. Additional revisions to the proposal are anticipated and will be needed to address comments obtained from the stakeholders. If applicable, DTSC recommends that PG&E reconsider using XRF and other screening techniques to potentially reduce investigation impacts and hopefully also expedite certain phases of the investigation. DTSC understands that PG&E is currently utilizing the XRF for the AOC-4 removal activities.	DTSC notes that the groundwater investigation component of the Part B soils investigations have been removed and will be addressed separately in the East Ravine/Topock Compressor Station Groundwater Investigation. The Tribe's comment will be addressed as part of the East Ravine groundwater investigation.	No additional response necessary.
5	In recognition that these comments raise significant concerns and issues on behalf of the Tribe, we offer our availability for further discussion to facilitate resolution of these comments as well as the many related site activities that comprise the cumulative adverse impacts to the sacred grounds. Please contact me if I can provide further information and/or arrangements along these lines.	Comment acknowledged. PG&E appreciates the Tribe's willingness to participate in this manner. PG&E defers to the agencies on the detailed process for stakeholders and tribal involvement,	DTSC appreciates the Tribe's participation and looks forward to working with the tribes and stakeholders in resolving all concerns and issues.	PG&E will continue to notify the Tribe regarding proposed investigation activities to ensure that the Tribe has the opportunity to provide input.

Comment No.	Comment	2010 PG&E Response	2010 DTSC Response	
1	Overall EMC found the Work Plan to be well written, organized and followed a logical progression and presentation of information with well documented tables and figures.	Comment acknowledged.	No response necessary.	No additional response necessary.
2	Section 1.1 Background describes that the investigation and remedial activities at the Topock Compressor Station are being performed under both the Resource Conservation and Recovery Act (RCRA) corrective action process and the Comprehensive Environmental Response, Compensation and Liability Act of 1980 (CERCLA). In February 1996, PG&E and the California Department of Toxic substances Control (DTSC) entered into a Corrective Action Consent Agreement. It is further stated that the United States Department of Interior (DOI) is the lead agency on land under its jurisdiction, custody and control, and that the DOI is responsible for oversight of the response actions being conducted by PG&E pursuant to CERCLA. Not referenced in this document is the additional voluntary corrective action cleanup agreement that may exist with the Arizona Department of Environmental Quality (ADEQ) who is responsible for the investigation and clean up activities in Arizona. EMC understood that DTSC was the sole responsible regulatory agency and final decision maker related to all corrective action and technical activities being conducted at the Topock site, regardless if activities were on federal lands or activities being conducted in California or Arizona. It would be helpful to provide additional clarification regarding the authorities and responsibilities of each of the three regulatory agencies, since it appears that there may be three separate regulatory agencies with separate decision making authority and responsibilities. It would also be helpful to understand if a Memorandum of Understanding (MOU) has been executed between these agencies to streamline and expedite the corrective action process.	The Arizona Department of Environmental Quality (ADEQ) has accepted PG&E's application for the ADEQ Voluntary Remediation Program (VRP). The VRP is not mentioned in RFI/RI documents because the RFI/RI documents are specifically prepared to meet the requirements of the RCRA Corrective Action and CERCLA. Separate documents are required by the VRP. DOI and DTSC continue to oversee the larger study area as part of the RCRA and CERCLA investigations. The VRP remains active as a stakeholder in these investigative activities as they relate to potential future impacts that could affect water quality under the jurisdiction of the State of Arizona There is not a Memorandum of Understanding between the agencies enforcing RCRA Corrective Action, CERCLA, and the VRP.	DTSC is the lead regulatory agency under the Resource Conservation and Recovery Act (RCRA) for the corrective action activities related to the PG&E Topock facility. DTSC shares regulatory lead responsibility with DOI which operates under the authority of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA). DTSC defers to PG&E regarding its voluntary agreement with the ADEQ. DTSC does not have any memorandum of agreement with the other agencies related to the PG&E Topock project; however, because RCRA and CERCLA requirements are often very similar, it is in the best interest of all parties that DTSC and DOI work closely to ensure that PG&E satisfy all regulatory requirements simultaneously to the extent possible.	No additional response necessary.
3	Section 3.1 describes the overall objectives of the soil	The DQOs process is being conducted in accordance with the requirements of DTSC and DOI. The Part B	DTSC agrees with the Tribe in expediting the investigation and remedial activities related to soils at	PG&E appreciates the Tribes' input on the Part A Data Gaps Evaluation and looks

Comment No.	Comment	2010 PG&E Response	2010 DTSC Response	
	investigation program as: 1. sufficiently characterize the investigation areas and; 2. minimize the number of samples and associated disturbance within the facility and facility operations. EMC noticed the absence of the significant basic objectives such as "expedite the final remedy selection" "reduce the length of time' or "eliminate delays in completing the investigation". It appears to the reader that the basic conceptual approach continues to be, minimize the samples and potentially conduct multiple phases of investigations over a long period of time. While EMC agrees that the Data Quality Objectives (DQO) process is a recognized procedure and the Environmental Protection Agency (EPA) has provided guidance on the DQO process, it appears that PG&E and the agencies are trying to fit the Topock project into the standard DQO process rather than using the DQO process to beneficially move the project forward and reach a final remedy as quickly as possible.	DQOs are being redrafted. The goal of the DQO process is to ensure that data collected at each stage of the investigation process are of sufficient quantity and quality to enable the specified decisions to be made.	the PG&E Topock facility. DTSC hopes that the soils-related activities will gain momentum now that the groundwater related activities are moving towards remedy design. DTSC believes that the DQO's that are currently being developed, along with the comments on the draft 2007 Part B Workplan, will result in a revised workplan that may be substantially different from the draft 2007 Part B RFI Workplan. It is DTSC's hope that the continuing discussions with the tribes and stakeholders will result in a final workplan that will present a streamlined approach and minimize potential physical and cultural impacts.	forward to continued participation by the Tribes.
4	Section 3.6 states that the existing values for background concentrations of metals are preliminary and that refined background concentrations will be evaluated pursuant to the Part A Work Plan. EMC agrees with this statement and believes that the previous background metal data set is not representative of actual background conditions and that separate background values should be developed for each lithologic unit within the study area.	The additional background investigation has been completed. The revised final technical memorandum was submitted and accepted by DTSC (*Revised Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California*; CH2M HILL, May 2009). Statistical evaluation of the background data indicated that the differences between the lithologic units were not significant enough to merit defining separate background data values for each unit. All background data were combined into one data set and used to develop the background threshold value (BTV) concentrations.	DTSC defers to PG&E's response to the Tribe's comment.	No additional response necessary.
5	EMC believes that direct active onsite participation by one of the regulatory agencies would greatly assist in	DTSC and DOI have the authority to be on-site for some or all of the sampling, and will make	DTSC agrees with the Tribe that expedited field decisions are valuable and will help streamline the	No additional response necessary.

Comment No.	Comment	2010 PG&E Response	2010 DTSC Response	
	expediting completion of the investigation activities. It would seem appropriate that an appropriate regulatory agency commit the necessary qualified professional staff and resources to actively observe drilling and sampling activities so that expedited field decisions could be made related to the inclusions of additional samples for analysis or the modification or addition of sample locations.	determinations regarding the value of having a representative in the field throughout the investigation program.	investigation process; however, DTSC unfortunately does not have the resources to commit staff to be present for all field activities. DTSC makes every effort to coordinate with DOI in sharing field oversight duties. In addition, DTSC is available via electronic mail and telephone should field personnel require immediate attention and response from DTSC.	
6	Section 5.7 (AOC 5 Cooling Tower) Considering the elevated chromium concentrations at PS-IS and PS-16, minimal sampling effort is being proposed in these areas. Additional sampling locations appear to be warranted.	The existing sampling data are classified as Category 1. The proposed sampling analysis will augment that sampling data and will provide sufficient data for characterization of the AOC.	DTSC concurs with the Tribe's comment and has provided comments to PG&E requesting additional sampling at the cooling towers.	Additional sampling at the cooling towers has been proposed in the work plan (see proposed sampling at AOCs 5 and 6).
7	Section 5.8 (AOC 6 Cooling Tower) Considering the elevated chromium concentration at PS-3, PS-4, and PS-S it would appear that additional sampling effort would be justified along the western boundary of the AOC.	The existing sampling data are classified as Category 1. The proposed sampling analysis will augment that sampling data and will provide sufficient data for characterization of the AOC.	DTSC concurs with the Tribe's comment and has provided comments to PG&E requesting additional sampling at the cooling towers.	Additional sampling at the cooling towers has been proposed in the work plan (see proposed sampling at AOCs 5 and 6).
8	Section 5.11 (AOC 15 Auxiliary Jacket Cooling Water Pumps) Elevated chromium concentration occur at JP-6 and JP-10 and show an increasing trend west of JP-5. Additional sampling locations along the western boundary appear to be appropriate. Elevated chromium concentrations occur at JP-9, JP-8 and JP-2. Additional sampling locations appear to be warranted. The sample locations on Figure 5-15 do not match Figure 5-16. Sample location JP-9 is shown to be located at a different location on each map.	The proposed boring locations and sample depths will be reviewed and adjusted as needed for consistency with the Part B DQOs. Figures 5-15 and 5-16 will be revised.	DTSC concurs with the Tribe's comment and also acknowledges PG&E's response to take the appropriate actions.	Proposed sampling at AOC 15 is described in the work plan.
9	While great effort was used to evaluate the Precision, Accuracy Representativeness, Comparability and Completeness of Laboratory data that ultimately placed the data into three usability categories, was there a similar QA/QC process to evaluate and determine the fundamental basic accuracy of previous sample locations.	The sample locations shown in the RCRA Facility Investigation (RFI) and RFI work plans are based on the best available information, including surveyed sample locations, descriptions of the sample locations, and/or sample locations shown in figures provided with published reports. In most cases, the approximate location is known, and sufficient additional samples are proposed in the Part A and Part B work plans to ensure that areas of potential concern are adequately	DTSC defers to PG&E's response to the Tribe's comment.	No additional response necessary.

Comment No.	Comment	2010 PG&E Response	2010 DTSC Response	
		evaluated and delineated. The degree of uncertainty as to the precise location of a historic sample must always be evaluated in conjunction with the degree of precision deemed appropriate for the original sampling. The inability to locate a precise sampling position does not, in itself, mean that the data from that sampling are unusable or of limited usability, provided that the location can be determined with confidence to exist within an area for which no one point was more or less appropriate to accomplish the goals of the original sampling.		
10	The Tribes would like to be notified, in advance, of any scheduled sensitivity training. The Tribes have previously requested to be contacted in advance of any field activities and may choose to provide Tribal Monitors.	PG&E is committed to involving the tribes in the RFI/RI program at the compressor station, and will notify the tribes in advance of any field activities. Furthermore, prior to each major phase of field activities, PG&E holds a project initiation meeting at the compressor station and invites tribes/stakeholders/agencies and pertinent contractors to attend. During these project initiation meetings, tribes and agencies are invited to discuss/ share their viewpoints relating to the project. Such open discussion of viewpoints and sharing of information have enhanced the understanding of the project sensitivity for all participants.	DTSC will continue to coordinate with PG&E in notifying the tribes, and all stakeholders, in advance of all field activities.	No additional response necessary.

1.0 Perimeter Area Investigation Program

1.1 Perimeter Area Description and History

The Perimeter Area is defined as the area extending from the facility fence line to the toe of the slope, outside of the fence line. The areas of the perimeter area that are topographically lower than the Topock Compressor Station (i.e., toe of the slope) could have received stormwater runoff as well as incidental spills from the compressor station in areas that are currently and/or historically unbermed. In areas where the ground slopes upward toward the fence line from the interior of the station or where the ground slopes up outside the station, deposition of chemicals through sheet flow would not have occurred. The perimeter does not include any areas that are currently defined as being part of an existing unit (i.e., Areas of Concern [AOCs] 4, 9, 10, and 11 and Solid Waste Management Unit [SWMU] 1 are all located in part or in their entirety on the slope). The Perimeter Area has not been previously investigated.

The majority of the facility is currently bermed or curbed. Figure C-1 shows the current bermed, curbed, and unbermed/curbed areas. Some of the areas that are currently bermed with soil are known to be or were likely to have been unbermed in the past. In areas that are currently or may historically have been unbermed, perimeter samples will provide information on potential recent discharges to the area outside the fence line.

Perimeter sampling locations were originally selected during a field walk with California Department of Toxic Substances (DTSC) and United States Department of the Interior (DOI) on October 18, 2007. Fifteen perimeter sampling locations were identified and proposed in the Draft Part B Work Plan (CH2M HILL 2007). The sample locations were included in AOC 13 (unpaved areas at the compressor station), and were named proposed sample locations AOC13-36 through AOC13-50. The remaining perimeter area samples have been renamed to clearly identify them as perimeter sample locations.

Two of the 15 locations identified during the field walk are within the interior of station (AOC13-39 and AOC13-40) and have been shifted from the perimeter investigation and assigned to AOC 13 (renumbered to AOC 13-33 and AOC 13-34) and one former perimeter sample (AOC13-47) was redundant with a proposed storm drain sample location (SD-3), so this perimeter sample was deleted. The remaining perimeter area samples are identified as PA1 through PA12 (see Figure C1).

The location of the former Tea Pot Dome oil pit overlaps with the Perimeter Area investigation. Proposed sample location AOC PA12 is located in the immediate vicinity of the tentatively identified location of the former Tea Pot Dome oil pit. This sample location in an area identified as having a circular area of dark soil approximately 3 to 4 feet in diameter, and is therefore the most likely potential location of the former oil pit. Investigation of the former Tea Pot Dome oil pit has been incorporated into the Perimeter Area investigation.

1.2 Summary of Past Soil Characterization

No prior sampling has been conducted specifically to evaluate the Perimeter Area. Several samples were collected at AOC 9 in the vicinity of the fence line. Samples were also collected on the slope at AOCs 4, 9, 10, and 11, and SWMU 1. As discussed above, these areas are already being investigated and are not considered part of the Perimeter Area investigation.

1.3 Perimeter Area Data Proposed Sampling

Sampling is required to collect data to use as inputs for the Part B data quality objective (DQO) Decisions 1 through 5. Table C-1 summarizes the proposed Perimeter Area sample locations, depths, description/rationale for each location (i.e., the data gaps they would address), and analytes. Proposed sample locations are also shown in Figure C-1. The proposed Perimeter Area sample locations are Pacific Gas and Electric Company's initial assessment of candidate locations for characterization of this area. The figures are provided to facilitate planning for additional sampling that may be needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

During the site walk with DTSC in 2007, proposed perimeter samples were selected based on the appearance of the area (e.g., dark material and red-colored soil to the east of the Cooling Tower B area) and in areas where there is current surface water runoff via sheet flow or storm drains. Perimeter samples PA-1 through PA10 and PA12 are located in areas with visible discoloration or other potential direct impacts and/or that may experience or have experienced surface water runoff through sheet flow.

Only hand sampling will be feasible for most perimeter sample locations. As agreed in response to DTSC comments on the *Soil Part B Data Quality Objectives Technical Memorandum, PG&E Topock Compressor Station Needles, California* (Soil Part B DQO Tech Memo) (CH2M HILL, 2010), soil samples will be collected from the surface to 1.0 feet below ground surface (bgs). The surface sample interval is larger than for typical surface soil samples because of the potential for erosion at the perimeter. In locations accessible by mechanical equipment (i.e., PA12 in the vicinity of the Tea Pot Dome oil pit) samples will also be collected at 2 to 3, 5 to 6, and 9 to 10 feet bgs, if feasible. All samples will be analyzed for Title 22 metals, hexavalent chromium, semivolatile organic compounds (SVOCs), polycyclic aromatic hydrocarbons (PAHs), total petroleum hydrocarbons (TPH), and polychlorinated biphenyls (PCBs). Ten percent of the samples will be analyzed for the United States Environmental Protection Agency Contract Laboratory Program Target Analyte List and Target Compound List. The proposed sample locations are shown in Figure C-1.

2.0 Data Evaluation

2.1 Data Evaluation Overview

The primary purpose of the Perimeter Area investigation is to establish whether there are existing concentrations of constituents immediately outside the fence line of the facility that could serve as ongoing sources to areas outside the fence line. The data evaluation process for the Perimeter Area will determine the unit(s) to which any portions of the Perimeter Area with detected concentrations of constituents above screening level will be assigned.

2.2 Evaluation of Perimeter Area Investigation Data

The data evaluation for the Perimeter Area will follow the general process established for soil samples collected at the compressor station. Once all samples have been analyzed, the data will be validated. The validated data will first be compared to the interim screening levels previously developed for areas outside the fence line (see Soil Part B DQO Tech Memo). The following steps will be followed when assessing the Perimeter Area data:

1. Identify perimeter locations with chemicals of potential concentrations (COPCs) above Part A screening levels.
2. Incorporate downslope soil areas with COPC concentrations above Part A screening levels into the appropriate Part A AOC.
3. Incorporate soil areas with COPC concentrations above Part A screening levels located in flat areas adjacent to compressor station fence into the appropriate Part B AOC or AOC 13.

The data will be further evaluated for the need for migration control based on the concentrations and types of constituents detected, the accessibility of the affected Perimeter Area, and the specific downslope area that may receive runoff from the affected Perimeter Area. Additionally, locations from within the fence line will be evaluated to assess if detected constituents around perimeter are likely to have originated from runoff within the fence line. If the detected constituents appear to have originated within the fence line of the compressor station, the apparent source will also be evaluated to assess any necessary steps to minimize the potential for further migration.

1.0 Storm Drain System Investigation Program

In addition to the hazardous waste treatment system piping (Area of Concern [AOC] 18) and industrial floor drain piping (AOC 20) described in Appendices B15 and B17, storm drain lines are present throughout the compressor station. This appendix describes the proposed investigation program for the storm drain system at the Topock Compressor Station.

1.1 Storm Drain Description and History

Storm drain lines are both potential sources and potential pathways for contaminant migration. The conceptual site model for the storm drain system includes releases of hazardous constituents into the storm drains as a result of contaminated soil carried in surface water runoff and/or liquid spills. Contaminants released to storm drains could then be released to surface soils via direct discharge at an outfall, or to the subsurface if the piping is degraded. Hazardous constituents may also be present in soil accumulated in the storm drains during station operations.

Only limited information is available regarding the locations of storm drain lines at the Topock Compressor Station. Thirteen active and inactive storm drain outfalls have been visually identified outside the fence line. Some portions of storm drain lines leading to these lines are also visible outside the fence line. Catch basins are visible within the compressor station. Written records (i.e., engineering drawings and updates to drawings) are limited. Available written information is summarized in Table D-1. Available written information was supplemented with employee interviews and on-the-ground surveys of outfalls and catch basins. Figure D-1 shows the 15 identified storm drain outfalls, as well as known and inferred storm drain alignments associated with these outfalls.

Employee interviews indicate that historically, storm drain lines were added when needed, for example when a storm drain line stopped draining and could not be unplugged. Similar to other abandoned underground utilities within the compressor station, abandoned storm drains were commonly abandoned in place rather than risk the additional dangers associated with removal (CH2M HILL, 2011a).

Some storm drain lines outside the compressor station were buried for their entire run (to the bottom of the slope); others were buried only to the edge of the top slope and are exposed for the remaining run. Exposed drain lines were repaired when they corroded; covered lines were often repaired or replaced when it became apparent that a leak had developed (this would typically be due to erosion along the line).

1.2 Summary of Past Storm Drain Characterization

No physical investigation has been conducted to specifically target the storm drains. A records review was conducted for the *Revised Final RCRA Investigation/Remedial Investigation Report, Volume 1 - Site Background and History, PG&E Topock Compressor Station, Needles,* *California* (CH2M HILL, 2007) and during subsequent phases of soil investigation work plan preparation. Some soil samples have been collected in the vicinity of or downslope from storm drain outfalls. The pertinent sample areas near various storm drain lines have been evaluated, and data gaps have been addressed in Appendices A and B to the main report.

1.3 Storm Drain System Data Needs

Two types of information will be generated by the storm drain investigation: information on the alignments of various storm drain lines, and soil sample information outside the fence line. Information on storm drain line alignments is required to satisfy Decision 4 of the Part B data quality objectives (DQOs) (CH2M HILL, 2011b). Because storm drains provide a potential transport pathway for constituents released within the fence line to areas outside fence lines, the potential for constituents in soil and spilled liquids to migrate to areas outside the fence line is dependent upon which catch basins discharge to the various outfalls.

In addition, to satisfy Part A and Part B DQO Decision 1, data are needed to characterize potential discharges from storm drains to soil. Finally, both types of information are required to satisfy Part A Decision 4 and Part B DQO Decision 5 (i.e., to ensure that there is sufficient information to proceed with the development of the corrective measures study/feasibility study, remedial design, and/or interim measures). The primary transport pathway associated with the storm drain system would be discharge of contaminants into the storm drains, followed by runoff from the storm drains to areas outside the fence line. Consequently, an important consideration in the storm drain alignment investigation is not only the physical location of the storm drains but the drainage pathways (i.e., assessing which storm drains discharge to specific outfalls).

No intrusive sampling is proposed alongside or underneath storm drains within the compressor station. Unless the investigation effort proposed in this appendix indicates that substantial releases of contaminants have occurred from the storm drain system, the potential risk associated with intrusive investigation along the storm drain lines within the fence line is not justified by the value of the information that would be obtained from the information. Furthermore, rainfall at the station is low and highly episodic. The episodic nature of flow events would minimize the likelihood of lateral migration along the storm drain bedding material, as it would be atypical for runoff to be present in the lines.

1.4 Storm Drain Alignment Investigation

1.4.1 Storm Drain Alignment Investigation Scope

As noted above, storm drains have been identified as potential sources as well as potential transport pathways. To assess whether a potential storm drain line may act as a transport pathway, it is valuable to understand which storm drain catch basins are currently connected to the various identified outfalls.

1.4.2 Storm Drain Alignment Investigation Process

The storm drain investigation process will consist of five steps:

1. Verification and expansion of the previous record search
2. Visual field verification of the record search results (as feasible)
3. Geophysical investigation
4. Flow testing
5. Video camera tracing(as feasible)

No intrusive investigation (i.e., uncovering of lines to trace them) will be performed to identify storm drain alignments.

The five steps will be performed in sequence so that each step benefits from the information collected during the previous steps. The output from this task will be a map showing all information collected during the alignment investigation. The map will show catch basins and visible pipes/outfalls. Connections between catch basins and outfalls will also be provided; some of the connections between outfalls and catch basins will most likely continue to be inferred. The majority of the storm drain alignment investigation will occur within the compressor station; accurately locating subsurface storm drain lines outside the compressor station is likely to be infeasible in most instances.

Because the tasks must be performed in sequence to maximize the value of the storm drain alignment investigation, the storm drain alignment investigation will span several months. Intrusive sampling (see Section 1.4.3) will be conducted after the alignment investigation has been completed, to verify that appropriate sample locations and analytical parameters have been selected. Each of the tasks is described in more detail below.

1.4.2.1 Record Search

Existing information regarding storm drain alignments is taken from available documentation pertaining to storm drains, past employee interviews, and visual observations at the station. This information consists primarily of one as-built drawing of the original system with very limited annotations regarding subsequent modifications. The most recent of the modifications on this drawing are dated 1993. It is unknown whether the many engineering drawings available at Topock contain further information on the storm drain system. While these drawings have been inventoried, it is possible that some of the drawings may contain information that is not reflected in the document title in the document inventory.

Pacific Gas and Electric Company (PG&E) will review engineering drawings on file at the Topock Compressor Station and at the Hinkley Station District Office for further information regarding modifications to the storm drain system. Any information found will be summarized in written form and will be reflected on the final storm drain system map.

1.4.2.2 Visual Field Verification

Any new information uncovered during the record search will be visually verified in the field to the degree feasible. This step will include consultation with knowledgeable employees currently employed at the station, as applicable. Items that cannot be verified visually will be further evaluated in subsequent phases of the storm drain alignment investigation, if feasible. The visual field verification may be an iterative process if additional information is located.

The current storm drain map included with this work plan shows all known catch basins. If accumulated soil material is encountered in any catch basin during the visual field verification, a sample will be collected and analyzed for Title 22 metals, hexavalent chromium, total petroleum hydrocarbons (TPH), polycyclic aromatic hydrocarbons (PAHs), and polychlorinated biphenyls (PCBs). If more than five samples of accumulated soil material are collected, at least one sample or 10 percent of all samples, whichever is more, will be analyzed for the full suite of Target Analyte List/Target Compound List (TAL/TCL) constituents. Should there be insufficient accumulated material to run the desired suite of chemical analyses, preferred analytical parameters will be determined based on available information regarding historical activities in the vicinity of the specific catch basin.

1.4.2.3 Geophysical Investigation

PG&E anticipates that there will still be various gaps in the information regarding the location of storm drain lines following the records review and visual verification. The next step in the storm drain alignment investigation will be a geophysical survey. The survey will attempt to trace lines between catch basins and outfall pipes for those areas where written records are incomplete. Due to the extensive presence of metallic equipment, buildings, and underground lines, there is a high likelihood of interference with geophysical methods causing uncertainty in the line tracing effort. For example, while it may be possible to trace a storm drain line for a certain distance, other lines may cross and/or join the line being traced, and it may be impossible to determine which direction the storm drain line takes at that point. In addition, tracing lines composed of a variety of pipe materials, both metallic and non-metallic, may also be necessary. Finally, as described earlier, because the historical practice at the station was to simply abandon blocked storm drain lines in place, distinguishing between active and inactive lines may not be feasible.

PG&E will attempt the geophysical survey; however, if the contractor and/or PG&E determine that the survey is yielding little or no usable information, the survey will be terminated and PG&E will proceed with the flow testing described in Section 1.4.2.4.

Currently, some of the visible storm drain outfall pipes are constructed of galvanized steel; however, subsurface portions of the storm drain lines may also be constructed of other materials. The specific materials of construction for each underground storm drain line segment are unknown. However, as a basis of comparison, available information indicates that underground piping associated with AOCs 18 and 20 may have been constructed from some of the following materials: polyethylene, polyvinyl chloride, aluminum, carbon steel, cast iron, vitrified clay, reinforced fiberglass, and acrylonitrile-butadiene-styrene. Consequently, various non-intrusive methods may be used as applicable. These include ground-penetrating radar, electromagnetic induction, and vertical magnetic gradient scans. There are likely to be some surface obstructions to the geophysical survey. The survey will avoid areas where access or other conditions (e.g., sparks) could create a hazard.

A survey grid will first be established to provide horizontal control for data acquisition. The grid size will be determined based on the size of the area being surveyed, presence of surface obstructions, and expected density of all subsurface utilities. Potential storm drain pipes will first be identified using vertical magnetic gradient and electromagnetic induction scans and may then be confirmed using ground-penetrating radar.

An attempt will be made to locate subsurface storm drain lines outside the fence line using geophysical survey methods; however, due to the topography, locating subsurface storm drain lines outside the compressor station using geophysical methods is likely to be largely infeasible. Equipment that has to be moved over the ground surface and/or bulky hand-carried equipment will not be usable on the steep slopes outside the station.

Geophysical instruments must be field tested frequently to ensure that they are operating properly. The field tests may include equipment warm-up, positioning systems accuracy, personnel test, vibration test (Cable Shake), static background and static spike, Azimuthal Test (magnetometer only), and Octant Test (Heading Error Test) (magnetometer only).

1.4.2.4 Flow Testing

The most direct method for establishing which catch basins are connected to specific outfalls is to discharge water to individual catch basins and determine where the water exits. In addition, by selecting the most "upstream" catch basin as the location to receive the test water and watching nearby catch basins, the investigation will be able to confirm that various catch basins are in fact located on the same line. In addition to verifying flow paths, the investigation will also identify drain lines that are blocked, as water will not discharge and will eventually fill up the storm drain line being tested. The amount of water to be discharged to specific catch basins will be determined based on available information regarding the size(s) of the pipeline and the length of the pipeline run to the outfall. Discharge of test water will be discontinued once the applicable outfall location has been verified.

The majority of the flow testing is expected to be performed using TCS water. It is possible, however, that it would be beneficial to conduct dye testing to enable PG&E to more completely understand the storm drain connections. Dye testing, if needed, would be performed using non-toxic dyes that are approved for discharge into sensitive aquatic environments.

Samples of discharge water will be collected from accessible outfalls, and analyzed for Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs. Prior to flow testing activities, PG&E will collect a source water sample from the water pipeline or truck providing the flow test water. The source water sample(s) will also be analyzed it for Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs to determine chemicals of potential concern (COPCs) concentrations in the source water, if any, and to allow comparison between source water and discharge water samples. If elevated concentrations of COPCs are present in the discharge water, some contamination can be presumed to be present in the storm drain line.

1.4.2.5 Video Camera Tracing

The final step in the storm drain alignment investigation will consist of confirming pipeline runs, and locating breaks, obstacles and known and unknown service connections using closed circuit television (CCTV) inspection techniques, if feasible. Each accessible segment of the storm drain lines will be viewed by panning and tilting a CCTV camera so that sags, connections, breaks, and potential accumulated soil material are clearly shown. To optimize the usefulness of the inspection, it will be conducted during dry weather only. The self-propelled camera will not be able to operate on the extremely slopes outside the fence line, so CCTV inspection is not proposed for storm drain lines on the slopes outside the compressor station.

The inspection will be completed on one storm drain pipe section at a time (i.e., catch basin to catch basin). The camera will travel through the line in either direction at a slow and uniform rate, stopping when necessary to ensure proper documentation of the storm drain pipe condition. The maximum speed of camera travel will be no greater than 30 feet per minute. It is likely that the CCTV camera will encounter obstructions that will interfere with the completion of the CCTV log. If obstructions are encountered, the survey crew will relocate to a catch basin downstream and attempt to survey the storm drain pipe from the opposite direction.

The location of defects, sags with or without soil accumulation, laterals, and physical location of the storm drain pipe will be marked above ground with a meter device capable of communicating with and locating the camera. If the video survey of the line shows no defects and no accumulation of soil material within a specific pipe segment, no additional evaluation will be required during the current investigation. Information on identified defects will be retained by PG&E to assist with future maintenance and engineering activities as well as remediation to be conducted following closure of the compressor station.

PG&E will attempt the video surveys; however, if the contractor and/or PG&E determine that the survey is yielding little or no usable information, the survey will be terminated and PG&E will proceed with producing the storm drain alignment maps based on available data.

Field observations may be recorded in up to three formats, as outlined below. A comprehensive summary of the relevant inspection results will be included with the investigation report.

Television Inspection Logs: Each segment inspection will have a separate inspection report, describing the direction of view, direction of flow relative to direction of view, pipe section length, pipe size, pipe material, lateral connections and a detailed logging of defects encountered. The inspection report will clearly show the location of defects, in relation to adjacent catch basins. In addition, other data of significance including joints, unusual condition, cracked or collapsed sections, presence of scale and corrosion, presence of accumulate soil material, and any pipe sections that the camera failed to pass through and reasons for failure will be included in the report.

Photographs: During the CCTV inspection, the camera will stop at all significant observations to provide a clear and focused view of the pipe condition.

DVD Recordings: The DVD recordings will supply a visual and audio record of the problem areas of the storm drain pipes in color.

1.4.2.6 Storm Drain Alignment Map

The information collected from the five steps described above will be used to compile a comprehensive map showing the known storm drain system on the compressor station and the locations of known outfalls. Abandoned storm drain alignments will be shown to the degree they can be identified from the records search. PG&E anticipates that the precise configuration of some storm drain lines cannot be determined (e.g., lines that are blocked and cannot be traced using geophysical methods); however, the discharge point(s) for each catch basin should be able to be identified using the flow test. Knowing the discharge location of each storm drain is adequate to determine whether the line poses a potential pathway for off-site migration. If uncertainties remain with regard to the precise alignment of any storm drains, the uncertainties will be captured in the storm drain investigation summary. Intrusive investigation of the storm drain system (i.e., uncovering of lines) will not be conducted.

1.4.3 Storm Drain Soil Investigation

Soil sampling along storm drains will be limited to areas outside the fence line. Samples will be collected at the storm drain outfalls and along visible storm drain lines. Sample locations shown on Figure D-1 are approximate and will be verified in the field, depending on the results of the storm drain alignment investigation.

Sampling below each storm drain outfall will consist of one sample location immediately below (downslope of) the outfall and lateral/downslope samples. The lateral/downslope sample locations are designed to evaluate soil conditions in the expected flow path from the storm drain to the bottom of the slope. Where pipes have broken off due to degradation, a sample will be collected at the end of the existing pipe, and an effort will be made to evaluate where the outfall may have been located historically, and a sample will be collected in that area. Lateral/downslope samples will be collected between the outfall and the bottom of the slope or the closest downslope sample locations (i.e., there are existing soil sample data downslope of storm drain locations in AOCs 1, 10, and 11). In some areas, adequate lateral/downslope samples may already have been collected during the Part A Phase 1 investigation; these areas will not be resampled. Samples will be collected at 0.0 to 0.5 foot below ground surface (bgs) unless it is apparent that erosion has occurred in the vicinity of the outfall, in which case a sample will be collected from 0.0 to 1 foot bgs to capture a larger potential interval of affected soil. Where feasible, based on the subsurface conditions and topography at the outfall (and downslope location, if applicable) samples will also be collected at 2 to 3, 5 to 6, and 9 to 10 feet bgs.

In addition to samples collected at and downslope of the outfalls, samples will be collected along the alignment of each visible storm drain line outside the fence line, where feasible. Samples will be collected at 0.0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet bgs, if possible. If pipeline bedding material is encountered that is obviously different from the surrounding native soil, the bedding material will be sampled as well. Samples will be collected at the edge of the slope (i.e., where the line bends), and every 50 feet, or at obvious breaks or other bends in the pipeline, if any bends or breaks were identified during the storm drain alignment investigation. The visible portion of the storm drain line at Outfalls 5, 6, 10, and 11 is less than 25 feet; therefore, no samples will be collected along the storm drain line in this area (a sample will be collected at the edge of the slope). Samples along the storm drain lines will be collected from alternating sides of the pipe. All sample locations will be recorded using a global positioning system.

Sampling within the fence line will be limited to any accumulated material encountered in catch basins. No intrusive sampling will be conducted.

All soil samples will be analyzed for Title 22 metals, hexavalent chromium, PAHs, TPH, and PCBs. Ten percent of all samples collected along the storm drains and below the storm drain outfalls will be analyzed for the full suite of TAL/TCL constituents. Samples of accumulated soil material collected from catch basins within the compressor station will be analyzed as described in Section 1.4.2.2 of this appendix. The proposed sample locations are shown on Figure D-1, and the sample ID, rationale, analytical suite, and sampling method are shown in Table D-2 and Appendix F of this work plan.

Sampling, sample analysis, data validation, and data management will follow standard operating procedures for this work plan, and investigation-derived waste associated with the storm drain soil sampling program will be managed in the same manner as for all other soil sampling efforts to be conducted pursuant to this work plan. The data evaluation process is described in Section 2.0.

2.0 Sample Data Evaluation

The sample data evaluation process for the storm drain lines will follow the general process established for soil samples collected at the compressor station. Once all samples have been analyzed, the data will be validated. The validated data will be compared to the interim screening levels previously developed for areas outside the fence line (see Appendix A of this work plan). The three types of data that may be collected include data at and below the outfalls (including lateral/downslope samples), data along the storm drain lines outside the compressor station, and data for accumulated soil material (if any accumulated material is encountered in the catch basins).

2.1 Samples at Outfalls and Associated Lateral/Downslope Samples

If chemical constituents above interim screening levels are detected in samples from the outfalls and/or associated lateral/downslope samples, the sample data will be combined with the data from the closest downslope AOC (i.e., the AOC that would have received the discharge from the outfall). As shown in Figure D-1, Storm Drain Outfall 9, for example, is located above AOC 11.

The potential sources for constituents to the outfall will be assessed by determining the types of activities that have occurred in the vicinity of the catch basins associated with the specific storm drain line.

2.2 Samples along Visible Storm Drain Lines

Detected chemicals along storm drain lines outside the compressor station could be due either to releases from the storm drain line or from surface water flow from the compressor station. Data for samples with constituents above interim screening levels will be compared to the closest available outfall and perimeter sample data, to evaluate whether there is an apparent source for the constituents present above interim screening levels. The sample data will be then be combined with the appropriate data set (AOC receiving the storm drain runoff or perimeter samples).

2.3 Accumulated Soil Material Samples

If accumulated material is encountered in any storm drain catch basins, and any of these samples contains constituents above interim screening levels, the data will be compared with data from the outfall associated with that catch basin. Depending on the concentrations of chemicals in the outfall area (i.e., if the chemical concentrations in accumulated soil material are greater than the Part A interim screening levels), it may be necessary to remove accumulated soil material from the storm drain line in question.

SD-3	0-0.5, 3, 5, and 10	To assess soil along degraded storm drain	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-4	0-0.5, 3, 5, and 10	To assess soil along degraded storm drain	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs and pH
SD-5	0-0.5*, 3, 5, and 10	To assess storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-6	0-0.5*, 3, 5, and 10	To assess storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-7	0-0.5, 3, 5, and 10	To assess soil along storm drain	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-8	0-0.5*, 3, 5, and 10	To assess storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-9	0-0.5, 3, 5, and 10	To assess soil along storm drain	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-10	0-0.5*, 3, 5, and 10	To assess storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-11	0-0.5*, 3, 5, and 10	To assess storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-12	0-0.5*, 3, 5, and 10	To assess storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-13	0-0.5*, 3, 5, and 10	To assess storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-14	0-0.5, 3, 5, and 10	To assess along storm drain	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-15	0-0.5, 3, 5, and 10	To assess soil storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-16	0-0.5*, 3, 5, and 10	To assess lateral/drownslope of storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-17	0-0.5, 3, 5, and 10	To assess along storm drain	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-18	0-0.5, 3, 5, and 10	To assess soil storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs
SD-19	0-0.5, 3, 5, and 10	To assess lateral/drownslope of storm drain outfall	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs

Notes:

* Samples will be collected at 0 to 0.5 feet bgs unless it is apparent that erosion has occurred in the vicinity of the outfall, in which case, a sample will be collected from 0 to 1 foot bgs.

Ten percent of samples will be analyzed for TAL/TCL.

VOC analysis will not be conducted on surface soil samples (0 to 0.5 feet bgs).

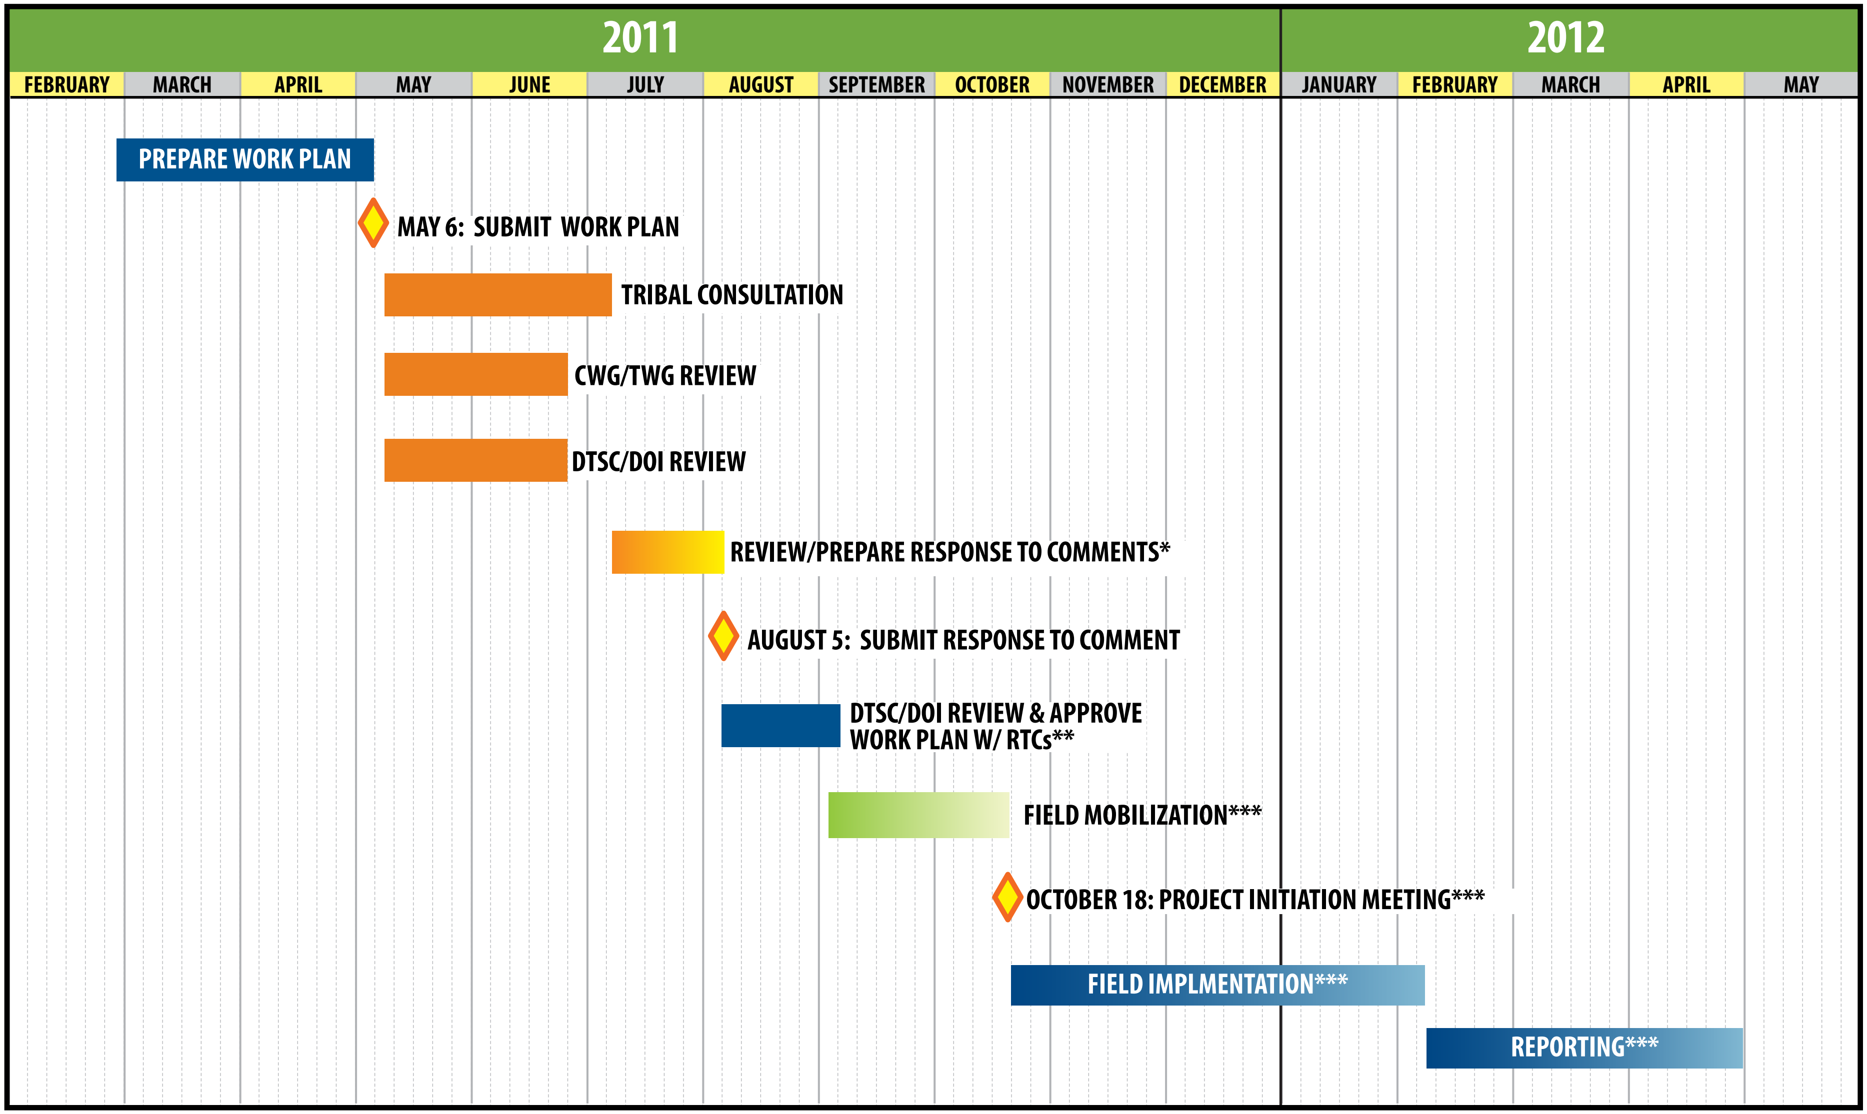
Appendix E
Preliminary Implementation Schedule for Complete Soil Work Plan



* Duration is estimated and will be refined after receipt of comments.

** Assume a revision of the Work Plan is not needed. If needed, additional time will be required to revise and resubmit for review and approval.

*** The timing and duration of the Field Implementation is estimated and will be refined following DTSC/DOI approval of the work plan.

NOTES:

NA	not applicable
TBD	to be determined

[1] These surface samples (0 to 0.5 feet) will be analyzed for the full inorganic and organic suites per Contract Laboratory Program Target Analyte List/Target Compound List (TAL/TCL), except VOCs and TPH-purgeables. Volatile organic compound and TPH-purgable analysis will only be performed on the 3 foot sample.

PLANNED SAMPLE TABLE

RFI Work Plan Part A

NOTES:

NA	not applicable
TBD	to be determined

[1] These surface samples (0 to 0.5 feet) will be analyzed for the full inorganic and organic suites per Contract Laboratory Program Target Analyte List/Target Compound List (TAL/TCL), except VOCs and TPH-purgeables. Volatile organic compound and TPH-purgable analysis will only be performed on the 3 foot sample.

PLANNED SAMPLE TABLE

Storm Drain Sampling

NOTES:

NA	not applicable
TBD	to be determined

[1] These surface samples (0 to 0.5 feet) will be analyzed for the full inorganic and organic suites per Contract Laboratory Program Target Analyte List/Target Compound List (TAL/TCL), except VOCs and TPH-purgeables. Volatile organic compound and TPH-purgable analysis will only be performed on the 3 foot sample.

Appendix G
Standard Operating Procedures

(Provided on CD Only)

SOP-B2

Soil Classification and Logging Procedures
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) provides guidance to obtain accurate and consistent descriptions of soil characteristics during soil-sampling operations. The characterization is based on visual examination and manual tests not on laboratory determinations.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan, work plan or event-specific field instructions. Planned borehole depth, proposed well construction/specifications, and field sampling summary table, if available.
2) Applicable project work plan or monitoring plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project* Plan (Procedures Manual), as required.
3) Topock Program Health and Safety Plan (HSP).
4) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available.
5) Blank field notebook.
6) Blank CH2M HILL soil boring log Form D1586.

PREPARATION AND SETUP

1) Review event-specific work plan or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Initiate field logbook for sampling activity.
3) Review sampling procedures and equipment, and planned sample depths with drilling contractor and field crew.

EQUIPMENT LIST

- Indelible pens
- Tape measure or ruler
- Field logbook
- Spatula
- HCl, 10-percent solution
- Squirt bottle/Spray bottle with water

- Rock- or soil-color chart (e.g., Munsell)
- Grain-size chart
- Hand lens
- Unified Soil Classification System index charts and tables to help with soil classification

PROCEDURES

This section covers several aspects of the soil characterization: instructions for completing the CH2M HILL soil boring log (see Form D1586, Attachment A) and the field logging of soil using the "Unified Soil Classification System and Logging Criteria" (Attachment B).

Instructions for Completing Soil Boring Logs

- Soil boring logs will be completed on field boring log forms. Information collected will be consistent with that required for Form D1586 (attached), a standard CH2M HILL form, or an equivalent form that supplies the same information.
- The information collected in the field to perform the soil characterization is described below.
- Field personnel should review completed logs for accuracy, clarity, and thoroughness of detail. Samples also should be checked to see that information is correctly recorded on both jar lids and labels and on the log sheets.

Heading Information

1) **Boring/Well Number.** Enter the boring/well number. A numbering system should be chosen that does not conflict with information recorded for previous exploratory work done at the site. Number the sheets consecutively for each boring.
2) **Location.** If stationing, coordinates, mileposts, or similar project layout information is available, indicate the position of the boring to that system using modifiers such as "approximate" or "estimated," as appropriate.
3) **Elevation.** Elevation will be determined at the conclusion of field activities.
4) **Drilling Contractor.** Enter the name of the drilling company and the city and state where the company is based.
5) **Drilling Method and Equipment.** Identify the bit size and type, drilling fluid (if used), and method of drilling (e.g., rotary, hollow-stem auger, sonic). Information on the drilling equipment (e.g., CME 55, Mobile B61) should be noted.
6) **Water Level and Date.** Enter the depth below ground surface to the apparent water level in the borehole. The information should be recorded as a comment. If free water is not encountered during drilling or cannot be detected because of the drilling method, this information should be noted. Record date and time of day (for tides, river stage) of each water level measurement.

7) **Date of Start and Finish.** Enter the dates the boring was started and completed. Time of day should be added if several borings are performed on the same day.

8) **Logger.** Enter the first initial and full last name of the logger.

Technical Data

1) **Depth Below Surface.** Use a depth scale that is appropriate for the sample spacing and for the complexity of subsurface conditions.

2) **Sample Interval.** Note the depth at the top and bottom of the sample interval.

3) **Sample Type and Number.** Enter the sample type and number. SS-1 = split spoon, first sample. Number samples consecutively regardless of type. Enter a sample number even if no material was recovered in the sampler.

4) **Sample Recovery.** Enter the length to the nearest 0.1 foot of soil sample recovered from the sampler. Often, there will be some wash or caved material above the sample; do not include the wash material in the measurement. Record recovery in feet.

5) **Soil Description.** The soil classification should follow the format described in the "Field Classification of Soil" subsection below.

6) **Comments.** Include all pertinent observations (changes in drilling fluid color, rod drops, drilling chatter, rod bounce as in driving on a cobble, damaged Shelby tubes, and equipment malfunctions). In addition, note if casing was used, the sizes and depths installed, and if drilling fluid was added or changed. You should instruct the driller to alert you to any significant changes in drilling (changes in material, occurrence of boulders, and loss of drilling fluid). Such information should be attributed to the driller and recorded in this column. Specific information might include:

   - The date and the time drilling began and ended each day.
   - The depth and size of casing and the method of installation.
   - The date, time, and depth of water level measurements.
   - Depth of rod chatter.
   - Depth and percentage of drilling fluid loss.
   - Depth of hole caving or heaving.
   - Depth of change in material.
   - Health and safety monitoring data.
   - Drilling interval through a boulder.

Field Classification of Soil

This section presents the format for the field classification of soil. In general, the approach and format for classifying soils should conform to the "United Soils Classification System and Logging Criteria" (see charts and criteria, Attachment B).

- The Unified Soil Classification System (USCS) is based on numerical values of certain soil properties that are measured by laboratory tests (ASTM D 2487). It is possible, however, to estimate these values in the field with reasonable accuracy using visual-manual procedures (ASTM D 2488). In addition, some elements of a complete soil description, such as the presence of cobbles or boulders, changes in strata, and the relative proportions of soil types in a bedded deposit can be obtained only in the field.
- Soil descriptions should be precise and comprehensive without being verbose. The correct overall impression of the soil should not be distorted by excessive emphasis on insignificant details. In general, similarities rather than differences between consecutive samples should be stressed.

Soil Descriptions

Soil descriptions must be recorded for every soil sample collected. The format and order for soil descriptions should be:

1) Soil name (synonymous with ASTM D 2488 Group Name) with appropriate modifiers. Soil name should be in all capitals in the log, for example "POORLY-GRADED SAND."
2) Group symbol, in parentheses, for example, "(SP)."
3) Color, using Munsell color designation.
4) Particle size distribution (i.e., sand, silt, clay).
5) Moisture content.
6) Relative density or consistency.
7) Soil structure, mineralogy, or other descriptors.

This order follows, in general, the format described in ASTM D 2488.

(1) Soil Name

The basic name of a soil should be the ASTM D 2488 Group Name on the basis of visual estimates of gradation and plasticity. The soil name should be capitalized.

Examples of acceptable soil names are illustrated by the following descriptions:

- A soil sample is visually estimated to contain 15-percent gravel, 55-percent sand, and 30-percent fines (passing No. 200 sieve). The fines are estimated as either low- or highly-plastic silt. This visual classification is SILTY SAND WITH GRAVEL with a Group Symbol of (SM).
- Another soil sample has the following visual estimate: 10-percent gravel, 30-percent sand, and 60-percent fines (passing the No. 200 sieve). The fines are estimated as low-plastic silt. This visual classification is SANDY SILT. The gravel portion is not included in the soil name because the gravel portion was estimated as less than 15 percent. The Group Symbol is (ML).

The gradation of coarse-grained soil (more than 50 percent retained on No. 200 sieve) is included in the specific soil name in accordance with ASTM D 2488.

- There is no need to further document the gradation.
- However, the maximum size and angularity or roundness of gravel and sand-sized particles should be recorded.
- For fine-grained soil (50 percent or more passing the No. 200 sieve), the name is modified by the appropriate plasticity/elasticity term in accordance with ASTM D 2488.

Interlayered soil should each be described starting with the predominant type.

- An introductory name, such as "Interlayered Sand and Silt," should be used.
- In addition, the relative proportion of each soil type should be indicated (see Table 1 for example).

Where helpful, the evaluation of plasticity/elasticity can be justified by describing results from any of the visual-manual procedures for identifying fine-grained soils, such as reaction to shaking, toughness of a soil thread, or dry strength as described in ASTM D 2488.

(2) Group Symbol

The appropriate group symbol from ASTM D 2488 must be given after each soil name.

1) The group symbol should be placed in parentheses to indicate that the classification has been estimated.
2) In accordance with ASTM D 2488, dual symbols (e.g., GP-GM or SW-SC) can be used to indicate that a soil is estimated to have about 10-percent fines.
3) Borderline symbols (e.g., GM/SM or SW/SP) can be used to indicate that a soil sample has been identified as having properties that do not distinctly place the soil into a specific group. Generally, the group name assigned to a soil with a borderline symbol should be the group name for the first symbol. The use of a borderline symbol should not be used indiscriminately. Every effort should be made to first place the soil into a single group.

(3) Color

Soil color is described by comparing the sample with the Munsell Soil Color Charts. The Munsell colors should be used unless directed otherwise by project sampling plans. Instructions for their proper use are in the color charts. The color name shall precede the Munsell color notation (e.g., "yellowish brown, 10 YR 5/4"), with color hue and chroma number parenthetically entered in the borelog description. If no color chip is available, the color should be simply described as primary color (i.e., green, brown, gray, yellow, tan, etc.).

(4) Particle Size Distribution

Within the gravel sizes and the sand sizes, there are further divisions based on particle sizes. Gravel is divided into fine and coarse gravel. Fine-gravel particles (pebbles) are those that would pass through 3/4-inch opening but not a 1/4-inch opening. The fine gravel ranges from pea- to marble-sized. Coarse-gravel particles are those that would pass through a 3-inch opening but not a 3/4-in opening. Common objects of this size are grapes and tennis balls. Cobbles range from 3 inches to 12 inches in size; boulders are larger than 12 inches.

Sand is divided into three sizes: fine, medium, and coarse. Sand passes a No. 4 sieve (approximately 1/4 inch) and is retained in a No. 200 sieve (0.003 inch). Fine-sand particles pass a No. 40 sieve (approximately 1/64 inch) and are retained in the No. 200 (0.003 inch) sieve. These particles are sugar- or table salt-sized. Medium sand passes the No. 10 sieve (approximately 1/2 inch) and retained on the No. 40 sieve. These particles are about the same size as the openings in window screening. Coarse-sand particles would pass a No. 4 sieve (approximately 1/4 inch) and be retained on a No. 10 sieve. Rock salt granules fall in this size range. Sand and gravel particle sizes are illustrated in ASTM D2488 along with percentage estimating charts. The percentages of different grain size fractions are important in the soil type determination.

(5) Moisture Content

Soil moisture content shall be estimated using only the terminology described below:

- Dry - Absence of moisture, dusty, dry to the touch
- Moist - Damp but no visible water
- Wet - Visibly free water, usually sampled from below the water table

(6) Relative Density or Consistency

An estimate of the consistency shall accompany descriptions of all fine-grained soil (silt and clay where more than 50 percent of the material would pass the No. 200 sieve). A pocket penetrometer is the most accurate method for estimating the consistency of fine-grained soils. The table below lists characteristics for soil consistency identification.

Consistency	Unconfined Compressive Strength (tons/ft)[a]	Blows/foot (SPT) [b]	Manual Procedure
Very soft	<0.25	0 – 4	Thumb will penetrate soil more than 1 inch (25 mm).
Soft	0.25 - 0.50	4 – 8	Thumb will penetrate soil about 1 inch (25 mm).
Firm (formerly stiff)	-1.50	8 – 15	Thumb will indent soil about 1/4 inch (6 mm).
Hard	-2.00	15 – 30	Thumb will not indent soil but readily indented with thumbnail.
Very hard	>4.0	> 30	Thumbnail will not indent soil.

Notes:

[a] Pocket penetrometer

[b] Blows/foot is defined as the total number of blows required to drive the second and third 6 inches of penetration (blow counts for the first 6 inches are also noted) while driving an 18-inch SPT sampler with a 140-pound hammer falling a free height of 30 inches. Conversion factors may be applied when the field log information is transferred to the final log when using a sampler other than an SPT (Standard penetrometer) (e.g., S&H or Modified California), or when using different hammer weights and drop. The conversion factor is approximately 0.5 for an S&H sampler with a hammer weight of 140 pounds falling 30 inches.

Descriptions of all coarse-grained soil (sand and gravel where less than 50 percent of the material would pass the No. 200 sieve and 100 percent would pass the 3-inch sieve) shall be accompanied by an estimate of the density based upon standard penetrometer (SPT) blow counts. The following terminology should be used:

Density	Blows/foot (SPT)
Very loose	< 4
Loose	4-10
Medium dense	10-30
Dense	30-50
Very dense	> 50

(7) Soil Structure, Mineralogy, and Other Descriptors

Discontinuities and inclusions are important and should be described. Such features include joints or fissures, slickensides, bedding or laminations, veins, root holes, and wood debris.

Significant mineralogical information such as cementation, abundant mica, or unusual mineralogy should be described.

Other descriptors may include particle angularity or shape, maximum particle size, hardness of large particles, plasticity of fines, dry strength, dilatancy, toughness, reaction to HCl, and staining, as well as other information such as organic debris, odor, or presence of free product. Criteria for the use of these other descriptions include:

- Structure:
  - Stratified - Alternating layers of varying material or color with layers at least 1/4-inch thick; note thickness.
  - Laminated - Alternating layers of varying material or color with the layers less than 1/4-inch thick; note thickness.
  - Fissured - Breaks along definite planes of fracture with little resistance.
  - Slickensides - Fracture planes appear polished or glossy, often striated.
  - Blocky - Cohesive soil that can be broken down into small angular lumps that resist further breakdown.
  - Lensed - Inclusion of small pockets of different soils, such as lenses of sand within clay; note thickness.
  - Homogeneous - Same color and appearance throughout.
  - Grading - Whether the particles increase or decrease in size toward the top of logged interval.
- Particle Shape:
  - Flat - Particles with width/thickness ratio > 3.
  - Elongated - Particles with length/width ratio > 3.

  - Elongated and flat - Particles meet criteria for both flat and elongated.
- Particle Angularity:
  - Angular - Particles have sharp edges and relatively planar sides with unpolished surfaces.
  - Subangular - Particles are similar to angular description but have rounded edges.
  - Subrounded - Particles have nearly planar sides but have well-rounded corners and edges.
  - Rounded - Particles have smoothly-curved sides and no edges.
- Cementation:
  - Weak - rumbles or breaks with handling or little finger pressure.
  - Moderate - Crumbles or breaks with considerable finger pressure.
  - Strong - Will not crumble or break with finger pressure.
- Reaction with HCl:
  - None - No visible reaction.
  - Weak - Some reaction, bubbles forming slowly.
  - Strong - Vigorous reaction, bubbles forming immediately.

Comments

This section should be reserved for information not pertaining to lithologic description. Sample information including sample identifier, analysis, matrix, and depth interval should be included in the boring log comments. Information related to drilling, such as drilling rate, chatter, and equipment malfunctions should also be well documented in the comments section of the boring log. Additionally interpretations of the lithologic data may also be presented in the comments section. Examples of this include “transition between Older Alluvium and Fanglomerate,” “paleosol horizon B,” or “conductive zone.”

Recovery

Recovery data are entered along the left side of the boring log. Enter the length of retrieved core to the nearest 0.1 foot of sample recovered and record the value in feet. Do not count slough or caved material as part of the total recovered length of core. Record total length and percent of sample recovered. If using a 5-foot sample barrel, multiply the total length by 2 and 100 to get a percentage number. Similarly, if using a 2.5-foot sampler, multiply by 4 and 100 to get the percent recovery.

Backfilling

When a boring is completed and the water level measured, the boring shall be backfilled to ground surface according to applicable regulations. The destruction of the hole shall be noted on the log. Borehole destruction should follow SOP 28 *Soil Boring Abandonment*

Attachments

- Unified Soil Classification System and Logging Criteria

Key Checks and Preventive Maintenance

Check entries to the soil boring log and field logbook in the field; because the samples will be disposed of, confirmation and corrections cannot be made later. Check that sample numbers and intervals are properly specified. Check that drilling and sampling equipment is decontaminated using the procedures defined in SOP *Decontamination of Drilling Rigs and Equipment*.

NOTE:
Percentages are based on estimating amounts of fines, sand, and gravel to the nearest 5%
(After ASTM Designation D2488 Standard Test Method for Classification of Soils for Engineering Purposes)

Flow Chart for Classifying Fine-grained Soil
(50% or more passing No. 200 sieve)
Field Guide for Soil Classification and Logging Procedures

similar, the material is classified as poorly graded or well sorted. If fines represent less than 5 percent of the total mass, the symbol SP is used for a poorly-graded sand and SW for a well graded sand. If silts and/or clays exceed 12 percent, the symbols GC, SC, GM, and SM are used, respectively.

If the silts and clays are between 5 to 12 percent of the total sample weight, a dual classification with two group symbols is used. The first symbol is GW, GP, SW, or, SP, and the second is GC, GM, SC, or SM. The group name corresponds to the first group symbol plus the modifying words "with clay" or "with silt" to indicate the plasticity characteristics. If the fines plot on the CL-ML range on the plasticity chart (Figure 2-2), possible dual classification group names are:

GW-GM	well graded gravel with silt
GW-GC	well graded gravel with clay
GP-GM	poorly graded gravel with silt
GP-GC	poorly graded gravel with clay
SW-SM	well graded sand with silt
SW-SC	well graded sand with clay
SP-SM	poorly graded sand with silt
SP-SC	poorly graded sand with clay

If silts and clays exceed 12 percent of the total weight of sample, the modifiers "M" and "C" are used, respectively. If a sand or gravel has more than 15 percent of the other coarse-grained constituent, the words "with gravel" or "with sand" are added to the group name. A flow chart for classifying coarse-grained soils is presented in Figure 2-3.

2.2 Fine-grained Soils

Particles passing the No. 200 sieve are silts (M) and clays (C). These soils must undergo testing in order to differentiate between them. Typical tests used are: dry strength, dilatancy, toughness, and plasticity. These terms are further discussed in Tables 2-2 through Table 2-6. Silts have little or no dry strength when dry, while clays have considerable dry strength. Dry strength, dilatancy, and toughness are also used to identify the fine-grained fraction of coarse-grained soils.

TABLE 2-2
Criteria for Describing Dry Strength

Description	Criteria
None	The dry specimen crumbles into powder with the mere pressure of handling.
Low	The dry specimen crumbles into powder with some finger pressure.
Medium	The dry specimen breaks into pieces or crumbles with considerable finger pressure.
High	The dry specimen cannot be broken with finger pressure. The specimen will break into pieces between the thumb and a hard surface.
Very high	The dry specimen cannot be broken between the thumb and a hard surface.

TABLE 2-3
Criteria for Describing Dilatancy

Description	Criteria
None	There is no visible change in the specimen.
Slow	Water appears slowly on the surface of the specimen during shaking, and does not disappear, or disappears slowly upon squeezing.
Rapid	Water appears quickly on the surface of the specimen during shaking, and disappears quickly upon squeezing.

TABLE 2-4
Criteria for Describing Toughness

Description	Criteria
Low	Only slight pressure is required to roll the thread near the plastic limit. The thread and the lump are weak and soft.
Medium	Medium pressure is required to roll the thread to near the plastic limit. The thread and the lump have medium stiffness.
High	Considerable pressure is required to roll the thread to near the plastic limit. The thread and the lump have very high stiffness.

TABLE 2-5
Identification of Inorganic Fine-grained Soils from Manual Tests

Soil Symbol	Dry Strength	Dilatancy	Toughness
ML	None to low	Slow to rapid	Low or thread cannot form
CL	Medium to high	None to slow	Medium
MH	Low to medium	None to slow	Low to medium
CH	High to very high	None	High

TABLE 2-6
Criteria for Describing Plasticity

Description	Criteria
Nonplastic	A 1/8-inch (3-mm) thread cannot be rolled at any water content.
Low	The thread can barely be rolled, and the lump cannot be formed when drier than the plastic limit.
Medium	The thread is easy to roll, and not much time is required to read the plastic limit. The thread cannot be re-rolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit.
High	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be re-rolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier that the plastic limit.

Fine-grained soils are accurately determined in the laboratory using the Atterberg Limits test. This test include liquid limit, plastic limit, and plasticity index measurements. The liquid limit is the water content of a soil at the point of transition from a plastic to a liquid state. The plastic limit is the water content of a soil at the point of transition from a semisolid to a plastic state. The plasticity index is the difference between the liquid limit and the plastic limit.

As shown in the Figure 2-2, five fields have been identified. These include:

- Silty Clays (CL), Organic Silts (OL) or Organic Silty Clays (OL) of low plasticity
- Fat Clays (CH) and Organic Clays (OH)
- Inorganic Silts (ML) and Organic Silty Clays (OL) of low plasticity
- Silts (MH) and Organic Clays (OH) of a high plasticity
- Silty Clays to Clayey Silt (CL-ML) of low plasticity

Fine-grained soils with a liquid limit > 50 are modified by the symbol H (MH or CH), and those with a liquid limit < 50 are modified by the symbol L (ML or CL). Fine-grained soils containing 30 percent or more coarse-grained fraction should be modified by descriptive terms, such as "gravelly" or "sandy." If the coarse fraction is between 15 and 30 percent, the words" with sand and/or gravel" should be added to the group name. A flow chart for classifying fine-grained soils is presented in Figure 2-4.

2.3 Organic Soils

To classify organic soils, the percentage organic material present in the soil as well as the non-organic fines must be estimated. When the organic content ranges from 18 to 36 percent, the material is an organic clay or an organic silt, depending on the nature of the fine-grained constituents. When the organic content is between 36 and 90 percent, the material is designated a muck or peaty muck (OL or OH). A flow chart for classifying organic soil is presented in Figure 2-4. The term "peaty" is added if the organic remains are

SOP-B3

Borehole Sampling and Logging of Soil Borings Standard Operating Procedures for PG&E Topock Program

---

This standard operating procedure (SOP) provides guidance for sample collection from soil borings during the drilling process, and proper documentation necessary. Detailed guidance for sample collection, preservation and handling is provided in Section 4.0 of the site Quality Assurance Project Plan (QAPP) and in the Topock Program *Sampling, Analysis, and Field Procedures Manual* (Procedures Manual). SOP-B2 provides detailed guidance for soil characterization and logging.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP), work plan or event-specific field instructions. Planned borehole depth, proposed well construction/specifications, and field sampling summary table, if available.
2) Applicable project work plan or monitoring plan. Refer to the Procedures Manual and QAPP, as required.
3) Topock Program Health and Safety Plan (HSP).
4) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available.
5) Blank sampling log and field notebook.

PREPARATION AND SETUP

1) Review event-specific work plan or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Initiate field logbook for sampling activity.
3) Review sampling procedures and equipment, and planned sample depths with drilling contractor and field crew.

Equipment List

- Field logbook
- Borehole log
- Blue or black waterproof or permanent ink pens
- Trash bags
- Plastic sandwich bags
- Paper towels

- Stainless steel sampling equipment (provided by driller)
- Decontamination equipment (Alconox® solution in spray bottle, brushes, buckets, rinse water spray bottle)
- Soil sample containers appropriate for sample analysis and preservation as called for in SAP and QAPP (glass jars, brass sleeves, Encore® containers, sandwich bags, etc.)
- Soil sampling equipment not provided by driller (spatula or putty knife, stainless steel compositing bowl, hand auger, etc.)
- Groundwater sample containers appropriate for sample analysis and preservation as called for in SAP and QAPP (glass jars, VOA vials, plastic jars, etc.)
- Groundwater sample equipment not provided by driller (pump, filters, tubing, power supply, etc.)
- Water quality meters
- Water level indicator
- Distilled water
- Coolers with ice
- Protective waterproof gloves (nitrile or latex)

GUIDELINES

Soil Boring Logs Documentation

Soil boring logs will be completed on the soil boring log forms during the drilling activities at the time of the logging and soil descriptions. Information collected will be consistent with the standard CH2M HILL form (See SOP-B2 attachment A). Sample data may also be documented in the comments section of the boring log.

Items documented on the borehole log include:

1) **Sample Interval:** The top and bottom depth of each sample run should be recorded on the borelog. Sampling includes samples collected for analysis as well as core retrieved for logging purposes.
2) **Sample Type and Number:** Enter the sample type and number consistent with the sampling and analysis plan at the correct depth intervals. An “x” should be placed across the vertical interval where the environmental soil, grab groundwater, or geotechnical sample was collected.
3) **Sample Recovery:** Enter the length of retrieved core to the nearest 0.1 foot of sample recovered, and record the value in feet. Do not count slough or caved material as part of the total recovered length of core. Record total length and percent of sample recovered. If using a 5-foot sample barrel, multiply the total length by 2 and 100 to get a percentage number. Similarly, if using a 2.5-foot sampler, multiply by 4 and 100 to get the percent recovery.

4) **Sampling:** Sampling difficulties shall be noted. Disturbed samples shall be noted on the log as well as the sample recovery. The top of the sample shall be marked on the container.

5) **Water Levels:** Water-level measurements, where groundwater is encountered, are required for each boring. Changes in soil moisture shall be noted and, if there is no water encountered, a note to that effect shall be included on the borehole log. The date and time of water-level measurements shall be documented.

At a minimum, sample identifiers (IDs) should be noted on boring logs at the depth collected. When time and space allows, a summary of analytical sample information can be included. When inclusion of these data prevents documentation of drilling information, sample data should be omitted in order to document drilling.

Borehole Sampling by Drilling—General Procedure

Split-spoon sampling procedures shall be executed in accordance with American Society for Testing and Materials (ASTM) D1586, "Standard Method for Penetration Test and Split-barrel Sampling of Soils" (ASTM 1984). California (2-inch) or Modified California (2.5-inch) split-barrel samplers may also be used.

1) The split-spoon or split-barrel sampler shall be advanced to the top of the sampling interval using a wire-line or sample rods such as A or AW. The larger-diameter samplers may be fitted with three 6-inch-long stainless-steel sleeves. The sampler shall be driven 18 inches or to refusal, with a 140-pound hammer dropping repeatedly 30 inches. Refusal shall be defined as requiring 50 blows with the hammer to advance the sampler less than 6 inches.

2) The number of blows required to drive the sampler each 6 inches shall be recorded on the borelog.

3) As the sample tubes are disassembled, an organic vapor monitor probe shall be inserted into the gap between two sample liners, and the liner exhibiting the highest reading shall be selected for analysis.

4) In general, the middle liner is collected for laboratory analysis, and 10 percent of the bottom liners are collected for quality assurance testing. A sample of the soil in the top liner typically is placed in a re-sealable plastic bag or 8-ounce clear glass jar and left in the sun for approximately 15 minutes to allow any volatile organic compounds (VOC) to volatilize.

5) After the 15 minute volatilization period, the soil vapor in the plastic bag is then measured for VOCs by taking a reading of the headspace. Background VOCs for the bag are determined by monitoring the air in an empty bag.

6) Results of the organic vapor monitoring are recorded on the boring log.

7) Small portions of soil at the ends of the sleeve are scraped off for classification.

Borehole Sampling by Drilling—Split Spoon Sampling

1) Samples collected for laboratory analysis using split spoon sampling device will be separated and transferred from the split-spoon halves into sample jars by clean stainless-steel utensils.

2) Samples for VOCs will be separated and collected first, followed by semivolatile organic compounds samples.

3) For VOC samples, avoid mixing the soil before sampling and sample directly from the split spoon. See SOPs for guidance on homogenizing soil samples and for VOC sampling using EnCore samplers, respectively.

Borehole Sampling by Drilling—Direct-push Sampling

1) Samples collected for laboratory analysis using a direct-push sampling drill rig will be handled by either opening the tube and placing the soil in sample jars or cutting the acetate tube and submitting it the laboratory directly.

2) For samples that will be removed from the acetate tube, the tube will be cut open longitudinally using a double-bladed razor knife.

    - Soil will be inspected and logged prior to removal of soil samples.
    - A short section of soil will be removed from the acetate sleeve using a stainless-steel utensil, homogenized in a clean stainless-steel bowl, and placed in sample jars.
    - Soil collected for VOC analysis will be sampled directly from the split acetate sleeve using EnCore samplers.

3) Alternatively, a short (6-inch) length of liner will be cut from the acetate sleeve and collected directly for laboratory analysis.

    - The section of acetate liner will be removed, capped with Teflon sheeting and plastic end caps at both ends, and taped with clear label or packing tape.
    - Labels shall be affixed to the liners with job designation, time, boring number, sample depth interval, sample number, date sampled, and the initials of the sampler clearly marked.
    - The samples shall then be enclosed in a plastic bag and stored in a cooler maintained at 4°C.
    - Sample information shall be placed on the chain-of-custody, the borelog, and the field logbook. All samples shall be handled in accordance with *Chain of Custody Procedures*.

Borehole Sampling by Drilling—Split-barrel Sampling

Soil samples can also be collected using a 3-foot-long or 5-foot-long split-barrel sampler. The split-barrel sampler is similar to the split-spoon sampler that is used to hold steel or brass sampling sleeves, but the split-barrel sampler typically is not used to hold sample sleeves.

1) The sampler is lowered to the base of the drill bit and is advanced slightly ahead of the drill bit and augers (or conductor casing). The weight of the drill string and sample barrel along with the drilling and cutting action of the drill bit advances the face of the split-barrel sampler into the formation.
2) Once the desired depth interval is reached, the split-barrel sampler is retrieved using a cable or tool steel sections.
3) The retrieved sampler is unscrewed, and one or both halves are laid on the sample table. The soil typically will form a continuous column of soil in one of the split-barrel halves.
4) The soil column is split longitudinally for soil descriptions using a putty knife or spatula.
5) Samples for VOC analysis are collected immediately directly from the soil column.
6) Other soil samples are collected after the core section has been described and logged. The soil is described following the procedures in the following sections.

Groundwater Sampling

1) Groundwater samples can be collected by hydropunch by bailer or by pumping from an isolated zone. Collection of groundwater by bailing is not an accurate method of collection depth discrete groundwater samples, as the zone sampled is poorly isolated.
2) Hydropunch samples are collected below the bit of the drill stem, in relatively undisturbed soil zone. This method of sample collection may be difficult in fine-textured soils and in very rocky soils. To collect these samples, a point is driven below the depth of the drill bit, then a screen zone is opened within this point and water allowed to flow in. The hydropunch tool must be decontaminated between samples.

Groundwater can also be collected from the open or cased borehole with a bailer. A disposable or decontaminated stainless-steel bailer is lowered into the boring, and water is collected. This method is preferable for collection of groundwater from the water table. Attempts can be made to collect discrete groundwater samples beneath the water table; however, the boring must be cased with watertight, stainless-steel pipe, and the boring must be evacuated prior to collection of samples.

Alternatively, discrete groundwater samples can be collected by isolating a zone with casing and packers. To collect these samples, the borehole is first advanced to the depth at which a sample is required. Then casing is advanced to within 20 feet of the sample zone. Next, a pump and packers are lowered into the hole. The zone from which samples are to be collected is isolated with a packer, and water is pumped directly from the target zone.

Sample Handling

Sample preservation and sampling procedures are detailed in Section 4.0 of the QAPP. Additional information is provided in the Procedures Manual and in the appropriate SAP.

KEY CHECKS AND ITEMS

- Check entries to the soil boring log and field logbook in the field during sampling activities because the samples will be disposed at the end of the fieldwork, confirmation and corrections cannot be made later.

- Check that the sample numbers and intervals are properly specified.
- Ensure that drilling equipment is decontaminated prior to the beginning of work and between each borehole.
- All materials generated during sampling (debris, PPE, decontamination liquids, etc.) will be placed in 55-gallon drums or roll-off bins for storage pending analysis and disposal off site, as outlined in SOP 39, Standard of Practice H-83, and Appendix D of the project *Soil and Groundwater Management Plan*.

NOTE:
Percentages are based on estimating amounts of fines, sand, and gravel to the nearest 5%
(After ASTM Designation D2488 Standard Test Method for Classification of Soils for Engineering Purposes)

Flow Chart for Classifying Fine-grained Soil
(50% or more passing No. 200 sieve)
Field Guide for Soil Classification and Logging Procedures

similar, the material is classified as poorly graded or well sorted. If fines represent less than 5 percent of the total mass, the symbol SP is used for a poorly-graded sand and SW for a well graded sand. If silts and/or clays exceed 12 percent, the symbols GC, SC, GM, and SM are used, respectively.

If the silts and clays are between 5 to 12 percent of the total sample weight, a dual classification with two group symbols is used. The first symbol is GW, GP, SW, or, SP, and the second is GC, GM, SC, or SM. The group name corresponds to the first group symbol plus the modifying words "with clay" or "with silt" to indicate the plasticity characteristics. If the fines plot on the CL-ML range on the plasticity chart (Figure 2-2), possible dual classification group names are:

GW-GM	well graded gravel with silt
GW-GC	well graded gravel with clay
GP-GM	poorly graded gravel with silt
GP-GC	poorly graded gravel with clay
SW-SM	well graded sand with silt
SW-SC	well graded sand with clay
SP-SM	poorly graded sand with silt
SP-SC	poorly graded sand with clay

If silts and clays exceed 12 percent of the total weight of sample, the modifiers "M" and "C" are used, respectively. If a sand or gravel has more than 15 percent of the other coarse-grained constituent, the words "with gravel" or "with sand" are added to the group name. A flow chart for classifying coarse-grained soils is presented in Figure 2-3.

2.2 Fine-grained Soils

Particles passing the No. 200 sieve are silts (M) and clays (C). These soils must undergo testing in order to differentiate between them. Typical tests used are: dry strength, dilatancy, toughness, and plasticity. These terms are further discussed in Tables 2-2 through Table 2-6. Silts have little or no dry strength when dry, while clays have considerable dry strength. Dry strength, dilatancy, and toughness are also used to identify the fine-grained fraction of coarse-grained soils.

TABLE 2-2
Criteria for Describing Dry Strength

Description	Criteria
None	The dry specimen crumbles into powder with the mere pressure of handling.
Low	The dry specimen crumbles into powder with some finger pressure.
Medium	The dry specimen breaks into pieces or crumbles with considerable finger pressure.
High	The dry specimen cannot be broken with finger pressure. The specimen will break into pieces between the thumb and a hard surface.
Very high	The dry specimen cannot be broken between the thumb and a hard surface.

TABLE 2-3
Criteria for Describing Dilatancy

Description	Criteria
None	There is no visible change in the specimen.
Slow	Water appears slowly on the surface of the specimen during shaking, and does not disappear, or disappears slowly upon squeezing.
Rapid	Water appears quickly on the surface of the specimen during shaking, and disappears quickly upon squeezing.

TABLE 2-4
Criteria for Describing Toughness

Description	Criteria
Low	Only slight pressure is required to roll the thread near the plastic limit. The thread and the lump are weak and soft.
Medium	Medium pressure is required to roll the thread to near the plastic limit. The thread and the lump have medium stiffness.
High	Considerable pressure is required to roll the thread to near the plastic limit. The thread and the lump have very high stiffness.

TABLE 2-5
Identification of Inorganic Fine-grained Soils from Manual Tests

Soil Symbol	Dry Strength	Dilatancy	Toughness
ML	None to low	Slow to rapid	Low or thread cannot form
CL	Medium to high	None to slow	Medium
MH	Low to medium	None to slow	Low to medium
CH	High to very high	None	High

TABLE 2-6
Criteria for Describing Plasticity

Description	Criteria
Nonplastic	A 1/8-inch (3-mm) thread cannot be rolled at any water content.
Low	The thread can barely be rolled, and the lump cannot be formed when drier than the plastic limit.
Medium	The thread is easy to roll, and not much time is required to read the plastic limit. The thread cannot be re-rolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit.
High	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be re-rolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier that the plastic limit.

Fine-grained soils are accurately determined in the laboratory using the Atterberg Limits test. This test include liquid limit, plastic limit, and plasticity index measurements. The liquid limit is the water content of a soil at the point of transition from a plastic to a liquid state. The plastic limit is the water content of a soil at the point of transition from a semisolid to a plastic state. The plasticity index is the difference between the liquid limit and the plastic limit.

As shown in the Figure 2-2, five fields have been identified. These include:

- Silty Clays (CL), Organic Silts (OL) or Organic Silty Clays (OL) of low plasticity
- Fat Clays (CH) and Organic Clays (OH)
- Inorganic Silts (ML) and Organic Silty Clays (OL) of low plasticity
- Silts (MH) and Organic Clays (OH) of a high plasticity
- Silty Clays to Clayey Silt (CL-ML) of low plasticity

Fine-grained soils with a liquid limit > 50 are modified by the symbol H (MH or CH), and those with a liquid limit < 50 are modified by the symbol L (ML or CL). Fine-grained soils containing 30 percent or more coarse-grained fraction should be modified by descriptive terms, such as "gravelly" or "sandy." If the coarse fraction is between 15 and 30 percent, the words" with sand and/or gravel" should be added to the group name. A flow chart for classifying fine-grained soils is presented in Figure 2-4.

2.3 Organic Soils

To classify organic soils, the percentage organic material present in the soil as well as the non-organic fines must be estimated. When the organic content ranges from 18 to 36 percent, the material is an organic clay or an organic silt, depending on the nature of the fine-grained constituents. When the organic content is between 36 and 90 percent, the material is designated a muck or peaty muck (OL or OH). A flow chart for classifying organic soil is presented in Figure 2-4. The term "peaty" is added if the organic remains are

SOP-B5

Decontamination of Personnel and Equipment, Well Drilling, and Subsurface Sampling and Investigations
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure provides general guidelines for the decontamination of personnel, sampling equipment, and monitoring equipment used in potentially-contaminated areas.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP).
2) Applicable project work plan or monitoring plan, which includes a health and safety plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project Plan*, as required.

PREPARATION AND SETUP

1) Initiate field log sampling book for activity.
2) Inspect all equipment necessary to carry out activities detailed in event-specific SAP.
3) Review decontamination guidelines for equipment necessary to carry out activities.

Equipment List

- Demonstrated analyte-free, deionized water (specifically, ASTM Type II water)
- Distilled water
- Potable water; must be from a municipal water supplier, otherwise an analysis must be run for appropriate volatile and semivolatile organic compounds and inorganic chemicals (e.g., Target Compound List and Target Analyte List chemicals)
- 2.5% (W/W) Liquinox® and water solution
- Large plastic pails or tubs for Liquinox® and water, scrub brushes, spray or squirt bottles for Liquinox® solution, and distilled or deionized water, plastic bags, and sheets
- Department of Transportation (DOT)-approved 55-gallon drum for disposal of waste
- Nitrile or latex gloves
- Decontamination pad and steam cleaner/high pressure cleaner for large equipment

GUIDELINES

Personnel Decontamination

Decontamination should be performed after completion of tasks whenever personnel come in contact with contaminated (or potentially-contaminated) soils or fluids. Full or emergency decontamination should be performed when contaminant concentrations are not known and when potentially-contaminated fluids come into contact with skin beneath clothing, eyes, nose, or ears.

Procedures for full/emergency decontamination are to:

1) Remove contaminated clothing.
2) Step into containment area (decontamination pad or large pail).
3) Rinse away fluids and soil.
4) Wash skin with Liquinox® solution in such a way as to not abrade skin. (Liquinox® solution should be made with potable water and sufficient detergent to create foamy suds.) Eyes and mucus membranes in contact with contaminants must be washed with eye wash or drinking water continuously for at least 15 minutes.
5) Rinse with potable water.
6) If no other clothes are available, wash affected clothes in Liquinox® solution prior to donning. If other clothes are available, contaminated clothes may be isolated for later wash or disposed of along with personal protective equipment (PPE).
7) Any PPE worn (including disposable latex booties, gloves, and disposable coveralls) should be discarded into DOT-approved 55-gallon drum located at the MW-20 bench.
8) Dispose of wash and rinseate water in an appropriate container with other chromium contaminated fluids. These fluids may be taken to the MW-20 bench for treatment or to a Baker® tank within the PG&E facility for containerization.
9) Replace all appropriate clothing and PPE before resuming work or departing site.

Moist soil or water containing known concentrations of hexavalent chromium less than 50 parts per billion that comes into contact with hands need not require full decontamination. Dry soil containing chromium that comes into contact with clothing can also be decontaminated in an abbreviated manner.

Daily decontamination and minor exposure contact decontamination procedures are to:

1) Wash hands and skin that comes in contact with soils or water that may contain small concentrations of chromium as soon as possible after contact. Wash with Liquinox® solution and rinse with potable water.
2) If contaminated soil or water contacts hands through hole or over lip of gloves, remove gloves and wash hands thoroughly before donning new gloves.
3) Discard gloves into DOT-approved 55-gallon drum located on the MW-20 bench at the end of the day or event.

4) Remove coveralls or dry soils from clothing before leaving site. Clothing contaminated by moist soil or water containing hexavalent chromium should be removed and promptly washed.

5) At the end of the work day, shower entire body, including hair, either at the work site or at hotel.

Sampling Equipment Decontamination—Groundwater Sampling Pumps

Sampling pumps are decontaminated after each use as follows:

1) Don waterproof (nitrile or latex) gloves.

2) Run pump and reusable tubing through with Liquinox® solution (made with potable water) so that the pump and all portions or the tubing have been flushed with the solution for at least 30 to 60 seconds. More time is required if water is present in the tubing. If unsure, run for 2.5 minutes. Outside of the tubing should also be submerged and washed in the solution.

3) Run pump and reusable tubing through first rinse (with potable or distilled water) so that the pump and all portions or the tubing have been flushed with the solution for at least 60 seconds. More time is required if any suds are present in the pump or tubing.

4) Run pump and reusable tubing through second rinse (with distilled water) so that the pump and all portions or the tubing have been flushed with the solution for at least 30 seconds. More time is required if water from first rinse is present in tubing.

5) Equipment blank samples may be taken at this point using ASTM Type II water or distilled water as required by laboratory.

Sampling Equipment Decontamination—Other Equipment

Reusable sampling equipment is decontaminated after each use as follows:

1) Don nitrile or latex gloves.

2) Wash all equipment surfaces that contacted the potentially contaminated soil/water with Liquinox® solution (made from potable water). Water quality meters that are not placed within wells should not be washed with detergent, as this will degrade sensors; these meters should be double-rinsed. Any portion of equipment that is placed inside wells (including cables and pipe) and that comes in contact with moisture should be washed with detergent.

3) Rinse equipment and supplies with potable water, if the equipment is not used to collect groundwater or soil samples. Equipment used to collect samples or take water quality parameters should be rinsed with distilled water.

4) Air dry or towel dry with paper towels.

5) Collect all rinseate and dispose of in Baker® tank within the PG&E facility or Denbeste® tank at the MW-20 bench.

6) Decontamination materials (e.g., plastic sheeting, tubing, etc.) that have come in contact with used decontamination fluids or sampling equipment will be disposed of in DOT-approved 55-gallon drums if highly contaminated. If not contaminated, equipment can be washed and disposed of in trash.

7) Preserved bottles may need to be washed before being packed or handed without gloves. The outsides of filled bottles should be rinsed and toweled dry to prevent contact with strong acids or based.

Heavy Equipment and Tools

Heavy equipment such as drilling rigs, drilling rods/tools, and the backhoe will be decontaminated upon arrival at the site and between locations as follows:

1) Set up a decontamination pad in designated area.

2) Steam clean heavy equipment until no visible signs of dirt are observed. This may require wire or stiff brushes to dislodge dirt from some areas.

KEY CHECKS AND ITEMS

- Clean with solutions of Liquinox® and potable water. Rinse with distilled or deionized water if equipment is used to collect samples or water readings; otherwise, rinse with potable water.
- Equipment placed within wells should be thoroughly decontaminated and before being placed in a well. All potions of this equipment that come into contact with moisture should be decontaminated.
- Decontaminate filled sample bottles before relinquishing them to anyone.

SOP-B4

Boring Abandonment
Standard Operating Procedures for PG&E Topock Program

The purpose of this standard operating procedure (SOP) is to describe methods to abandon drill borings to the surface. The guideline covers all drilling methods and includes borings through surface casings.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan, work plan or event-specific field instructions. Planned borehole depth, proposed well construction/specifications, and field sampling summary table, if available.
2) Applicable project work plan or monitoring plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project Plan* (Procedures Manual), as required.
3) San Bernardino County Department of Health well abandonment (destruction) permit.
4) Topock Program Health and Safety Plan (HSP).
5) Blank sampling log and field notebook.

PREPARATION AND SETUP

1) Review event-specific work plan or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Initiate field logbook for sampling activity.
3) Review sampling procedures and equipment, and planned sample depths with drilling contractor and field crew.
4) Inspect all required field equipment.

Equipment List

- Truck-mounted drilling rig, skid rig, or barge-mounted tripod rig
- Hollow-stem augers and associated equipment or either rotary-drilling or sonic- drilling equipment
- Steel or Schedule 40 PVC casing, of appropriate diameter for required installations (at least 6.25-inch inside diameter if surface casing is required)
- Approved water source
- Cement
- Bentonite

GUIDELINES

California Department of Water Resources, June 1991, Bulletin 74-90 (Supplement to Bulletin 74-81) *California Well Standards*.

PROCEDURES

Abandonment

1) The borehole will be grouted from total depth to the surface with bentonite-cement grout. The cement-bentonite grout will be installed continuously in one operation from the bottom of the space to be grouted to the ground surface.
2) The grout mixture will consist of 94 pounds of cement (1 bag) per 6 gallons of water and 2 to 3 pounds of powdered bentonite per bag of cement to reduce shrinkage.
3) The source of the water used in the grout mixture must be from a pre-approved source.
4) If there is any risk of borehole collapse upon removal of the drill casing, then the grout will be added prior to the removal of the drill casing. The grouting can be completed in stages, grouting 50 to 100 feet at a time, removing 50 to 100 feet of drill casing, and then repeating until the grout has reached the surface and the final casing removed.
5) When installing grout in soil borings, the grout will be installed through a tremie pipe that is placed inside the drill casing to the bottom of the borehole.
6) The production of grout will be completed to eliminate the preparation of excess/waste grout.

Waste Disposal

1) The soil cuttings are to be drummed and managed as described in SOP *Disposal of Waste Fluids and Soils* and the investigation-derived waste management plan.
2) Minimal quantities of grout may be included in the water or soil waste streams. The quantity of grout will be limited to that produced during cleaning of grouting equipment or decontamination of drill casing.

KEY CHECKS AND PREVENTATIVE MAINTENANCE

- Check that the drilling rig or soil-coring rig is in working order.
- Check that the borehole is grouted to the ground surface at the completion of drilling and sampling.

SOP-B5

Decontamination of Personnel and Equipment, Well Drilling, and Subsurface Sampling and Investigations
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure provides general guidelines for the decontamination of personnel, sampling equipment, and monitoring equipment used in potentially-contaminated areas.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP).
2) Applicable project work plan or monitoring plan, which includes a health and safety plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project Plan*, as required.

PREPARATION AND SETUP

1) Initiate field log sampling book for activity.
2) Inspect all equipment necessary to carry out activities detailed in event-specific SAP.
3) Review decontamination guidelines for equipment necessary to carry out activities.

Equipment List

- Demonstrated analyte-free, deionized water (specifically, ASTM Type II water)
- Distilled water
- Potable water; must be from a municipal water supplier, otherwise an analysis must be run for appropriate volatile and semivolatile organic compounds and inorganic chemicals (e.g., Target Compound List and Target Analyte List chemicals)
- 2.5% (W/W) Liquinox® and water solution
- Large plastic pails or tubs for Liquinox® and water, scrub brushes, spray or squirt bottles for Liquinox® solution, and distilled or deionized water, plastic bags, and sheets
- Department of Transportation (DOT)-approved 55-gallon drum for disposal of waste
- Nitrile or latex gloves
- Decontamination pad and steam cleaner/high pressure cleaner for large equipment

GUIDELINES

Personnel Decontamination

Decontamination should be performed after completion of tasks whenever personnel come in contact with contaminated (or potentially-contaminated) soils or fluids. Full or emergency decontamination should be performed when contaminant concentrations are not known and when potentially-contaminated fluids come into contact with skin beneath clothing, eyes, nose, or ears.

Procedures for full/emergency decontamination are to:

1) Remove contaminated clothing.
2) Step into containment area (decontamination pad or large pail).
3) Rinse away fluids and soil.
4) Wash skin with Liquinox® solution in such a way as to not abrade skin. (Liquinox® solution should be made with potable water and sufficient detergent to create foamy suds.) Eyes and mucus membranes in contact with contaminants must be washed with eye wash or drinking water continuously for at least 15 minutes.
5) Rinse with potable water.
6) If no other clothes are available, wash affected clothes in Liquinox® solution prior to donning. If other clothes are available, contaminated clothes may be isolated for later wash or disposed of along with personal protective equipment (PPE).
7) Any PPE worn (including disposable latex booties, gloves, and disposable coveralls) should be discarded into DOT-approved 55-gallon drum located at the MW-20 bench.
8) Dispose of wash and rinseate water in an appropriate container with other chromium contaminated fluids. These fluids may be taken to the MW-20 bench for treatment or to a Baker® tank within the PG&E facility for containerization.
9) Replace all appropriate clothing and PPE before resuming work or departing site.

Moist soil or water containing known concentrations of hexavalent chromium less than 50 parts per billion that comes into contact with hands need not require full decontamination. Dry soil containing chromium that comes into contact with clothing can also be decontaminated in an abbreviated manner.

Daily decontamination and minor exposure contact decontamination procedures are to:

1) Wash hands and skin that comes in contact with soils or water that may contain small concentrations of chromium as soon as possible after contact. Wash with Liquinox® solution and rinse with potable water.
2) If contaminated soil or water contacts hands through hole or over lip of gloves, remove gloves and wash hands thoroughly before donning new gloves.
3) Discard gloves into DOT-approved 55-gallon drum located on the MW-20 bench at the end of the day or event.

4) Remove coveralls or dry soils from clothing before leaving site. Clothing contaminated by moist soil or water containing hexavalent chromium should be removed and promptly washed.

5) At the end of the work day, shower entire body, including hair, either at the work site or at hotel.

Sampling Equipment Decontamination—Groundwater Sampling Pumps

Sampling pumps are decontaminated after each use as follows:

1) Don waterproof (nitrile or latex) gloves.

2) Run pump and reusable tubing through with Liquinox® solution (made with potable water) so that the pump and all portions or the tubing have been flushed with the solution for at least 30 to 60 seconds. More time is required if water is present in the tubing. If unsure, run for 2.5 minutes. Outside of the tubing should also be submerged and washed in the solution.

3) Run pump and reusable tubing through first rinse (with potable or distilled water) so that the pump and all portions or the tubing have been flushed with the solution for at least 60 seconds. More time is required if any suds are present in the pump or tubing.

4) Run pump and reusable tubing through second rinse (with distilled water) so that the pump and all portions or the tubing have been flushed with the solution for at least 30 seconds. More time is required if water from first rinse is present in tubing.

5) Equipment blank samples may be taken at this point using ASTM Type II water or distilled water as required by laboratory.

Sampling Equipment Decontamination—Other Equipment

Reusable sampling equipment is decontaminated after each use as follows:

1) Don nitrile or latex gloves.

2) Wash all equipment surfaces that contacted the potentially contaminated soil/water with Liquinox® solution (made from potable water). Water quality meters that are not placed within wells should not be washed with detergent, as this will degrade sensors; these meters should be double-rinsed. Any portion of equipment that is placed inside wells (including cables and pipe) and that comes in contact with moisture should be washed with detergent.

3) Rinse equipment and supplies with potable water, if the equipment is not used to collect groundwater or soil samples. Equipment used to collect samples or take water quality parameters should be rinsed with distilled water.

4) Air dry or towel dry with paper towels.

5) Collect all rinseate and dispose of in Baker® tank within the PG&E facility or Denbeste® tank at the MW-20 bench.

6) Decontamination materials (e.g., plastic sheeting, tubing, etc.) that have come in contact with used decontamination fluids or sampling equipment will be disposed of in DOT-approved 55-gallon drums if highly contaminated. If not contaminated, equipment can be washed and disposed of in trash.

7) Preserved bottles may need to be washed before being packed or handed without gloves. The outsides of filled bottles should be rinsed and toweled dry to prevent contact with strong acids or based.

Heavy Equipment and Tools

Heavy equipment such as drilling rigs, drilling rods/tools, and the backhoe will be decontaminated upon arrival at the site and between locations as follows:

1) Set up a decontamination pad in designated area.

2) Steam clean heavy equipment until no visible signs of dirt are observed. This may require wire or stiff brushes to dislodge dirt from some areas.

KEY CHECKS AND ITEMS

- Clean with solutions of Liquinox® and potable water. Rinse with distilled or deionized water if equipment is used to collect samples or water readings; otherwise, rinse with potable water.
- Equipment placed within wells should be thoroughly decontaminated and before being placed in a well. All potions of this equipment that come into contact with moisture should be decontaminated.
- Decontaminate filled sample bottles before relinquishing them to anyone.

SOP-B6

Disposal of Waste Fluids and Solids (IDW) Standard Operating Procedures for PG&E Topock Program

---

This standard operation procedure (SOP) describes the procedures used to dispose of hazardous fluid and solid materials generated as a result of the site operations. This SOP does not provide guidance on the details of Department of Transportation (DOT) regulations pertaining to the transport of hazardous wastes; the appropriate Code of Federal Regulations (49 CFR 171 through 177) should be referenced. Also, the site investigation-derived waste management plan should be consulted for additional information and should take precedence over this SOP.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan.

2) Applicable project work plan or monitoring plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project Plan*, as required.

3) Topock Program Health and Safety Plan.

PREPARATION AND SETUP

1) For soil and groundwater collection and storage, a subcontractor (either Denbeste Transportation, Inc. or a drilling or sampling contractor) will bring clean, empty drums, roll-off bins, Denbeste® tanks, or Baker® Tanks to the site.

2) Locate the empty drums at the field staging area and move drums to drilling locations as required.

EQUIPMENT LIST

- DOT-approved 55-gallon steel drums, Denbeste® Tanks, Baker® Tanks or roll-off bins
- Portable polytanks for transferring water from well samples locations to tanks or bins
- Tools for securing drum lids
- Funnel for transferring liquid into drum
- Water pump to transfer liquids
- Labels
- Marking pen for appropriate labels
- Seals for 55-gallon steel drums
- Plastic sheets and buckets to catch leaks and drips

PROCEDURES

General Methodology

1) Prior to filling soil bins, determine if plastic sheeting is required for soil disposal bins. Line bins with plastic sheeting as required by disposal contractor and facility. Seal bins and

check for water tightness on soil bins and water tanks. Inventory all bins and tanks by unique identifier.

2) Fill soil bins with drilling and well installation wastes. When three-fourths full, cap or close, and update inventory. The drilling, sampling, or waste disposal subcontractor will move the drums to the on-site drum storage area. Fill tanks with clear water. Muddy water should be allowed to settle out in soil bins or separator tanks prior to transfer to Denbeste® or Baker® Tanks.

3) Separate full drums by waste and media types.

4) As the drums are filled in the field, affix labels indicating that the contents are potentially hazardous. Update bin log with type of waste and locations from which soil is obtained.

5) Drums may be used for temporary storage of soil or water. The drums should be closed and sealed at the end of each work day or when full. Drums used for soil should not be used for clear water storage without decontamination. Drums should be labeled if the contents are not transferred to a tank or bin by the end of the day.

6) Portable polytanks are used to transfer water from wells being sampled or developed to Denbeste® or Baker® tanks. These tanks should be emptied at the end of each day or when full. Sediment that accumulates that the bottom of these tanks should be removed and disposed of with contaminated soil on a regular basis.

7) Soils and groundwater from the site have been characterized for waste disposal. Wastes, which have not been included in the characterization, should be labeled sampled and separated from other wastes.

8) Typically Denbeste Transportation, Inc. should be contacted for disposal of wastes and movement of soil bins and large water tanks. Other contractors may also be involved in waste disposal.

Labeling

1) Label drums and other containers used for storing wastes from drilling, development, and sampling operations when accumulation in the container begins. Labels will include the following minimum information:

   - Container number
   - Container contents
   - Origin (source area including individuals wells, piezometers, and soil borings)
   - Date that accumulation began
   - Date that accumulation ended

2) When laboratory results are received, complete or revise drum labels to indicate the hazardous waste constituents in compliance with 40 CFR, Part 262, Subpart C.

Groundwater and Drilling Fluids

1) Collect water and drilling fluids generated during well sampling and development and during soil boring in polytank or hopper (water-tight bin used to transport cuttings with forklift).

2) When a polytank is full, or hopper is half full, secure the tank or hopper and transfer fluid to appropriate separator tank or to Denbeste® or Baker® tanks.

3) When fluids are being transferred from polytanks or drums to larger tanks, use an appropriate pump (often referred to as trash pump) used for contaminated fluids. Subcontractors should decontaminate trash pumps before they are brought to the site. When transferring liquids, materials to contain spills and drips should be at hand, and appropriate PPE should be worn. Nitrile or latex gloves should be worn at a minimum. If water is being transferred by bucket, plastic sheeting should be used to contain drips.

4) Water that is allowed to settle in soil bins or separator tanks should be removed prior to movement of bin. Water stored in a soil bin, should not be stored longer than one week after filling to minimized dripping and leaking. Water may be transferred using a vacuum truck or pump and tank.

5) A separate tank will be needed for waste that cannot be treated by on-site water treatment. This waste will be characterized and disposed of off site.

6) Any tanks containing waste fluids for more than one day shall be labeled.

Solids

The soil cuttings from well and boring drilling will constitute a large portion of the solids to be disposed of. The solid waste stream also include plastic sheeting used for decontamination pads, Tyveks, disposable sampling materials, and any other disposable material used during the field operations that appears to be contaminated.

1) Place these materials in the designated bins and indicate what materials, other than soil, are present in logbook.

2) Contact Denbeste Transportation, Inc. or drilling company for removal and disposal of bins.

3) Dispose waste solid materials that contain hazardous constituents at an off-site location in a manner consistent with applicable solid waste, hazardous waste, and water quality regulations.

KEY CHECKS AND ITEMS

- When fluids are being transferred from polytanks or drums to larger tanks, use an appropriately designated pump.
- If wastes are stored in drum, tank, or bin for longer than 1 day, this container should be labeled.
- Waste characterization profiles should be checked prior to waste accumulation to determine if samples should be collected for further characterization and if wastes need to be segregated from others on site.

SOP-B7

Homogenization of Soil and Sediment Samples
Standard Operating Procedures for PG&E Topock Program

The homogenization of soil and sediment samples is performed to minimize any bias of sample representativeness introduced by the natural stratification of constituents within the sample. Standard techniques for soil and sediment homogenization and equipment are provided in this SOP. These procedures do not apply to aliquots collected for volatile organic compounds (VOCs) or field gas chromography screening; samples for these analyses should NOT be homogenized.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP).
2) Applicable project work plan or monitoring plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project Plan,* as required.
3) Topock Program Health and Safety Plan (HSP).
4) Previous sampling logs.
5) Blank sampling logs and field notebook.

PREPARATION AND SETUP

1) Review event-specific SAP or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Initiate field logbook for sampling activity.

EQUIPMENT LIST

- Sample containers
- Stainless-steel spoons or spatulas
- Stainless-steel pans
- Phthalate-free gloves

PROCEDURES

Sample Homogenization

1) Soil and sediment samples to be analyzed for semivolatiles, pesticides, polychlorinated biphenyls, metals, cyanide, or field x-ray fluorescence screening should be homogenized in the field.
2) After a sample is taken, a stainless-steel spatula should be used to remove the sample from the split spoon or other sampling device. The sampler should not use fingers to do this, as gloves may introduce organic interferences into the sample.

3) Samples for VOCs should be taken immediately upon opening the spoon and should not be homogenized.
4) Prior to homogenizing the soil or sediment sample, any rocks, twigs, leaves, or other debris should be removed from the sample.
5) The sample should be placed in a decontaminated stainless-steel pan and thoroughly mixed using a stainless-steel spoon. The soil or sediment material in the pan should be scraped from the sides, corners, and bottom, rolled into the middle of the pan, and initially mixed.
6) The sample should then be quartered and moved to the four corners of the pan. Each quarter of the sample should be mixed individually, then rolled to the center of the pan and mixed with the entire sample again.

Equipment Decontamination

1) All stainless-steel spoons, spatulas, and pans must be decontaminated following procedures specified in SOP *Decontamination of Personnel and Equipment* prior to homogenizing the sample.
2) A composite equipment rinse blank of homogenization equipment should be taken each day it is used.

SOP-B9

Drilling--Sonic Method
Standard Operating Procedures for PG&E Topock Program

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP), Work Plan or event-specific field instructions. Planned borehole depth, proposed well construction/specifications, and field sampling summary table, if available.
2) Applicable project work plan or monitoring plan. Refer to Topock Program Sampling, Analysis, and Field Procedures Manual and QAPP (Procedures Manual), as required.
3) Topock Program Health and Safety Plan (HSP)
4) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available
5) Blank sampling log and field notebook

Equipment List:

- Drilling rig (Sonic)
- Drill rods and core barrel

GUIDELINES

PRIOR TO INTRUSIVE ACTIVITIES AT ANY DRILLING LOCATION THE AREA WILL HAVE BEEN CLEARED OF ALL UTILITIES AND THE CLEARANCE RECORDED IN THE FIELD LOGBOOK. It is also the field team leader's responsibility to confirm that all required access permits are in place.

Prior to the start of drilling, the area of site activity will be identified and delineated using stakes and/or flagging. The extent of impact will be mineralized at all times and the delineated area of activity decreased when possible. All sensitive vegetation or habitats will be delineated with stakes and/or flagging and no impact will occur in these areas.

Sampling depths and total depths of holes shall be determined by temporary marking of drill equipment, by reference to standard equipment dimensions (for example, 5-foot hollow-stem auger flights), or by measurement using a fiberglass tape. Final total depth measurements will be confirmed using a weighted fiberglass tape. Observations by the field geologist or engineer shall be recorded directly in the borehole log.

The field borehole log is the standard form used to document subsurface geologic conditions. The borehole log is divided into two areas. One portion contains spaces for noting information on the drilling and sampling methods. The second portion contains space for noting lithologic descriptions. All sheets shall be filled out completely, legibly, and in ink. The borehole log will be filled out in the field at the time of the drilling and sampling. The original logs shall be permanent records, and information on the logs may not be erased. If corrections are needed, information shall be crossed out with a single line and the correction shall be initialed and dated.

The use of water and drilling fluid to assist in sonic drilling for monitoring well installation will be avoided, unless required for such conditions as running sands or drilling bedrock formations.

Temporary outer casing, drill rods, core barrels, and other downhole drilling tools will be properly decontaminated prior to the initiation of drilling activities and between each borehole location. Core barrels and other downhole soil sampling equipment will also be properly decontaminated before and after each use.

Sonic inner casing (sample tube) will have an inside diameter of at least 3.25 inches. Samples may be collected for chemical analysis. For sonic drilling, these samples are collected in a metal trough. A continuous core is collected and the sample interval is selected from the length of core run.

Surface casing may be installed where soil borings will penetrate a confining layer or when there is risk of eroding soil during the drilling process if water is used.

PROCEDURES

Instructions for Completing Soil Boring Logs

Soil boring logs will be completed in the field log books. Information collected will be consistent with that required for Form D1586 (attached), a standard CH2M HILL form or an equivalent form that supplies the same information. Procedures will follow the SOP "*Soil*

Non-Core Collection Drilling

At locations or depths from which core collection is not required, drilling may proceed without the recovery of soil cores. The drilling will include advancing the larger outer casing and the use of water to facilitate cuttings removal from the boring. The inner casing drill rods may or may not be used, depending on the cuttings recovery when drilling with the larger outer casing.

Continuous Core Drilling

At locations or depths when core collection is required, drilling will proceed using an outer casing and an inner core sample tube. The inner core sampling tube will be advanced first without the use of water. Before removal of the sampling tube, the outer casing will be advanced, using water only as needed for cuttings removal, to the same total depth as the inner casing. The outer casing will stabilize the boring when the sampling tube is removed. The process is repeated in 10 to 20 foot intervals, as the lithology of the boring permits.

The length of each drilling interval should be adjusted depending on the lithology and the quality and recovery percentage of the sample cores retrieved. At locations with very hard drilling (i.e. with large cobbles or hard materials) or when percent recovery decreases, the drilling interval should be decreased until such time that the conditions change.

After retrieval of the inner sampling core tube, the minimally disturbed sample cores will be collected into plastic liner sleeves in intervals of 2 to 3 feet. The plastic sleeves will be immediately sealed on both ends. The cores will be used for visual descriptions and may be used for analysis for geochemical and geotechnical parameters.

KEY CHECKS AND ITEMS

- Check entries to the soil boring log and field logbook in the field during sampling activities because the cores will be disposed at the end of the fieldwork, confirmation and corrections cannot be made later.
- Check that the sample numbers and intervals are properly specified.
- Ensure that drilling equipment is decontaminated prior to the beginning of work and between each borehole.
- All materials generated during sampling (debris, PPE, decontamination liquids, etc.) will be placed in approved IDW storage containers pending analysis and disposal off site as outlined in SOP-B6, *Disposal of Waste Fluids and Solids (IDW)*.

SOP-B11

Site Clearance and Permitting
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures for site clearance and permitting at the Topock site. This SOP should be used to obtain proper site clearance and permits before any work is performed at a site.

REQUIRED DOCUMENTS

1) Applicable project work plan, event-specific sampling and analysis plan (SAP), and/or Procedures Manual, if applicable.
2) Topock Program Health and Safety Plan (HSP).
3) Site map with work locations identified.

PREPARATION AND SETUP

1) Review applicable project work plan, event-specific SAP, Procedures Manual, and HSP.
2) Identify locations where work will be performed, determine if any subsurface work will be needed.
3) Before the start of any work obtain approval by the appropriate land agencies (such as BLM, USFWS, County of San Bernardino). Activities located on PG&E property fall under the jurisdiction of the County; however, approval may also be required from BLM and/or USFWS for activities such as access, waste management, etc. Work in Topock, Arizona falls under the jurisdiction of the Arizona Department of Water Resources.
4) Before the start of any work obtain appropriate approval by the regulatory agencies. These include at a minimum the DTSC if in California, and ADEQ is in Arizona. Other regulatory approvals that may be required include, but are not limited to CDFG, USFWS, USACE and RWQCB. Approval from the Arizona Land Department may also be required for wells drilled in Arizona.

If subsurface work will be involved, follow the following steps:

1) Follow the guidelines of the Southern California Underground Service Alert (USA) agency to mark the edges of the work location as outlined on their web page (http://www.digalert.org). If in Arizona, the Arizona Blue Stake should be contacted for location of buried facilities (www.azbluestake.com). Make sure to:
   - Identify delineated areas with white markings with the requesters company name or logo within the pre-marked zones
   - Delineate the exact area of excavation with white paint through the use of dots or dashes, or a continuous solid line. Limit the size of each dash to approximately 6" in length and 1" width with interval spacing not less that approximately 4 feet. Dots of

approximately 1" diameter are typically used to define arcs or radii and may be placed at closer intervals in lieu of dashes. Limit width of lines to 1".

- For point locations (such as a soil boring or well) mark the exact location in the USA or Blue Stake box with a stake. Make sure the delineated area around the stake is of adequate radius (50 to 100 feet is appropriate for drilling).

2) Call USA at 1-800-227-2600 or Arizona Blue Stake at 1-800-782-5348 at least three working days before the start of work at the identified location and provide them with the information requested on the location request form. Be ready to give the location in terms of feet relative to I-40 and to Park Moabi Road when calling. You will be assigned a Dig Alert Number, file this number until work at the delineated area is complete. (The number does expire after two weeks and a new number may need to be obtained if work has been delayed.)

3) Mark the Dig Alert Number in the delineated area using white paint as soon as possible after calling USA or Arizona Blue Stake.

4) If the location is in a developed area, contact a private utility locator and have them perform a sweep of the delineated work area. Util-Locate at (866) 421-5325 is typically used for this service.

5) In some cases the utility companies may need to be contacted directly by CH2M HILL. If the following companies do not respond to the USA or Blue Stake ticket or if we are working in their easements, use the following contact information and procedures:

Southwest Gas: Main contact is Jim Default/702-365-2097 (The required minimum clearance distance from gas pipelines is 18-inches. Potholing may need to be performed in advance of design completion Southwest Gas should be called prior to construction activities). If Southwest Gas does not come to the site after the USA call, contact them at their Bullhead City office at (928) 763-7766

Southern California Gas Co.: Main contact is Frank Castro/818-701-4566; secondary contact is Martin Woodsworth/818-701-4543. If we need to work in their easement, we must provide a letter from BLM giving us permission to be on the property. Southern California Gas Co. also requires advance notification of construction activities. They may also require a copy of the design drawing, potholing activities, and the issuance of a "Non-Interference" letter, if applicable, before work can proceed. One of their representatives may need to be in the field when digging is occurring near their pipeline.

TransWestern Pipeline Co.: Main contacts are Ron Westbrook (ROW Department)/713-345-3067 and Mike Baxter (Operations)/928-757-3620. They may require potholing if proposed construction activities are near their pipelines. Crossing pipeline requires filling out a simple form.

Burlington Northern Santa Fe Railroad: Main contact is Greg Rousseau (BNSF)/909-386-4079. Prior to work in their easements submit the proper application with the $250 fee to the Staubach Company.

City of Needles Utility Dept: Main contact is Ron Myers/760-326-5700 (ext. 7 for the utilities department). Work activities may need to be a minimum of 10 to 15 feet from their utility poles.

6) Do not start subsurface work at the site until the delineated area has been marked or cleared by the appropriate utility agencies.

If the work includes a performing a well installation or abandonment, or drilling a boring in California:

1) Apply for a San Bernardino County well permit two to three weeks before the start of drilling (one permit per well; cost is /$212.00 per well). Obtain a permit application by calling the Environmental Health Services Department at 1-909-387-4666 (open Monday through Friday, 8:00 a.m. to 5:00 p.m. The fee schedule for permits is located at http://www.sbcounty.gov/ dehs/FEESCHEDULE/feeschedule.htm#wateranchor. Fill out the appropriate permit form and provide it to the California-licensed driller contracted to perform the well installation. The driller is expected to review and file the permit with the San Bernardino County Department of Environmental Health Services (Steve Sesler), address below.

Environmental Health Services
385 N. Arrowhead, 2nd Floor
San Bernardino, CA 92415-0160

2) A well permit needs to be obtained from San Bernardino County for well abandonment by the same procedure described in #11. Check the 'destruction' box on the same permit form used for well installation.

3) A permit also needs to be obtained from San Bernardino County for any boring that reaches to or below the water table, even if a well is not actually installed. The permit process is the same as described in #11.

If the work includes a performing a well installation or abandonment, or drilling a boring in Arizona:

1) Apply for an Arizona Department of Water Resources (DWR) well permit two to three weeks before the start of drilling (one permit per well; cost is /$150.00 per well). Obtain a permit application by calling the DWR at 1-(602) 771-8500 (open Monday through Friday, 8:00 a.m. to 5:00 p.m. MST). All ADW permits and instructions can be found at http://www.azwater.gov/dwr/Content/Find_by_Category/Permits_Forms_Applications/default.htm
Fill out the appropriate permit form (55-44A) and provide it to the Arizona-licensed driller contracted to perform the well installation. The driller is expected to review and file the permit with the Arizona Department of Water Resources address below.

Arizona Department of Water Resources
3550 N. Central Avenue
Phoenix, AZ 85012

Upon completion of the well, the driller must submit a Driller Report and Well Log (Form 55-55) to the DWR within 30 days. The form and instructions can be found on the DWR webpage.

2) A well abandonment permit needs to be obtained from the Arizona Department of Water Resources prior to well abandonment (form 55-38). Exploratory wells that are abandoned before the drill rig leaves the site are exempt from the well abandonment permit requirements. The well abandonment form and instructions are included as Attachment 4 and can be found at the ADW webpage . No fee is required for filing this form.

   Within 30 days of well abandonment a Well Abandonment Completion Report (Form 55-58) must be filed with the DWR.

SOP-B15

Volatile Organic Compound (VOC) Soil Sampling Standard Operating Procedures for PG&E Topock Program

---

This standard operating procedure (SOP) provides guidance for Volatile Organic Compound (VOC) sample collection from soil. Additional guidance for sample collection, preservation and handling is provided in Section 4.0 of the PG&E Quality Assurance Project Plan (QAPP). SOP-B2 and SOP-B3 *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL, 2005) provides additional guidance for soil characterization and logging.

Required Documents

1) Event-specific planned sample table (PST).
2) Applicable project work plan or monitoring plan. Refer to the Procedures Manual and QAPP as required.
3) Topock Program Health and Safety Plan (HSP).
4) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available.
5) Field notebook.
6) Database generated sampling logs.

Preparation and Setup

1) Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Coordinate with the Project Chemist for coolers, sample containers, and courier pickup of the samples.
3) Initiate field logbook for sampling activity.
4) Review sampling procedures and planned sample depths with field crew.
5) Field-check and set up equipment for sampling, decontamination, spill prevention, and health and safety.

Equipment List

- Pre-labeled soil sample containers appropriate for sample analysis and preservation as called for in PST and QAPP (Pre-weighed Vials, glass jars, auger sleeves, etc.)
- Soil sampling equipment (stainless steel trowel, spatula, EnCore™ Sampler, EasyDraw Syringe®, or a disposable plastic syringe with a barrel smaller than the neck of the soil vial with the cap removed from the plunger, etc.)
- Field notebook
- Sediment sampling logs generated from database

- Blue or black waterproof or permanent ink pens
- Trash bags
- Paper towels
- Decontamination equipment (Alconox® solution in spray bottle, brushes, buckets, rinse water spray bottle)
- Water level indicator
- Distilled water
- Coolers with ice
- Protective waterproof gloves (nitrile or latex)

SOIL SAMPLING LOGS DOCUMENTATION

Soil sampling logs or boring logs (SOP-B2 and SOP-B3 *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* [CH2M HILL, 2005]) will be completed at the time of sample collection. Items to be documented on the sampling log include:

6) **Sample Interval:** The top and bottom depth of each sample run should be recorded on the log. Sampling includes samples collected for analysis as well as retrieved for logging purposes.
7) **Sample Type and Number:** Enter the sample type and number consistent with the sampling and analysis plan at the correct depth intervals. An “x” should be placed across the vertical interval where the environmental soil, grab groundwater, or geotechnical sample was collected.
8) **Sample Recovery:** Enter the length of retrieved sample to the nearest inch of sample recovered. Record total length and percent of sample recovered.
9) **Sampling:** Sampling difficulties shall be noted. The top of the sample shall be marked on the container.
10) **Water Levels:** Water-level measurements, where groundwater is encountered, are required for each boring. Changes in soil moisture shall be noted and, if there is no water encountered, a note to that effect shall be included on the sediment sampling log. The date and time of water-level measurements shall be documented.

At a minimum, sample identifiers (IDs) should be noted on sampling logs at the depth collected. When time and space allows, a summary of analytical sample information can be included.

VOLATILE ORGANIC COMPOUNDS (VOC) SOIL SAMPLING - COLLECTION OF SAMPLES FOR ANALYSIS

It is recommended (EPA Method 5035A) that VOC soil samples be collected in a coring device to minimize volatilization and soil disturbance to prevent constituent losses. After collection, the sample shall be immediately transferred to the sample vial (to be used for analysis) and stored for no longer than 48 hours at 4 C ± 2^{o} C prior to analysis. Freezing the samples between -7 and -20° C within 48 hours and maintaining them frozen until analysis allows a 14 day holding time. Chemical preservation techniques are also available as options.

Use either a commercially available sampler (such as the EnCore™ Sampler or EasyDraw Syringe®) or a disposable plastic syringe to collect VOC soil samples. To use a syringe, cut the syringe end of the barrel off and removed the rubber 'cap' from the plunger, prior to sampling (barrel of the syringe needs to be smaller than the neck of the soil vial). One sampler is needed for each sample aliquot to be collected (typically the laboratory will supply the sampler along with the sample vials, but arrangements must be made prior to sampling).

11) Weigh 3 empty samplers and note the weight. Using the same 3 samplers collect several trial samples (try to collect 5.0 ± 0.2g). Weigh each trial sample (total weight – syringe weight = sample weight) and note the length of the soil column in the syringe. Use the data to determine the length of soil in the syringe that corresponds to 5.0 grams. The length of the soil column equal to 5 grams becomes the volume for the project location. Discard each trial sample.

12) The VOC sample collection process should be completed in the least amount of time as possible in order to minimize the loss of VOCs. Sample collection should be done with the least amount of disturbance/disruption as possible. Additional, exposure of the sampling location's surface layers should be considered if the material may have already lost VOCs or if it may have been contaminated by other means. Removal of surface layers can be accomplished by scraping the surface using a clean spatula, scoop, knife, or shovel.

13) Insert a clean coring tool into a freshly exposed surface; do not trap air between the sample and the plunger. For greater ease in pushing into the solid matrix, the front edge of these tools can be sharpened. The optimum diameter of the coring tool depends on the size of the opening of the collection vial (tool should fit inside mouth), the sample characteristics (e.g., particles size, cohesion), and volume of sample required for analysis. After an undisturbed sample has been obtained by pushing the barrel of the coring tool into a freshly exposed surface, quickly wipe the exterior of the barrel with a clean disposable towel. Transfer the sample into a pre-weighted vial by gently pushing the plunger, (use extreme care to ensure none of the preservative is lost if the sample is collected into a pre-preserved vial – water, methanol or NaHSO4), verify the sealing surfaces are clean, and secure the cap (the transfer should take less than 10 seconds). **Note: Samples are collected in pre-weighed and pre-labeled vials provided by the laboratory; no additional labels are to be added to the vials!** Complete the label attached by the laboratory (fill in sample ID-only). All vials from one sample location will be placed into a zip-lock bag and the sample information shall be recorded on a label attached to the bag.

14) As a last resort non-cohesive granular samples (sand, gravel, or a mixture of gravel and fines) that can not be easily obtained or transferred using coring tools, can be quickly sampled using a decontaminated stainless steel spatula or scoop. Decontamination is covered in section 3.3 of the PG&E Program QAPP and in SOP-B5 *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL, 2005).

15) As with the collection of aqueous samples for volatiles, collect at least 3 replicate samples. This will allow the laboratory an additional sample for reanalysis, if needed. The replicate samples should be taken from the same soil stratum or the same section of the solid waste

being sampled, and within close proximity to the location from which the original sample was collected.

16) In addition, if a VOC sample is the only sample to be collected at a given location, collect at least one additional aliquot for the determination of percent moisture. Trip blanks and equipment blanks should be collected per the PG&E Program QAPP. However, trip blanks do not apply to samples that have been frozen upon collection.

17) Transport the sample at 4^{o} C, to the lab in less than 48 hours or freeze (reagent water preserved samples to between -7 and -20^{o} C) within 48 hours and transport frozen.

18) Complete Soil Sampling Logs and Chain of Custody Logs.

SOP-B16

Field-portable X-Ray Fluorescence Soil Sampling Standard Operating Procedures for PG&E Topock Program

---

This SOP describes the analysis of *in-situ* and *ex-situ* soil samples using a field portable X-Ray Fluorescence instrument (XRF). SOP-B2 and SOP-B3- in the *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL, 2005) provides additional guidance for soil characterization and logging.

Required Documents

1) Event-specific planned sample table (PST).
2) Applicable project work plan or monitoring plan. Refer to the Procedures Manual and QAPP as required.
3) Topock Program Health and Safety Plan (HSP).
4) Field notebook.
5) Database generated chain-of-custody.
6) XRF Functional Check Log

Preparation and Setup

1) Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Coordinate with the Project Chemist for coolers, sample containers, and courier pickup of the samples.
3) Initiate field logbook for sampling activity.
4) Initiate electronic file for X-Ray Fluorescence (XRF) instrument download.
5) Review sampling procedures and planned sample depths with field crew.
6) Field-check and set up equipment for functional checks, sampling, decontamination, spill prevention, and health and safety.

Equipment List

- Niton XRF Meter and stand
- Spare battery chargers
- Field notebook
- Trowel for smoothing soil surfaces
- Reusable plastic bags or stainless steel tray
- Disposable Sample cups with X-ray film and lids

- X-Ray window film (Mylar, Kapton, Spectrolene, polypropylene, or equivalent; 2.5 – 6.0 micrometers (um) thick)
- Disposable scoops, stainless steel spoons or other appropriate mixing tools
- Appropriate quality control (QC)/quality assurance (QA) standards, and blank sand
- Chemwipes
- Decontamination equipment (Alconox® solution (or equivalent) in spray bottle, brushes, buckets, rinse water spray bottle) for mixing tools and trowels
- Protective waterproof gloves (nitrile or latex)

XRF SOIL ANALYSIS DOCUMENTATION

The XRF sample results will be recorded by the associated software in an excel format. The files will be downloaded at the end of each day and emailed to the project chemist for review. Any additional sample logging and sample collection should follow the protocol and procedures found in the *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL,2005). Detailed notes should be recorded in the sampler's field notebook or in a log generated from the field database. Items to be documented on the sampling log include (note: include as much of the following information in the XRF software as possible):

1) Record type of boring or excavation equipment and the total boring or excavation depth.
2) If multiple samples are being collected at one location at a variety of depths, record all sample depths.
3) Record date and time of sample collection in addition to the full sample ID that is listed in the PST.
4) Sampling difficulties shall be noted (i.e. difficult slope or abnormal debris in sample location).
5) Analysis start time and the source count time (i.e. 60 sec, 90 sec, or 120 sec etc.) will be documented on sample collection sheet. Note: analysis and count time are automatically recorded in the XRF software.

Field-portable X-Ray Fluorescence Soil Sampling- COLLECTION OF SAMPLES FOR ANALYSIS

In-Situ Sample Preparation

When the soil moisture is less than 20 percent, the error associated with moisture may be minimal. If areas are encountered where the moisture content is greater than 20 percent (moisture is visible), consult with the project chemist for options available for proceeding with field analysis.

For *in-situ* analysis,

1) Large or non-representative debris must be removed from the selected location. This debris includes rocks, gravel, vegetation and concrete.

2) The location chosen for analysis should be homogenized by mixing in place an area approximately 4″ by 4″ by 3″ deep, using a clean (or decontaminated) stainless steel or disposable spoon. The location should then be smoothed and firmly tamped to provide as flat and smooth an area as possible.

1) A section of x-ray window film should be stretched over the area to be tested to maintain a dust free environment for the nose of the instrument. (Note: use in-situ analysis for metals only samples).

2) To initiate a reading, the nose of the XRF will be positioned against the x-ray film, squeezing the shutter release, and firmly pressing the instrument flat against the surface. Source count times for *in-situ* analysis usually range from one to two minutes, varying among instruments and depending on requirement detection limits.

3) After the *in-situ* field screening is performed, inspect the nose of the instrument for contamination, which may affect future analysis. If necessary, clean it with a soft cloth or tissue.

For confirmation samples, or where samples for organic analysis are to be collected the soil samples should be treated as *ex-situ* samples, below.

***Ex-Situ* Sample Preparation**
For *ex-situ* analysis,

There are several possible correct methods for the ex-situ analysis of samples. The area that previously would have been homogenized for the in-situ analysis should be scooped out and placed into a clean (or decontaminated) stainless steel or disposable pan (do not use plastic if organic analysis will be performed on any of this homogenized sample), using a stainless steel or disposable spoon or spatula (do not use plastic if organic analysis are associated with the homogenized sample). The sample should then be thoroughly mixed (homogenized) using the same spoon or spatula.

1) The preferred method is to setup the portable field stand in an area where the XRF can be stationed and left in place for the day. Use the Niton software and a laptop computer to setup the method criteria and control the XRF instrument during the soil analysis.
    a) Starting with the previously homogenized sample, use the supplied soil sieves, bowl, and mortar to generate a finely ground well homogenized sample. (Note: This step is not required if the soil sample was passed through a sieve during the homogenization step.)
    b) Transfer the prepared sample into a new sample cup (order replacement supplies from Niton), place the X-ray film over the cup and snap the lid in place. Place the sample cup in the portable field test stand (The XRF points upward, the sample rests on top of the XRF with the X-ray film directly in contact with the nose of the XRF - cup lid facing down).
    c) Using the computer, start the analysis. The source count time should be at least two minutes for chromium. Consult previous analysis to determine if multiple scan frequencies are required (or contact the project chemist).
    d) Prepare the next sample while the XRF is analyzing the current sample.

2) An alternative method to using the portable field stand is to identify the sample for XRF analysis and homogenize the sample (as described above).
   a) Transfer the sample to a re-sealable plastic bag and firmly molded into a flat smooth surface.
   b) Use the Niton software and a laptop computer or the included PDA to setup the method criteria.
   c) To start the analysis, position the nose of the XRF against the flat smooth surface of the sample and squeeze the shutter release (or press the start button on the laptop or PDA). Be sure to maintain constant pressure against the sample. If contact is broken, the analysis will need to be restarted. The source count time for *ex-situ* analysis usually range from one to two minutes, depending on the required detection limits (see *c* above for count times).
   d) After the ex-situ field screening is performed, inspect the nose of the instrument for contamination, which may affect future analysis. If necessary, clean it with a soft cloth or tissue.

3) Transfer the sample to a labeled glass jar for shipment to the confirmation laboratory (if applicable).

Sample Analysis
In today's modern XRF models:

1) An X-ray source is used for detection. Expose the sample to the X-ray source for a minimum of one minute. Longer exposure times may be needed depending on the media that is being analyzed and the required detection levels. The time needed for analysis will be determined in the field by analyzing standards that have concentrations of the metals of concern near the required detection levels. Better detection limits can usually be obtained by homogenizing the sample, increasing the exposure time, and using two or more scan frequencies (Use a minimum of a two minute exposure for Chromium analysis).

2) When the XRF instrument displays the results they include the analyte, the result, and a percent confidence (displayed as a ± value). The result is displayed as non-detect for analytes that do not meet the percent confidence established in the instrument. The lower the required detection levels, the longer the analysis time required to meet the percent confidence.

3) Download saved data from XRF instrument daily (if data is collected in PDA). Foreword the data files to the project chemist daily.

4) All samples collected for off-site confirmation will also be analyzed using the XRF and treated as *ex-situ* samples.

Using older models:

1) Expose the sample to the energy source for a minimum of one minute. Longer exposure times may be needed depending on the media that is being analyzed as well as the age of the detector (non X-ray detectors). The time needed for analysis will be determined in the field by analyzing standards that have concentrations of the metals of concern near the required detection levels. Better detection limits can usually be obtained by homogenizing the sample, increasing the exposure time. (Use a minimum of a two minute exposure for Chromium)

2) When the XRF instrument indicates the results for the suite of analyzed elements and their concentrations, it includes a standard deviation for the reported concentrations. An analyte concentration is considered **not detected** if the result value is **less than two times the standard deviation**. The lower the required detection levels, the longer the analysis time required to reduce the result's standard deviation.

3) Record the readings (electronically or documented on the sampling log). Review the standard deviations for the elements of interest and determine if a longer analysis time is needed to reduce the standard deviations, thereby allowing the desired accuracy and precision for the concentrations. The standards will be analyzed using increasingly longer times until the required detection level is achieved.

4) Record values in field notebooks.

5) Download saved data from XRF instrument daily.

6) Samples collected for off-site confirmation will also be analyzed using the XRF and will be treated as *ex-situ* samples.

Calibration

Two forms of calibration are important with XRF testing: an energy calibration and a sample matrix calibration.

Energy Calibration

The Niton XLi 702 automatically re-calibrates the energy scale when powered on. The energy scale can also be re-calibrated by pressing "Reset" on the instrument. The energy calibration should be performed every two hours.

Sample Matrix Calibration

Modern XRF instruments, such as the Niton Xli 702, do not require site specific calibrations to account for sample matrix effects. EPA Method 6200 allows both fundamental parameters and Compton normalization as two techniques to eliminate site specific calibrations. Niton uses the Compton normalization method to automatically correct for sample specific matrix effects. The XRF is calibrated internally at the factory on NIST standard reference soil samples. Ensure the annual factory calibration certification is on file. This internal calibration is used for subsequent field work, without need for adjustment or recalibration at other sites.

Quality Assurance and Quality Control (Functional Checks)

Even though no onsite calibration will be performed, the method does require QA/QC Functional check testing protocols. The QA/QC that will be used to document that the XRF is operating properly will have the following steps:

- A startup operations check
- Analysis of a blank sample (clean sand)
- Analysis of standard sample(s)
- Analysis of duplicate samples
- QA/QC procedures will be compliant with manufacture's instructions.

1) At the beginning of each day perform QA/QC functional check procedure or when the instrument is turned on after more than 2 hours of down time or if the operating environment changes, such as a temperature change of more than 20 degrees Fahrenheit.
2) Two types of blanks should be analyzed, an instrument blank and a method blank. An instrument blank sample (silicon dioxide, provided by Niton) will be analyzed at the start and end of each day and once every 20 samples, to confirm proper zero calibration of the XRF. The blank will be analyzed following the procedure for the *ex-situ* sample analysis. A method blank is used to monitor for any field induced contamination. The method blank should follow any preparation procedures performed on the samples, such as mixing or *exsitu* analysis. **A method blank will be analyzed each day**.
3) A set of three to ten QC samples will be collected from the site during the initial field activities. These samples will be well homogenized, and a portion sent to the off-site laboratory for characterization. The remaining sample will be collected in re-sealable bags, labeled and stored with the XRF for use as standards. Three to five of the on-site standards will be analyzed at the start of each day. The results of the standards will be plotted against the original XRF results and a correlation value calculated. A correlation coefficient of 0.90 or greater must be achieved to meet the project objectives. A running log of all on-site standards analyzed will be maintained. One of the standards will be analyzed after every 20 samples. The readout from the XRF **must be within 20 percent RPD of the known QC sample concentration**.
4) The last QA/QC step will be to analyze duplicate samples (two separate aliquots) at a rate of 1 in 10. These duplicate measurements must be within 35 percent of each other for the analysis to continue. If the sample results are not in agreement, then the reason for this discrepancy must be determined.
5) The Niton XL3t 600 displays both concentration and precision for each sample analyte measurement. The precision displayed by the Niton's 95% (2-sigma) confidence intervals; where as the precision calculated in EPA method 6200 is at a 68% (1-sigma) level. The Niton also calculates and displays detection limits for analytes if the concentration is below three standard deviations. This bypasses the need for replicate measurements on low level standards.

Note: VOC, SVOC, and other organic samples can not be collected from the homogenized soil if plastic is used for homogenizing or after XRF analysis, if contacted by plastic.

QC	quality control
RCRA	Resource Conservation and Recovery Act
RL	reporting limit
RPD	relative percent difference
RRF	relative response factor
RSD	relative standard deviation
RT	retention time
SAP	sampling and analysis plan
SIM	selected ion monitoring
SOP	standard operating procedure
STLC	soluble threshold limit concentration
SVOC	semivolatile organic compound
TB	trip blank
TCLP	Toxicity Characteristic Leaching Procedure

TDS	total dissolved solids
TKN	total Kjeldahl nitrogen
TOC	total organic carbon
TPH	total petroleum hydrocarbon
TSS	total suspended solids
TTLC	total threshold limit concentration
VOA	volatile organic analysis
VOC	volatile organic compound

SECTION 1
Introduction

This *Pacific Gas and Electric Company Program Quality Assurance Project Plan* (QAPP), Revision 1 was prepared to ensure that data of appropriate quality are collected and used for multiple sites for Pacific Gas and Electric Company (PG&E) projects that CH2M HILL supports. Each project will have a sampling and analysis plan (SAP), this QAPP, and QAPP addenda required to meet the project-specific requirements.

1.1 Background

CH2M HILL has been providing services to PG&E since the 1970s. Currently, CH2M HILL and affiliate companies are working at approximately 35 sites for PG&E. CH2M HILL provides services for the following:

- **Site management.** Projects include soil and groundwater monitoring, site characterization, and remediation design systems.
- **Remediation construction.** Projects include soil excavation, disposal, and treatment system construction.
- **Ecosystems and permitting.** Projects include proponent's environmental assessments, California Environmental Quality Act documentation, and other permitting and planning projects.
- **Engineering design.** Projects include computer-aided design and support and structural analysis.

1.2 Program Objectives

1.2.1 Program Objectives and Scope

This QAPP presents the quality assurance (QA) and quality control (QC) requirements designed to ensure that environmental data collected for the PG&E Program will be of the appropriate quality to achieve the objectives defined in the project-specific SAPs or QAPP addenda, unless otherwise defined. Specific protocols for sampling, sample handling and storage, chain-of-custody (CoC), laboratory analyses, data handling, and data evaluation and assessment are discussed. Requirements for performance evaluations, corrective actions, and preventive maintenance of equipment are specified. The elements included in this QAPP are consistent with those specified in the U.S. Environmental Protection Agency (EPA) *Requirements for Quality Assurance Project Plans, EPA QA/R-5,* March 2001. The objectives of this QAPP are as follows:

- Ensure that data collection and measurement procedures are standardized among all participants.

- Monitor the performance of the various measurement systems within the program to maintain statistical control and provide rapid feedback so that corrective measures, if needed, can be implemented before data quality is compromised.
- Periodically assess the performance of these measurement systems and their components.
- Verify that reported data are sufficiently complete, comparable, representative, unbiased, and precise so that they are suitable for their intended use.

This QAPP is intended for use by CH2M HILL and its subcontractors that provide services associated with the environmental data collection effort. The QAPP supplements all SAPs and any other project-specific documents. The program quality officer and the program chemist are primarily responsible for implementation of this QAPP.

1.2.2 Program QAPP versus SAPs and QAPP Addenda

Elements such as the general description, sources of contamination, information from previous investigations, and proposed investigations are addressed in project or site-specific SAPs or QAPP addenda. The guidance set forth in this QAPP will be followed in the absence of site specific SAPs or QAPP addenda.

1.2.3 Analytical Project Planning

The PG&E Program has a laboratory procurement process, modeled after the Air Force Center for Engineering and the Environment (AFCEE) (formerly the Air Force Center for Environmental Excellence), EPA, the U.S. Navy, and other federal programs. The process balances the program quality, defensible data, and costs. The model has identified three steps in planning the analytical needs of a project:

1. **Determine the requirements.** To determine project-specific requirements, the program chemist should attend kick-off meetings (or equivalent) to understand the project goals and help develop the analytical scope of work.
2. **Determine the laboratory needs and select the laboratory.** Factors influencing the selection of analytical, geotechnical, radiochemistry laboratories include the matrices sampled; laboratory capabilities, recent performance, and location; and price. The program chemist ensures that the laboratory selected is appropriate to meet project objectives. The more information regarding the project objectives given to the chemists, the better chance they have to control liabilities related to analytical work.
3. **Decide what level of data validation is required to provide defensible data at the appropriate level of QC.** See Section 6.3 for descriptions of the data validation process. When a request for proposal is received from PG&E, there is a kickoff meeting of key people, including the project manager, the responsible contract administrator, the program chemist (or sometimes a project-specific chemist), a representative from project delivery, and others, depending on the type of project. Laboratory scope is discussed and a plan is determined that will provide the appropriate analytical services.

1.2.4 Data Quality Objectives

The specific needs for the data collected during each activity will be examined to evaluate whether project objectives for each investigation will be optimally achieved. Specific data quality objectives (DQO) are considered independently through EPA's seven-step DQO process (EPA, 2000). The DQO process includes the following steps:

1. **State the problem.** Concisely describe the problem to be investigated. This determines the need for data collection. Review existing information to define the problem.
2. **Identify the decision**. Identify the decision that will solve the problem by using the data to be collected.
3. **Identify the inputs to the decision**. Identify the information and environmental measurements that are needed to support the decision.
4. **Define the study boundaries**. Specify the times, spatial areas, and other conditions (e.g., target analytes) that determine when and where data should be collected.
5. **Develop a decision rule**. For each decision, define the conditions that would cause the decision maker to choose between alternate actions (the decision rule is usually in the form of an "if…then" statement).
6. **Specify tolerable limits for decision errors**. Define how much uncertainty can be tolerated by the decision maker. Determine the acceptable error rates based on the consequences of making an incorrect decision.
7. **Optimize the design**. Evaluate information from the previous steps and choose the most resource-efficient design for data collection that will support a reliable decision.

SECTION 2

Program Organization and Responsibility

2.1 Program Organization

The PG&E Program management team has been structured with a client service manager, program manager, program quality control manager, program health and safety manger and a program chemist to ensure that the goals of the program are met.

2.2 Project/Task Organization

The organization chart and descriptive text identifying task managers and individuals charged with specific responsibilities for each project can be found in project-specific SAPs. Lines of authority and the scope of authority given to each key member of the project team, including the authority to initiate and approve corrective actions, are discussed in the SAPs. All subcontractors and scopes of work are also identified in the project- or site-specific SAPs.

2.3 Training and Certification Requirements

All personnel engaged in field activities will have completed the Occupational Safety Health Administration, 40-hour health and safety training that meets the requirements of Title 29 Code of Federal Regulations Section 1910.120 and Title 8 Code of California Regulations Section 5192. All CH2M HILL personnel working on the PG&E Program will read applicable project-specific health and safety plans. Documentation will be maintained to demonstrate that all requirements of the plan are followed.

All laboratories contracted for analytical services will be certified under the California Department of Health Environmental Laboratory Accreditation Program, when appropriate and where accreditation is afforded under the California program. No analyses may be performed or reported if accreditation is revoked. Any loss or suspension of accreditation must be communicated to CH2M HILL within 24 hours of notification. Laboratory managers will ensure that all laboratory personnel have been properly trained and are qualified to perform the assigned tasks.

SECTION 3

Sampling Procedures

3.1 Sampling Design

The number and location of samples are specific to each site and are discussed in the project-specific SAPs. The rationale for the sampling design is also described in the SAPs. The sampling design is a function of the medium sampled, information about the sampling site, the type of data to be collected, and how the data are to be used.

Projects with multiple large sampling events should use the field database and provide a planned sample table (PST), CoC forms, and other database-generated paperwork.

The procedures described in the following sections may be superseded or supplemented by the project-specific SAPs or QAPP addenda.

3.2 Sampling Method Requirements

This section addresses the requirements for soil and groundwater sampling. It is meant to provide guidance for projects that do not otherwise require additional documentation to implement field activities. Many projects will require site-specific SOPs because of unique conditions that should be addressed in the project-specific work plan, SAP, QAPP addenda or other project-specific documents. The *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program (CH2M HILL, 2005)* or its update is an excellent source for field SOPs.

3.2.1 Soil Sampling

Sampling locations will be specified in the project-specific SAPs, but the exact locations will be determined in the field based on such factors as accessibility and topography. The exact locations will be recorded in the field logbook or on the field sampling form when sampling is completed. A sketch of the sampling location will be entered into the logbook, if necessary, with reference points labeled including distances to the sampling location.

Soil sampling using decontaminated equipment will be performed as described in the following sections. Each sample container will be closed as soon as it is filled; it will be chilled and processed for shipment to an offsite laboratory to allow laboratory analysis within the applicable holding time.

All soils sample results will be reported in dry weight unless otherwise specified in the SAP.

3.2.1.1 Surface Soil Sampling

Surface soil samples will be collected as grab samples at the depth interval specified in the project-specific SAP for each location. Samples will be collected using a decontaminated stainless steel or nonmetallic hand trowel or equivalent equipment (sampling equipment should be chosen based on the analyte of concern for the specific sample). An EnCore™ sampler, EasyDraw Syringe®, cutoff disposable syringe or equivalent equipment will be used for volatile organic compounds (VOC), as described in Section 3.2.1.4. Samples to be analyzed for VOCs will be collected first. Samples to be analyzed for all other analytes should be placed in a sample-dedicated, 1-gallon, disposable pail or a decontaminated stainless steel bowl. The samples will be homogenized (using the trowel), and transferred to the appropriate containers. To prevent potential contaminant migration from the sample, sample containers will be filled to the top, taking care to prevent soil from remaining in the lid threads prior to being sealed.

3.2.1.2 Subsurface Soil Sampling

Subsurface soil samples will be collected by boring to the depth specified in the project-specific SAP using an appropriately sized hand auger or equivalent equipment. Once the specified depth is reached, the hand auger will be removed, and accumulated soil will be set aside in a sample-dedicated disposable pail or tarp. A different, clean hand auger will be inserted into the hole to collect the sample (decontamination of the boring implement is sufficient if multiple boring implements are not available). Other sampling devices, such as push tubes or split-spoon samplers, may be used. An EnCore™ sampler, EasyDraw Syringe®, cutoff disposable syringe, or equivalent equipment will be used for VOCs, as described below. Samples to be analyzed for VOCs will be collected first. Samples to be analyzed for all other analytes should be placed in a sample-dedicated, 1-gallon, disposable pail or a decontaminated stainless steel bowl. The samples will be homogenized (using the trowel) and transferred to the appropriate containers. To prevent potential contaminant migration from the sample, sample containers will be filled to the top, taking care to prevent soil from remaining in the lid threads prior to being sealed.

3.2.1.3 Confirmation Sampling for Soil Excavation

Confirmation sampling will be performed prior to closure of any excavation. Confirmation samples are usually collected from the bottom and sides of the excavation. The number and type of samples collected should be of sufficient quantity to be representative of the excavated site. The project- or site-specific SAP should address the number, type, and quantity of samples to be collected. All confirmation samples should be analyzed by the analytical methodology specified herein or in the project-specific QAPP addendum (collection of soil samples for determination of VOCs shall be in accordance with Section 3.2.1.4.). Field or laboratory screening data should not be used to verify that contamination has been removed below project action levels unless specifically approved by the overseeing regulatory agency.

3.2.1.4 Soil Sampling for Volatile Organic Compounds

Guidelines for collecting soil samples for VOC analysis are provided in Method SW5035A. These sampling techniques are applicable to analysis by methods SW8260B, SW8021, and SW8015B (volatile parameters). Sampling for VOCs may be accomplished by using an EasyDraw Syringe®, an EnCore™ sampler, a cutoff plastic syringe, or any equivalent sampling device.

VOC samples will be frozen or chilled in the field. If, chilled to 4 degrees Celsius (°C) (±2°C) the samples should be shipped by overnight express delivery the same day they are collected. If frozen, appropriate measures should be taken to ensure that frozen samples remain frozen until receipt by the laboratory. If samples remain frozen, the laboratory has 14 days from date of collection to analyze the samples. If samples thaw to temperatures higher than 4°C (±2°C), they must be analyzed within 48 hours of collection. If the temperature does not exceed 4°C (±2°C), the laboratory may (1) freeze the samples between -7 and -20ºC within 48 hours of collection and keep them frozen or (2) preserve them in sodium bisulfate or methanol within 48 hours of collection. Either of these procedures will extend the holding time to 14 days.

Sampling Using Cutoff Syringe. A disposable syringe capable of measuring 1 to 5 milliliters (ml) (±0.5 ml) is required. Calibration in the field will be needed for the specific soil type and the type of syringe to determine the proper setting on the syringe to collect the samples. For example, the plunger is set to 5 ml, and the sample is collected and weighed; if 5 grams (±0.5 gram) are not obtained, the process is repeated until the correct plunger setting is identified. The same procedure is repeated for the 1-gram sample. Once the volume setting is identified, all soils of similar type will be collected at this volume. Samples can be collected with or without field preservation. When field preservation is chosen, the samples are collected into vials pre-preserved with methanol or sodium bisulfate. Otherwise, samples can be collected into vials without preservative, and preservation can be performed by the laboratory upon receipt of the samples.

Sampling with EnCore™ Sampler or EasyDraw Syringe®. The sample is collected into the EnCore™ or equivalent sampler following the manufacturer's instructions. A minimum of three samples will be collected. Two aliquots are needed for low-level analysis and reanalysis if necessary. The third aliquot is needed for extraction in methanol by the laboratory in case high-concentration analysis is indicated. Exposure to air must be minimized.

Sampling with Field Preservation. Before using this option, determine if the soil is amenable to the sodium bisulfate preservative. Soil samples that contain carbonate minerals may effervesce upon contact with the preservative. If the amount of gas generated is small (little if any effervescence with the preservative), field preservation may be used. If rapid or vigorous gas generation is observed, the sample should be collected without field preservation. If the sample is amenable to field preservation, it is collected using one of the methods listed above and quickly transferred into a VOC vial with preservative. The vial should be quickly sealed to avoid significant loss of volatiles components. The laboratory will supply a minimum of three preweighed VOC vials with 5 ml of aqueous sodium bisulfate preservative as described in Method SW5035, as well as a single preweighed VOC vial without the preservative for each sample to be analyzed for VOCs. Two 5-gram aliquots in bisulfate are required for low-concentration analysis and reanalysis, when necessary. One 5-gram aliquot without sodium bisulfate is required for extraction in methanol by the laboratory in case high-concentration analysis is indicated by a low-concentration or screening analysis of the sample. One 1-gram sample in bisulfate is needed because the possibility exists that neither the 5-gram sample intended for low-concentration analysis, nor the 5-gram sample intended for high-concentration analysis, will have all target analyte concentrations within the calibration range. Exposure of the sample to air must be minimized.

If VOC analyses are the only analyses being performed for samples collected from any location; an additional 2- or 4-ounce soil sample must also be collected to analyze for percent moisture.

Sampling without Field Preservation. The samples will be collected using one of the methods listed above and quickly transferred into a minimum of three preweighed, vials without preservative supplied by the laboratory. These preweighed vials may be empty, they may contain reagent water, or they may be preserved with methanol, depending on whether the contaminant concentration is at low- or high-level concentration. Two 5-gram aliquots are needed for low-concentration analysis and reanalysis, when necessary. In addition, one 5-gram aliquot is required for extraction in methanol by the laboratory in case high-concentration analysis is indicated by a low-concentration or screening analysis of the sample. One 1-gram sample is also recommended because the possibility exists that neither the 5-gram sample intended for low-concentration analysis, nor the 5-gram sample intended for high-concentration analysis, will have all target analyte concentrations within the calibration range. Exposure of the sample to air must be minimized. Freezing the samples between -7 and -20° C within 48 hours and keeping them frozen until analysis allows a 14-day holding time.

If VOC analyses are the only analyses being performed for samples collected from any location; an additional 2- or 4-ounce soil sample must also be collected to analyze for percent moisture.

3.2.2 Groundwater Sampling

3.2.2.1 Water Level Measurement

Field meter probes and water level sounding equipment will be decontaminated before and after each use at each well. Water levels in wells that are known or suspected to be least contaminated will be measured first. Water levels in wells that are known or suspected to have the highest contamination will be measured last.

If well heads are accessible, all wells will be sounded from the top of the casing to determine the depth to water and total well depth prior to purging. An electronic sounder, accurate to ±0.01 foot, will be used to measure depth to water in each well. Annual calibration documentation shall be maintained on file. The serial number of the meters shall be recorded in the sampling logbook. When using an electronic sounder, the probe will be lowered down the casing to the top of the water column, and the graduated markings on the probe wire or tape will be used to measure the depth to water from the surveyed point on the rim of the well casing. (Typically, the measuring device emits a constant tone when the probe is submerged in standing water. Most electronic level sounders have a visual indicator consisting of a small light bulb or diode that turns on when the probe encounters water.) The total well depth will be sounded from the surveyed top of the casing by lowering the weighted probe to the bottom of the well. The weighted probe will sink into silt, if present, at the bottom of the well screen. The total well depth will be measured by recording the depth to the nearest 0.1 foot.

3.2.2.2 Field Calibration

Field equipment will be calibrated before the start of work and recorded in the field notebook or daily calibration log. Any instrument drift from prior calibration should be noted. Calibration will be in accordance with procedures and schedules in the particular instrument's operations manual.

Calibrated equipment will be uniquely identified by using the manufacturer's serial number or other means. A label with the identification number and the date when the next calibration is due (scheduled calibrations) will be physically attached to the equipment. If this is not possible, records traceable to the equipment (e.g., showing the equipment identification) will be readily available for reference. In addition, instrument identifications and the results of calibrations and records of repairs will be recorded in the logbook or daily calibration log.

Scheduled periodic calibration of testing equipment does not relieve field personnel of the responsibility of using properly functioning equipment. If equipment malfunction is suspected, the device shall be removed from service, tagged so that it is not inadvertently used, and the appropriate personnel notified so that a recalibration can be performed or substitute equipment can be obtained.

Equipment that fails calibration or becomes inoperable during use will be removed from service and either segregated to prevent inadvertent use or tagged to indicate it is out of calibration. Such equipment will be repaired and satisfactorily recalibrated. Equipment that cannot be repaired will be replaced.

3.2.2.3 Well Purging

All wells will be purged prior to sampling. All equipment that will contact the sample during purging and sampling will be decontaminated prior to each use.

Low-flow Purge. One option for well sampling is low-stress (low-flow) purging using a pump capable of a purge rate of 1 liter per minute or less. Typically, a pneumatic or small electric submersible pump is used. The water level should be monitored approximately every 5 minutes. The flow rate should be started at the minimum flow capacity of the pump, then gradually increased until initial drawdown is observed. The flow rate should then be reduced slightly to achieve a stabilized pumping level. This reduced rate should become the maximum purge rate for the well. Each adjustment to the flow rate and the water level measured after each adjustment should be recorded. The flow rate should not exceed 1 liter per minute. Care should be taken to maintain pump suction and avoid entrapment of air in the tubing.

Casing Volume Purge. Another option for well sampling is three casing volume (macro-purging) using a pump capable of purging 1 to 5 gallons per minute, usually an electrical submersible pump. Purging will be conducted at a flow rate sufficient to remove water from the entire screened interval of the well. However, the purge rate should not result in substantial drawdown, which is defined as 5 percent of the water column or the top of the screened interval. Purging will consist of the removal of a minimum of three casing volumes of water.

For low-yield wells (wells that exhibit less than 80 percent recovery [%R], within 2 hours), one casing volume of water shall be removed. If pump capability allows, the well will be purged at a rate of less than 1 gallon per minute. The well will then be allowed to recover to 80 percent and sampled within 24 hours of purging.

Water Quality Parameter Stabilization. To ensure representative sampling, water quality parameters (dissolved oxygen, pH, redox potential, specific conductance, and turbidity) must be stable before samples are collected, regardless of purge technique. Parameters will be measured approximately every 3 to 5 minutes, depending on the rate and duration of the purge. Purging is considered complete when the following water quality parameters are stable (i.e., for three consecutive readings):

- The pH varies by no more than 0.1 pH unit.
- Specific conductance readings are within 10 percent of the average.
- The redox potential varies by no more than 10 millivolts.
- The dissolved oxygen readings are within 10 percent of the average.

The water used to make measurements will not be used to fill sample bottles.

If the macro-purge technique is used, three casing volume well purges must be complete **and** the water quality parameters must be stable before the sample is collected. The total amount of water purged will be recorded in the field logbook or well-specific purge and sample collection form.

Grab-sample Collection. In some instances, it is appropriate to collect a grab sample from a monitoring well. For example, when a low-yield well has been purged and allowed to recharge. A bailer can be used to collect the sample without additional purge, eliminating the need to deploy a well pump for sample collection.

If a bailer is used to collect samples, a sufficient volume of water must be collected to fill the sample bottles and perform one measurement of water quality parameters. The water quality parameters will be recorded in the field logbook or well-specific purge and sample collection form.

3.2.2.4 Well Sampling

Prior to sampling each well, the water level will be measured and the well purged, as previously described. All wells will be sampled within 24 hours of purging. Wells without a dedicated pump will be sampled using a bailer of appropriate material, such as Teflon or stainless steel. Wells with a dedicated pump will be sampled directly from the tap closest to the well head. All aerators, strainers, and hoses will be removed from the tap prior to sample collection. The flow will be adjusted so that a gentle stream is obtained. To minimize volatilization, a flow rate of less than 100 milliliters per minute is recommended for samples to be analyzed for VOCs.

At each sampling location, sample bottles designated for a particular analysis will be filled sequentially before bottles designated for other analyses are filled. Vials for VOCs will be filled first to minimize aeration of water in the well. All vials for VOCs will be provided, pre-preserved by the subcontract laboratory. The vials will be filled directly from the tap. Each vial will be inverted and checked for air bubbles and checked for headspace. If a pea-size or larger air bubble appears, the cap can be removed and additional sample added to eliminate the air space. If there is any likelihood of contamination being introduced into the sample, the vial contents will be emptied into the container used to measure purge volumes, the vial discarded, and a new sample collected in a new vial.

If a duplicate sample is to be collected, all sample bottles designated for a particular analysis for both duplicates will be filled sequentially before bottles for another analysis are filled. For example, duplicate samples will be collected sequentially for semivolatile organic compounds (SVOC), followed by duplicate samples collected sequentially for metals. EPA recommends the following collection order:

1. Volatile organic compounds and total organic compounds
2. Dissolved gasses and total organic carbon
3. Semivolatile compounds – Acid/Base extractables, pesticides, and PCBs
4. Metals and general chemistry
5. Radionuclides

It is considered good management practice to plan sample collection from the least to the most contaminated area of the site to decrease the risk of cross contamination (assuming no other factors that drive the priority of sampling location order).

Groundwater samples will be transferred from the bailer, tap, or pump tubing directly into the appropriate pre-preserved sample containers, if required. When transferring samples, care must be taken not to touch any nondedicated equipment to the sample container. The containers will be chilled and processed for shipment to the laboratory.

3.3 Equipment Decontamination

Sampling equipment must be consistently decontaminated to ensure the quality of the samples collected. All equipment that comes into contact with potentially contaminated soil or water samples will be decontaminated. Disposable equipment intended for one use will not be decontaminated but will be packaged for appropriate disposal. In addition, equipment that is dedicated for repeated use at only one location does not need to be decontaminated. Equipment decontamination will occur prior to each use.

The following decontamination sequence is recommended:

1. Nonphosphate detergent and tap water wash, using a brush if necessary

2. Tap water rinse

3. Two rinses with deionized/distilled water

4. Organic-free water rinse (high-performance liquid chromatography grade) for organic samples

Large and bulky sampling equipment might need to be steam cleaned. Equipment will be decontaminated in a predesignated area on pallets or plastic sheeting. The cleaned equipment will be wrapped or covered to prevent contamination and stored in an uncontaminated area.

3.4 Disposal of Investigation-derived Wastes

The disposal of investigation-derived waste (IDW) should be addressed in the project-specific SAP. Each project or task can have different IDW disposal requirements, depending on site-specific conditions and the work performed. The following potentially contaminated IDW might be generated during field activities:

- **Used personal protective equipment (PPE) and disposable equipment.** Used PPE will be double-bagged and placed in a municipal refuse dumpster onsite. PPE and disposable equipment that is still serviceable will be rendered unusable before disposal into the dumpster.
- **Decontamination fluids.** Decontamination fluids include dilute nitric acid, deionized water, residual contaminants, and water with nonphosphate detergent. These fluids will be collected and disposed of in accordance with site requirements and applicable regulatory requirements
- **Soil cuttings.** Soil cuttings generated during subsurface sampling will be collected and disposed of in accordance with site requirements and applicable regulatory requirements.
- **Purged groundwater and excess groundwater collected for sample container filling.** These wastes will be collected and disposed of in accordance with site requirements and applicable regulatory requirements.

Each project SAP should address IDW. Any samples collected for waste characterization should include IDW in the sample identifier (ID).

3.5 Field Quality Control Samples

QC samples will be collected to monitor accuracy, precision, and the potential presence of field contamination for analytical methods to be performed in the offsite laboratory. All field QC samples, except matrix spike/matrix spike duplicates (MS/MSD), will be sent double-blind to the laboratory along with regular field samples. These double-blind samples will be labeled similar to regular field samples to disguise them. Sampling frequencies may vary according to the project needs, as defined in the project-specific SAP or QAPP addendum. The recommended frequency of collection for QC samples is discussed in the following sections and should be reviewed and updated to achieve project-specific DQOs.

3.5.1 Field Duplicate Samples

A field duplicate (FD) is an independent sample collected as close as possible to the original sample, from the same source, and under identical conditions. FDs are used to document sampling and analytical precision. FDs will be collected at a minimum frequency of 10 percent or one per sampling event, whichever is more frequent, for each matrix and type of analysis. The sampling procedures described in Section 3.2 will be followed. The sampling locations for FD samples will be recorded in the field logbook or field sampling form, or both.

3.5.2 Equipment Blanks

Equipment blanks (EB) will be collected to evaluate field sampling and decontamination procedures by pouring deionized water over the decontaminated equipment. EBs will be collected at a frequency of one EB per day for each nondedicated equipment type per sampling team. EBs will be analyzed in the offsite laboratory for the same parameters specified for the corresponding matrix or for the main contaminate of potential concern (COPC).

3.5.3 Field Blanks

Field blanks (FB) (also known as ambient blanks [AB]) are collected to evaluate (or to monitor) whether contaminants have been introduced during sampling. FBs will be collected by pouring deionized water (or organic free water for organic samples) into a sample container at the sampling location and leaving the sample exposed to the atmosphere for a minimum of 30 minutes. FBs will be collected at a frequency of one per location that warrants concern because of environmental conditions or project-specific QC concerns, as determined by the project chemist or project manager. Generally, FBs need to be collected if the analyte concentrations are high enough to allow mobile contaminants to affect the sample results. FB will be analyzed for the same parameters specified for the associated samples.

3.5.4 Trip Blanks

Trip blanks (TB) are used to monitor contamination during sample shipping and handling and for cross contamination through VOC migration among the collected samples. They are prepared in the laboratory by pouring American Society for Testing and Materials (ASTM) Type II or organic-free water into a VOC sample container. They are then sealed, transported to the field, stay sealed while VOC samples are taken, and transported back to the laboratory in the same cooler as the VOC samples. One TB should accompany each VOC sample cooler.

3.5.5 Matrix Spike/Matrix Spike Duplicate

A MS/MSD consists of duplicate field sample aliquots spiked by the laboratory with analytes of concern to evaluate the effects of the matrix on the recoveries of these analytes. For every 20 field samples of each matrix collected at each site, additional duplicate aliquots of one of the samples should be collected for each analysis and designated on the CoC form for use as an MS/MSD by the laboratory. Separate line entries are not required for matrix spikes. The increased number of sample containers should be noted. The duplicate aliquots for MS/MSD analyses should be collected simultaneously or in immediate succession with the parent sample. They will be treated in exactly the same manner as the parent sample during storage and shipment. The sampling locations for the MS/MSD will be documented in the field logbook or the field sampling form, or both if the MS/MSD are specifically requested by the project; if not, document the extra volume on the CoC and in the field logbook or on the field sampling form.

3.5.6 Split Samples

Split samples may be collected periodically for comparison of data between analytical laboratories. A split sample is collected from a thoroughly homogenized original sample and is used to document analytical precision. Split samples will be collected for each matrix and for each analytical method, except those for volatiles when project objectives dictate the need. The sampling procedures described in Section 3.2 or those described in the project- or site-specific SAPs or QAPP addenda will be followed. The sampling locations will be recorded in the field logbook or field sampling form, or both. Split samples will be sent to a second certified laboratory, and results will be compared with those from the primary laboratory.

3.6 Sample Documentation and Tracking

Projects with large sampling events should take advantage of the field database to provide a PST, CoCs, and sample container labels. The use of Mobil Integrated Sample Tracking (MIST) and the field database are recommended.

Prelabeled, pre-preserved sample containers should be received from the laboratory. The laboratory labeling must indicate the type of preservative in the container. The sample ID, date, and time of sampling are recorded on the label immediately prior to collection. The labels must be secured using clear tape to protect the label. Double bagging the ice used in shipping containers and using laser printed labels and indelible ink pens to complete sample labels will ensure that the samples arrival at the laboratory dry and appropriately marked. Vital information regarding the collection of each sample will be recorded in a field logbook, field sampling form, and CoC form.

A separate logbook will be used for each project. It will be bound with consecutively numbered pages. All entries will be legibly written in black ink and signed and dated by the individual making the entries. Factual and objective language will be used. All entries will be complete and accurate to allow reconstruction of each field activity. A line will be placed through any portion of a field notebook that is unused. One line strike-through will be used to show corrections to entries. The strike-through will be initialed and dated. No correction fluid will be used. The following information for each sample will be recorded in the field logbook, field sampling form, or CoC form, whichever is appropriate:

- Sampling location and description (sketch and measured distances from reference points will be recorded if there is no established identification for the sample location)
- Sample ID
- Sampler's name
- Date and time of sampling
- Sample designation as composite or grab
- Sample matrix
- Type and ID of sampling equipment

- Field measurement data (e.g., pH, temperature, conductivity)
- Field observations that may be relevant to the analysis or sample integrity (e.g., odor, color, and weather conditions)
- Associated QC blanks
- Preservative used
- CoC form number, custody seal number, and lot numbers of sample containers (when appropriate)
- Shipping details (if the laboratory is providing courier service, the courier must sign and date the CoC forms; copies of the signed CoC forms should be transmitted to the office as soon as practical; if FedEx, UPS, or other courier is used, include shipping information for each shipment)
- Destination laboratory

SECTION 4

Sample Handling and Custody

4.1 Containers and Preservatives

The contracted analytical laboratory will provide the required sample containers for all samples including QC samples. All containers will have been cleaned and certified free of the analytes of concern for this project. No sample containers will be reused. The contracted laboratory will add preservatives, if required, prior to shipping the sample containers to the field or supply the preservative as appropriate. The laboratory, upon receipt of the samples, will verify and record the adequacy of preservation and will add additional preservative, if necessary. For VOCs, the sample label or CoC will indicate the presence of preservative and the laboratory will verify and record the pH after the analysis. The containers, minimum sample quantities, required preservatives, and maximum holding times for many parameters are shown in Table 4-1 (tables appear at the end of the section in which they are first referenced). The project- or site-specific SAP or QAPP addendum will contain the specific containers required for each project.

4.2 Chain-of-Custody

Collecting data of known quality begins at the point of sample collection. Legally defensible data are generated by using proven evidentiary procedures. These procedures are described in the following sections and must be followed to preserve and ensure the integrity of all samples from the time of collection through analysis. Sample custody records must be maintained in the field office (if there is a field office) and subcontractor laboratory. A sample is considered to be in custody if it is either in physical possession or view, locked up, or kept in a secured and restricted area. Until the samples are shipped, custody will be the responsibility of the sampling team leader.

CoC forms document sample collection and shipment to the laboratory. A CoC form will be completed for each sampling event. The original copy will be provided to the laboratory with the sample shipping cooler, and a copy will be retained in the field documentation files. The CoC form will identify the contents of each shipment and maintain the custodial integrity of the samples. All CoC forms will be signed and dated by the responsible sampling team personnel, as applicable. The "Relinquished By" field will be signed by the responsible sampling team personnel, with the date, time, and air bill number noted on the CoC form. The laboratory will provide a PDF copy of the CoC forms, with the sample login information included, within 48 hours of sample receipt. The laboratory will also include the original or a copy with the final hardcopy report (the final "hardcopy" can be in a paper or PDF format or both, depending on project-specific requirements).

A self-adhesive custody seal will be placed across the lid of each sample to maintain its integrity until the laboratory opens it. The shipping coolers containing the samples will be sealed with a custody seal any time they are not in an individual's possession or view before shipping. All custody seals will be signed and dated by the responsible sampling team personnel.

At a minimum, the CoC form must include the following information:

- Project information such as project number or identification of investigation monitoring program, Project Manager, etc.
- Unique sample ID
- Date and time of sample collection
- Source of sample (including name, location, sample type, and matrix)
- Number of containers
- Designation of MS/MSD (if applicable)
- Preservative used
- Analyses required
- Name of sampler
- Custody transfer signatures, dates, and times of sample transfers from the field to transporters and to the laboratories
- Bill of lading or transporter tracking number (if applicable)

4.3 Laboratory Responsibilities

After the samples reach the laboratory, they shall be checked against information on the CoC form for anomalies. The condition, temperature, and appropriate preservation of samples shall be checked and documented on the CoC form or a sample receipt checklist. Checking an aliquot of each sample container, at the time of receipt, using litmus paper is an acceptable procedure to determine the pH of all sample containers received, except VOCs. The pH check should be conducted in the sample receiving area or in the appropriate laboratory department. Samples for VOC analysis require that the pH check be performed after the vial has been opened for analysis; the pH shall be recorded at the time of analysis in the department log books. Anomalies in the received samples and their resolution shall be documented in laboratory records and summarized in the final analytical report case narrative. All sample information shall then be entered into a tracking system, and unique analytical sample IDs shall be assigned. A copy of this information shall be reviewed by the laboratory for accuracy. Sample holding time tracking begins with the collection of samples and continues until the analysis is complete.

Samples not preserved or analyzed in accordance with the requirements in this QAPP or the project-specific SAP or QAPP addendum shall be resampled and analyzed at no additional cost to CH2M HILL. Any subcontracted analyses shall be documented on a CoC form by the laboratory and noted in the case narrative. Internal laboratory CoC procedures shall also be documented and implemented by the laboratory. Sample custody within the laboratory will, at a minimum, include storage of samples in a secure, restricted access area when not in use; samples must be checked out and checked back in by the analysts who use them. Internal custody records must be maintained by the laboratory as part of the documentation file for each sample. Specific instructions concerning the analysis specified for each sample shall be communicated to the analysts. Analytical batches shall be created, and laboratory QC samples shall be introduced into each batch.

While in the laboratory; samples shall be stored in limited-access, temperature-controlled areas. Refrigerators, coolers, and freezers shall be monitored for temperature 7 days a week. Acceptance criterion for the temperatures of the refrigerators and coolers is 4°C ±2°C. Acceptance criterion for the temperatures of the freezers shall be between -7°C and -20°C. All of the cold-storage areas shall be monitored by using thermometers that have been calibrated with a National Institute of Standards and Technology approved traceable thermometer. As indicated by the calibration results, correction factors shall be applied to each thermometer.

Records that include acceptance criteria shall be maintained. Samples for volatile organics analysis shall be stored separately from other samples, standards, and sample extracts. Samples shall be stored after analysis until disposed of in accordance with applicable local, state, and federal regulations. Disposal records shall be maintained by the laboratory.

The following information shall be documented on the CoC form, the sample receipt form, or the sample login form (or on more than one of these forms, as applicable):

- Date samples received
- CH2M HILL sample ID
- Laboratory sample ID
- Analytical tests requested for the sample batch
- Sample matrix
- Number of samples in the batch
- Container description and location in the laboratory
- Verification of sample preservation

All of the information must be retained and traceable in the laboratory sample tracking system, with summary information provided in the analytical reports.

Standard operating procedures (SOP) describing sample control and custody shall be maintained by the laboratory.

4.4 Sample Packaging and Transport

The following sections provide guidelines for sample packaging and transport that may be superceded, amended, or replaced in the project- or site-specific SAPs or QAPP addenda.

4.4.1 Sample Container Preparation

The following procedures shall be implemented:

- Labels will be secured to each container with clear tape, if not previously done.

- Container lids will be checked for tightness; if the container is not full, the outside of the container will be marked with indelible ink to indicate the sample volume level.
- Sample bottles will be double-bagged in heavy-duty plastic. Glass sample containers will be covered with bubble wrap to prevent breakage.

4.4.2 Shipping Cooler Preparation

The following procedures shall be implemented:

- All previous labels and broken custody seals used on the sample shipping cooler will be removed.
- Drain plugs will be sealed with fiberglass or similar tape (outside and inside) to prevent melting ice from leaking.
- A cushioning layer of packing material, such as bubble wrap (approximately 1 inch thick), will be placed at the bottom of the cooler to prevent breakage during shipment.
- The cooler will be lined with a large plastic bag (same type used to contain samples).
- All ice will be double-bagged in zip-lock plastic bags.

4.4.3 Placing Samples in the Cooler

The following procedures shall be implemented:

- The CoC form will be placed in a zip-lock bag and taped inside the top of the cooler if shipment is to be made through commercial carrier.
- Samples will be placed in an upright position in the cooler.
- Ice will be placed on top of samples and between samples. Ideally, ice will be placed in resealable plastic bags in duplicate to minimize leakage of ice melt into the cooler.
- Void space between samples should be filled with packing material or ice packs (vermiculite is not acceptable packing material unless required by DOT).

4.4.4 Closing the Cooler

The following procedures shall be implemented:

- The cooler lid will be taped with strapping tape, encircling the cooler several times.
- Custody seals may also be affixed to the cooler lid to further ensure the integrity of the samples. Custody seals should be initialed and dated.

4.4.5 Transport

Sample coolers will be transported to the laboratory immediately after sample collection. An overnight courier may be used to transport the samples. Intermediate stops should be avoided, except for emergencies, in which case, the situation should be noted in the field notebooks. The laboratory should be notified that samples are being shipped.

TABLE 4-1
Sample Containers, Preservation, and Holding Times
PG&E Program Quality Assurance Project Plan

		Container and Minimum Quantity			
Analyte	**Method**	**Water**	**Soil/Sediment**	**Preservation**	**Holding Time**
Metals (except hexavalent chromium)	SW6010B, SW6020A, EPA200.7, EPA200.8, SM3120B, EPA245.1, SW7000 series methods	1-liter P or G	8-oz/P, G, or T	Water: Add HNO_3 to pH<2; soil/sediment: None	28 days for mercury; 180 days for all others
Hexavalent Chromium	SW7196A	250-ml P or G	4-oz/P, G, or T	Water/Soil: Chill to 4°C (±2°C)	Water: 24 hours
Hexavalent Chromium	SW7199	250-ml P or G	4-oz/P, G, or T	Water: Chill to 4°C (±2°C). Laboratory or field filtration. After filtration adjust the pH to 9–9.5 by adding $(NH_4)_2SO_4$/ NH_4OH buffer solution Soil/sediment: Chill to 4°C (±2°C)	Water: 24 hours Soil: 30 days to extraction, 7 days to analysis
Hexavalent Chromium	EPA218.6	250-ml P	Not applicable	chill to ≤6°C Laboratory or field filtration within 24 hours. After filtration adjust the pH to 9–9.5 by adding $(NH_4)_2SO_4$/ NH_4OH buffer solution	28 days
Hexavalent Chromium	SM3500-Cr B	250-ml P	Not applicable	chill to ≤6°C Laboratory or field filtration within 24 hours. After filtration adjust the pH to 9–9.5 by adding $(NH_4)_2SO_4$/ NH_4OH buffer solution	28 days
Purgeable TPH	SW8015B Preparation methods: SW5035B (soil) SW5030B (water)	Three 40-ml G-TLC	4 EnCore™ samplers or equivalent (see Section 3.2.1.4)	Water: Add HCl to pH<2; chill to 4°C (±2°C) Soil/sediment: Chill to 4°C (±2°C)	Water: 14 days (preserved); 7 days (unpreserved) Soil: 48 hours if only cooled to 4ºC; 48 hours by Encore™ or equivalent sampler unless extruded and preserved within 48 hours
BTEX	SW8021	Three 40-ml G-TLC	4 EnCore™ samplers or equivalent (see Section 3.2.1.4)		14 days if solid samples preserved by: • 4ºC/frozen in 48 hours • Frozen onsite • Sodium bisulfate • Methanol

TABLE 4-1
Sample Containers, Preservation, and Holding Times
PG&E Program Quality Assurance Project Plan

Analyte	Method	Container and Minimum Quantity		Preservation	Holding Time
		Water	Soil/Sediment		
Extractable TPH	SW8015B	Two 1-liter G	8-oz/G or T	Chill to 4°C (±2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis
Pesticides	SW8081A	Two 1-liter G	8-oz/ G or T	Chill to 4°C (±2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis
PCB	SW8082	Two 1-liter G	8-oz/ G or T	Chill to 4°C (±2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis
VOCs	SW8260B Preparation methods: SW5035B (Soil) SW5030B (Water)	Three 40-ml G-TLC	4 EnCore™ samplers or equivalent; see Section 3.2.1.4	Water: Add HCl to pH<2; chill to 4°C (±2°C) Soil/sediment: Chill to 4°C (±2°C)	Water: 14 days (preserved); 7 days (unpreserved) Soil: 48 hours if only cooled to 4ºC 48 hours by Encore™ or equivalent sampler unless extruded and preserved with 48 hours 14 days if solid samples preserved by the following methods: • 4ºC/frozen in 48 hours • Frozen onsite • Sodium bisulfate • Methanol
SVOC	SW8270C	Two 1-liter G	8-oz G or T	Chill to 4°C (±2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis
Herbicides	SW8151A	Two 1-liter G	8-oz G or T	Chill to 4°C (± 2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis

Gross Alpha	SM7110C	500 ml P or G		Add HNO_3 to pH<2	6 months
Gross Beta	E900.0	500-ml P or G		Add HNO_3 to pH<2	6 months
Radium-226	E903.1	500-ml P or G	4-oz P, G, or T	Add HNO_3 to pH<2; soil/sediment: None	6 months
Radium-228	E904.0	500-ml P or G	4-oz P, G, or T	Add HNO_3 to pH<2; soil/sediment: None	6 months
Strontium	E905.0	500-ml P or G	4-oz P, G, or T	Add HNO_3 to pH<2; soil/sediment: None	6 months
Tritium	E906.0	500-ml P or G	4-oz P, G, or T	Add HNO_3 to pH<2; soil/sediment: None	6 months
Uranium	R908.0	500-ml P or G	4-oz P, G, or T	Add HNO_3 to pH<2; soil/sediment: None	6 months

TABLE 4-1
Sample Containers, Preservation, and Holding Times
PG&E Program Quality Assurance Project Plan

		Container and Minimum Quantity			
Analyte	**Method**	**Water**	**Soil/Sediment**	**Preservation**	**Holding Time**

Notes:

> = greater than

< = less than

≤ = less than or equal to

BTEX = benzene, toluene, ethylbenzene, and xylene

CF-IRMS = continuous-flow isotope ratio mass spectrometry

DOC = dissolved organic compounds

G = glass

G-TLC = glass with teflon-lined cap

H_2PO_4 = phosphoric acid

H_2SO_4 = sulfuric acid

HCl = hydrochloric acid

HNO_3 = nitric acid

NaOH = sodium hydroxide

NH_4 = ammonium

NH_4OH = ammonium hydroxide

$(NH_4)_2SO_4$ = ammonium sulfate

oz = ounce

P = polyethylene

PCB = polychlorinated biphenyls

PNA = polynuclear aromatic hydrocarbons

SIM = selected ion monitoring

SO_4 = sulfate

T = brass sleeves in the sample barrel (sometimes called California brass)

TDS = total dissolved solids

TKN = total kjeldahl nitrogen

TLC = teflon lined closure

TOC = total organic compounds

TPH = total petroleum hydrocarbons

TSS = total suspended solids

SECTION 5

Data Quality Objectives and Quality Assurance Program

The DQOs for each individual project are specified in the project-specific work plan or SAP. DQOs are the basis for the design of the data collection plan; they specify the type, quality, and quantity of data to be collected and how the data are to be used to make the appropriate decisions for the project. The final output of the process is a data collection design that meets the qualitative and quantitative needs of the project.

5.1 Data Categories

Both screening and definitive data may be generated. Screening data are generated by rapid analytical methods, and calibration and QC requirements are less rigid than those required for definitive data. Quantitation from a screening method is usually imprecise. Definitive data are generated by rigorous analytical methods using standardized calibration and QC and are reported on specified deliverables. The data are analyte-specific, and both identification and quantitation are confirmed.

In general, screening data will be confirmed by definitive data for use in decision making for this program. However, screening data may be used for decision making purposes on a project-specific basis, depending upon the DQOs. The project-specific documents will describe the advantages of collecting screening data that might be less precise but will more adequately define the characteristics of the site by increasing the number of samples collected. This approach can reduce overall error in the data collection process.

5.2 Precision, Accuracy, Representativeness, Completeness, and Comparability

Data quality will be evaluated for precision, accuracy, representativeness, completeness, and comparability (PARCC). Both definitive and screening data will be subject to PARCC requirements. PARCC objectives for screening methods may be identical to those for definitive data, or they may be less stringent depending on the project-specific objectives. Sampling frequencies may vary according to the project needs, as defined in the project-specific SAPs or QAPP addenda.

5.2.1 Precision

Precision is a measure of reproducibility of analytical results. It can be defined as the degree of mutual agreement among individual measurements obtained under similar conditions. Total precision is a function of the variability associated with both sampling and analysis. Precision will be evaluated as the relative percent difference (RPD) between field duplicate sample results or between the MS and MSD results. Field duplicates will comprise

10 percent of the sampling effort. MS/MSD samples will be analyzed at a 5-percent frequency. The MS/MSD samples will be field designated, if so required by project specific requirements. Laboratory-generated precision control limits can be used for data evaluation; however, all precision control limits listed in Tables 5-2A through 5-27 must be met.

5.2.2 Accuracy

Accuracy is the degree of agreement between a measured value and the “true” or expected value. It represents an estimate of total error from a single measurement, including both systematic error, or bias, and random error that may reflect variability due to imprecision. Accuracy is evaluated in terms of percent recovery (%R) determined from results of MS/MSD and laboratory control sample (LCS) analyses. Surrogate recoveries from samples analyzed for organic parameters are also used to assess accuracy. Laboratory-generated accuracy control limits can be used for data evaluation; however, the accuracy control limits listed in Tables 5-2A through 5-27 must be met.

5.2.3 Representativeness

Representativeness is the degree to which sample data accurately reflect the characteristics of a population of samples. It is achieved through a well-designed sampling program and by using standardized sampling strategies and techniques and analytical procedures. Factors that can affect representativeness include site homogeneity, sample homogeneity at a single point, and available information around which the sampling program is designed. Using multiple methods to measure an analyte can also result in nonrepresentative sample data.

5.2.4 Completeness

Completeness is the number of valid measurements compared with the total number of measurements generated. Completeness will be determined for each method, matrix, and analyte combination. The completeness goals of each project are optimized to meet the DQOs. The goals for this program are 95 percent for aqueous samples and 90 percent for soil samples.

5.2.5 Comparability

Comparability is the confidence with which one data set can be compared to another. It is achieved by maintaining standard techniques and procedures for collecting and analyzing samples and reporting the analytical results in standard units. Results of performance evaluation samples and systems audits will provide additional information for assessing comparability of data among subcontracting laboratories.

5.3 Method Detection Limits, Reporting Limits, and Instrument Calibration Requirements

5.3.1 Method Detection Limits

The method detection limit (MDL) is the minimum concentration of a substance that can be measured and reported with 99 percent confidence that the analyte concentration is greater than zero. Each participating laboratory will determine the MDL for each method, matrix, and analyte for each instrument that will be used to analyze samples. The MDLs will be initially determined prior to analyzing samples and again at least once every 12 months; a quarterly MDL verification can be substituted for the annual MDL study. The following steps should be followed:

1. Estimate the MDL using one of the following:
    - The concentration value that corresponds to an instrument signal/noise ratio in the range of 2.5 to 5
    - The concentration equivalent of three times the standard deviation of replicate measurement of the analyte in reagent water
    - The region of the standard curve where there is a significant change in sensitivity (i.e., a break in the slope of the standard curve)
2. Prepare (e.g., extract and digest) and analyze seven samples of an MS (ASTM Type II water for aqueous methods; Ottawa sand for soil methods; 1-mm glass beads, or smaller, for metals) containing the analyte of interest at a concentration three to five times the estimated MDL.
3. Determine the variance for each analyte by using Equations 1 and 2:

$$S^2 = \frac{1}{n-1}\left[\sum_{i=1}^{n}\left(x_i - \bar{x}\right)^2\right] \tag{1}$$

where:

S^2 = variance
^{x}I = the nth measurement of the variable x and
$\bar{x}$ = the average value of x

$$\bar{X} = \frac{1}{n}\sum_{i=1}^{n} x_i \tag{2}$$

4. Determine the standard deviation(s) for each analyte by using Equation 3:

$$s = (S^2)^{1/2} \tag{3}$$

5. Determine the MDL for each analyte by using Equation 4:

$$\text{MDL} = 3.14(s) \tag{4}$$

Note: 3.14 is the one-sided t-statistic at the 99-percent confidence level appropriate for determining the MDL using seven samples.

6. If the spike level used in Step 2 is more than 10 times the calculated MDL, repeat the process using a smaller spiking level.

CH2M HILL requires a verification check be performed on the calculated MDLs for each target compound (AFCEE, 2006). The MDL check standard shall be spiked at approximately two times the current reported MDL. The MDL is verified if the check standard produces a response at least 3 times above the instrument's noise level and greater than the blank associated with the MDL verification study. If the verification response is too low, spike at a successively higher concentration until verification criteria are met, and use the first successful concentration as the reported MDL. The MDL verification check will be sent to CH2M HILL for review and approval.

5.3.2 Reporting Limits

In general, reporting limits (RL) should be greater than two times the calculated MDL. RLs used by the laboratory should not be greater than the reporting limit objectives listed in Tables 5-2 through 5-13

When calibrating instruments, a standard at a concentration equal to or less than the RL must be included. In the project-specific SAP or QAPP addendum, reporting of analytical data will be addressed. One of the following options will be selected when establishing reporting requirements for each project:

- Analytes at concentrations greater than the laboratory MDL but less than the RL will be flagged "J" and reported as an estimate. Analytes that are not detected at or above the laboratory MDL will be flagged "U" and reported as not detected at the RL.
- Only analytes at a concentration greater than the project-specific RL will be reported. Analytes detected at less than the RL will be flagged "U" and reported as not detected at the RL.

For consistency, RLs and sample results shall be reported to two significant figures if less than 10 μg/L (parts per billion) and to three significant figures otherwise.

RLs shall be reported on a dry-weight basis for soil samples.

5.3.3 Instrument Calibration

Laboratory instruments shall be calibrated by qualified personnel prior to sample analysis according to the procedures specified for each method. Calibration shall be verified at method-specified intervals throughout the analysis sequence. The frequency and acceptance criteria for calibration are specified for each analytical method in Tables 5-16 through 5-27, with supplemental requirements defined in the following sections for organic methodologies. When multipoint calibration is specified, the concentrations of the calibration standards should bracket those expected in the samples. Samples should be diluted, if necessary, to bring analyte responses within the calibration range. Data that exceed the calibration range cannot be reported by the laboratory. The initial calibration (ICAL) curve shall be verified as accurate with a standard purchased or prepared from an independent second source. ICAL verification involves the analysis of a standard containing all the target analytes, typically in the middle of the calibration range, each time the ICAL is performed. Quantitation based on extrapolation is not desirable.

5.3.3.1 Initial Calibration Models for the Determination of Organic Compounds

Organic methodologies often provide multiple options for ICAL curve fits and associated acceptance criteria for use. The following sections describe the required laboratory practices that will be employed by the laboratory. The hierarchy that the laboratory will use when selecting the calibration curve fit for use in quantitation of sample results is described in the following section.

Calibration Techniques. The following procedures will be implemented:

- The analyst will verify that correct instrument operating conditions and routine maintenance as specified in the method and laboratory SOP are employed. All maintenance activities will be documented in a laboratory notebook for troubleshooting and scheduling of future routine, periodic maintenance.
- Ensure that the instrument is free of contamination prior to calibration. **Do not** perform any blank subtraction.
- The entire ICAL must be performed and meet method performance criteria prior to sample analyses. The calibration standards must be analyzed in sequential order from the lowest to highest concentration. If **one** calibration standard fails to meet criteria, it may be reanalyzed at the end of the calibration sequence. Justification for removing a calibration point from the selected curve fit includes circumstances such as, improper purge, injection failure, nonspiked level, or other obvious failures. The failure of multiple standards suggests an instrument problem or operator error and corrective action is required.
- Only the lowest or the highest calibration points can be removed from the calibration curve without justification. If the lowest calibration point is removed, the RL for that compound increases to the level of the next lowest calibration point. Approval to elevate RLs greater than the project-specific objectives **must** be approved by the program or project chemist. If the highest calibration point is removed, the linear range is shortened for that compound.
- The lowest calibration point in the calibration curve must be at or below the required RL.
- The other standard concentrations must define the working range of the instrument or the expected range of concentrations found in the samples.
- Either external or internal calibration can be employed for methods not involving mass spectrometry detectors. Internal calibration must be used when a mass spectrometry detector is employed.
- A minimum of five calibration points must be used for the calibration curve for gas chromatography/mass spectrometry and gas chromatography methods.
- Most compounds tend to be linear, and a linear approach should be favored when linearity is suggested by the calibration data. Nonlinear calibration should be considered only when a linear approach cannot be applied. It is not acceptable to use an alternate calibration procedure when a compound fails to perform in the usual manner. When this occurs it is indicative of instrument issues or operator error.
- If a nonlinear calibration curve fit is employed, a minimum of six calibration levels must be used for second-order (quadratic) curves, and a third order polynomial requires a minimum of seven calibration levels.

- When more than five levels of standards are analyzed in anticipation of using second- or third-order calibration curves, all calibration points **must** be used regardless of the calibration option employed. The highest or lowest calibration point may be excluded to narrow the calibration range and meet the requirements for a specific calibration option. Otherwise, unjustified exclusion of calibration data is expressly forbidden.
- Using the average (mean) relative standard deviation (RSD) of all analytes to meet ICAL criteria is **not** acceptable.

Calibration Options. This section describes the acceptable calibration options and the hierarchy that the laboratory should use when selecting a specific option. The choice of calibration option may also be based on previous experience or prior knowledge of detector response.

The following are calibration options:

- **Linear calibration using average calibration or response factors.** Calibration factors for external calibrations or response factors for internal calibrations must have RSDs not exceeding 20 percent or 15 percent, respectively, for quantitation. A minimum response factor of 0.05 for most target analytes or 0.01 for the least responsive target analytes must be achieved to ensure detectability.
- **Linear calibration using a linear regression equation (y=mx+b).** The correlation coefficient must equal 0.995 or better. The line should **not** be forced through the origin. The equation and a plot of the linear regression must be included in the raw data generated by the laboratory and made available in the data package upon request.
- **Nonlinear calibration.** This model may be a second-order or third-order polynomial. The model must be continuous without a break in the function and should **not** be forced through the origin. The coefficient of determination of the nonlinear regression must be 0.99 or better. The equation and a plot of the nonlinear regression must be included in the raw data generated by the laboratory and made available in the data package upon request. This method of calibration **must** be approved by the program or project chemist prior to analysis and is intended for nonlinear responding compounds only.

5.3.3.2 Continuing Calibration

Periodic verification of the ICAL is essential in generating analytical data of known quality. The continuing calibration verification analyses ensure that the instrument has not been adversely affected by the sample matrix or other instrument failures that would increase or decrease the sensitivity or accuracy of the method. The laboratory will perform continuing calibration for all methods in accordance with the specific requirements in the method and laboratory SOP.

Method SW8000B allows the use of the average of all analytes percent difference or drift (%D) to meet the continuing calibration requirements for the method. Using the average (mean) %D to meet continuing calibration criteria is **not** acceptable. All analytes must meet the continuing calibration criteria for %D.

5.4 Elements of Analytical Quality Control

Laboratory QC checks indicate the state of control that prevailed at the time of sample analysis. QC checks that involve field samples, such as matrix and surrogate spikes and field duplicates, also provide an indication of the presence of matrix effects. Field-originated blanks provide a way to monitor potential contamination that field samples are subjected to. The QAPP specifies requirements for method blanks, LCSs, surrogate spikes, and MS/MSD that must be followed by subcontracting laboratories.

A laboratory QC batch is defined as a method blank, LCS, MS/MSD, or a sample duplicate (depending upon the method) and 20 or fewer environmental samples of similar matrix that are extracted or analyzed together. For gas chromatography/mass spectrometry volatile analyses, a method blank, LCS, and MS/MSD must be analyzed in each 12-hour calibration period. The number of environmental samples allowed in the laboratory QC batch is defined by the remaining time in the method-prescribed 12-hour calibration period divided by the analytical run time. Each preparation or analytical batch should be identified in a way that will associate environmental samples with the appropriate laboratory QC samples.

5.4.1 Method Blanks

Method blanks are used to monitor each preparation or analytical batch for interference or contamination from glassware, reagents, and other potential contaminant sources in the laboratory. A method blank is an analyte-free matrix (laboratory reagent water for aqueous samples or Ottawa sand for soil samples) to which all reagents are added in the same amount or proportions as are added to samples. It is processed through the entire sample preparation and analytical procedures along with the samples in the batch. There should be at least one method blank per preparation or analytical batch. If a target analyte is found at a concentration that exceeds the RL, corrective action must be performed to identify and eliminate the contamination source. **All** associated samples must be re-prepared or reanalyzed, or both, after the contamination source has been eliminated if the compounds detected in the associated blank are also present in the field samples. No analytical data may be corrected for the concentration found in the blank (no blank correction).

5.4.2 Laboratory Control Sample

An LCS consists of an analyte-free matrix (laboratory reagent water for aqueous samples and Ottawa sand or glass beads for soil samples) spiked with known amounts of analytes that come from a source different than that used for calibration standards. A **complete target analyte list** for each method specified in the QAPP will be spiked into the LCS. The spike levels should be less than or equal to the midpoint of the calibration range. If LCS results are outside the specified control limits, corrective action must be taken, including sample re-preparation or reanalysis, or both, if appropriate. Documentation of the re-preparation or reanalysis, or both, must be provided in the analytical report. If more than one LCS is analyzed in a preparation or analytical batch, the results for each of the LCSs analyzed must be reported. Any LCS recoveries that are above or below the QC limits affect the accuracy for the entire batch and requires corrective action.

5.4.3 Surrogates

Surrogates are organic analytes that behave similarly as the analytes of interest but are not expected to occur naturally in the samples. They are spiked into the standards, the samples, and QC samples prior to sample preparation. Surrogate recoveries are used as an indicator of accuracy, method performance, and extraction efficiency. If surrogate recoveries are outside the specified control limits, corrective action must be taken, including sample re-preparation or reanalysis, or both, if appropriate. Documentation of the re-preparation or reanalysis, or both, must be provided in the analytical report.

5.4.4 Matrix Spike/Matrix Spike Duplicate

An MS is a sample matrix fortified with known quantities of specific compounds; it is subjected to the same preparation and analytical procedures as the native sample. Target analytes are spiked into the sample. MS recoveries are used to evaluate the effect of the sample matrix on the recovery of the analytes of interest. An MSD is a second fortified sample matrix. The RPD between the results of duplicate MSs measures the precision of sample results. One MS/MSD (MSD where appropriate) per 20 project-specific samples will be analyzed. A complete target analyte list for each method specified in the QAPP will be spiked into the MS/MSD (with the exception of PCBs; see Table 5-7). Project-specific samples designated on the CoC form will be spiked. The spike levels will be less than or equal to the midpoint of the calibration range. Exceedances of control limits should be flagged in the analytical report.

5.4.4.1 Matrix Spike for Hexavalent Chromium Analyses

Interference from groundwater is known to reduce the sensitivity of Methods SW7199 and EPA218.6. This can result in an incorrect assessment of the analyte identification or the specific RL if the “Matrix Spike and Dilution Protocol” is not followed. Samples being analyzed by Methods SW7199 and EPA218.6 will follow the protocol in the following section.

Matrix Spike and Dilution Protocol. Matrix interference has been encountered that affects the sensitivity for hexavalent chromium by ion chromatography methods. CH2M HILL shall direct the laboratories to perform an additional QA/QC analyses to aid in assessing any effect on method sensitivity for each project due to the sample matrix.

For nondetect sample results, the laboratory will analyze an MS by spiking the samples with 1 µg/L of hexavalent chromium to ensure that identification is accurate and verify that false negatives are detected. For samples with detected results, the laboratory will analyze an MS by spiking the sample with hexavalent chromium at a level not less than 25 percent of the sample concentration. Laboratories will follow the standard protocol of 1 MS and 1 laboratory sample duplicate per 20 samples, unless directed by the project chemist to analyze the MS more frequently.

If the MS is not recovered or the peak is outside of the established retention time window for either detected or nondetect results, the laboratory will make a fivefold dilution of two aliquots of the sample. The first aliquot will be analyzed without the spike; the second aliquot will be spiked with hexavalent chromium at a concentration consistent with the concentrations previously listed and the recovery and peak retention times evaluated. If this

MS recovery is not within laboratory QC limits or the peak is not within the laboratory retention time window, the laboratory will dilute two additional aliquots of the sample tenfold, spike one of the aliquots, analyze the sample/MS. This procedure will be performed at successively greater dilutions of 25:1, 50:1, or 100:1 until the peak identified in the post spike analysis is within the established retention time window for hexavalent chromium and the recovery of the spike is within the laboratory QC limits listed in Tables 5-2 or 5-3.

The detected result that is reported by the laboratory on the final data package will be chosen from the dilution where both the peak detected in the unspiked and the spiked sample are within the appropriate retention time and the MS is recovered within the QC control limits. The RLs will be raised to the level of the appropriate dilution.

For nondetect results, the dilution selected by the laboratory for reporting will be taken from the smallest dilution that yields an MS recovery within QC control limits and within the appropriate retention time window.

5.4.5 Internal Standards

Internal standards are compounds that have similar properties as the analytes of interest but are not expected to occur naturally in the samples. Some methods require the use of internal standards to compensate for losses during injection or purging or losses due to viscosity. A measured amount of the internal standard is added to the standards, the samples, and QC samples following preparation. When the internal standard results exceed the control limits, corrective action must be taken, including sample reanalysis, if appropriate. Corrective action must be documented in the analytical report.

5.4.6 Laboratory Sample Duplicate

For some methods, a laboratory duplicate is performed instead of a matrix spike duplicate. A laboratory sample duplicate is a sample duplicate selected by the laboratory. It is subjected to the same preparation and analytical procedures as the native sample. The RPD between the results of the native sample and laboratory sample duplicate measures the precision of sample results. The data collected may also yield information regarding whether the sample matrix is homogenous or heterogeneous.

5.4.7 Interference Check Samples

Interference check samples are used in inductively coupled plasma (ICP) analyses to verify background and interelement correction factors. They consist of two solutions, A and AB. Solution A contains the interfering analytes, and Solution AB contains the analytes of interest and the interfering analytes. Both solutions are analyzed at the beginning and at the end of each analytical sequence. When the interference check sample results exceed the control limits, corrective action must be taken, including sample reanalysis, if appropriate.

5.4.8 Retention Time Windows

Retention time windows for gas and liquid chromatographic analyses must be established by replicate injections of the calibration standard over multiple days as described in SW846 8000B, analytical method, or appropriate laboratory SOP. The absolute retention time of the calibration verification standard at the start of each analytical sequence will be the centerline of the window. For an analyte to be reported as positive, its elution time must be within the retention time window.

5.4.9 Equipment Blank

EBs are used to assess the effectiveness of the sampling equipment decontamination procedure. They are obtained immediately after sampling equipment decontamination by rinsing the decontaminated sampling equipment with deionized or ASTM Type II water. The rinse water is collected in sample bottles, preserved, handled, and analyzed in the same manner as the samples. EBs will be collected at a frequency of one per day for each nondedicated equipment type per sampling team.

5.4.10 Ambient Blank

ABs are collected to monitor contamination from ambient sources (e.g., active runways, engine test cells, operating motor vehicles) during collection of VOC samples. An AB is prepared by pouring ASTM Type II water into a VOC sample container at the sampling site where VOC samples are collected. The blank is preserved, handled, and analyzed in the same manner as the VOC samples.

5.4.11 Trip Blank

TBs are used to monitor contamination during sample shipping and handling and for cross contamination by VOC migration among the samples. TBs are prepared in the laboratory by pouring ASTM Type II water into a VOC sample container. The sample containers are then sealed, transported to the field, and remain sealed while VOC samples are collected; they returned to the laboratory in the same cooler as the VOC samples. One TB should accompany each VOC sample cooler.

5.4.12 Field Duplicates

A FD is an independent sample collected as close as possible to the original sampling location, from the same source, and under identical conditions. FDs are used to evaluate sampling precision. The FDs are collected simultaneously or in immediate succession and are treated in exactly the same manner during storage, shipment, and analysis. FDs will be collected at a minimum frequency of 10 percent or one per sampling event, whichever is more frequent, for each matrix and each type of analysis. The sampling locations for field samples will be recorded in the field logbook or on the field sampling form.

The FDs will be identified in a manner that will not allow the laboratory to recognize them.

5.5 Additional Quality Control Requirements

5.5.1 Holding Time

The holding time requirements specified in this QAPP (Table 4.1) must be met. For methods requiring both sample preparation and analysis, the preparation holding time will be calculated from the time of sampling to the completion of preparation. The analysis holding time will be calculated from the time of completion of preparation to the time of completion of the analysis, including required dilutions, confirmation analysis, and reanalysis. For methods requiring analysis only, the holding time is calculated from the time of sampling to completion of the analysis, including required dilutions, confirmation analysis, and reanalysis.

5.5.2 Confirmation

Confirmation analysis must be performed as specified for specific organic methods when the result is at or above the RL. Both the primary and confirmation results will be reported. Unless one of the analysis is specifically designated as the confirmation by the method, the more concentrated result will be reported as the sample result and the lesser concentration result as the confirmation. All calibration and QC requirements must be met when confirmation analysis is performed.

5.5.3 Cleanup Procedures to Minimize Matrix Effects

To maintain the lowest possible RLs, appropriate cleanup procedures should be employed when it is indicated by the method to remove or minimize matrix interference. Methods for sample cleanup include, but are not limited to, gel permeation chromatography, silica gel, alumna, florisil, mercury (sulfur removal), sulfuric acid, and acid/base partitioning. Method blanks, MS/MSDs, and LCSs must be subjected to the same cleanup procedures performed on the samples to monitor the efficiencies of these procedures.

5.5.4 Sample Dilution

Dilution of a sample results in elevated RLs and ultimately affects the usability of the data related to potential actions at the sampling site. It is important to minimize dilutions and maintain the lowest possible RLs. When dilutions are necessary because of high concentrations of target analytes, lesser dilutions should also be reported to fully characterize the sample for each analyte. The level of the lesser dilution should be such that it will provide the lowest possible RLs without having a lasting deleterious effect on the analytical instrumentation.

When a sample exhibits characteristics of matrix interference that are identified through analytical measurement or visual observation, appropriate cleanup procedures specified in Section 5.5.3 must be proven ineffective or inappropriate prior to proceeding with dilution and analysis. Any analyses conducted at a dilution where all analytes will be reported as non-detect above the QAPP RL, must be discussed with the project chemist prior to finalizing the report.

5.5.5 Standard Materials and Other Supplies and Consumables

Standard materials must be of known high purity and traceable to an approved source. Pure standards must not exceed the manufacturer's expiration date or 1 year after receipt if no expiration date is provided. Solutions prepared by the laboratory from the pure standards must be used within the expiration date specified in the laboratory's SOP.

All other supplies and consumables must be inspected prior to use to ensure that the supplies meet the requirements specified in the appropriate SOP. The laboratory's inventory and storage system should ensure their use within the manufacturer's expiration date and storage under proper conditions.

5.5.6 Manual Integration

The laboratory is required to provide all analysts performing methods that rely on interpretation of chromatographic data with training on appropriate software or manual integration practices. The laboratory also will make every effort to minimize the use of manual integration of data. If the need arises to use manual integration to correct a software autointegration error, the manual integration will be clearly identified in the instrument data. Before and after enlargements of the region of the chromatogram where the manual integration was performed will be provided on an appropriate scale that allows an independent reviewer to evaluate the need and quality of the manual integration. The analyst will also document the reason for the manual integration on the chromatogram along with their date and initials. The laboratory manager or designee will approve the manual integration by dating and initialing the chromatogram.

5.5.7 Laboratory Quality Assurance Program

The laboratory will maintain a quality assurance manual or equivalent document. The manual must include all of the requirements provided in the California Environmental Laboratory Accreditation Program (ELAP), and, if applicable, the National Environmental Laboratory Accreditation Program (NELAP). The manual will define the laboratory's internal procedures for QA/QC as follows:

- QA policies, objectives, and requirements
- Organization and personnel
- Document control
- SOPs (analytical methodology and administrative)
- Data generation
- Software verification
- Quality assurance
- Quality control
- Nonconformance/corrective action procedures
- Data review

5.5.7.1 Laboratory Standard Operating Procedures

The laboratory will maintain SOPs for all analytical methods and laboratory operations. The format for SOPs will conform with the following:

- *Test Methods for Evaluating Solid Waste, Physical and Chemical Methods, SW-846, Third Edition, Update III, Section 1* (EPA, 1996)

- "Good Laboratory Practices" in *Principles and Guidance to Regulations for Ensuring Data Integrity in Automated Laboratory Operations* (EPA, 1995)

All SOPs must have a unique identification number that is traceable to previous revisions of the same document.

5.5.7.2 Demonstration of Capability

Laboratory QA department personnel will maintain records documenting the ability of each analyst to perform applicable method protocols. Documentation will include annual checks for each method and analyst. In addition, internal, blind performance evaluation samples for each method and matrix demonstrating overall laboratory performance must be submitted annually. The laboratory may receive additional blind performance evaluation samples in conjunction with this program.

5.6 Analytical Procedures

The allowed sample preparation methods are presented in Table 5-1. Any changes or alternatives to this list will be included in site-specific SAPs or QAPP addenda. Analytical and preparation methods for SW7000 series are provided in Table 5-1 as alternate methods to SW6020. These methods will be allowed, provided the RL objectives are met. After a method is chosen, it must be used throughout the duration of a specific project to maintain data comparability.

This QAPP includes common analytical procedures that may be required for the PG&E Program. Tables 5-2 through 5-14 contain representative lists of the analytes of concern, the methods to be used, and the RL objectives. Some of the listed analytes may not necessarily be of concern for a particular project; project-specific SAPs or QAPP addenda will list the analytes of concern. The RLs included herein reflect quantifiable levels that are attainable with a specified degree of confidence using the specified methods. The RLs should meet most preliminary cleanup goals or action levels. If changes to the methods or RLs are necessary to meet cleanup goals, the QAPP will be updated or amended by addendum.

General QC requirements are discussed in Section 5.3.3. The calibration and QC requirements specified for each method will be followed and are included in Tables 5-2 through 5-27. Appropriate corrective action will be taken when acceptance criteria are not met. If corrective action is not effective, and data quality is potentially degraded, the occurrence must be documented in a corrective action report and in the data package case narrative. The laboratory manager or a designated person must notify the project chemist.

Analytical services will be provided by laboratories contracted by CH2M HILL or its subcontractors. Analytical laboratories will be accredited, in accordance with the California ELAP, for all parameters where accreditation is available. Subcontract laboratories will be required to follow the SAP and QAPP addenda that are applicable to specific projects or activities.

Field measurements will be performed or supervised directly or indirectly by CH2M HILL field personnel.

5.7 Analytical Requirements

The project-specific SAPs or QAPP addenda shall specify project-specific analytes and analytical methods. The project manager or designee for the project-specific SAPs will determined the RL requirements, evaluate the QAPP specification to assure they meet those requirements, and address any differences in a QAPP addendum. The QAPP addendum will be included as part of the project-specific documents.

Project-specific preliminary cleanup goals or action levels will be included in the SAPs or QAPP addenda, if available. The sources for the preliminary cleanup goals or action levels will be indicated in the project-specific documents. In cases where available technology does not offer analytical methods that are sufficiently sensitive to detect concentrations at or below the reference levels cited by the source, the method RLs are used as the preliminary cleanup goals or action levels. All goals are subject to revision and will be documented.

The analytical requirements are presented in the following tables.

TABLE 5-1
Extraction and Digestion Methods
PG&E Program Quality Assurance Project Plan

Analytical Method	Parameter	Preparatory Methods
SW6010B	Trace metals by ICP	SW3005A, SW3010A, SW3015, SW3050B, SW3051
SW6020	Trace metals by ICP-MS	SW3005A, SW3010A, SW3015, SW3050B, SW3051
SW7000 Series	Various elements (unless specified separately)	SW3015, SW3020A, SW3050B, SW3051
EPA200.7 and EPA200.8	Trace metals by ICP/ICP-MS	See analytical method
SW7470A, SW7471A, and EPA245.1	Mercury by cold vapor atomic adsorption	See analytical method
SW7196A, SW7199, and EPA218.6	Hexavalent chromium	See analytical method for water, Use SW3060A for soil preparation prior to SW7199
SW7041	Antimony (water and soil)	See analytical Method SW3005A
SW7060A	Arsenic (water and soil)	See analytical Method SW3050B
SW7740	Selenium (water and soil)	See analytical Method 3050B
SW8015M	TPH volatile and extractable (water and soil)	Volatiles: SW5030BB, SW5031, SW5035 Extractables: SW3510C, SW3520C, SW3545C, SW3541, SW3545, SW3550B
SW8081A	Organochlorine pesticides (water and soil)	SW3510C, SW3520C, SW3540C, SW3541, SW3545, SW3550B
SW8082	PCBs (water and soil)	SW3510C, SW3520C, SW3540C, SW3541
SW8151A	Chlorinated herbicides (water and soil)	SW3510C, SW3520C, SW3540C, SW3541, SW3550B
SW8021B	BTEX (water and soil)	SW3585, SW5021, SW5030B, SW5031, SW5032, SW5035
SW8260B	Volatile organics (water and soil)	SW3585, SW5021, SW5030B, SW5031, SW5032, SW5035
SW8270C and SW8270C SIM	Semivolatile organics (water and soil)	SW3510C, SW3520C, SW3535, SW3540C, SW3541, SW3545, SW3550B

*CHHSL for Chromium (III), CAS 16065-83-1, 100,000 gm/kg for both Residential and commercial.

Notes:

CHHSL = California Human Health Screening Levels
DTSC = California Department of Toxic Substance Control
mg/kg = milligrams per kilogram

All soils sample results will be reported in dry weight unless otherwise specified in the SAP.

Title 22 Metals

California waste characterization protocol specifies following a stepped procedure for the determination of hazardous waste disposal.

1. If the sample is suspected of containing high levels of metals; analyzed for the Title 22 metals – TTLC Table 5-3C
2. Compare the TTLC sample results with Column 5 of Table 5-3C.
3. If the TTLC sample results are greater than the concentrations listed in Column 5 of Table 5-3C, extract and analyze the samples using the Waste Extraction Test (WET) for any analytes that exceeded the concentrations listed in Column 5 of Table 5-3C.
4. If the soluble threshold limit concentration (STLC) sample result, from WET, is greater than the concentration listed in Column 4 of Table 5-3D for any of the Resource Conservation and Recovery Act (RCRA) metals listed in Table 5-3E, extract the sample by TCLP Method 1311 and analyze for the specific metals that exceeded the STLC threshold.

TABLE 5-16
Calibration and QC Requirements for Metals – SW6010B and EPA200.7
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
ICAL (a blank and at least one standard)	Before sample analysis, every 24 hours, when modifications are made to the system, or when continuing calibration verification fails.	If more than one standard is used, correlation coefficient must be >0.995.	Not applicable.
Second-Source Calibration Verification	Immediately following each ICAL.	All analytes within ±10% of expected value for SW6010B and within ±5% of expected value for EPA200.7.	Correct problem and repeat ICAL.
Calibration Blank	After every second-source or continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem and reanalyze previous 10 samples.
Continuing Calibration Verification	After every 10 samples and at the end of the analysis sequence.	All analytes within ±10% of expected value for SW6010B and within ±10% of expected value for EPA200.7.	Recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Interference Check Standard	At the start and end of each analytical sequence or twice during an 8-hour period, whichever is more frequent.	All analytes within ±20% of expected value.	Correct the problem, recalibrate, and reanalyze ICS and all affected samples.

TABLE 5-16
Calibration and QC Requirements for Metals – SW6010B and EPA200.7
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
MS/MSD	One set per 20 project-specific samples. MSD is optional if a laboratory sample duplicate is performed.	All analytes within limits specified in Tables 5-3A through 5-3E.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified in Tables 5-3A through 5-3E.	Correct the problem, re-prepare and reanalyze the LCS and all samples in the analytical batch.
Dilution Test	Each new sample matrix.	Result from 1:5 dilution must be within ±10% of the undiluted sample result (applies only if undiluted sample result is at least 25 times the RL).	Perform postdigestion spike addition.
Linear Range Calibration Check Standard	Once per quarter.	All analytes within +10% of expected value.	Correct problem and reanalyze or reset linear range.
Postdigestion Spike Addition	When dilution test fails.	Recovery within 75 to 125% of expected value.	None.

TABLE 5-17
Calibration and QC Requirements for Metals – SW6020 and EPA200.8
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
ICAL (a blank and at least one standard)	Before initial sample analysis, every 24 hours, when modifications are made to the analytical system, or when continuing calibration verification fails.	Not applicable	Not applicable
Second-source Calibration Verification	Immediately following each ICAL.	All analytes within ±10% of expected value.	Correct problem and repeat ICAL.
Calibration Blank	After every Second-source or Continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem and reanalyze previous 10 samples.
Continuing Calibration Verification	After every 10 samples and at the end of the analysis sequence.	All analytes within ±10% of expected value.	Recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Interference Check Standard	At the start and end of each analytical sequence or twice during an 8-hour period, whichever is more frequent.	All analytes within ±20% of expected value.	Correct the problem, recalibrate and reanalyze ICS and all affected samples.
MS/MSD	One set per 20 project-specific samples. MSD is optional if a laboratory sample duplicate is performed.	All analytes within limits specified in Tables 5-3A through 5-3E.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified in Tables 5-3A through 5-3E.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
Dilution Test	Each new sample matrix.	Result from 1:5 dilution must be within ±10% of the undiluted sample result (applies only if undiluted sample result is at least 25 times the RL).	Perform postdigestion spike addition.
Postdigestion Spike Addition	When dilution test fails.	Recovery within 75 to 125% of expected value.	None.

TABLE 5-18
Calibration and QC Requirements for Metals – SW7000 Series and EPA245.1
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (a blank and at least five standards)	Before initial sample analysis, every 24 hours, when modifications are made to the analytical system, or when continuing calibration verification fails.	Correlation coefficient of linear regression is ≥0.995.	Correct the problem and repeat the ICAL.
Second-source Calibration Verification	Immediately following each ICAL.	All analytes within ±20% of expected value.	Correct the problem and repeat ICAL.
Calibration Blank	After every second-source or continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem, then reanalyze previous 10 samples.
Continuing Calibration Verification	After every 10 samples and at the end of the analysis sequence.	All analytes within ±20% of expected value.	Recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
MS/MSD	One set per 20 project-specific samples. MSD is optional if a laboratory sample duplicate is performed.	All analytes within limits specified in accuracy and precision table.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified Tables 5-3A through 5-3E.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
Dilution Test	Each new sample matrix.	Result from 1:5 dilution must be within ±10% of the undiluted sample result (applies only if undiluted sample result is at least 25 times the RL).	Perform recovery test.
Recovery Test	When dilution test fails.	Recovery within 85 to 115% of expected value.	Analyze all samples by MSA.

Note:
MSA = method of standard addition

TABLE 5-19
Calibration and QC Requirements for General Chemistry and Other Parameters[a]
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (a blank and at least five standards); Does Not Apply to Titrimetric Method	Before initial sample analysis, every 24 hours, when modifications are made to the analytical system, or when continuing calibration verification fails.	Correlation coefficient of linear regression is ≥0.995.	Correct the problem and repeat the ICAL.
Second-source calibration verification	Immediately following each ICAL.	Analytes within ±15% of expected value (±10% for SW9056/EPA300.0).	Correct the problem and repeat ICAL.
Calibration blank; does not apply to titrimetric method	After every second-source or continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem, then reanalyze previous 10 samples.
Continuing calibration verification	After every 10 samples and at the end of the analysis sequence.	Within ±15% of expected value (±10% for SW9056/EP300.0).	Recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Method blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
MS/MSD	One set per 20 project-specific samples. MSD is optional if a laboratory sample duplicate is performed.	All analytes within limits specified in Tables 5-2A, 5-2B, 5-12, and 5 13.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified in Tables 5-2A, 5-2B, 5-12, and 5 13.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
IPC (EPA314.0 only)	Daily, before sample analysis.	Conductance within 10% of original value (original value within ±10% of MCT).	Prepare fresh IPC solution.
		$PD_{A/H}$ <25%, instrument response within ±20% of expected response.	Redetermined MCT or correct problem and reanalyze IPC.
		Retention time shifts <5%, or overall retention time <80% of original recorded value.	Correct problem, clean or replace column.

TABLE 5-19
Calibration and QC Requirements for General Chemistry and Other Parameters[a]
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
ICAL Verification (ICCS) (EPA314.0 only)	Daily, before sample analysis or when eluent is changed.	Instrument response within ±25% of expected value using a standard at or below the RL.	Correct problem then repeat ICAL.
Pretreated Laboratory Reagent Blank (EPA314.0 only)	Required in any analytical batch which includes samples that have been pretreated to reduce the common anion levels.	Perchlorate must be ≤½ RL.	Correct problem, re-prepare, and analyze method blank and all samples processed with the contaminated blank.
Low-level MDL Check Standard (EPA314.0 only)	Weekly and with ICAL.	Must meet QC acceptance criteria, 50 to 150% of its true concentration.	Reanalyze low-level MDL check standard, if still out of criteria, repeat ICAL.

[a] Unless calibration and QC requirements are specified for an individual method.

Notes:

ICCS = initial calibration check standard
IPC = instrument performance check
MCT = matrix conductivity threshold

TABLE 5-20
Calibration and QC Requirements for Hexavalent Chromium – SW7199 and EPA218.6
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (a blank and at least five standards)	Before initial sample analysis, every 24 hours, when modifications are made to the analytical system, or when continuing calibration verification fails.	Correlation coefficient of linear regression is ≥0.999.	Correct the problem and repeat the ICAL.
Second-source Calibration Verification	Immediately following each ICAL.	All analytes within ±10% of expected value.	Correct the problem and repeat ICAL.
Calibration Blank	After every second-source or continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem, then reanalyze previous 10 samples.
Continuing Calibration Verification	After every 10 samples and at the end of the analysis sequence.	All analytes within ±10% of expected value for SW7199 and within ±5% of expected value for EPA218.6.	Recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Duplicate Sample Injections (SW7199 only)	Every sample.	RPD between injections must be <20%.	Correct the problem, re-prepare, and reanalyze all associated samples.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.

TABLE 5-20
Calibration and QC Requirements for Hexavalent Chromium – SW7199 and EPA218.6
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
MS	One per 20 project-specific samples.	All analytes within limits specified in Tables 5-2A, 5-2B, 5-3A, and 5-3B.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified in Tables 5-2A, 5-2B, 5-3A, and 5-3B.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
pH Buffer Solution Modification	As needed because of sample matrices that cause the analytical column to overload. All QC samples and analyses will use the modified buffered solution when needed.	A modified pH-adjustment buffer that contains 10 times less ammonium sulfate (33 g/L) but the same concentration of ammonium hydroxide as the buffer prescribed in SW7199/ EPA218.6.	None.
MS Dilute and Spike (see Section 5.3.3.1)	As directed in Section 5.3.3.1.	Spike recovery 85 to 115% and peak within RT window.	Dilute two aliquots 1:5, spike one with 1 μg/L of hexavalent chromium and analyze the other unspiked. Continue the procedure using successively greater dilutions of two aliquots until RT and recovery criteria are met.

Notes:

RT = retention time

μg/L = micrograms per liter

TABLE 5-21
Soil Preparation Method SW3060A for Method SW7199
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
2.5 grams sample to a final volume of 100 ml must be used for each sample	Each sample in the preparation batch.	Follow method preparation for all samples, method blank, and QC samples.	
Method Blank	One per preparation batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
LCS	One per preparation batch.	Spike at concentration specified in method. Recovery range 80 to 120%.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
Soluble Matrix Spike	One per preparation batch.	Spike at concentration specified in method. Recovery range 75 to 125%.	None.
Insoluble Matrix Spike	One per preparation batch.	Spike at concentration specified in method. Recovery range 75 to 125%.	None.
Post Digestion Spike	One per preparation batch.	Spike at concentration specified in method. Recovery range 85 to 115%.	None.

TABLE 5-22
Calibration and QC Requirements for Stable Isotopes[a]
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Instrument Standardization	Daily, prior to sample analysis.	Laboratory SOP.	Perform instrument maintenance.
Laboratory Sample Duplicate	Every sample analyzed five times.	Laboratory SOP.	Perform instrument maintenance and reanalyze samples.

[a] ^{18}O and deuterium

TABLE 5-23
Calibration and QC Requirements for TPH, BTEX, Herbicides, and Dissolved Gases – SW8015B, SW8021B, SW8151A, and RSK-175S
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (minimum 5 points)	Prior to sample analysis, or when calibration verification fails.	If the %RSD is ≤20%, the average RRF may be used for quantitation; otherwise use calibration curve with coefficient of correlation or determination ≥0.99.	Correct the problem and repeat the ICAL.
Continuing Calibration Verification	At the start of each analytical sequence and after every 10 samples, and at the end of the sequence.	Analytes within ±15% of expected value.	Correct the problem, recalibrate, and reanalyze all samples since the last acceptable continuing calibration verification.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Surrogate Spike	Every standard, sample, method blank, MS/MSD, and LCS.	All surrogates in samples, method blank, MS/MSD, and LCS within limits specified in Tables 5-4A, 5-4B, 5-5A, 5-5b, 5-8A, 5-8B, and 5-13.	Correct the problem and reanalyze (re-prepare if necessary).
MS/MSD	One set per 20 samples.	Full target list spike required within limits specified in Tables 5-4A, 5-4B, 5-5A, 5-5b, 5-8A, and 5-8B. Not applicable for RSK-175.	None.
LCS	At least one per analytical batch.	Full target list spike required within limits specified in Tables 5-4A, 5-4B, 5-5A, 5-5b, 5-8A, 5-8B, and 5-13.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
Second Detector or Second Column Confirmation (does not apply to SW8015B or RSK-175)	All samples with results above the RL objectives must be confirmed within the holding time.	Confirmation to be done using a second detector, or second column of dissimilar phase and retention characteristics (or gas chromatography/mass spectrometry if sample concentration is sufficiently high). All calibration and QC acceptance criteria specified for primary analysis must be met in the confirmation analysis.	Failure to perform confirmation will result in potential resampling and analysis at no cost to the project.

Note:
RRF = relative response factor

TABLE 5-24
Calibration and QC Requirements for Pesticides and PCBs – SW8081A and SW8082
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (minimum 5 points) for single-response pesticides; single-point calibration for toxaphene and chlordane; multipoint calibration for Aroclors 1016 and 1260 only, but include midpoint standard for all other Aroclors for pattern recognition; if a specific Aroclor is found in any sample, quantitation for that Aroclor must be done using 5-point calibration	Prior to sample analysis or when calibration verification fails.	To use average RRF for quantitation of any analyte, % RSD must be ≤20%; otherwise use calibration curve with coefficient of correlation or determination ≥0.99.	Correct the problem and repeat the ICAL.
Second-source calibration verification – pesticides and Aroclors 1016 and 1260 (or Aroclors identified in samples)	Once for each multipoint ICAL.	All analytes within ±15% of expected value.	Correct the problem, then recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Continuing calibration verification – pesticides and Aroclors 1016 and 1260 (or Aroclors identified in samples)	At the start of each analytical sequence; after every 12 hours or 10 samples, whichever is more frequent; and at the end of the sequence.	All analytes within ±15% of expected value.	Correct the problem, then recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Endrin/DDT breakdown check (not applicable when analyzing for Aroclors/PCBs only)	At start of each 12-hour period.	Breakdown of either endrin or DDT ≤15%.	Evaluate injector port and take corrective action; recalibrate and reanalyze affected samples if necessary.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Surrogate Spike	Every standard, sample, method blank, MS/MSD, and LCS.	At least one of the surrogates in samples, method blank, MS/MSD, and LCS within limits specified in Tables 5-6A, 5-6B, 5-7A, and 5-7B.	Correct the problem and reanalyze (re-prepare if necessary).
MS/MSD	One set per 20 project-specific samples.	Full target list spike required within limits specified in corresponding Tables 5-6A, 5-6B, 5-7A, and 5-7B.	None.
LCS	At least one per analytical batch.	Full target list spike required within limits specified in corresponding Tables 5-6A, 5-6B, 5-7A, and 5-7B.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.

Calibration and QC Requirements for VOCs – SW8260B
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
BFB Tuning	Prior to ICAL and calibration verification (every 12 hours).	Refer to criteria listed in the method.	Retune instrument and verify.
Multipoint ICAL (minimum 5 points)	Prior to sample analysis, or when calibration verification fails.	SPCCs average RRF ≥0.30a and %RSD for RRFs for CCCs ≤30% and one of the following options: Option 1 Linear – RSD for each analyte <15%. Use of the mean %RSD for all analytes ≤15% may **not** be used. Option 2 Linear – least squares regression r ≥0.995. Option 3 Nonlinear – coefficient of determination ≥0.99 (6 standards to used for a second order; 7 standards to be used for a third order).	Correct the problem and repeat the ICAL.
Second-source Calibration Verification	Once for each multipoint ICAL.	All analytes within ±25% of expected value.	Correct the problem and repeat ICAL.

TABLE 5-25
Calibration and QC Requirements for VOCs – SW8260B
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Continuing Calibration Verification	At the start of each analytical sequence and every 12 hours thereafter.	SPCCs average RF ≥0.30c and %D for RFs for CCCs ≤20%. All other analytes within ±20% of expected value.	Correct the problem, recalibrate, and reanalyze all samples since the last acceptable continuing calibration verification.
Retention Time Window Calculated for Each Analyte	Each analyte.	Relative retention time of each analyte within ±0.06 relative retention time units of the ICAL.	Not applicable (used for identification of analyte).
Internal Standards	Each sample and QC sample, method blank, MS/MSD and LCS.	Continuing calibration verification retention time within ±30 seconds from retention time of the ICAL midpoint standard. Sample retention time within ±30 seconds from retention time of the daily continuing calibration verification. Continuing calibration verification EICP area within –50% to +100% of the internal standard responses in the ICAL midpoint standard. Sample EICP area within –50% to +100% of the daily continuing calibration verification.	Inspect mass spectrometer and gas chromatography for malfunctions; reanalyze all affected samples.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Surrogate Spike	Every standard, sample, method blank, MS/MSD and LCS.	All surrogates in samples, method blank and LCS within limits Tables 5-9A and 5-9B.	Correct the problem and reanalyze (re-prepare if necessary).
MS/MSD	One set per 20 project-specific samples.	Full target list spike required within limits specified in Tables 5-9A and 5-9B.	None.
LCS	At least one per analytical batch.	Full target list spike required within limits specified in Tables 5-9A and 5-9B.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.

[a] SPCC average RRF ≥0.10 for bromoform, chloromethane, and 1,1-dichloroethane.

Notes:

BFB = bromofluorobenzene
CCC = calibration check compounds
EICP = extracted ion current profile SPCC

SECTION 6

Data Reduction, Validation, and Reporting

6.1 Laboratory Data Management

Data reduction will be performed manually or by using appropriate computer software. Quantitation procedures specified for each method must be followed. If data reduction is performed manually, the documentation must include the formulas used. Computer software used for data reduction must have been previously verified by the laboratory for accuracy. Documentation of the software verification must be maintained in the laboratory. All data reduction documentation must allow re-creation of the calculations.

All data will undergo a minimum of three levels of review at the laboratory prior to release. The analyst performing the tests shall initially review 100 percent of the data. After the analyst's review has been completed, 100 percent of the data shall be reviewed independently by a senior analyst or by the section supervisor for accuracy, completeness and compliance with calibration, QC requirements, and holding times. Analyte identification and quantitation must be verified. Calibration and QC results will be compared with the applicable control limits. RLs should be reviewed to make sure they meet the project objectives. Results of multiple dilutions should be reviewed for consistency. Any discrepancies must be resolved and corrected. Laboratory qualifiers will be applied when there are nonconformances that could potentially affect data usability. These qualifiers must be properly defined as part of the deliverables. All issues that are relevant to the quality of the data must be addressed in a case narrative. The laboratory QC manager will review a minimum of 10 percent of data or deliverables generated for this program against the project-specific requirements. A final data review will be conducted by the laboratory manager or client services representative to ensure that all required analyses were performed and that all documentation is complete.

The hardcopy and electronic data deliverable (EDD) laboratory reports for all samples and analyses will contain the information necessary to perform data evaluation.

The PG&E Program will request four types of deliverables from the laboratory, depending upon the DQOs of the individual project. The following is a synopsis of when it is appropriate to use each type deliverable:

- **Level 1.** Appropriate for screening-level sampling results. Noncritical project decisions are made using this data.
- **Level 2.** Appropriate for investigative sampling results that will be replaced with confirmatory data or results used for disposal purposes. Less critical project decisions are made using this data.

- **Level 3.** Appropriate for investigative, confirmatory, or closure results. Critical project decisions may be made using this data.
- **Level 4.** Appropriate for investigative, confirmatory, or closure results. Critical decisions may be made using this data and should be used for projects that require a high degree of confidence in the accuracy of the data.

Hardcopy deliverables (and a electronic copy in portable document format [PDF]), in summary format, equivalent to those specified in the latest versions of EPA *Contract Laboratory Program Statements of Work for Organics and Inorganics Analyses* are preferred. The laboratory data report should be organized in a format that facilitates identification and retrieval of data. Alternate reporting formats require approval from the program chemist or project chemist.

A Level 1 report will include, at a minimum, the following information (when applicable):

- Cover letter with the following information:
  - Title of report and laboratory unique report identification (e.g., sample delivery group number)
  - Project name and site location
  - Name and location of laboratory and second-site or subcontracted laboratory
  - Client name and address
  - Statement of authenticity and official signature and title of person authorizing release of the report
- Table of contents
- Summary of samples received that correlates field sample IDs with the laboratory IDs
- Laboratory qualifier flags and definitions
- Field identification number
- Date received
- Date prepared
- Date analyzed (and time of analysis if the holding time is less than or equal to 48 hours)
- Preparation and analytical methods
- Result for each analyte (dry-weight basis for soils)
- Percent solids results for soil samples
- Dilution factor (provide both diluted and undiluted results when available)
- Sample-specific RL adjusted for sample size, dilution/concentration

- Sample-specific MDL adjusted for sample size, dilution/concentration (when project objectives require reporting less than the RL)
- Units of measure
- Applicable flags for data associated with QC that are outside of control limits
- CoC forms

A Level 2 report will consist of all the elements included in a Level 1 deliverable plus the following:

- Case narrative that addresses the following:
  - Sample receipt discrepancies (e.g., bubbles in VOA samples or temperature exceedances)
  - Descriptions of all nonconformances in the sample receipt, handling, preparation, analytical and reporting processes, and the corrective action taken for each occurrence
  - Identification and justification for sample dilution
  - Serial dilution recoveries, if applicable (required in hardcopy format only)
  - Postdigestion spike recoveries, if applicable (required in hardcopy format only)
- Surrogate %Rs
- MS/MSD and LCS spike concentrations, native sample results, spiked sample results, %R, and RPDs between the MS and MSD results; associated QC limits must also be provided
- Method blank results
- Analytical batch reference number that cross references samples to QC sample analyses
- Completed sample receipt checklist

A Level 3 report will consist of all the elements included in Level 1 and 2 reports plus the following:

- Analytical sequence or laboratory run log that contains sufficient information to correlate samples reported in the summary results to the associated method QC information, such as initial and continuing calibration analyses
- Confirmation results
- Calibration blank results for inorganic analyses (required in hardcopy format only)
- ICP and ICP/MS interference check sample results that include true concentrations, measured concentrations, and the calculated %R of the elements included (required in hardcopy format only)
- Method of standard addition results, if applicable (required in hardcopy format only)

- Internal standard recovery and retention time information, as applicable
- ICAL summary, including standard concentrations, response factors, average response factors, RSDs or correlation coefficients, and calibration plots or equations, if applicable (required in hardcopy format only)
- Continuing calibration verification summary, including expected and recovered concentrations and percent differences (required in hardcopy format only)
- Instrument tuning and mass calibration information for gas chromatography/mass spectrometry and ICP/MS analyses
- Any other method-specific QC sample results

A Level 4 report will include all elements for Levels 1 through 3 and all of the associated raw data. It is imperative that the relative scale used for all chromatographic and other instrument data be supplied in a scale that facilitates review from hardcopy. Enlargements of sufficient size and clarity for complex areas of sample chromatograms will be provided. Additional information to be supplied includes the following:

- Sample preparation logs that include the following:
  - Preparation start and end times
  - Beginning and ending temperatures (e.g., water baths and digestion blocks)
- Each algorithm and an example calculation for at least one sample for each matrix analyzed
- Reconstructed total ion chromatograms or selected ion current profiles for each sample (or blank) analyzed and mass spectra(s) for each compound identified including the following:
  - Raw compound spectra
  - Enhanced or background spectra
  - Laboratory generated library spectra (for tentatively identified compounds, provide the reference mass spectra from software spectra library)
- Ion ratio information for dioxin/furan methods

6.2 Hardcopy and Electronic Deliverables

Within the timeframe specified in the laboratory statement of work, contract, or purchase order from sample receipt, the laboratory shall deliver two hardcopies and one PDF of documentation, as specified in this QAPP. In addition, the laboratory shall deliver one electronic copy of the data (i.e., EDD), as specified in the format described in Table 6-1 (or as directed in the project-specific addendum), on CD-ROM or by e-mail (in ASCII format) within the same timeframe (LabSpec-7 format [see Table 6-1]).

All electronic data files shall match the final hardcopy results. CH2M HILL requires receipt of final hardcopy results with electronic files.

All raw data will be maintained in the laboratory and will be available upon request. Complete documentation of sample preparation and analysis and associated QC information will be maintained in a manner that allows easy retrieval if additional validation or information is required. Appropriate back-up procedures must be implemented by the laboratory for data that are stored electronically. All data generated using gas chromatography/mass spectrometry must be maintained on COD-ROM or equivalent format and provided to CH2M HILL upon request. All documentation must be retained for a minimum of 5 years after data acquisition.

The primary responsibility for implementing these procedures in the laboratory will reside with the laboratory manager or equivalent. The laboratory manager will approve laboratory reports before submittal.

6.3 Data Validation and Verification

Depending on the project-specific objectives, the analytical results of the data collection effort will be validated by CH2M HILL. In general, there will be different levels of validation employed for the program that correspond to the reports described in Section 6.1. In some instances a Level 3 or Level 4 data package may be obtained from the laboratory, but only a Level 1 or Level 2 validation may be conducted. Specific validation levels will be identified in the site-specific SAP or QAPP addendum. Validation of Levels 1 through 4 will always be performed by the project chemist or designee. The levels are summarized as follows:

Level 1	Import the laboratory results into the project database; use automated data validation (AutoDV), as applicable, to the project database. Verify that samples were analyzed by the methods requested, and review the data for outliers and anomalies. Prepare a brief summary validation report.
Level 2	Import the laboratory results into the project database; use AutoDV as applicable, to the project database. Verify that samples were analyzed by the methods requested, review the laboratory case narrative for events in the laboratory that affect the accuracy or precision of the data, review QC indicator data, and perform a cursory review of the data. Prepare a summary validation report.
Level 2B	Import the Laboratory results into the project database; use AutoDV, as applicable, to the project database. Verify that samples were analyzed by the methods requested, review the laboratory case narrative for events in the laboratory that affect the accuracy or precision of the data, review QC indicator data, and perform a cursory review of the data. Review specific raw data, as specified in the QAPP addendum, and compare the current data with historical data. Prepare a summary validation report.
Level 3	Import the laboratory results into the project database; use AutoDV, as applicable, to the project database. Validate the analytical data, as described in the following sections, without reviewing any raw data or analyte verification. Prepare a summary validation report.

Level 3B	Import the laboratory results into the project database; use AutoDV, as applicable, to the project database. Validate the analytical data as described in the following sections with review of specific raw data, as specified in the QAPP addendum, and compare the current data with historical data. Prepare a summary validation report.
Level 4	Import the laboratory results into the project database; use AutoDV, as applicable, to the project database. Validate analytical data as described in the following sections, including a review of the analytical raw data, and compare the current data with historical data. Prepare a summary validation report.

6.4 Level 3 and 4 Validation Procedures

Personnel involved in the data validation function will be independent of any data generation effort. The project chemist will have responsibility for oversight of the data validation effort. Data validation will be performed when the final data packages are received from the laboratory. Data validation will be performed on an analytical batch basis within each analytical report using the summary results of calibration and laboratory QC and the results from associated field samples. Data packages will be reviewed for all constituents of concern. Raw data will be reviewed when deemed necessary by the project chemist or as specified in QAPP addenda. Data validation procedures will include the following:

- Review of the data package for completeness
- Review of CoC records for discrepancies that might degrade data quality
- Review for compliance with holding time and QC frequency requirements
- Evaluation of all calibration and QC summary results against the project requirements
- Verification of analyte identification and calculations for at least 10 percent of the data
- Qualification of the data using appropriate qualifier flags, as necessary, to reflect data usability limitations
- Initiation of corrective actions, as necessary, based on the data review findings

Data validation will be patterned after the *Contract Laboratory National Functional Guidelines for Inorganic Data Review* (EPA, 2002) and *Contract Laboratory National Functional Guidelines for Organic Data Review* (EPA, 1999), substituting the calibration and QC requirements specified in this QAPP for those specified in the guidelines. The national functional guidelines will primarily be used as a guidance document for the application of data qualification criteria. The level of validation will be defined in the SAP or QAPP addendum.

The flagging criteria presented in Tables 6-2 and 6-3 will be used; the qualifier flags are defined in Table 6-4. Qualifier flags, if required, will be applied to the electronic sample results. A summary table of the data qualifications will be provided in the validation report. If multiple flags are required for a result, the most severe flag will be applied to the electronic result. The hierarchy of flags, from the most severe to the least severe, will be as follows: R, UJ, U, J.

A validation report will be generated for each method and sample delivery group. A copy of the validation report will be retained with the data package in the project chemistry file. The project chemist will be notified of any significant data quality problems.

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
1	VersionCode	Text	15	R	Yes	Code identifying the version of the EDD deliverable.
2	LabName	Text	10	R	Yes	Identification code for the laboratory performing the work. This value is used to distinguish between different facilities.
3	SDG	Text	15	R	No	Sample delivery group designation; always populated for all samples, including QC.
4	FieldID	Text	30	R	No	Client sample ID as appears on CoC forms with optional laboratory-assigned suffixes or prefixes to make it unique. If the sample ID on the CoC form and the prefix or suffix is more than 20 characters, abbreviate the value but make it unique. For laboratory QC samples (e.g., method blanks and laboratory control samples), use a unique laboratory sample ID.
5	NativeID	Text	30	R	No	Client sample ID, **exactly** as on CoC forms. **No prefix or suffix allowed** in client sample IDs. Used to identify the native sample from which other samples are derived (e.g., QAQCType = LR, MS, or SD). For laboratory QC samples (i.e., method blanks and laboratory control samples), use the FieldID value that was assigned. However, for laboratory blank spike duplicate samples, use the FieldID value that was assigned to the associated laboratory blank spike sample.
6	QAQCType	Text	2	R	Yes	The code for the sample type. Any field sample that is not used as laboratory QC and is not otherwise marked on the CoC forms should have the designation of “N” (normal field sample). No suffix allowed (i.e., do not add numbers as suffixes to the QAQCType values as called for in the ERPIMS guidelines). If all analyses for a given sample are diluted, the first dilution should be designated as the normal sample. If more dilutions are required, the next dilution should be designated as the first true dilution with a QAQCType value of “LR” and a LRType value of “DL” (see LRType,).

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
7	LRType	Text	3	C	Yes	This is the code for laboratory replicate sample type. Values are as follows: • Blank (if QAQCType value is not LR) • DL (dilution) • RE (re-analysis) • D (inorganic duplicate) • CF (confirmation) For multiple dilutions or reanalyses of the same sample, append the replicate number after the LRType value (e.g., RE, RE2, and RE3).
8	Matrix	Text	5	R	Yes	Sample matrix code. Valid values are as follows: “AIR”, “WATER”, or “SOIL” unless otherwise provided by the project data manager and marked on CoC forms. The use of other terms (e.g., “liquid” or “solid”) for laboratory QC is not allowed.
9	LabSampleID	Text	12	R	No	Laboratory sample ID assigned by the laboratory. Prefix or suffix is allowed. Dilutions or re-extractions are noted here. For example, “D97-11111RE” is acceptable.
10	AnalysisMethod	Text	20	R	Yes	Analysis method code. This is the ID of the analytical method performed on the sample. For example, “SW8260A.” Generic names such as “EPA” should not be used.
11	ExtractionMethod	Text	20	R	Yes	Preparation method code. A value in this field is required. If the preparation is described in the method, use “METHOD”. If there is no separate preparation required, use “NONE”. Total and dissolved metal analyses are differentiated by the value in this column. Total, TCLP, and SPLP analyses are differentiated by the value in the LeachMethod column (see below).
12	SampleDate	Date		C	No	Date of sample collection. A value is required for all samples sent to the laboratory and samples derived from those samples. Format = mm/dd/yyyy.
13	SampleTime	Time		C	No	Time of sample collection. A value is required for all samples sent to the laboratory and samples derived from those samples. Twenty-four-hour format (hh:mm).
14	ReceiveDate	Date		C	No	Date of sample receipt in the laboratory. A value is required for all samples sent to the laboratory and samples derived from those samples. Format = mm/dd/yyyy.

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
15	ExtractDate	Date		C	No	Date of sample preparation (extraction or digestion). A value is required if the ExtractionMethod field value is other than “NONE”. Format = mm/dd/yyyy
16	ExtractTime	Time		C	No	Time of sample preparation. A value is required if the ExtractionMethod field value is other than “NONE”. Twenty-four-hour format (hh:mm).
17	AnalysisDate	Date		R	No	Date of sample analysis. A value is required for all records. Format = mm/dd/yyyy
18	AnalysisTime	Time		R	No	Time of sample analysis. A value is required for all records. Twenty-four-hour format (hh:mm).
19	PercentSolids	Number		R	No	Percent solids within the sample; should be zero for water samples.
20	LabLotCtlNum	Text	10	C	No	ID for an autonomous group of environmental samples and associated QC samples prepared together. For example, the value can be a digestion or extraction batch ID. If there is no separate extraction or preparation performed, the field is left blank.
21	CAS	Text	20	R	No	CAS registry number of analyte, if available.
22	ParamID	Text	12	R	Yes	Parameter ID code for the parameter listed in the Analyte field.
23	Analyte	Text	60	R	No	Name of analyte, chemical name.
24	Result	Text	10	R	No	Result of the analysis. Surrogate analytes are reported in units of percent. All others are reported in sample concentration units. If undetected, report the adjusted MDL or adjusted RL, depending on the project. (Reported as a text field to preserve significant figures.)
25	ExpectedValue	Number		C	No	Report “100” for surrogates; report “0” for blanks; spike level plus parent result for LCS, and MS/MSD; parent value for laboratory duplicate.
26	Units	Text	10	R	Yes	Units of measure used in the analysis. Report “PERCENT” for surrogate analytes; report concentration units for all others.
27	Dilution	Number		R	No	Total dilution reported in the analysis. Default value is “1”. This value reflects changes to sample preparation amounts as defined by the method (e.g., less sample used for standard VOC analysis).

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
28	MDL	Number		C	No	Minimum detection limit adjusted for preparation and dilution. This value may be the method detection limit or the instrument detection limit, depending on the method and the project requirements. This value is **not** adjusted for percent moisture.
29	RL	Number		C	No	Reporting limit adjusted for preparation and dilution. Value is **not** adjusted for percent moisture. Equivalent to PQL.
30	LabQualifier	Text	6	R	No	Laboratory qualifier for the results, as reported on the hardcopy. Use "=" as first (or only) qualifier value for detected results if there are no other qualifiers for the result.
31	Surrogate	Text	1	R	Yes	If the chemical is a surrogate = Y; if not = N.
32	Comments	Text	240	O	No	Comment field.
33	ParValUncert	Text	16	C	No	Radiological parameter value uncertainty.
34	Recovery	Number		C	No	Percent recovery for MS, SD, LCS, LCSD, and surrogate compounds.
35	LowerControlLimit	Number		C	No	Lower control limit value for spiked compounds, expressed in units of percent. A value in this field is required if there is a value in the Recovery field (Field 34).
36	UpperControlLimit	Number		C	No	Upper control limit value for spiked compounds, expressed in units of percent. A value in this field is required if there is a value in the Recovery field (Field 34).
37	Basis	Text	1	R	Yes	Weight basis for soil (or solid) sample analysis; D = dry-weight basis, W = wet-weight basis, and X = not applicable.
38	ConcQual	Text	1	R	Yes	Concentration qualifier. Use "=" for detects, "J" for estimated value (value between detection limit and reporting limit), "U" for undetected result, and "E" for exceeded result.
39	MDLAdjusted	Number		C	No	Minimum detection limit adjusted for preparation, dilution **and percent moisture**. See the description of the MDL field (Field 28) for an explanation of the contents of this field.
40	RLAdjusted	Number		C	No	Reporting limit adjusted for preparation, dilution **and percent moisture**. Equivalent to PQL

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
41	SampleDescription	Text	30	C	No	Full sample ID as it appears on CoC forms. In some cases, this may be the name of the sampling location instead of the sample. Required for all samples that are either collected in the field and specified on CoC forms, or derived from samples that are collected in the field and specified on COC forms.
42	LeachMethod	Text	20	R	Yes	Analytical method used for leaching the sample; applies to TCLP, SPLP, or other leaching or pre-extraction leaching procedures. Use “NONE” if the sample was not leached.
43	LeachDate	Date		C	No	Date that the leaching method was performed (use the start date for multidate leaching procedures). Value is required if the LeachMethod field value is other then “NONE”. Format = mm/dd/yyyy.
44	LeachTime	Time		C	No	Time that the leaching procedure started. Value is required if the LeachMethod field value is other then “NONE”. Twenty-four-hour format (hh:mm).
45	LeachLot	Text	10	C	No	ID of an autonomous group of environmental samples and associated QC samples **leached** at the same time. Value is required if the LeachMethod field value is other then “NONE”. If the sample was not leached, the field is left blank.
46	AnalysisLot	Text	10	R	No	ID of an autonomous group of environmental samples and associated QC samples **analyzed** together. A value in this field is required (i.e., it should not be blank).
47	CalRefID	Text	10	C	No	ID of a group of environmental and QC samples linked by a common set of calibration records. All results with the same CalRefID value will have had the same initial calibration run.

[a] For a list of valid values see Table 6-1B.

Notes:

The EDD file from the laboratory will be a comma-delimited ASCII file in the format listed above. There will be one EDD file per hardcopy report and the filename of the EDD file will be in the format REPORTID.csv, where REPORTID is the hardcopy report ID of sample delivery group.

C = Conditionally Required
EPRIMS = Environmental Restoration Program Information Management System
R = Required
STLC = soluble threshold limit concentration
TCLP = toxicity characteristic leaching procedure

	Area <LT but not <10%	J = positive results; UJ = nondetects	
	Area <10%	J = positive results; R = nondetects	
Field Duplicates	Concentration of reported analytes are >5 times the RL in either sample and RPD >UT (30% for water samples; 50% for soil samples)	J = positive results	Field duplicate pair
	One or both sample results <5 times the RL and a difference of ±2 times the RL for water (±4 times for soil).	J = positive; UJ = nondetect	

TABLE 6-2
Flagging Conventions for Organic Methods
PG&E Program Quality Assurance Project Plan

Quality Control Check	Evaluation	Flag	Samples Affected
Confirmation (SW8015B; SW8021B,SW8081A; SW8151A;)	RPD between primary and confirmation results > 25%	J = positive results	Sample

Notes:

All QA/QC criteria are included in Tables 5-16 through 5-27 and will be used for validation criteria.

Organic methods include SW8015B, SW8081A, SW8082, SW8151A, SW8260B, SW8270C, and SW8270C SIM.

Spike recovery limits do not apply when sample concentration exceeds the spike concentration by a factor of four or more.

For methods requiring confirmation, the qualifications apply to primary analysis results (either of the two columns/detectors may be designated as the primary column/detector).

Where one MS recovery meets acceptance criteria and the other MS of the pair does not, professional judgment may be used to determine if the parent sample should be qualified for matrix effects by comparing the MS recoveries to other QC results within the batch or sample site.

Qualifier may not apply in cases where a surrogate coelutes with a nontarget analyte.

Qualifier may not apply in cases where low surrogate recoveries are due to sample dilution.

< = less than
> = greater than
%R = percent recovery
LT = lower tolerance
UT = upper tolerance

TABLE 6-3
Flagging Conventions – Minimum Data Evaluation Criteria for Inorganic Methods
PG&E Program Quality Assurance Project Plan

Quality Control Check	Evaluation	Flag	Samples Affected
Holding Time	Holding time exceeded for extraction, digestion, or analysis	J = positive results; R = nondetects for mercury; UJ = nondetects for all other analytes	Sample
	Holding time for digestion or analysis exceeded by a factor of two	J = positive results; R = nondetects	
Sample Preservation	Sample preservation requirements not met (If sample preservation was not done in the field, but was performed at the laboratory upon sample receipt, no flagging is required)	J = positive results; R = nondetects	Sample
Temperature	>6°C (not applicable to metals except mercury)	J = positive results; UJ = nondetects	Samples in same cooler
ICAL (Multipoint only)	Correlation coefficient ≤0.995	J = positive; UJ = nondetects	All associated samples in analytical batch
Calibration verification (ICAL verification, continuing calibration verification)	%R >UT	J = positive results	All associated samples in analytical batch
	%R <LT	J = positive results, UJ = nondetects	
Interference check sample (SW6010B/SW6020 only)	%R >UT	J = positive results	All associated samples in analytical batch
	%R <LT	J = positive results; UJ = nondetects	
Laboratory Control Sample	%R >UT	J = positive results	All samples in preparation batch
	%R <LT	J = positive results; UJ = nondetects	
	%R <10%	J = positive results; R = nondetects	
Calibration Blank (ICB,CCB) Method Blank	Multiply the highest blank concentration by five	U = positive sample results <5x highest blank concentration	All samples in preparation batch or analytical batch, whichever one applies, associated with method blank or calibration blank
Equipment Blank			All samples, same site, matrix and date
MS/MSD	%R >UT	J = positive results	MS analytes in parent sample and field duplicate
	%R <LT	J = positive results; UJ = nondetects	
	%R <10%	J = positive results; R = nondetects	
	RPD >UT	J = positive results	

TABLE 6-3
Flagging Conventions – Minimum Data Evaluation Criteria for Inorganic Methods
PG&E Program Quality Assurance Project Plan

Quality Control Check	Evaluation	Flag	Samples Affected
MS Dilute and Spike for hexavalent chromium by Methods SW7199 or EPA218.6 (see Section 5.3.3.1)	Spike recovery 85-115% and peak within recovery time window. If criteria are not met, the laboratory is required to dilute two aliquots 1:5, spike one with 1 μg/L of hexavalent chromium and analyze the other unspiked. Continue the aforementioned procedure using successively greater dilutions of two aliquots until recovery time and recovery criteria are met.	Choose the dilution where the RT/recovery criteria are met. If RT/recovery criteria are met at a 1:1 dilution, data qualification is not required for detected or nondetected results. If RT/recovery criteria met at dilution greater than a 1:1, elevate the RL for nondetected results and qualify the data U at a level equal to the RL multiplied by the dilution factor of the acceptable analysis (apply ValAdj validation reason). If RT/recovery criteria are not met: a) Analysis performed only at a 1:1 dilution: J positive results (apply LabA&P validation reason) UJ or R nondetects determined in conjunction with Project Chemist (apply LabA&P validation reason) b) Analysis performed at subsequent dilutions and criteria are still not met: J flag positive apply LabA&P validation reason) Elevate RL - UJ or R nondetects, determined in conjunction with project chemist (apply LabA&P validation reason)	Sample
Dilution Test	If concentration is >25 times the RL and percent difference >UT	J = positive results UJ = nondetects	Analytes in parent sample if analytical spike not performed
Postdigestion Spikes/Recovery Test (Metals only)	Spike results indicate performance of MSA required, but MSA not done.		All samples in digestion batch if MSA not performed
	%R >UT	J = positive	
	%R <LT	J = positive results, UJ = nondetects	

TABLE 6-3
Flagging Conventions – Minimum Data Evaluation Criteria for Inorganic Methods
PG&E Program Quality Assurance Project Plan

Quality Control Check	Evaluation	Flag	Samples Affected
MSA (GFAA only) for samples where postdigestion spike (performed as a result of unacceptable serial dilution) fails	r <0.995	J = positive results	Sample
Field Duplicates Laboratory Sample Duplicates	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%	J = positive results	Field duplicate pair
	One or both sample results <5 times the RL and a difference of ±2 times the RL	J = positive results; UJ = nondetects	

Notes:

< = less than
> = greater than

All QA/QC criteria are included in Tables 5-16 through 5-27 and will be used for validation criteria.

Spike recovery limits do not apply when sample concentration exceeds the spike concentration by a factor of four or more.

CCB = continuing calibration blank
ICB = Initial calibration blank
LabA&P = laboratory accuracy and precision criteria not met
LT = lower tolerance
MSA = method of standard addition
UT = upper tolerance
ValAdj = Value reported by laboratory adjusted because of matrix issues.

TABLE 6-4
Qualifier Flag Definitions
PG&E Program Quality Assurance Project Plan

Flag	Definition
J	Analyte was present but reported value may not be accurate or precise.
R	The result has been rejected.
U	Analyte was analyzed for but not detected at the specified detection limit.
UJ	Analyte was not detected above the detection limit objective; however, the reported detection limit is approximate and might not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

SECTION 7

Performance Evaluations

To assess sample and data collection procedures, performance evaluations will be conducted that include of technical systems audits and performance audits.

7.1 Technical Systems Audits

7.1.1 Laboratory Audits

The laboratories participating in the data collection effort will be prequalified by the project management teams. A surveillance audit program that requires routine technical system audits will be instituted. Laboratory prequalification and the surveillance audits may also be undertaken by regulatory agencies. Laboratory prequalification audits may be performed as onsite audits, desk audits, or a combination of both, depending on the scale and sensitivity of the project.

7.1.1.1 Onsite Laboratory Prequalification Audit

An onsite laboratory prequalification audit in conjunction with a desk audit (see Section 7.1.1.2) is the preferred audit when using a new laboratory. The onsite laboratory audit will start with a pre-audit meeting during which the auditor will discuss with the laboratory staff the purpose of the audit, the schedule and areas to be audited, and the procedures that will be followed. The meeting may include a brief tour of the laboratory. The audit will then be conducted. The auditor will assemble the findings at the conclusion of the audit and discuss the findings with laboratory staff.

Critical items that will be addressed in a technical system audit include the following:

- Calibration procedures and documentation
- Treatment and handling of standards
- Completeness of data forms, notebooks, and other reporting requirements
- Data review and verification procedures
- Data storage, filing, and recordkeeping procedures
- Sample custody procedures
- QC procedures, tolerances, and documentation
- Operating conditions of facilities and equipment
- Documentation of staff training and instrument maintenance activities
- Systems and operations overview

A written audit report will be sent to the laboratory within a specified time. A copy of the audit report will be sent to the project manager, and a copy will be retained in the project files.

The need for follow-up action will be determined based on the laboratory's responses. If an audit identifies an unacceptable condition or unacceptable data, the laboratory will be responsible for developing and initiating corrective action to resolve the situation. The project manager will be notified if the nonconformance impacts the project and requires resources not normally available to the project team. In such cases, the project manager will decide whether resources to pursue corrective action will be made available. Disposition may include the following:

- Reanalysis of samples if holding time has not expired
- Resampling and analysis
- Amending analytical procedures
- Acceptance of suspect data, acknowledging the limits on usability

7.1.1.2 Desk Prequalification Audit

In part, a prequalification audit is performed to provide a perspective of the laboratory operations and the internal auditing and data review processes. Noncritical samples, split samples, or performance evaluation samples will be sent to the laboratory as part of the prequalification audit to ascertain the laboratory's ability to produce quality data. Generally, this process starts by sending guidance documents (e.g., QAPP, SAP, and SOW) to the laboratory for review. After a review and confirmation, the laboratory will follow the guidance documents to the best of their ability and to the project chemist's satisfaction. The auditor will request copies of accreditation audits (e.g., ELAP, NELAP, or AFCEE), SOPs, an example data package, and the laboratory's quality assurance manual. After a review of the laboratory's documentation (including instrument output, analytical reports, and other documentation specific to a batch of samples), samples can be sent to the laboratory. The data will be validated by using the Level 4 protocol described in Section 6.3 and reviewing the laboratories QC documentation. The corrective actions described in Section 7.1.1.1 may also apply.

7.1.2 Field Audits

Field audits will be performed annually to verify the performance of field procedures. The audit will evaluate the following:

- Sample containers and preservatives
- Sample collection and identification procedures
- Sample custody, handling, and shipping procedures
- Equipment decontamination procedures
- Calibration of field instruments and performance of field tests
- Documentation of field activities, maintenance of field records, and document control

7.2 Performance Audits

7.2.1 Performance Evaluations

Laboratories are required to participate in a performance testing program, in accordance with the California ELAP. Any method or analyte failure in a performance evaluation that affects the certification status of the laboratory with the National Environmental Laboratory Accreditation Program or the state of California must be immediately communicated to the program chemist.

7.2.2 External Audits

Announced and unannounced audits of the field operations and laboratories may be conducted during any stage of the project.

7.2.3 Internal Audits

Annual audits of the laboratory shall be conducted by the laboratory's quality assurance officer. The audits shall verify, at a minimum, that written SOPs are being followed; standards are traceable to certified sources; documentation is complete; data review is being done effectively and is properly documented; and data reporting, including electronic and manual data transfer, is accurate and complete. All audit findings shall be documented in QA reports to management. Necessary corrective actions shall be taken within a reasonable timeframe. The quality assurance office shall verify that such actions are effective and complete and document their implementation in an audit closeout report to management.

SECTION 8

Preventive Maintenance

The primary objective of preventive maintenance is to promote the timely and effective completion of a data collection effort. The maintenance program should be designed to minimize the downtime of crucial sampling and analytical equipment caused by component failures. The maintenance program should establish the following:

- Maintenance responsibilities
- Maintenance schedules
- An adequate inventory of critical spare parts and equipment

8.1 Maintenance Responsibilities

Laboratory instrument maintenance is the responsibility of the participating laboratory. Generally, the laboratory manager or supervisor is responsible for the instruments in their work areas; they will establish maintenance procedures and schedules for each instrument. Laboratories should maintain service agreements with instrument manufacturers or a reputable service company to minimize downtime if there is an instrument malfunction.

Maintenance responsibilities for field equipment are assigned to the field team leader for specific sampling tasks. However, the field team using the equipment is responsible for checking the status of the equipment prior to use and reporting any problems encountered. The field team is also responsible for ensuring that critical spare parts are included as part of the field equipment checklist. Nonoperational field equipment should be removed from service and a replacement obtained. All field instruments will be properly protected against inclement weather conditions during the field investigation.

8.2 Maintenance Schedules

The effectiveness of any maintenance program depends, to a large extent, on adherence to specific maintenance schedules for each piece of equipment. Nonroutine maintenance activities are conducted as needed. Manufacturers' recommendations should provide the primary basis for establishing maintenance schedules. Service contracts may be used to implement maintenance schedules.

Each analytical instrument should be assigned an instrument logbook; all maintenance activities for will be the documented instrument in the logbook. Logbooks should contain the following information:

- Date of service
- Person performing the service
- Type of service performed and the reason for service
- Replacement parts installed, if appropriate
- Date of next scheduled service
- Any other useful information

8.3 Spare Parts

An adequate inventory of spare parts is required to minimize equipment down time. The inventory will include the following:

- Parts and supplies that are subject to frequent failure
- Parts and supplies that have limited useful lifetimes
- Parts and supplies that cannot be obtained in a timely manner should failure occur

Field managers and laboratory managers are responsible for maintaining an adequate inventory of spare parts. In addition to spare parts and supply inventories, an in-house source of backup equipment and instrumentation should be available.

SECTION 9

Data Assessment

9.1 Data Quality Assessment

All data will be evaluated according to the QA acceptance criteria specified in Tables 5-16 through 5-27. Limitations regarding data usability will be assigned, if appropriate, in accordance with the validation process described in Section 7.

9.2 Reconciliation with Project Objectives

The program includes projects and sites with varying tasks and objectives. The procedure for data reconciliation will be a function of the project-specific objectives and will be addressed in the project-specific documents.

SECTION 10

Corrective Action

Corrective action may be required as a result of deviations from field or analytical procedures. Deficiencies identified in audits and data quality evaluations may also call for corrective action. All project personnel have the responsibility to identify, report, and solicit approval for corrective actions to resolve conditions that are adverse to data quality.

Tables 5-16 through 5-27 specify the corrective actions to be taken when deviations from calibration and QC acceptance criteria occur. Field and laboratory staff may encounter conditions requiring immediate corrective action that are not addressed in this QAPP, the SAPs, or QAPP addenda. These staff will document conditions and the results of corrective actions in a field logbook or laboratory nonconformance report and communicate their actions as soon as feasible to the appropriate people (field team leader, laboratory supervisor, project chemist, project manager, and if necessary, the program quality manager) for immediate input. A mechanism must be in place to allow for supervisory review or client input, or both, for all deviations or deficiencies. A corrective action reporting system that requires immediate documentation of deviations or deficiencies and for supervisory review of the actions taken to correct them will be established. At a minimum, the corrective action report should include the following information:

- The type of deviation or deficiency
- The date of occurrence
- The impact of the deviation or deficiency, such as samples affected
- The corrective action taken
- Documentation that the process has been returned to control

The only time that a corrective action report may be waived is when a deviation or deficiency is immediately corrected and its impact is precluded. An example would be an unacceptable ICAL that is repeated before samples are analyzed.

Each corrective action report must be reviewed and approved by a person of authority, such as the field team leader or laboratory supervisor. The ultimate responsibility for the laboratory corrective action process is the QC manager, who must ensure that proper documentation, approval, and close out of all out-of-control or nonconformance events is performed. A nonconformance report will summarize each nonconformance condition. Corrective action reports that could potentially affect data quality must be brought to the attention of the project chemist. Report disposition will be the responsibility of the project chemist. The project manager may be notified about a particular report at the project chemist's discretion. Copies of corrective action reports must be maintained in the laboratory or field project files.

SECTION 11

Quality Assurance Reports

Where specified in the SAP, work plan, or QAPP addendum, a QA report or data quality evaluation will be submitted by the project chemist to the project manager on a predetermined interval established in the SAP or QAPP addendum. The report will summarize the results of the data validation and the data assessment. The results should be presented in a manner that facilitates decision making. For example, temporal data may be more effectively presented if supplemented by a time plot. Any significant quality problems and recommended solutions should be included in the report. Limitations on data usability identified during data validation should be highlighted. Results of the data assessment should be reconciled with the project objectives.

SECTION 12

Data Management

Electronic data associated with CH2M Hill projects will be used to generate validation reports, risk assessment calculations, modeling results, data summary tables, maps, and other figures. The data management program will follow CH2M HILL standard procedures for environmental data collection. All environmental data collected for the PG&E Program will follow the policies, procedures, and protocols as required in the *PG&E Program Data Management Plan* (CH2M HILL, 2004a). Other consultants or contractors may use other electronic data management programs, which will be described in the SAP or QAPP addendum. However, any system used must be capable of storing and managing the information listed in the *PG&E Program Data Management Plan* (CH2M HILL, 2004a) or its revision. The CH2M Hill plan provides data users with the following:

- Simple procedures to get rapid access to stored data
- Data entry methods of known accuracy and efficiency
- Well-documented validation procedures for electronic databases
- Sampling data management using unique sample IDs
- A sampling inventory of newly collected data and methods of sample inventory reconciliation
- Sample-specific attributes, including location IDs, sample type and media, and sample date
- Reporting and delivery formats to support data analysis and reduction

12.1 Archiving

Hardcopy and electronic versions will be archived in project files and on electronic archive tapes for the duration of the project, as specified in contractual agreements, or for a minimum of 5 years. All electronic data will be subject to routine back-up until it is archived for long-term retention.

12.2 Data Flow and Transfer

The data flow from the laboratory and field to the project staff and data users will be sufficiently documented to ensure that data are properly tracked, reviewed, and validated.

12.3 Record Keeping

In addition to the data management procedures for analytical data provided in Section 6.1, the laboratory will maintain electronic and hardcopy records sufficient to re-create each analytical event. At a minimum, laboratory will maintain the following records:

- Raw data, including instrument printouts, bench work sheets, and chromatograms, with compound identification and quantitation reports
- Laboratory-specific, written SOPs for each analytical method and QA/QC function implemental during the analysis of project samples

Record keeping requirements for non-analytical data are included in the *PG&E Program Data Management Plan* (CH2M HILL, 2004a).

Addenda

Addendum to the PG&E Program Quality Assurance Project Plan for Dioxins and Furans

Prepared for

Pacific Gas and Electric Company

January 2010

CH2MHILL
155 Grand Ave. Suite 1000
Oakland, CA 94612

1.0 Introduction

This Addendum to the *PG&E Program Quality Assurance Project Plan* (QAPP) (CH2M HILL, 2008) has been prepared to address relevant variations that may be encountered with the dioxin and furans data for the Topock compressor station that are not specifically addressed in the QAPP or SW-846 Method 8290. Laboratories will be required to adhere to the QAPP and then use the specific information outlined within this QAPP Addendum to supersede the QAPP and method information.

2.0 Project Organization and Responsibility

2.1 Project/Task Organization

TABLE 2-1
Project Staff
Addendum to the PG&E Program Quality Assurance Project Plan for the RCRA Facility Investigation/Remedial Investigation for Soil

3.0 Sampling Procedures

3.1 Sampling Design

The number and location of samples collected should be addressed in a work plan (WP) or sampling analysis plan (SAP). The WP or SAP should address or include a planned sample table, chain of custody forms, and other database-generated paperwork.

3.2 Field Sampling Procedures

Sample collection will follow the standard operating procedures (SOP) provided in the *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL, 2005). Updated SOPs may be available, check with the project manager and the project chemist for the latest approved SOPs.

4.0 Data Quality Objectives and Quality Assurance Program

The data quality objectives for all projects are specified in the WPs. They are the basis for the design of the data collection plan, and as such, they specify the type, quality, and quantity of data to be collected, and how the data are to be used to make the appropriate decisions for the project. The final output of the process is a data collection design that meets the qualitative and quantitative needs of the project.

4.1 Analytical Requirements

This QAPP Addendum addresses analytical methods that were not addressed in the QAPP. Method, analyte, or quality control parameters specified in this QAPP Addendum that differ from the QAPP supersede the criteria in the QAPP as the QAPP supersedes the methods.

The following discussion is presented as a process to be used for the purposes of confirming low level detected results (as defined by the method).

Congeners with results that are less than 5 times the signal to noise, but are considered detects for the purpose of reporting (under the method protocols both as an estimated detection level [EDL] or an estimated maximum potential concentration [EMPC]) will be re-analyze for confirmation. To confirm the results, the existing extract will be re-analyzed and compared to the original result. (Re-analyze the associated blank if it contains a similar low-level detect.)

If the confirmation results are considered detects for the purpose of reporting (under the method protocols) the more conservative result (higher concentration) will be reported and the result will be qualified as estimated and flagged “J”.

If the confirmation results are not considered detects for the purpose of reporting (under the method protocols, EDL or EMPC) the results will be reported at the previously detected concentration and flagged “U”.

The laboratory will be required to record and summarize the results of the above deviation (from the SW8290 method) in the report case narrative.

Other calibration and QC criteria will follow the SW8290 method.

4.2 Data Validation

The validation for this QAPP addendum will follow the Level 3B designation from the QAPP and in accordance with National Functional Guidelines, *USEPA Contract Laboratory Program National Functional Guidelines for Chlorinated Dioxin/Furan Data Review, EPA-540-R-05-001*, September 2005 and will be performed by the project chemist and designees.

Addendum to the PG&E Program Quality Assurance Project Plan for the RCRA Facility Investigation/Remedial Investigation for Soil

Prepared for

Pacific Gas and Electric Company

Revision 0 (December 2008); Revision 1 (January 2010)

CH2MHILL
155 Grand Ave. Suite 1000
Oakland, CA 94612

1.0 Introduction

This addendum to the *PG&E Program Quality Assurance Project Plan* (QAPP) (CH2M HILL, 2008) has been prepared to address any variations (from the QAPP) associated with the RCRA facility investigation/remedial investigation (RFI/RI) of the Topock compressor station that are not included in the QAPP. Laboratories will be required to adhere to the QAPP and then use the specific information outlined within this addendum to supersede the QAPP information.

2.0 Project Organization and Responsibility

2.1 Project/Task Organization

TABLE 2-1
Project Staff
Addendum to the PG&E Program Quality Assurance Project Plan for the RCRA Facility Investigation/Remedial Investigation for Soil

2.2 Certification Requirements

All laboratories participating in analytical services will be certified under the state of California, Department of Health Environmental Laboratory Accreditation Program where applicable. The laboratory managers will be responsible for ensuring that all personnel have been properly trained and are qualified to perform their assigned tasks.

3.0 Sampling Procedures

3.1 Sampling Design

The number and location of samples collected for the soil RFI are discussed in the Draft *RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan, Part A and Part B* (CH2M HILL, 2007). The work plan also addresses the medium sampled, information about the sampling site, the type of data to be collected, and how the data are to be used. The soil RFI/FI projects have multiple large sampling events and will use the field database, a planned sample table, chain of custody forms, and other database-generated paperwork.

3.2 Field Sampling Procedures

Sample collection will follow the standard operating procedures (SOP) provided in the *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL, 2005). Updated SOPs may be available, check with the assistant project manager and the project chemist for the latest approved SOPs.

4.0 Data Quality Objectives and Quality Assurance Program

The data quality objectives for the soil RFI/FI are specified in the WPs. They are the basis for the design of the data collection plan, and as such, they specify the type, quality, and quantity of data to be collected, and how the data are to be used to make the appropriate decisions for the project. The final output of the process is a data collection design that meets the qualitative and quantitative needs of the project. See Appendix A (Soil RFI Analyte Comparison Table) for additional screening level information used for decisions making.

4.1 Analytical Requirements

This QAPP addendum specifies project-specific analytes and analytical methods that differ from the QAPP. All method, analyte, or quality control parameters specified in this addendum that differ from the QAPP supersede the criteria in the QAPP as the QAPP supersedes the methods.

For purpose of reporting all analytes, with the exception of dioxins and furans (SW8290), that are not detected at or above the laboratory RL will be flagged “U” and reported as not detected at the RL.

For dioxins and furans (SW8290) congeners with results that are less than 5 times the signal to noise, but are considered detects for the purpose of reporting (under the method protocols) will be re-analyze for confirmation. To confirm the results the extract will be re-analyzed and compared to the original result. (Re-analyze the associated blank if it contains a similar low-level detect.)

If the confirmation results fall within an acceptance criteria of ± 50% RPD the more conservative result (higher concentration) will be reported.

If the confirmation results do not fall within the ± 50% RPD acceptance criteria and the result is less than the original result the congener will be flagged “U” and reported as non-detect at 5 times the signal to noise.

If the confirmation results do not fall within an acceptance criteria of ± 50% RPD and the result is higher than the original result – the project chemists will work with the laboratory to determine and correct the issue with the data.

The soil RFI/FI projects will use the Contract Laboratory Program (CLP) full list of metals (ILM05.3/ILM05.4 Target Compound List, 2007), pesticides, polychlorinated biphenyls (PCB), volatile organic compounds and semivolatile organic compounds (SOM01.2 Target Compound Lists, 2006) on 10 percent of the initial sampling for Part A and Part B. The remaining 90 percent of the initial sampling will use the method criteria as specified in the QAPP (Project Standard List, Table 4-1 through Table 4-7).

The analytes and analytical requirements are presented in the following tables.

4.2 Data Validation

The validation for this QAPP addendum will follow the Level 3B designation from the QAPP and will be performed by the project chemist and designees.

TABLE 4-1
Reporting Limits, Accuracy, and Precession Limits for General Chemistry
Addendum to the PG&E Program Quality Assurance Project Plan for the RCRA Facility Investigation/Remedial Investigation for Soil

					EPA Regional Screening Levels 2008				**LCS/MS/MSD Accuracy Control Limits (%R)**

Fluoranthene	206-44-0	330	2,300,000	22,000,000	2,300,000	No	54	125	30
Fluorene	86-73-7	330	2,300,000	22,000,000	2,300,000	No	49	125	30
Hexachlorobenzene	118-74-1	330	300	1,100	300	Yes	47	125	30
Hexachlorobutadiene	87-68-3	330	6,200	22,000	6,200	No	40	125	30
Hexachloroethane	67-72-1	330	35,000	120,000	35,000	No	34	125	30
Indeno (1,2,3-c,d) pyrene	193-39-5	330	150	2,100	150	Yes	38	125	30
Isophorone	78-59-1	330	510,000	1,800,000	510,000	No	43	125	30
Naphthalene	91-20-3	330	3,900	20,000	3,900	No	40	125	30
Nitrobenzene	98-95-3	330	31,000	280,000	31,000	No	41	125	30
n-Nitrosodi-n-propylamine	621-64-7	330	69	250	69	Yes	40	125	30
n-Nitrosodiphenylamine	86-30-6	330	99,000	350,000	99,000	No	49	125	30
Pentachlorophenol	87-86-5	700	3,000	9,000	3,000	No	25	125	30
Phenanthrene	85-01-8	330					50	125	30
Phenol	108-95-2	330	18,000,000	180,000,000	18,000,000	No	39	125	30
Pyrene	129-00-0	330	1,700,000	17,000,000	1,700,000	No	46	125	30

Notes:

DTSC CHHSL: Residential benzo (a) pyrene 38 (µg/kg), pentachlorophenol – 4,400 (µg/kg)

DTSC CHHSL: Commercial benzo (a) pyrene 130 (µg/kg), pentachlorophenol – 130,00 (µg/kg)

All soils sample results will be reported in dry weight unless otherwise specified in the SAP.

TABLE 4-7B

Reporting Limits, Accuracy, and Precession Limits for Semivolatile Organic Compounds – SW8270C – Additional CLP Parameters

Addendum to the PG&E Program Quality Assurance Project Plan for the RCRA Facility Investigation/Remedial Investigation for Soil

			EPA Regional Screening Levels 2008				LCS/MS/MSD Accuracy Control Limits (%R)		
Constituent	**CAS**	**QAPP RL (µg/kg)**	**Residential (µg/kg)**	**Commercial (µg/kg)**	**Most Stringent Screening Level (µg/kg)**	**Does RL Exceed Screening Level?**	**Lower Limit**	**Upper Limit**	**Precision Soil % RPD**
1,1'-Biphenyl	92-52-4	700	3,900,000	51,000,000	3,900,000	No	*	*	30
