1.0 Introduction

Pacific Gas and Electric Company (PG&E) is conducting investigative and remedial activities at the Topock Compressor Station in Needles, California. Investigative and remedial activities at the Topock site are being performed under the Resource Conservation and Recovery Act (RCRA) and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), pursuant to agreements with the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI), respectively. The Topock Compressor Station is located in San Bernardino County, approximately 15 miles to the southeast of Needles, California. Figure 1-1 presents the site location map. (All figures are located at the end of this main report.)

This Soil RCRA Facility Investigation/Remedial Investigation (RFI/RI) Work Plan (Work Plan) presents the proposed soil and related investigation activities for all areas of the site. It is comprised of two geographically adjacent areas: Part A (areas outside the compressor station fence line) and Part B (areas inside the compressor station fence line). The perimeter areas adjacent to the compressor station fence line and the storm drains leading from the compressor station to areas outside the fence line are also included in this Work Plan. A DTSC letter dated January 4, 2011 (DTSC, 2011a) provided direction for preparing a combined Part A and Part B work plan.

1.1 History of the Soil Investigation Program

The *Revised Final RFI/RI Volume 1, PG&E Topock Compressor Station, Needles, California* (Revised Final RFI/RI Volume 1) (CH2M HILL, 2007a) identified 19 Solid Waste Management Units (SWMUs), Areas of Concern (AOCs), and other undesignated areas (UAs) at the Topock Compressor Station to be carried forward in the soil RFI/RI. These areas included:

- SWMU 1 – Former Percolation Bed
- AOC 1 – Area Around Former Percolation Bed
- AOC 4 – Debris Ravine
- AOC 5 – Cooling Tower A
- AOC 6 – Cooling Tower B
- AOC 7 – Hazardous Materials Storage Area
- AOC 8 – Paint Lockers
- AOC 9 – Southeast Fence Line (Outside Visitor Parking Area)
- AOC 10 – East Ravine
- AOC 11 - Topographic Low Area
- AOC 12 – Fill Area
- AOC 13 – Unpaved Areas within the Compressor Station
- AOC 14 – Railroad Debris Site
- AOC 15 – Auxiliary Jacket Water Cooling Pumps

- AOC 16 – Sandblast Shelter
- AOC 17 – Onsite Septic System
- AOC 19 – Former Cooling Liquid Mixing Area
- AOC 20 – Industrial Floor Drains
- UA-1 – Potential Pipe Disposal Area

The Revised Final RFI/RI Volume 1 also identified eight additional units and one UA (UA-2) requiring further investigation. These eight units consist of five units associated with the former hazardous waste management system (SWMUs 5, 6, 8, and 9, and AOC 18) that were closed by DTSC in 1995, and three units associated with the former oily water treatment system (Units 4.3, 4.4, and 4.5) that were also closed by DTSC in 1995. In a letter dated July 13, 2006, DTSC requested that additional sampling be conducted at these units. Similarly, UA-2, the Former 300B Pipeline Liquids Tank, was also previously closed, and DTSC requested additional sampling for this area in the same July 13, 2006 letter.

An addendum to the Revised Final RFI/FI Volume 1 will be prepared to document the new units (SWMU 11 and AOCs 21 through 26) that have been added to the investigation program since the Revised Final RFI/FI Volume 1 was prepared. These units were added at the direction of DTSC and DOI.

Two draft work plans were prepared to describe collection of additional soil data to complete site characterization activities at the SWMUs, AOCs, and UAs identified in the Revised Final RFI/RI Volume 1. Investigation areas outside the compressor station fence line were addressed in the *Draft RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A, PG&E Topock Compressor Station, Needles, California* (Draft Soil Part A Work Plan) (CH2M HILL, 2006). Investigation areas within the compressor station fence line were addressed in the *Draft RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part B, PG&E Topock Compressor Station, Needles, California* (Draft Part B Work Plan) (CH2M HILL, 2007b). To minimize the number of samples and disturbances to sensitive resources, the Part A and Part B investigation programs are being conducted in two phases. The objective of Phase 1 is to collect supplemental soil data, and the objective of Phase 2 is to fill data gaps identified in the Phase 1 data. Phase 2 sampling will only be necessary where data gaps are identified after evaluation of the combined soil data set (existing data and supplemental Phase 1 data).

1.1.1 Soil Part A Investigation History

DTSC and DOI conditionally approved the Draft Soil Part A Work Plan on August 10, 2007 (DTSC, 2007) and June 4, 2008 (DOI, 2008), respectively. Clarification of DTSC's conditional approval was documented in an email containing the table titled "Clarification to Responses to PG&E Topock Compressor Station Soil Investigation Part A Work Plan August 10, 2007 Conditional Approval Letter" (CH2M HILL, 2007c).

DTSC's conditional approval letter specifically rejected the data quality objectives (DQOs) and associated data gaps evaluation process presented in Sections 3.0 and 4.0 of the Draft Soil Part A Work Plan, while directing PG&E to implement Phase 1 of soil sampling. In August 2008, the Draft Soil Part A Work Plan was implemented. Items of note for the Part A field implementation include:

- At DOI’s direction, no intrusive sampling was performed at UA-1 (Potential Pipe Disposal Area).
- Two areas located near UA-1, called UA-1B and UA-1C Alternate, were identified by PG&E as a potential alternate locations for the Potential Pipe Disposal Area.
- Investigation work at AOC 4 was not conducted in 2008 due to the then-pending AOC 4 time-critical removal action, which was completed in December 2010. Subsequently, the AOC 4 time-critical removal action confirmation soil samples were used to conduct a data gaps evaluation; the results of the evaluation are included in Appendix A of this document.

From June 2008 to February 2010, DTSC, DOI, and PG&E convened a series of meetings to draft the DQO Steps 1 through 5 for the Soil Part A investigation. The steps are presented in the technical memorandum *Data Quality Objectives – Part A Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2010a) (referred to as the Soil Part A DQO Tech Memo, which is included in Appendix A). Between May 2009 and January 2010, through additional employee interviews and site reconnaissance after a major storm event, two new investigation areas were identified near AOC 11, along with a new investigation area, the MW-24 Bench. These new areas were added to Part A data gaps evaluation.

A data gaps evaluation was conducted for each of the Part A investigation areas using the Part A DQO process to ensure that data collected are of sufficient quantity and quality to enable the specified decisions to be made. The data gaps evaluation was initially completed through Step 5 of the DQO process. DQO Steps 6 and 7 were completed through a series of meetings with DTSC, DOI, Tribes, other stakeholders, and PG&E in 2010. Specifically, two meetings were held at the Topock Compressor Station on October 6 and 7, 2010 and November 2 and 3, 2010. In these meetings, data were reviewed with stakeholders, the AOCs were visited, and preliminary data gaps evaluations were discussed. A meeting was held on December 7, 2010 between DOI, DTSC, and Tribes to discuss UA-1/UA-1 Alternate and sampling at the mouth of Bat Cave Wash. On December 13, 2010, DTSC issued direction to PG&E on UA-1 and UA-1 Alternate (DTSC, 2010a). On December 15, 2010, DOI issued direction to PG&E on sampling at the mouth of Bat Cave Wash (DOI, 2010). On January 13, 2011, a meeting was held to discuss Tribes’ comments on the preliminary data gaps evaluation. Additional direction to PG&E on the Part A data gaps evaluation was issued in a joint letter from DTSC and DOI dated February 25, 2011 (included in Appendix A; Attachment 1). The Soil Part A Phase 1 Data Gaps Evaluation Report (providing the agreed-upon Phase 2 sample locations) is included as Appendix A of this document.

Based on the Part A data gaps evaluation, no further investigations are needed at two areas (AOC 12, Fill Areas and UA-2 – Former 300B Pipeline Liquids Tank). Nine investigation areas located outside of the compressor station fence line are proposed for further investigation in this work plan and are shown on Figure 1-2. The Part A investigation areas are:

- SWMU 1 – Former Percolation Bed
- AOC 1 – Area Around Former Percolation Bed
- AOC 4 – Debris Ravine

- AOC 9 – Southeast Fence Line
- AOC 10 – East Ravine
- AOC 11 – Topographic Low Areas, including the two new areas
- AOC 14 – Railroad Debris Area
- UA-1 – Potential Pipeline Disposal Area
- MW-24 Bench Area

The identified data gaps for these areas and Soil Part A Phase 2 Soil sample locations are presented in Appendix A of this report.

1.1.2 Soil Part B Investigation History

DTSC and DOI provided comments on the Draft Part B Work Plan in March 2008. PG&E requested clarification of several of the agencies' comments on April 21, 2008. DTSC and DOI provided clarification and direction on March 10, 2010 (DTSC and DOI, 2010b). DTSC's letter informed PG&E that no responses were necessary to DTSC's previous comments on the DQOs for the Draft Part B Work Plan, but it did require responses to all other comments to the Draft Part B Work Plan, as summarized in DTSC's March 26, 2008 letter. DOI's letter requested that PG&E not respond to DOI's previous comments on the Draft Part B Work Plan. Both DTSC and DOI letters directed PG&E to develop a Soil Part B DQO Technical Memorandum (similar to the Soil Part A DQO Tech Memo) and, once the Soil Part B DQO Tech Memo had been prepared and approved by DTSC and DOI, to develop a new Part B Work Plan.

The Soil Part B DQO Steps 1 through 5 are presented in the technical memorandum *Data Quality Objectives – Part B Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (Soil Part B DQO Tech Memo) (CH2M HILL, 2011). DTSC and DOI provided comments on initial drafts of the data gaps evaluation flow charts and the draft of the Tech Memo, and final Tech Memo was revised in accordance with the agencies' input. Steps 6 and 7 will be completed once the initial Part B data have been collected. The Soil Part B DQO Tech Memo, the Soil Part B Investigation Program (Soil Part B Work Plan), and responses to DTSC comments on the 2007 Draft Part B Work Plan are included as Appendix B of this document.

In DTSC's July 20, 2010 comments on PG&E's "Response to Comments to the Draft Soil Part B Work Plan"(DTSC, 2010c), DTSC requested the addition of seven additional areas located inside the compressor station fence line, including one new SWMU and six new AOCs.

Twenty-five investigation areas inside the compressor station fence line are proposed for further investigation in this Work Plan, as shown on Figure 1-3. Two new areas of potential concern were identified recently based on employee interviews. These new investigation areas are the Teapot Dome Restaurant oil pit and a potential burn area near AOC 17, shown in Figure 1-3. The Teapot Dome Restaurant oil pit will be investigated in conjunction with the Perimeter Area (discussed in Section 2.4.2), and the potential burn area will be evaluated in conjunction with AOC 13. The Part B investigation areas are:

- AOC 5 – Cooling Tower A
- AOC 6 – Cooling Tower B

- AOC 7 – Hazardous Materials Storage Area
- AOC 8 – Paint Locker
- AOC 13 – Unpaved Areas within the Compressor Station
- AOC 15 – Auxiliary Jacket Water Cooling Pumps
- AOC 16 – Sand Blast Shelter
- AOC 17 – Onsite Septic System
- AOC 18 – Combined Waste Water Transference Pipelines
- AOC 19 – Former Cooling Liquid Mixing Area
- AOC 20 – Industrial Floor Drains
- AOC 21 – Round Depression near Sludge-drying Beds
- AOC 22 – Unidentified Three-sided Structure (in the upper yard)
- AOC 23 – Former Water Conditioning Building (now used as a storage building)
- AOC 24 – Stained Area Associated with a Potential Former Oil/Water Separator (in lower yard near northern bank of scrubbers)
- AOC 25 – Station Compressor and Auxiliary Engines and Associated Basements
- AOC 26 – Former Scrubber Sump
- SWMU 5 – Sludge Drying Beds
- SWMU 6 – Chromate Reduction Tank
- SWMU 8 – Process Pump Tank
- SWMU 9 – Transfer Sump
- SWMU 11 – Former/Current Sulfuric Acid Tanks (associated with the cooling towers)
- Units 4.3 – Oil/Water Holding Tank
- Unit 4.4 – Oil/Water Separator, and
- Unit 4.5 – Portable Oil Storage Tank

The Soil Part B Phase 1 sampling program, including sample locations, are provided in Appendix B of this report.

1.1.3 Other Investigation Areas

In addition to the specific units described above, two other investigation program components are identified: the Perimeter Area and the storm drain system. The Soil Part A and Part B investigations overlap in the Perimeter Area and are also potentially connected through the storm drains that discharge into SWMU 1, AOC 1, AOC 10, and AOC 11. The

Perimeter Area is defined as the area outside the immediate fence line of the compressor station to the bottom of the slope. The storm drain system consists of active and abandoned storm drain lines within the compressor station and outfalls from the system outside the fence line.

Table 1-1 lists investigation areas, whether the area is inside or outside the compressor station fence line, approximate size, and where to find additional information for the area in this work plan.

1.1.4 Perimeter Area Investigation

Previous investigations have not been conducted within the Perimeter Area. The DTSC identified the Perimeter Area as a potential concern during the development of the Draft Part B Work Plan in 2007. On October 18, 2007, DTSC and PG&E conducted a site walk to identify appropriate perimeter sampling locations. Fifteen perimeter sample locations were identified and incorporated into the Draft Part B Soil Work Plan and are incorporated into this combined investigation program. The proposed Perimeter Area investigation program is included as Appendix C of this document. The following is a summary of the Perimeter Area investigation program.

The Perimeter Area investigation program was developed to evaluate the potential effects from contamination at SWMUs and AOCs inside the facility on areas outside the fence line. Soil samples will be collected along the perimeter of the compressor station just outside the fence line; the need for step-out samples further downslope will be based on initial perimeter sample results that will be evaluated during the data gaps evaluation. Perimeter sample locations, sample depths, and the analytical suite are presented in Appendix C.

The Perimeter Area investigation data will be used to help evaluate whether human receptors outside the fence line could be exposed to surface soil impacted by chemicals originating within the fence line of the compressor station through the offsite migration pathway. The specific pathways through which receptors outside the fence line could be exposed to constituents that have migrated outside the facility fence line are defined in the *Remedial Action Work Plan, PG&E Topock Compressor Station Needles, California* (ARCADIS, 2008) and the Soil Part A DQO Tech Memo (CH2MHILL, 2010a). The decision process for the offsite migration evaluation is described in the Soil Part B DQO Tech Memo (CH2M HILL, 2011).

1.1.5 Storm Drain System Investigation

DTSC directed PG&E to conduct a comprehensive evaluation of the facility storm drain system in its October 5, 2010 comments on the Draft Soil Part B DQO Tech Memo (DTSC 2010d). DTSC directed PG&E to conduct a storm drain investigation program because no physical investigation has been conducted to specifically target the storm drains at the Topock Compressor Station.

Prior investigation associated with the storm drain system has been limited to investigation conducted at AOC 9, AOC 10a, and low areas that would receive stormwater runoff outside the fence line. A records review for storm drain locations was conducted for the Revised Final RFI/RI Volume 1 and during subsequent phases of soil investigation work plan preparation. The proposed storm drain system investigation program is included as Appendix D of this document. This subsection is a summary of the storm drain system investigation.

Two types of information will be generated by the storm drain investigation: information on the alignments of various storm drain lines and soil sample information outside the fence line. Information on storm drain line alignments is required to satisfy Decision 4 of the Part B DQOs (CH2M HILL, 2011). Because storm drains provide a potential transport pathway for constituents released within the fence line to areas outside fence lines, the potential for constituents in soil and spilled liquids to migrate to areas outside the fence line is better addressed with information regarding which catch basins discharge to the various outfalls.

In addition, to satisfy Part A and Part B DQO Decision 1, data are needed to characterize potential discharges from storm drains to soil. Finally, both types of information are required to satisfy Part A Decision 4 and Part B DQO Decision 5 (i.e., to ensure that there is sufficient information to proceed with the development of the corrective measures study/feasibility study [CMS/FS], remedial design, and/or interim measures). The primary transport pathway associated with the storm drain system would be discharge of contaminants into the storm drains, followed by runoff from the storm drains to areas outside the fence line. Consequently, a consideration in the storm drain alignment investigation is not only the physical location of the storm drains, but the drainage pathways; that is, assessing which storm drains discharge to specific outfalls. The storm drain investigation process, proposed storm drain outfall sample locations, sample depths, and analytical suite are presented in Appendix D.

1.2 Objectives

Data collected from implementation of this Work Plan will be combined with the existing data set to use as inputs to DQO decisions or confirm unit closure. The combined data set will be presented in the Final RFI/RI Volume 3 (Soil). The objectives of the Soil Part A and Part B investigation programs are presented in the Soil Part A DQO Tech Memo (Appendix A) and Soil Part B DQO Tech Memo (Appendix B).

1.3 Report Organization

This Soil RFI/RI Work Plan is organized as follows:

- **Section 1.0, Introduction**, contains background information, objectives, and report organization.
- **Section 2.0, Field Investigation Activities**, provides an overview of various field activities including site preparation, access and staging, standard operating procedures, site restoration, and investigation program.
- **Section 3.0, Quality Control, Data Management, and Data Validation**, presents the sampling and analysis plan, analytical methods and associated quality control samples, summary of the data management process, and data validation.
- **Section 4.0, Data Evaluation**, presents summary of the overall data evaluation process for those investigation areas in Part A and Part B, as well as for the Perimeter Area and storm drain system investigation programs.
- **Section 5.0, Approvals and Authorizations**, presents the anticipated approvals needed to implement this work plan, as well as the biological evaluation and archeological surveys, reviews, and consultations.
- **Section 6.0, References,** presents a list of works cited when preparing this document.

- **Appendix A, Part A Data Gaps Investigation Program,** contains the Part A data gaps investigation program, which presents identified data gaps and additional samples needed to resolve the data gaps and the Soil Part A DQO Tech Memo.
- **Appendix B, Part B Data Gaps Investigation Program,** contains the Part B data gaps investigation program, which describes additional data needs and proposed sample locations and the Soil Part B DQO Tech Memo.
- **Appendix C, Perimeter Area Investigation Program**, presents the proposed sampling approach to evaluate soil conditions along the perimeter of the compressor station.
- **Appendix D, Storm Drain Investigation Program**, presents the proposed evaluation and sampling approach for the storm drain system at the compressor station.
- **Appendix E, Preliminary Implementation Schedule for Complete Soil Work Plan**, contains the preliminary implementation schedule for completing the Soil RFI/RI Work Plan.
- **Appendix F, Summary of Proposed Sampling Program (Planned Sampling Table)**, contains the planned sample table for Part A, Part B, Perimeter Area, and storm drain system samples.
- **Appendix G, Standard Operating Procedures**, contains standard operating procedures (SOPs). This appendix is provided on CD only.
- **Appendix H, PG&E Program Quality Assurance Project Plan and Quality Assurance Program Plan Addendum**, contains the PG&E Program Quality Assurance Project Plan (QAPP) and QAPP Addendum. This appendix is provided on CD only.

1.4 Schedule

The preliminary implementation schedule for the complete soil work plan is presented in Appendix E.

2.0 Field Investigation Activities

This section describes the field investigation activities associated with implementation of the Part A, Part B, Perimeter Area, and storm drain system investigation programs. Topics addressed in this section include site preparation, access, and staging; applicable SOPs; site restoration activities; and the investigation programs. Detailed discussions of the Part A and Part B investigation programs, including sampling locations, are provided in Appendices A and B, respectively. The Perimeter Area and storm drain system investigation programs are provided in Appendices C and D, respectively. Specific sample information for all proposed sample locations (e.g., sample depth, analytical suites, etc.) is provided in the planned sampling table (PST) included as Appendix F.

2.1 Pre-construction Activities

This section presents activities to be conducted prior to intrusive work.

2.1.1 Project Initiation Meeting

Consistent with other phases of work conducted at the Topock site, PG&E will invite agency representatives and other stakeholders (including representatives of Native American Indian tribes involved with the Topock project) to the site for a project initiation meeting. This meeting will be scheduled to occur prior to the start of intrusive activities; however, it is anticipated that various site preparation activities will be conducted prior to this meeting. During the meeting, PG&E will present an overview of the activities that will be conducted as part of this work plan, discuss various cultural and biological sensitivities associated with the project, introduce key project team members (including subcontractors), identify certifications required for site visitors, describe applicable site safety and communication protocols, and review plans for project communications with the agency and stakeholders during work.

2.1.2 Surveys

In accordance with the programmatic biological assessment (PBA), a qualified biologist will conduct a pre-construction biological survey of all work areas prior to ground-disturbing activities. Prior to beginning of site preparation, a survey of aboveground and underground utilities will be conducted within all work areas. An asbestos survey will be performed by State of California-certified asbestos professional in the MW-24 Bench Area. The survey will include a visual inspection of surface materials and debris and collection of material and debris samples to determine asbestos content and friability.

In addition, pre-project archeological survey field verification will be conducted prior to ground-disturbing activities. Areas covered with vegetation will be surveyed after the vegetation is cleared for access.

2.1.3 Site Access and Demarcation

The proposed access routes and drilling sites will be field-checked and will be clearly delineated before equipment mobilization. Minor road improvements and/or minor grading might be necessary to access a few sample locations in AOC 1 and the lower check berm in AOC 11. Topographic low areas modified during the 2008 Part A Field Sampling event may require further modifications to access proposed samples in the upper reaches of AOC 11. Access to the area at the mouth of Bat Cave Wash within AOC 1 will require extensive pruning of the vegetation in this area to allow access for sampling equipment. Detailed discussions of site-specific access restrictions are presented Appendices A and B. Access routes for the Part A investigation are shown on the sampling figures; access for the Part B investigation will be to the compressor station via the plant access road.

2.1.4 Staging Areas

Staging areas previously used for other projects will be used for this soil investigation. Staging areas for the Part A investigation are shown on the sampling figures for the individual units. The proposed equipment decontamination area and primary staging area for drilling equipment and investigation-derived waste (IDW) management will be on PG&E property, as shown on Figure 2-1; all staging areas for the Part B investigation are also shown on Figure 2-1.

Drill rigs will be cleaned before mobilization to the site and following completion of drilling at the site if visible grease, oil, or other contamination is present on the equipment. After the drill rigs have been mobilized into place, the localized staging areas will be established in the drilling work area. Plastic sheeting will be laid on the ground surface in the staging areas to keep the drilling materials and equipment clean and to minimize impacts to the ground surface from the drilling materials and equipment. In accordance with Occupational Safety and Health Administration requirements, the exclusion zones for the drilling sites will be demarcated.

Drilling will conform to state and local regulations. PG&E will obtain all necessary authorizations required for drilling. The specific drilling locations within the areas indicated on individual investigation areas figures in Appendices A, B, C, and D will be based on the results of utility clearance surveys, including hand-digging where needed to ensure safe working distances from overhead and underground utility hazards. Approvals and authorizations are discussed in Section 4.0. Additional site-specific access restrictions, site preparation (e.g., embankment modifications), and access routes are presented in Appendices A and B.

2.2 Standard Operating Procedures

Soil sample collection and handling activities will follow SOPs from the *Topock Program Sampling, Analysis, and Field Procedures Manual, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2005). The SOPs relevant for the investigation activities for this project are included in Appendix G. The methods, equipment, and procedures for borehole drilling requirements, surface soil sampling, subsurface soil sampling, debris sampling, geophysical surveys, potholing/trenching and sampling, surveying, vegetation removal, waste management, and decontamination are briefly described in the following subsections.

2.2.1 Installation of Boreholes and Soil Sample Collection

Four methods of subsurface soil collection may be used during implementation of this work plan. Methods for collecting soil samples include drilling, potholing/trenching, hydrovac potholing, and hand sampling.

2.2.1.1 Drilling

The drilling and core/borehole logging will be performed under the supervision of a California Professional Geologist. The methods, equipment, and procedures for drilling and core logging are described in the following subsections.

Drilling Requirements. The drilling methods used may vary depending on the conditions encountered. The preferred drilling method is rotosonic (SOP-B9, *Drilling – Sonic Method*). Rotosonic methods are preferred for drilling through unconsolidated materials above bedrock. This method involves advancing a rotating and vibrating drill casing or core barrel through the subsurface. Rotosonic drilling can produce a continuous core from the ground surface to the target drilling depths; generates minimal drilling wastes; and typically can drill through gravel, cobble, and softer bedrock formations. Rotosonic boreholes drilled for sample collection will be a minimum of 4 inches in diameter but may go up to 6 inches in diameter, as necessary. Alternative drilling methods, including GeoProbe and hollow-stem auger, have been attempted in the past and are generally not effective in the rocky soils encountered at Topock.

Rotosonic drilling activities will be conducted using either standard truck-mounted or a track-mounted rotosonic drilling rig. A tracked or balloon-tired vehicle will be used to support the drilling rig by transporting cuttings, tools, and excess core generated from the drilling sites to the staging area. Given the proximity of most drilling locations to National Trails Highway, one or more standard highway vehicles or small all-terrain vehicles may be used to transport crew, equipment, and materials from the staging area to the drill site. Disposal procedures for IDW are discussed in Section 2.2.9.2.

Core Logging and Preservation. Lithologic descriptions of each borehole will be logged based on visual inspection of the retrieved core under the supervision of a California Professional Geologist and will follow the SOPs for Topock drilling investigations (SOP-B2, *Borehole Sampling and Logging of Soil Borings*). At a minimum, the field log will document the information listed below.

General

- Unique boring identification
- Purpose of the boring (e.g., soil sample collection)
- Location in relation to an easily identifiable landmark
- Names of the drilling subcontractor and logger
- Start and finish dates and times
- Drilling method
- Drilling rate and rig reactions, such as chatter, rod drops, and bouncing

Soil Core Logging

- Lithologic descriptions (based on the Unified Soil Classification System)
- Sampling interval depths

- Zones of caving or heaving
- Depth at which saturated conditions were first encountered (if applicable)
- Debris or staining

The results of the continuous core logging of the boreholes will be summarized in boring logs, which will be included in the RFI/RI Volume 3.

Soil Sample Collection for Laboratory Analysis. Soil samples will be collected from drilled boreholes at pre-designated depth intervals (see Appendix F, Planned Sampling Table) in accordance with sample collection and handling procedures described in Section 2.2.5. Once drilling and sampling activities are complete, the boreholes will be filled and site will be restored, as discussed in Section 2.3.

2.2.1.2 Potholing/Trenching

An excavator or backhoe will be used to install potholes to evaluate the presence, nature, and extent of white powder material in certain investigation areas and to collect soil samples in areas where site conditions are unsuitable for drilling (e.g., on steep slopes). Potholes/trenches will be deepened gradually so that subtle changes in lithology and/or white powder material can be documented in the logs.

Soil samples will be collected directly from the excavator or backhoe bucket at pre-designated depth intervals (see Appendix F, Planned Sampling Table) in accordance with sample collection and handling procedures described in Section 2.2.5. Excavated material will be used to backfill the excavation from which it originated.

2.2.1.3 HydroVac Potholing

Hydrovac excavation consists of using a vacuum truck to suction soil from a small diameter pothole directly into the vacuum truck. If necessary, soil may be wetted to loosen it. Soil samples will be collected at the pre-designated depth intervals from undisturbed soil by hand or by using a decontaminated hand auger. All potholes will be backfilled following sample collection. Bentonite chips will be used to seal the each pothole. The surface will be repaired to match existing surface, for example, potholes installed in asphalt will be repaired with asphalt patch; potholes in concrete will be repaired with pre-mix concrete. The hydrovac process can only be used for unconsolidated materials; utility of this method is likely to be limited in many areas due to the presence of bedrock or large gravel.

2.2.1.4 Hand Tools

Hand tools, which include stainless-steel trowels, slide hammers, and hand augers, will be used for samples collected between 0 and 3 feet below ground surface (bgs) in areas that cannot be accessed by drilling or potholing equipment. Soil samples collected in the depth interval from 0 to 1 foot bgs may be collected using a stainless-steel trowel. Soil samples collected in the depth interval from 1 to 3 feet bgs may be collected using a hand auger or a slide hammer to drive a core sampler into the undisturbed soil to the desired sampling depth. In areas where pre-excavation is required to provide adequate utility clearance, soil samples may be collected with hand tools up to 6 feet bgs. Soil samples will be collected at pre-designated depth intervals (see Appendix F, Planned Sampling Table) in accordance with the sample collection and handling procedures described in Section 2.2.5.

Each hole created using hand tools will be backfilled using the material removed from that hole. Pavement will be restored where needed.

2.2.2 X-ray Fluorescence Field Screening

In an effort to reduce intrusive sampling, a portable X-ray fluorescence (XRF) analyzer will be used to assist with identifying possible sample locations in debris areas located in AOC 10 and AOC 14. Up to 20 XRF samples will be collected from each of the debris areas in AOC 10 and AOC 14 and in the MW-24 bench area one XRF sample will be collected from each grid cell of a 50-foot grid. Figures C4-10 and C7-7 in Appendix A show the AOC 10 and AOC 14 debris areas and the MW-24 area grid. All XRF analyses will be performed in accordance SOP-B16, *Field-portable X-Ray Fluorescence Soil Sampling*. Corrected XRF results will be compared to applicable screening levels on Appendix A Table 3-1 on a point-by-point basis. (For field screening purposes, XRF concentration readings will be adjusted using least square regression equations calculated from the RFI/RI samples analyzed in the lab and by the XRF.) If the applicable screening levels are not exceeded, no further sampling will occur at that location. However, if applicable screening levels are exceeded, soil samples are planned to be collected at 0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet bgs at that location and will be submitted to the laboratory for analysis for inorganic and organics.

2.2.3 Sample Collection and Handling

This section describes the procedures for the collection and handling of soil, debris, and white powder material samples.

2.2.3.1 Soil, White Powder Material, and Debris Sample Collection for Inorganic, Semivolatile Organic Compounds, Total Petroleum Hydrocarbons-diesel/-motor-oil, Pesticides, and Polychlorinated Biphenyls Analyses

Soil and white powder samples requiring inorganic, semivolatile organic compounds, total petroleum hydrocarbons (TPH)-diesel/-motor-oil, pesticides, and polychlorinated biphenyls analyses will be collected directly from the drilling core or backhoe/excavator bucket or surface soil using stainless-steel trowels. The collected material will then be put through a stainless-steel sieve to remove any rocks and other debris prior to being homogenized in a stainless-steel bowl (SOP-B7, *Homogenization of Sediment and Soil Samples)*. After homogenization, the soil will be transferred to unpreserved glass sample jars and labeled. Samples of white powder material will not be homogenized.

Debris (e.g., wood) samples will be collected using stainless-steel trowels, as appropriate, and depending on the size of the debris, either placed into glass sample jars or large plastic zip-top bags.

2.2.3.2 Soil Sample Collection for Volatile Organic Compounds and Total Petroleum Hydrocarbons-gasoline Analyses

Soil sample aliquots designated for volatile organic compounds (VOCs) and TPH-gasoline analyses will be collected immediately upon opening the relatively undisturbed drilling core or recovery from a pothole (i.e., before geologic logging or the collection of other soil sample aliquots) to minimize the potential for volatilization of compounds to the atmosphere. VOC and TPH-gasoline aliquots will be collected using dedicated plastic syringes (SOP-B16, *VOC Soil Sampling Protocols)*. Using the syringes, a specific volume of sample, which correlates to an approximate target mass, will be transferred directly from the drilling core or backhoe/excavator bucket into pre-preserved sample vials. The sample vials will be chilled prior to use to minimize evaporation of the preservative when opened. Syringes cannot be used to collect sample from soils consisting of loose sand and gravel. In this case, stainless-steel trowels will be used to transfer the soil into the vials for volume measurement prior to preservation.

2.2.3.3 Sample Management and Storage

Samples will be placed immediately into field coolers with ice; VOC and TPH-gasoline containers will be arranged in the sample cooler standing upright. The field coolers will be taken to the sample management area, where the samples will be transferred into a refrigerator and/or freezer. If transport of a sample to the laboratory is scheduled for a pickup more than 24 hours after sampling, samples will be stored in the freezer.

2.2.3.4 Shipping

Samples collected for chemical analysis will be transported to the laboratory via courier, generally daily. Samples collected for geotechnical analyses will be shipped via Federal Express or a similar carrier. Chains-of-custody will accompany all samples to the laboratory.

2.2.4 Geophysical Surveying

Geophysical surveys will be conducted at three investigation areas to identify potential buried pipe at UA-1, buried debris at MW-24 Area, and septic system leach field in AOC 17. For these investigation areas, geophysical surveying will be conducted using ground-penetrating radar (GPR), electromagnetic induction (EM), and vertical magnetic gradient (VMG) scans. There are likely to be some surface obstructions to the geophysical survey. The survey will avoid areas where access or other conditions (e.g., sparks) could create a hazard.

A survey grid will be established first to provide horizontal control for data acquisition. The grid size will be determined based on the size of the area being surveyed, presence of surface obstructions, and expected density of all subsurface utilities. Potential buried pipes, debris, and leach fields will be identified using VMG and EM scans and may be confirmed using GPR.

VMG surveys are used to determine the presence of buried ferrous objects. VMGs provide better resolution of near-surface objects and are less affected by surface objects than those than measure only the total field magnetometers that measure only total magnetic intensity. The distribution and configuration of VMG contours depict the distribution and intensity of VMG values within the surveyed area. Areas where contours are closely spaced indicate steep magnetic gradients caused by buried objects. If the source of a steep gradient is linear, then the contours tend to parallel the linear feature; if a buried object is localized (tank, drum, etc.) the contours tend to enclose the object. Lower values may indicate the presence of non-ferrous buried objects.

EM scans are used to delineate variations in the electrical conductivity of the shallow subsurface. These variations can be caused by variations in lithology or moisture content as well as buried metallic objects. EM scans also provide contour maps that are analyzed to identify magnetic anomalies that may be due to buried ferrous metal. Contours take similar forms as VMG scans. The larger the object and closer it is to the instrument (i.e., ground surface), the more contours are present in the area.

GPR is used to locate the depth and position of metallic and non-metallic objects. The system works by sending a small pulse of energy from an antenna into the surveyed material and recording the strength and the time required for the return of any reflected signal. The strength, or amplitude, of the reflection is determined by the contrast in the dielectric constants of the two materials. Antenna frequency is a major factor in depth penetration. The higher the frequency of the antenna, the shallower into the ground it will penetrate. A higher frequency antenna will also identify smaller targets. GPR data are used to provide a plan view through the area scanned.

GPR and magnetometry equipment are relatively portable; all of the equipment can fit into the back of a pickup truck. Both proposed methods are capable of rapidly locating underground anomalies such as pipes. Using a magnetometer or GPR requires establishing survey stations at relatively close intervals of 5- to 50-foot spacing along closely spaced (10- to 50-foot) parallel lines.

Geophysical investigation will also be conducted within the fence line of the compressor station in an effort to locate storm drain system pipes. The geophysical survey for the storm drain system is described in Appendix D.

2.2.5 Surveying

Following sample collection, the horizontal location and elevation of each sample location will be documented using an industry-standard (Trimble or similar), resource-grade, handheld global positioning system unit capable of 1-meter accuracy. A sketch of the sampling location will also be entered into the logbook, with any reference points labeled including distances to the sampling location.

2.2.6 Vegetation Removal

Due to the thick vegetation in the tamarisk thicket area near the mouth of Bat Cave Wash in AOC 1, a path will need to be cut through the vegetation to allow passage of necessary sampling equipment. The vegetation removal will be completed using small excavators (i.e., Bobcat or similar) fitted with rubber tracks to minimize soil disturbance. The vegetation will be cut above the roots as close to the ground surface as possible to establish an even path for the drilling equipment and crew and allow for vegetation regrowth. Chainsaws or similar equipment may be used to cut larger limbs, however, every effort will be made to preserve large tree species and species of interest during the vegetation removal. How the removed vegetation will be handled and/or disposed will be discussed and agreed upon in advance with the property owner and stakeholders.

2.2.7 Waste Management and Decontamination

The project approach for IDW management and equipment decontamination is presented in the following subsections.

2.2.7.1 Equipment Decontamination

Downhole drilling tools, excavator and backhoe buckets, tracks on track rigs, and the back ends of the drilling rigs will be decontaminated prior to arrival at the site and will be cleaned between investigation areas as determined necessary by the field team leader. Decontamination will be accomplished by steam-cleaning or pressure washing the core barrel, drill stem, drive casing, and back of the drilling rig. Equipment may also be cleaned using dry methods prior to leaving an excavation area to prevent the tracking of material out of the area.

The steam-cleaning will be conducted on a temporary decontamination pad (lined with plastic sheeting) located on PG&E compressor station property, shown on Figure 2-1. Rinsate from the decontamination operation will be collected on the containment pad and will be transferred to the cuttings bin/drum or portable storage tank. Decontamination is described in SOP-B5, *Decontamination of Personnel and Equipment, Well Drilling and Subsurface Sampling and Investigation.*

2.2.7.2 Investigation-derived Waste Management

Several types of waste materials will be generated during the drilling and sampling of soil borings, excavation of potholes, and hand excavation for utility clearance. IDW materials that will be generated include drill cuttings, incidental trash, equipment decontamination water, and possibly small quantities of soil from pothole or hand excavation areas.

Drill cuttings include the fragments of rock and soil that are removed to create the borehole. The cuttings will be contained in lined roll-off bins at the staging areas during the drilling and sampling activities. After sampling and characterization, the cuttings bins will be removed from the staging areas. It is estimated that the soil IDW bins temporarily stored in the staging area(s) will not remain longer than 45 days. If cuttings or soil are free from contaminants every effort will be made to repatriate the material. Also, cuttings may be placed onsite if acceptable to the property owner and in compliance with applicable laws and regulations. Cuttings and any soil from excavation areas that are contaminated will be transported to a permitted offsite disposal facility.

Incidental trash will be collected at the end of each drilling shift and will be hauled from the drill site to an appropriate offsite disposal facility.

Water generated during equipment decontamination will be collected in bins or portable storage tanks temporarily located in staging areas near the drilling sites or at the PG&E Topock Compressor Station as needed. Secondary containment will be set up at the drilling area for the portable storage tanks or bins.

IDW disposal is described in SOP-B6, *Disposal of Waste Fluids and Solids*.

2.3 Post-construction Activities

Post-construction activities will consist of survey, site restoration, and reporting.

In accordance with the PBA, a post-construction survey will be conducted by a qualified biologist. The Proposed Part A Phase 2 sample locations are located on federal and PG&E property. Federal property consists of a portion of the Havasu National Wildlife Refuge (HNWR) managed by United States Fish and Wildlife Service (USFWS) and Bureau of Reclamation lands. Proposed Part B and Perimeter Area sample locations are located on PG&E property. All but one storm drain investigation soil sample locations are on PG&E property. With the exception of the proposed sampling near the mouth of Bat Cave Wash, all areas have been previously disturbed and contain limited to no vegetation. No more than two acres of vegetation are proposed to be removed in the tamarisk area near the mouth of Bat Cave Wash. Given the proposed limited impacts to vegetation near the mouth of Bat Cave Wash, vigorous growth habit of the tamarisk vegetation in this area, and sparse vegetation in the other proposed work areas, no formal site restoration and revegetation plan is needed. Temporary signage or other items that may be put in place during borehole drilling, or pothole or hand excavation activities will be removed upon completion of the sampling activities. After sampling activities at the sites located on federal property are completed, PG&E will work with DOI to evaluate the need for any additional restoration activities.

3.0 Quality Control, Data Management, and Data Validation

3.1 Sampling and Analysis Plan

Before each field sampling event, the Project Manager or designated representative will coordinate the organization of field personnel and preparations for field activities. The Project Chemist will notify the laboratory of the pending sampling event and arrange for the appropriate type and number of sample containers. A planned sampling table (PST) listing each location to be sampled and the analysis to be performed at each location included is provided in Appendix F. The frequency of field duplicates and equipment blanks and with other quality assurance/quality control requirements will follow the *PG&E Program Quality Assurance Project Plan, Revision 1* (CH2M HILL, 2008a) or the *Addendum to the Topock Quality Assurance Project Plan (*CH2M HILL, 2008b), provided as Appendix H. Field duplicates are listed in the PST. Field sampling instruction will be given to the field teams and will include the PST; number, size, and type of containers required for each sample location; map of sample locations; SOPs; chain-of-custody forms; soil sampling logs; brief summary of the purpose of the sampling; and any special protocols required for this sampling event.

3.2 Analytical Methods

Soil samples collected during this effort will be analyzed for parameters listed in the PST using the methods specified in Appendix H. All field quality control measures data will follow the *PG&E Program Quality Assurance Project Plan, Revision 1* (CH2M HILL, 2008a) and the *Addendum to the Topock Quality Assurance Project Plan* (Appendix H).

The *PG&E Program Quality Assurance Project Plan, Revision 1* (CH2M HILL 2008a) and the *Addendum to the Topock Quality Assurance Project Plan* also outline quality control requirements for laboratory analyses to be conducted for all PG&E Topock projects. The QAPP addresses DQOs; method detection limits, reporting limits, and instrument calibration requirements; laboratory quality control samples; laboratory data management procedures; performance evaluations; preventive maintenance; corrective action; and quality assurance reports. Project chemists will review laboratory analytical data generated from soil sampling to assess data quality and identify deviations from analytical requirements.

3.3 Data Management

The electronic data will be used to generate validation reports, data summary tables, and figures. Management of data generated from soil sampling will be conducted in accordance with the *PG&E Program Data Management Plan* (CH2M HILL 2004). The Data Management Plan outlines standardized procedures for field data collection and review, analytical data loading into the information system (environmental database), verification of uploaded data, quality assurance/quality control procedures associated with data management, and reporting formats.

This program will follow standard procedures for environmental data collection listed in the *PG&E Program Data Management Plan* (CH2M HILL, 2004) and the *PG&E Program Quality Assurance Project Plan, Revision 1 (*CH2M HILL, 2008*)*. These provide procedures that give data users rapid access to stored data; provide methods of data entry with known accuracy and efficiency; apply well documented validation procedures to an electronic database; manage sample data using unique sample identification numbers; establish a sample inventory of new data collected and provide methods of sample inventory reconciliation; store and provide sample-specific attributes, including location identifiers, sample type and media, and sample date; and provide reporting and delivery formats to support data analysis and reduction.

3.4 Data Validation

Data validation will be performed when data packages and electrical data deliverables are received from the laboratory using a combination of manual review and automated software. Validation will be performed on an analytical batch basis, using the summary results of calibration and laboratory quality control, as well as those of associated field samples. Data packages will be reviewed for all analytes. Data validation will include:

- Review of the data package for completeness.
- Review of chain-of-custody records for discrepancies that might degrade data quality.
- Review for compliance with holding time and quality control frequency requirements.
- Evaluation of all calibration and quality control summary results against project requirements.
- Verification of analyte identification and calculations for at least 10 percent of the data.
- Qualification of data using appropriate qualifier flags, as necessary, to reflect data usability limitations.
- Initiation of corrective actions, as necessary, based on data review findings.

Data validation will be patterned after the United States Environmental Protection Agency (USEPA) *Contract Laboratory National Functional Guidelines for Inorganic Data Review* (USEPA, 2002) and *Contract Laboratory National Functional Guidelines for Organic Data Review* (USEPA, 1999), substituting the qualifiers, the calibration and quality control requirements specified in the *PG&E Program Quality Assurance Project Plan, Revision 1* (CH2M HILL, 2008a), the Addendum to the QAPP (Appendix H), and the *PG&E Program Quality Assurance Project Plan for Dioxins and Furans* (CH2M HILL, 2010b).

4.0 Data Gaps Evaluation

The Soil Part A and B investigation programs employ the DQO process to ensure that data collected at each stage of the investigation process are of sufficient quantity and quality to enable the specified decisions to be made. The DQO process is a recognized procedure for defining project objectives and decisions and for optimizing sampling and other information-gathering programs to balance uncertainty, site disturbances, and cost in an acceptable manner.

The data evaluation process is designed to determine whether the sampling objectives outlined in the Part A DQO Tech Memo (CH2M HILL, 2010a) and Part B DQO Tech Memo (CH2M HILL, 2010b) have been met. The sampling objectives will have been met if the decision rules for all problem statements presented in the Soil Part A DQO Tech Memo (Appendix A) and Soil Part B DQO Tech Memo (Appendix B) indicate that no further sampling is required, and the previously identified Part A and B data gaps have been satisfied. If sampling objectives have not been met (i.e., data gaps have been identified) or previously-identified data gaps have not been resolved, additional sampling will be conducted, if feasible. If sampling is not feasible, remaining uncertainties will be addressed in the risk assessment and/or CMS/FS or interim measures.

The following subsections summarize the results of the data gaps evaluation process for Part A and the forthcoming data gaps evaluation process for Part B data.

4.1 Soil Part A Data Evaluation Process

After implementation of the Soil Part A Investigation Program (see Appendix A), the new validated data meeting the criteria set forth in the QAPP will be combined with existing Soil Part A data (all of which is considered Category 1 and can therefore be used for all DQO decisions). The combined data set will be used to assess if the data are sufficient to resolve the Part A Phase 1 data gaps. Summaries of the Part A Phase 1 data gaps by Part A DQO decision are presented in Table 4-1; complete lists of data gaps for each investigation area for each decision are presented in Appendix C of the Part A Data Gaps Report, included as Appendix A of this report.

TABLE 4-1
Summary Part A Phase 1 Data Gaps
Soil RCRA Facility Investigation/Remedial Investigation Work Plan
Pacific Gas and Electric Company Topock Compressor Station Needles, California

	Summary of Data Gaps			
Unit	**Decision 1 – Nature and Extent**	**Decision 2 – Data Sufficiency to Calculate EPCs**	**Decision 3 – Potential Impacts to Groundwater**	**Decision 4 – Data Sufficiency for CMS/FS**
SWMU 1	• Vertical extent of contamination within the SWMU 1 boundary. • Lateral extent of white powder upslope from white powder area to the compressor station boundary.	None	• Vertical extent of contamination of information to support refinement of the vadose leaching zone model	• Soil physical parameters to support the CMS/FS.
AOC 1	• Lateral and vertical extent of contamination in the bottom of Bat Cave Wash (within the portion of AOC 1 surrounding the SWMU 1 boundary and between the northern boundary of SWMU 1 and Interstate 40). • Extent of constituents associated with the discharge from the Debris Ravine (AOC 4), including polychlorinated biphenyls and dioxins and furans. • Chemical concentrations soil and sediment in the tamarisk area at the mouth of Bat Cave Wash and at potential impoundment areas (i.e., culvert under railroad tracks and at Interim Measures No. 3 road crossing). • Characteristics of the potential white powder material on the eastern slope of Bat Cave Wash	None	None	• Soil physical parameters to support the CMS/FS.
AOC 4	• Lateral extent of various metals, PAHs, PCBs, and dioxins/furans to the east and near the south-southeastern corner of the AOC. • Vertical extent of contamination across the AOC; however, given the shallow depth to bedrock, additional sampling is limited to the northern portion of AOC, where bedrock is not near the surface. • Lateral and vertical extent of contamination at the mouth of the ravine near and in Bat Cave Wash.	None	None	• Soil physical parameters to support the CMS/FS.

AOC 9	• Vertical extent of contamination in and downslope of the previous stained soil removal area. • Lateral and vertical extents of contamination near the western (downslope portion of AOC 9) and along the bottom of the ravine.	None	• Vertical extent of contamination of information to support refinement of the vadose leaching zone model	• Soil physical parameters to support the CMS/FS.
AOC 10	• Lateral and vertical extent of contamination in the western portion of AOC 10 (Subarea AOC 10a, downslope from AOC 9, and downslope from the outfall of the former trench drain). • Nature and extent of contamination associated with runoff from station access road to the low point north of Subarea 10d and in and between drainage depression subareas. • Nature and extent of contamination associated with the newly identified white powder areas (on the slope below the station access road) and the newly identified debris areas (on the slopes of AOC 10)	None	• Vertical extent of contamination of information to support refinement of the vadose leaching zone model	• Soil physical parameters to support the CMS/FS.
AOC 11	• Lateral and vertical extent of contamination within AOC 11c. • Nature and extent of contamination associated with New Investigation Areas 1 and 2, the newly identified burn area (near the location of the current decontamination pad and Transwestern Meter Station), and the white powder area (upslope of AOC 11e).		• Vertical extent of contamination of information to support refinement of the vadose leaching zone model	• Soil physical parameters to support the CMS/FS. • Volume and extent of debris in New Investigation Areas 1 and 2 and volume and extent of white powder material on the upper slope of AOC 11, if applicable.
AOC 12	None	None	None	None
AOC 14	• Western extent of benzo(a)pyrene, metals, and pesticides contamination in the southwestern corner of AOC 14. • Nature and extent of contamination in the newly identified burn area west of AOC 14 and the newly identified debris area east of AOC 14. • Nature and extent of contamination in the newly identified debris area in the MW-24 bench area.	None	None	• Soil physical parameters to support the CMS/FS.
UA 1	Not applicable	Not applicable	Not applicable	Not applicable
UA 2	None	None	None	None

4.2 Soil Part B Data Evaluation Process

After implementation of the Soil Part B Investigation Program (see Appendix B), the new validated data meeting the criteria set forth in the QAPP will be combined with existing Category 1 and 2 Soil Part B data. Category 1 and 2 data will be used to delineate the nature and extent of contamination (Decision 1), potential threat to groundwater from residual soil concentrations (Decision 3), and to assess whether sufficient information is available to complete the CMS/FS and remedial design and/or interim measures (Decision 5). However, only Category 1 data can be used for risk assessment (Decision 2) and for the evaluation of potential offsite migration (Decision 4).

The following evaluations will be completed for each of the five DQO decisions:

- **Decision 1**. The nature and extent of contamination at the Part B investigation areas will be described and evaluated to determine whether the nature and extent of contamination are adequately understood. The evaluation will follow the Decision 1 rules outlined in Part B DQO Tech Memo Figure 2 (see Appendix B).
- **Decision 2**. A data sufficiency evaluation will be conducted to determine if sufficient data exist for within the fence line to calculate representative exposure point concentrations for each applicable exposure interval for human health receptors. The evaluation will follow the Decision 2 Rules outlined in Part B DQO Tech Memo Figure 3 (see Appendix B).
- **Decision 3**. Soil screening levels (SSLs) will be calculated for any metal exceeding background concentrations at one or more locations within the individual Part B investigation areas. For constituents where the detected concentrations exceed the SSLs, vadose zone modeling will be conducted to further evaluate the potential threat to groundwater. If organic compounds are detected in one or more locations within the investigation areas, vadose zone modeling will be conducted to evaluate the potential threat to groundwater from detected organic compounds. The evaluation will follow the Decision 3 rules outlined in Part B DQO Tech Memo Figure 4 (see Appendix B).
- **Decision 4**. An offsite migration evaluation will be conducted to estimate potential risks to offsite receptors due to potential migration of contaminants, in a surface migration pathway, from areas within the fence line to areas outside the fence line. This evaluation will use Category 1 soil concentrations in shallow soil in areas where soil may be transported to areas outside the fence line; soil physical and chemical property information; potential mechanisms, directions, and rates of migration; information on structures; and other features that may prevent or facilitate offsite migration. The evaluation will follow the Decision 4 rules outlined in Part B DQO Tech Memo Figure 5 (see Appendix B).
- **Decision 5**. A data sufficiency evaluation will be conducted to determine whether sufficient data exist at the Part A Investigation Areas to support the CMS/FS (specifically, remedial technology feasibility assessment and estimation of soil and debris volumes potentially requiring remediation). The evaluation will follow the Decision 5 rules outlined in Part B DQO Tech Memo Figure 6 (see Appendix B).

Data generated from the Perimeter Area and storm drain system investigation programs will first be reviewed to determine whether any constituents exceed background or applicable screening levels for organic compounds. Areas with exceedances of background concentrations and/or applicable screening levels for organic compounds will be assigned to the applicable Part A or Part B unit(s), and the data evaluation process for these areas will follow the applicable process for the assigned unit. A detailed description of the data evaluation process for the Perimeter Area and the storm drain system investigation is provided in Appendices C and D, respectively.

5.0 Approvals and Authorizations

5.1 Anticipated Approvals

Implementation of work plan activities will require prior approval from DTSC and DOI pursuant to their authority under RCRA and CERCLA, respectively. Anticipated approvals and authorizations for implementation of the soil investigation outlined in this work plan are listed in Table 5-1.

TABLE 5-1
Approvals and Authorizations for Drilling
Soil RCRA Facility Investigation/Remedial Investigation Work Plan,
PG&E Topock Compressor Station, Needles, California

Agency/Organization	Approvals and Authorizations
DOI/HNWR	Approval letter from DOI/HNWR anticipated. Approval subject to National Historic Preservation Act (NHPA) Section 106 and Endangered Species Act (ESA) Section 7 consultations (see below).
DTSC	As state lead agency, approval letter from DTSC is required. DTSC will comply with California Environmental Quality Act prior to workplan approval.
California Department of Fish and Game	Project activities have been previously authorized by Streambed Alteration Agreement No. 1600-2005-0140-R6.
U. S. Bureau of Land Management	DOI lead with Section 7 ESA requirements. Guides work plan compliance within the scope of the PBA (CH2M HILL, 2007d) and conducts associated Section 7 consultation.
State Historic Preservation Office	USFWS HNWR approval subject to NHPA Section 106 process involving a minimum 30-day Tribal consultation followed by a minimum 30-day State Historic Preservation Office consultation.
California Department of Transportation	Project activities within I-40 right-of-way (MW-24 Bench) will require a permit. A separate permit is needed if I-40 lane closure is required.
Burlington Northern Santa Fe Railway (BNSF)	Project activities (AOC 14 and AOC 1) require a permit to cross BNSF railroad tracks and to pass through a BNSF railroad culvert.
Private Pipeline Companies	As needed, activities located in the right-of-way of any pipelines will be subject to prior coordination with the owner/manager of the associated facilities.

Portions of the proposed activities are located on the HNWR, which is managed by the USFWS. DOI is the parent agency of the USFWS; the anticipated approval mechanism is an approval letter from DOI. It is expected that the DOI's approval letter will address CERCLA approval, and conditions imposed to comply with Section 7 of the Endangered Species Act (ESA) and Section 106 of the National Historic Preservation Act (NHPA).

As discussed further in Section 5.3, Biological Evaluation, the proposed work plan activities will be conducted in a manner consistent with the PBA (CH2M HILL, 2007d) and therefore will be in compliance with ESA requirements. Compliance with Section 106 of the NHPA is expected to involve a minimum 30-day consultation with local Native American tribes and a minimum 30-day consultation with the State Historic Preservation Office.

Approval from the DTSC is subject to compliance with the California Environmental Quality Act (CEQA).

Portions of the work plan activities are within the jurisdiction of the California Department of Fish and Game, pursuant to Section 1600 et seq. of the Fish and Game Code. Compliance with Section 1600 requirements is provided via the existing California Department of Fish and Game Streambed Alteration Agreement No. 1600-2005—0140-R6, as amended in January 2007.

Portions of the work plan activities are within the right-of-way maintained by the California Department of Transportation (Caltrans). Caltrans approval is required for work in AOC 14 and in the MW-24 bench area. Given the limited access to AOC 14, drilling equipment (i.e., drill rig) may need to be lifted by crane onto AOC 14. If lifting this equipment is necessary, a lane of Interstate 40 will need to be closed. Lane closure will require Caltrans approval and coordination with the California Highway Patrol, and may require coordination with the Arizona Department of Transportation.

To access AOC 14, personnel and equipment will need to cross the Burlington Northern Santa Fe (BNSF) railroad tracks. To access the area of Bat Cave Wash between the Interstate 40 and BNSF railroad culverts, a drill rig will need to pass through the BNSF culvert. The crossing of the railroad tracks and passing through the BNSF culvert will require a permit from BNSF.

Pipeline infrastructure owned and/or maintained by private entities is located at and near the project site; approximate locations are shown on Figure 2-1. Prior to field work, the precise right-of-way associated with any nearby pipelines will be determined. Coordination with the affected pipeline company will occur as needed to obtain prior approval and comply with applicable requirements. In addition, prior to implementation of the subject activities, Underground Service Alert notifications will be made so that utility companies can locate and mark the locations of their underground facilities.

5.2 Environmental Impact Report Mitigation Measures

In January 2011, DTSC issued the *Topock Compressor Station Environmental Impact Report* (EIR), which documented the proposed remedy for groundwater contamination at Topock Compressor Station (DTSC, 2011b). Some of the remedy implementation impacts were found to be significant, and DTSC has adopted mitigation measures to avoid or reduce those impacts to less-than-significant levels (DTSC, 2011b) to the extent possible.

5.3 Biological Evaluation

5.3.1 Introduction

The PBA addresses a variety of PG&E Topock remedial and investigative actions, including those identified in the soil investigation work plan, within the Area of Potential Effect

(APE). The intent of the PBA is to provide programmatic coverage of these actions up to the final remedy expected by 2012 and avoid the need for individual project-specific consultations under the federal Endangered Species Act (FESA). The purpose of this biological evaluation is to outline the soil investigation activities as they relate to federally listed species in the area and determine if the actions are within the context and boundaries of the PBA as requested by the U.S. Bureau of Land Management (BLM). The following topics are outlined in this section: project timing, project location and habitat sensitivity, habitat loss, conservation measures, listed species determinations, and conclusion. The federally listed species being considered and evaluated include the southwestern willow flycatcher (*Empidonax traillii extimus*), Yuma clapper rail (*Rallus longirostris yumanensis*), Mojave desert tortoise (*Gopherus agassizii*), bonytail chub (*Gila elegans*), and razorback sucker (*Xyrauchen texanus*).

5.3.2 Project Timing

The soil investigation activities are anticipated to be conducted between November 2011 and January 2012. The start date is dependent upon receipt of necessary approvals and authorizations. The anticipated start of the avian nesting season is defined as March 15 to September 30 in the PBA. Additionally, May 1 has been identified as the start of the southwestern willow flycatcher nesting season. It is anticipated that the work activities will be completed prior to these dates; thus, the investigation will not disturb nesting habitat of southwestern willow flycatcher and Yuma clapper rail during nesting season. However, the activities will take place within potential roosting and foraging habitats in the tamarisk thicket located near the mouth of Bat Cave Wash. However, necessary approvals and authorizations may prolong the start date. Should the activities be delayed and take place within the avian migration or nesting season, the required measures outlined in the PBA will be implemented for any upland migratory or nesting birds.

5.3.3 Project Location and Habitat Sensitivity

The soil investigation sites within the compressor station are in an industrialized area which located upland from the Colorado River floodplain and which does not include any sensitive biological habitat. Most of the soil investigation sites outside the compressor station are primarily located within either creosote bush scrub or Mojave wash scrub habitats. The tamarisk thicket area near the mouth of Bat Cave Wash includes habitat that is suitable for birds and other wildlife. , including the federally listed southwestern willow flycatcher, as well as other migratory bird species protected by the Migratory Bird Treaty Act may occur in the tamarisk habitat. Because southwestern willow flycatchers may potentially use the tamarisk habitat for roosting and foraging during the spring and fall migration seasons, it is possible that operational activities and loss of tamarisk could alter the behavior of migrating individuals. The tamarisk thicket within Bat Cave Wash and adjacent to the National Trails Highway is considered potential habitat for this species and is surveyed annually per U.S. Fish and Wildlife Service (USFWS) protocol as required per the PBA. The soil investigation will involve cutting a 25-foot wide access road and sampling within the thicket and some vegetation will be impacted by the proposed activity.

The desert tortoise is the only federally listed species that may occur within the creosote bush scrub or Mojave wash scrub habitat types at the proposed soil investigation sites. Desert tortoise critical habitat does not exist within the APE. Additionally, the habitat in the area is considered marginal due to limited suitable plants and soils for forage and cover sites, past habitat disturbance and fragmentation, and natural and man-made barriers that deter this species from entering the site.

Other listed species that may potentially occur or are known to occur within the APE include the Yuma clapper rail, bonytail chub, and razorback sucker. Project activities will not take place within the floodplain, Topock Marsh, or Colorado River where these species reside. However, several tamarisk thickets within the APE have been identified as potential habitat for the southwestern willow flycatcher. The soil investigation activities will disturb less than 2.5 acres of tamarisk habitat and will be below the threshold disturbance established in the PBA. The remaining sites are not within or directly adjacent to any sensitive habitat for the southwestern willow flycatcher or desert tortoise. Therefore, no impacts to sensitive habitats will occur as a result of the soil investigation activities.

5.3.4 Habitat Loss

Other than the disruption to the tamarisk habitat near the mouth of Bat Cave Wash, very little, if any, additional habitat loss will occur during the soil investigation activities. Any vegetation removal will be coordinated with the project biologist and documented as outlined in the PBA. The biologist will ensure that the 3.0 acre upland vegetation loss threshold and that the 2.5 acre threshold for disturbance in tamarisk is not met or exceeded. It is expected that some vegetation may need to be pruned or crushed for equipment access to some sites. The pruning or crushing of vegetation is not considered habitat loss as defined in the PBA. Any pruned or crushed vegetation is expected to recover.

5.3.5 Conservation Measures

The conservation measures identified in the PBA for listed species and habitat will be implemented. Any habitat loss is expected to be well below the 3.0 acre upland threshold and the 2.5-acre disturbance threshold for tamarisk established in the PBA. The project biologist will perform pre- and post-activity surveys to document any habitat loss and ensure the sites are clear of desert tortoises and any nesting birds as deemed necessary. Revegetation of the soil investigation sites is considered unnecessary in the context of the PBA.

5.3.6 Listed Species Determinations

Southwestern willow flycatcher: This action will have no effect upon this species based on the planned schedule during the winter season and minimizing disturbance of habitat at the soil investigation sites. However, any proposed drilling activities that may occur after May 1 near suitable habitat for this species “may affect, but is not likely to adversely affect” the species. The rationale for this determination accounts for the species expected arrival in the area in May. The behavior of this species may be affected by project-related activities during the spring migration. Indirect effects such as habitat loss may occur as a result of the soil investigation activities. However, the project will stay below the 2.5-acre disturbance threshold. In addition, USFWS protocol surveys were performed in 2005 - 2009 that resulted in no positive confirmation of species nesting within the APE. Therefore, any potential direct and indirect effects during the nesting season will not be adverse. This determination is within the context of the PBA.

Yuma clapper rail: This action will have no effect upon this species. The project will not occur within the Topock Marsh or the Colorado River. Therefore, any potential direct and indirect effects to this species will be avoided. This determination is within the context of the PBA.

Desert tortoise: This action will have no direct effect upon this species based on the planned schedule during the winter season and implementation of the measures identified in the PBA. Additionally, USFWS protocol surveys were performed in 2004 - 2009 that resulted in no recent evidence of species presence within the APE. Therefore, any potential direct effects will be avoided. However, indirect effects such as habitat loss may occur as a result of the soil investigation activities. The habitat within the APE is considered marginal and any loss would be minor and well below the 3.0 acre upland threshold as established in the PBA. This determination is within the context of the PBA.

Razorback sucker: This action will have no effect upon this species. The project will not occur within the Colorado River or affect the bed and bank of the river. Therefore, any potential direct and indirect effects to this species will be avoided. This determination is within the context of the PBA.

Bonytail chub: This action will have no effect upon this species. The project will not occur within the Colorado River or affect the bed and bank of the river. Therefore, any potential direct and indirect effects to this species will be avoided. This determination is within the context of the PBA.

5.3.7 Conclusion

The soil investigation activities proposed in the work plan are within the context and boundaries outlined in the PBA. Therefore, this action will be compliant with FESA as long as the measures identified in the PBA are implemented. No additional consultation with the USFWS is required.

5.4 Archeological Surveys and Reviews

The area subject to activities described in this work plan was included in an archaeological survey of the Area of Potential Effect (Applied Earthworks, 2007). Only one significant archaeological resource was found in this area—a small portion of historic Route 66 (CA-SBR-2910H) is located along an existing gas pipeline (Line 300B) and road alignments in this area. The Former 300B Pipeline Liquids Tank (UA-2) is the closest to this section of Route 66. This portion of Route 66 has been greatly disturbed by the construction of Line 300B. A recent examination of this area indicated that only a very small portion of the original Route 66 pavement is intact. Although deteriorated, the original Route 66 guardrail is still in place at a majority of this location. The narrow roadbed and guardrail at this portion of Route 66 provides this National Register of Historic Places property with integrity of location and feel. Because of the past disturbance to this portion of the Route 66 roadbed, restrictions on temporary vehicle use are not deemed necessary. The general configuration and historic guardrail at the section of Route 66 will be protected so as to not impact the integrity of location and feel of this National Register of Historic Places historic property.

Sites within Part A were previously surveyed in 2007, and soil sampling was conducted in 2008. These historic sites will be assessed prior to drilling activities. Part A sites not included in that survey included two new sites near AOC 11 and the recently added MW-24 Bench. Sites within Part B were also previously surveyed in 2007, and soil sampling was conducted in 2008. Part B sites that were not previously included in the 2007 survey include the Teapot Dome Restaurant oil pit and the potential burn area near AOC 17. In addition, areas previously not included in the 2008 soil sampling include a debris area near AOC 10 and AOC 14, tamarisk area, and the lower end of the Bat Cave Wash. The historic sites will be protected from work activities and will be monitored during the course of work. The PG&E FCR will be responsible for providing archaeological sensitivity training to the workers implementing this work plan and for ensuring compliance with all applicable archaeological measures during drilling activities.

The Topock site and adjacent lands are contained within a larger geographic area that is considered sacred by the Fort Mojave Indian Tribe and by other Native American tribes. In recognition of this, work activities will be conducted in a manner that recognizes and respects these resources and the spiritual values of the surrounding lands. PG&E understands that the environmental, cultural, and spiritual resources may not be physically perceptible. To this end, site orientation will stress that all site activities must be conducted in a respectful manner that is conscious of this context.

1.0 Introduction

Pacific Gas and Electric Company (PG&E) is conducting investigative and remedial activities at the Topock Compressor Station in Needles, California. The Topock Compressor Station is located in San Bernardino County approximately 15 miles to the southeast of Needles, California, as shown in Figure 1-1. Investigative and remedial activities at the Topock site are being performed under the Resource Conservation and Recovery Act (RCRA), as well as the Comprehensive Environmental Response, Compensation, Liability Act (CERCLA), pursuant to agreements with the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) and United States Department of the Interior (DOI), respectively.

Two draft work plans, Soil Part A Work Plan and Soil Part B Work Plan, have been prepared to address supplemental soil characterization activities at the Solid Waste Management Units (SWMUs), Areas of Concern (AOCs), and other undesignated areas (UAs) identified in the *Revised Final RCRA Facility Investigation/Remedial Investigation Report, Volume 1 – Site Background and History* (referred to as the RFI/RI Volume 1) (CH2M HILL, 2007a). Investigation areas outside the compressor station fence line are addressed in the *Draft RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A, PG&E Topock Compressor Station, Needles California* (CH2M HILL, 2006), (referred to as the Soil Part A Work Plan). Investigation areas within the compressor station fence line are addressed in the Draft Soil Part B Work Plan (CH2M HILL, 2007b).

To minimize the number of samples and disturbances to sensitive resources, the Part A supplemental soil investigation program is being conducted in two phases. Phase 1 was conducted in 2008. Phase 2 will be conducted to fill data gaps identified in the Phase 1 data. Phase 2 sampling will only be necessary where data gaps are identified after evaluation of the combined soil data set (existing data and supplemental Phase 1 data) for the identified SWMUs, AOCs, and UAs.

DTSC and DOI conditionally approved the Soil Part A Work Plan on August 10, 2007 (DTSC, 2007) and June 4, 2008 (DOI, 2008a), respectively. Clarification of DTSC's conditional approval was documented in an email containing the table titled "Clarification to Responses to PG&E Topock Compressor Station Soil Investigation Part A Work Plan August 10, 2007 Conditional Approval Letter" (CH2M HILL, 2007b).

DTSC's conditional approval letter specifically rejected the data quality objectives (DQOs) and associated data gaps evaluation process presented in the Soil Part A Work Plan (Sections 3.0 and 4.0 of the Work Plan) while directing PG&E to implement the first phase of soil sampling (Phase 1). Between June 2008 and February 2010, DTSC, DOI, and PG&E convened a series of meetings to draft the Soil Part A DQOs Steps 1 through 5. These first five DQO steps are used to evaluate the combined soil data (Phase 1 data and previously collected data [referred to as existing data in this document]) and to identify sampling needs for Phase 2. The Soil Part A DQO Steps 1 through 5 are presented in the technical memorandum *Data Quality Objectives – Part A Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2010) (referred to as the

Soil Part A DQO Tech Memo). The Soil Part A DQO Tech Memo is included as Appendix A to this report. Appendix B of this report describes Investigation Procedures, Field Methodology and White Powder/Debris Mapping Results as a result of the Part A soil investigation. Step 6 was drafted during a meeting with DTSC, DOI, and PG&E on August 30 and 31, 2010. PG&E provided Step 7, proposed Phase 2 sampling locations in the September 2010 Draft Topock Part A Phase 1 Data Gaps Report (CH2M HILL, 2010). The Phase 1 data gaps and the proposed Phase 2 sampling plan were presented at two meetings with DOI, DTSC, and Tribes held at the Topock Compressor Station on October 6 and 7, 2010 and November 2 and 3, 2010. During the meeting, soil data were reviewed with stakeholders, each AOC was visited, and preliminary data gaps evaluations were discussed. A subsequent meeting was held on December 7, 2010 between DOI, DTSC, and Tribes to discuss UA-1/UA-1 Alternate and sampling at the mouth of Bat Cave wash.

On December 13, 2010, DTSC issued direction to PG&E on UA-1 and UA-1A alternate location (DTSC, 2010). On December 15, 2010, DOI issued direction to PG&E on sampling at the mouth of Bat Cave wash (DOI, 2010). On January 13, 2011, a meeting was held to discuss Tribes' comments on the preliminary data gaps evaluation.

In response to concerns raised by the Tribes through letters provided by the Fort Mohave Indian Tribe consultant (Hargis + Associates, November 22, 2010) and the Hualapai Department of Cultural Resources (December 3, 2010), and as a result of the tribal meetings held December 7, 2010, and January 13, 2011, DOI and DTSC evaluated the possibility of reducing the number of Phase 2 samples. In order to reduce the number of samples and disturbances to sensitive cultural resources, the agencies evaluated each sample location to determine which, if any, sample locations could be eliminated based on several criteria. DOI and DTSC issued in a joint letter dated February 25, 2011 (included in Attachment 1) with a revised Phase 2 sampling plan. The resulting Phase 2 sample locations are presented in this document.

AOC 4, Debris Ravine, was not included in the September 2010 version of the Draft Part A Phase 1 Data Gaps Evaluation Report (CH2M HILL, 2010) because the AOC 4 time-critical removal action was being conducted during the preparation of the previous report and AOC 4 soil data were not yet available. The AOC 4 time-critical removal action was completed in December 2010, and AOC 4 soil data representing current conditions have been included in this report and are provided Appendix C10.

1.1 Soil Part A Phase 1 Investigation (August – November 2008)

Field activities for the Soil Part A Phase 1 soil investigation were implemented between August and November 2008. The Part A Phase 1 soil investigation encompassed the following 10 investigation areas outside of the compressor station fence line:

- SWMU 1 – Former Percolation Bed
- AOC 1 – Area Around Former Percolation Bed
- AOC 4 – Debris Ravine
- AOC 9 – Southeast Fence Line
- AOC 10 – East Ravine

- AOC 11 – Topographic Low Areas
- AOC 12 – Fill Areas
- AOC 14 – Railroad Debris Area
- UA 1 – Pipeline Disposal Area
- UA 2 – Former 300B Pipeline Liquids Tank Area

These 10 areas are shown in Figure 1-2. Boundaries shown for the SWMUs, AOC, and UA are from the RFI/RI Volume 1.

Field activities included soil boring installation, embankment modifications at AOC 10, sample collection, white powder material and debris mapping, geophysical surveys, and trenching. A summary of these activities is included in Appendix B. Six hundred fifty-nine soil samples, seven white powder material samples, and four debris/wood samples were collected (sample counts do not include duplicate samples collected for quality control purposes). Two samples were also collected from one location in an area of Bat Cave Wash where soil is transitioning into sediment near the mouth of Bat Cave Wash. The DTSC also collected three soil samples of white powder at locations in AOC 10.

It is important to note that while geophysical investigation was conducted at UA 1, no intrusive sampling was performed. During field implementation of the Phase 1 investigation, DOI directed PG&E to stop planned investigation in this area (DOI, 2008b).

1.2 Newly Identified Debris, Historic Burn, and White Powder Areas (May 2009 to January 2010)

In 2009, at DTSC's direction, PG&E conducted additional interviews with current and former employees to collect new anecdotal information pertaining to historic compressor station practices. To confirm the new anecdotal information collected, additional site walks, including debris mapping, were conducted. The information gathered was provided in letters dated August 14, 2009 (PG&E, 2009a), October 15, 2009 (PG&E, 2009b), January 15, 2010 (PG&E, 2010a), and January 29, 2010 (PG&E, 2010b). In addition, a major storm event in January 2010 exposed new white powder areas on the hillsides above Bat Cave Wash, AOC 10, and AOC 11. The newly-identified area in Bat Cave Wash was shown to representatives of DTSC, DOI, Fort Mojave Indian Tribe, and the Hualapai Indian Tribe during a site visit on January 26, 2010. The new area in AOC 10 was discussed with the agencies in e-mails dated February 22, 2010 and February 24, 2010. The new area in AOC 11 was discovered during a site reconnaissance on February 10, 2010.

At the agencies' direction, these new areas will be incorporated for evaluation in this data gaps evaluation effort. Available information regarding these new areas is provided in the Appendix C sub-appendices.

1.3 Purpose of Soil Part A Phase 1 Data Gaps Evaluation Report

This Soil Part A Phase 1 Data Gaps Evaluation Report has been prepared to:

- Present the combined soil data collected to date for the identified SWMU, AOCs, and UAs outside of the compressor station fence line.
- Present the results of the data gaps evaluation using the decision and criteria described in the Soil Part A DQO Steps 1 through 5.
- Present Phase 2 sampling recommendations.

This document identifies proposed sample locations based on specific DQO rules as developed at the direction of DTSC and DOI, input from stakeholders during the October and November 2010 workshops, and the joint DTSC and DOI February 2011 direction letter. The Soil Part A Phase 2 proposed sample locations shown on figures and tables in Appendix C of this report are considered the Soil Part A Phase 2 sampling program for the Soil RFI/RI Work Plan. These additional data are needed to fill quantitative data gaps, meet agency requirements, and make further progress toward remedial decision-making.

1.4 Report Organization

This Soil Part A Phase 1 Data Gaps Evaluation Report is organized into eight sections and six appendices, as follows:

- **Section 1.0, Introduction**, contains background information, objectives, and report organization.
- **Section 2.0, Overview of Data Gaps Evaluation Process**, provides an overview of the data gaps evaluation process and the four DQO decisions applicable to the Soil Part A investigation.
- **Section 3.0, Decision 1 – Nature and Extent**, presents the inputs and process for evaluating nature and extent of contamination.
- **Section 4.0, Decision 2 – Data Sufficiency to Calculate Exposure Point Concentrations**, presents the inputs and process for the data sufficiency evaluation with regard to calculation of exposure point concentrations (EPCs) for use in the risk assessment.
- **Section 5.0, Decision 3 – Threat to Groundwater from Residual Soil Concentrations**, presents the inputs and process for assessing the potential for residual soil to impact groundwater.
- **Section 6.0, Decision 4 – Data Sufficiency to Support Corrective Measures Study/ Feasibility Study**, presents the inputs and process for the data sufficiency evaluation with regard to preparation of the corrective measures study/feasibility study (CMS/FS).
- **Section 7.0, Data Gaps Evaluation Summary**, provides a summary of the data gaps evaluation, including the proposed Phase 2 sampling.
- **Section 8, References,** presents a list of works cited when preparing this document.
- **Attachment 1**, DOI Direction Letter. PG&E Topock Compressor Station Remediation Site – *Topock Soil Investigation Part A Phase 1 Data Gaps Evaluation Report – Proposed Sample Locations, PG&E Topock Compressor Station, Needles, California*

- **Appendix A,** ***Data Quality Objectives Technical Memorandum – Part A Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California*,** contains the Soil Part A DQO Tech Memo.
- **Appendix B, Investigation Procedures, Field Methodology and White Powder/Debris Mapping Results**, summarizes field methodology, debris and white powder material mapping, trenching observations, and deviations from the Soil Part A Work Plan.
- **Appendix C, Part A Phase 1 Soil Investigation Data Gaps Evaluation Results**, presents the results of the data gaps evaluation and proposed Phase 2 sample locations.
- **Appendix D, Review of Analytical Data for the RCRA Facility Investigation/Remedial Investigation for Soil at the Topock Compressor Station**, presents the data quality evaluation of the analytical results from sampled collected as part of the 2006 Soil Part A Work Plan.
- **Appendix E, Additional Inorganic Compounds**, summarizes the data evaluation and calculation of representative background concentrations for detected inorganics.
- **Appendix F, Documentation of Compliance and Response to California Department of Toxic Substances Control and United States Department of the Interior Comments,** contains responses to DTSC's comments and conditional approval of the Soil Part A Work Plan and DOI's directions on the Soil Part A Work Plan (DOI, 2008a-b).

2.0 Overview of Data Gaps Evaluation Process

The Part A supplemental soil investigation program employs the DQO process to ensure that data collected at each stage of the investigation process are of sufficient quantity and quality to enable the specified decisions to be made. The DQO process is a recognized procedure for defining project objectives and decisions and for optimizing sampling and other information-gathering programs to balance uncertainty, site disturbances, and cost in an acceptable manner. The United States Environmental Protection Agency (USEPA) has issued detailed guidance for the seven-step DQO process (USEPA, 2000, 2006a-b):

- Step 1 – State the Problem
- Step 2 – Identify the Decision(s)
- Step 3 – Identify the Inputs to the Decision
- Step 4 – Define the Study Boundaries
- Step 5 – Develop a Decision Rule
- Step 6 – Specify Tolerable Limits on Decision Errors
- Step 7 – Optimize the Design

Between June 2008 and February 2010, DTSC, DOI, and PG&E drafted Steps 1 through 5 of the Soil Part A DQOs, which are used in this report to evaluate combined soil data and identify data gaps. DQO Steps 6 and 7 are presented in this report have been modified, as appropriate, based on stakeholder input. The Soil Part A DQO Steps 1 through 5 are summarized in the Soil Part A DQO Tech Memo (CH2M HILL, 2010), which is included as Appendix A to this report. DQO Steps 6 and 7 are summarized in Section 7.0.

Below are the four Part A DQO decisions to be made using the combined soil data collected to date and the decision process results for each decision for each of the investigation areas:

- **Decision 1.** Determine the nature and extent of residual soil and/or sediment concentrations resulting from historic compressor station practices. If determination of the full nature and extent of contamination based on sample data is not feasible or is not warranted, address uncertainties in the risk assessment or CMS/FS.

- **Decision 2 (Data Sufficiency Evaluation).** Determine representative EPCs for residual soil and/or sediment contamination resulting from historic compressor station practices that may pose unacceptable risks to current or future human or ecological receptors. If determination of representative EPCs based on sample data is not feasible, address uncertainties in the risk assessment or CMS/FS.

- **Decision 3.** Determine whether residual soil concentrations resulting from historic compressor station practices may threaten groundwater. If so, conduct additional site-specific assessment of the threat or implement response actions to mitigate the threat. If not, no further assessment or response actions are necessary to address threat to groundwater.

- **Decision 4 (Data Sufficiency Evaluation).** Determine the site-specific soil property and contaminant distribution information necessary to support the CMS/FS decisions and remedial action design. If full determination of site-specific soil property and contaminant distribution information based on sample data is not feasible, address uncertainties in the CMS/FS and remedial design.

The following evaluations were completed for each of the four DQO decisions:

- **Decision 1**. The nature and extent of contamination at Part A SWMU, AOCs, and UAs are described and evaluated to determine whether the nature and extent of contamination are adequately understood. The evaluation followed the Decision 1 rules outlined in the Part A DQO Tech Memo Figure 6 (see Appendix A).
- **Decision 2**. A data sufficiency evaluation was conducted to determine if sufficient data exist for Part A SWMU, AOCs, and UAs to calculate representative EPCs for each applicable exposure interval for human health and ecological receptors. The evaluation followed the Decision 2 Rules outlined in the Part A DQO Tech Memo Figure 7 (see Appendix A).
- **Decision 3**. Groundwater soil screening levels (SSLs) were calculated for any metal exceeding background concentrations at one or more locations within Part A SWMU, AOCs, and UAs. For constituents where the detected concentrations exceeded the SSLs, vadose zone modeling was conducted to further evaluate the potential threat to groundwater. Vadose zone modeling was also conducted evaluate the potential threat to groundwater from all detected organic compounds, with the exception of PCBs and dioxins/furans, which were evaluated based on a worst-case scenario where the lowest Kd was used in combination with the highest concentration observed at each depth interval. The evaluation followed the Decision 3 rules outlined in the Part A DQO Tech Memo Figure 8 (see Appendix A).
- **Decision 4**. A data sufficiency evaluation was conducted to determine whether sufficient data exist at Part A SWMU, AOCs, and UAs to support the CMS/FS (specifically, remedial technology feasibility assessment and estimation of soil and debris volumes potentially requiring remediation). The evaluation followed the Decision 4 rules outlined in the Part A DQO Tech Memo Figure 9 (see Appendix A).

The following sections summarize the process used to evaluate the four DQO decisions. Results of the evaluation for the nine Part A SWMU, AOCs, and UAs, including proposed Phase 2 sample locations if recommended, are provided in Appendix C.

3.0 Decision 1 – Nature and Extent

This section presents the inputs and process used to evaluate Decision 1 – Nature and Extent for the Part A SWMU, AOCs, and UAs. Results of the Decision 1 – Nature and Extent evaluation by SWMU/AOC/UA, including proposed Phase 2 sample locations if recommended, are provided in Appendix C.

3.1 Inputs to Decision 1

The following three types of information are needed and considered when assessing whether the nature and extent of contamination at a site are adequately understood: (1) usable and appropriate chemicals of potential concern (COPCs) and chemicals of potential ecological concern (COPECs) concentration data, (2) potential fate and transport mechanisms, and (3) preliminary screening comparison values, as described in the Soil Part A DQO Tech Memo provided as Appendix A. The following subsections describe the inputs required to evaluate Decision 1 – Nature and Extent.

3.1.1 Data Usability

The data collected during the Part A Phase 1 Soil Investigation were validated as described in the *Draft PG&E Quality Assurance Project Plan* (CH2M HILL, 2008a) and the *Draft Soil Addendum for the Topock Compressor Station, RCRA Facility Investigation/Remedial Investigation (*CH2M HILL, 2008b*)*. Appendix D presents the results of the data validation and data quality evaluation of Phase 1 data. The validated Part A Phase 1 data were combined with existing data. Existing data were evaluated in the *Final Soil and Sediment Data Usability Technical Memorandum, PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2008c). All data meeting Category 1 data quality standards were included in the combined data set.

The existing Category 1 data were also reviewed to assess whether they are still considered reliable due to changing site conditions. If site conditions had changed substantially (e.g., as in Bat Cave Wash following 2006 and 2010 storm events with high runoff), the data were assessed to determine whether it is likely that the changes have altered the conditions at particular locations. This data assessment process was limited to surface and near-surface samples, as deeper samples would not be expected to be affected by storm event erosion and deposition.

The Soil Investigation Part A Work Plan acknowledged that both deposition and erosion occurs in Bat Cave Wash after significant storm events; however, the precise nature of erosion and deposition patterns are difficult to assess. A significant storm event in 2006 resulted in erosion and deposition in many areas of SWMU 1 and, as such, the reliability of the shallow samples from pre-2006 data is suspect. Consequently, at the direction of DTSC, the Part A Phase 1 investigation included six sample transects, containing at least three sample locations each, across the wash perpendicular to the direction of flow to characterize the wash at the time of the Part A Phase 1 investigation. The Part A Phase 1 investigation conducted in 2008 provided data to develop an accurate assessment of conditions in the wash following the last major runoff event that occurred in 2006. Another significant storm event occurred in early January 2010. A site reconnaissance was performed on February 10 and 11, 2010 to evaluate whether the existing Part A Phase 1 data were still considered reliable. Based on the site reconnaissance, the Part A Phase 1 data are considered reliable. Deposition of large amounts of material occurred in the southern reaches of Bat Cave Wash near the confluence of AOC 4-debris ravine, but erosion and deposition appeared to be limited in SWMU 1 and AOC 1, as most sample location stakes were still present.

3.1.2 Potential Fate and Transport Mechanisms

Conceptual site models (CSMs) were developed for the *Human Health and Ecological Risk Assessment Work Plan* [RAWP], *Topock Compressor Station, Needles, California* (ARCADIS, 2008a) and RAWP Addendum (ARCADIS, 2009a) and were updated in the *Human and Ecological Risk Assessment of Groundwater Impacted by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1, and SWMU 2, Topock Compressor Station, Needles, California* (ARCADIS, 2009b). The updated CSMs are shown in Figures 2 through 5 of the Soil Part A DQO Tech Memo in Appendix A. The CSMs focus on evaluation of potential exposure pathways to human and to human and ecological receptors. Site-specific CSMs, providing a more detailed assessment of contaminant fate and transport mechanisms at each unit, were also developed and are presented in Appendix C.

The CSMs rely on the detailed information on the physical characteristics and setting of each unit, including surface features, topography, meteorology, site geology, surface water hydrology, site hydrogeology, land use, cultural resources, and ecology. Potential transport mechanisms and fate of COPCs and COPECs potentially released into the environment outside the fence line of Topock Compressor Station are presented in the CSMs.

3.1.3 Comparison Values

Six types of comparison values identified for this evaluation include:

- Soil background threshold values (BTVs) for metals and inorganic compounds, which are discussed in the *Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2009a) and in Appendix E to this report.
- Ecological comparison values (ECVs), which are calculated to be protective of the species potentially present in the area outside the fence line (ARCADIS, 2008b, 2009a-b).
- Threshold effect concentrations (TECs) that were obtained from MacDonald, et al. (2000) for comparison with sediment results, in accordance with the approved RAWP (ARCADIS, 2008a).
- DTSC California human health screening levels (CHHSLs) for residential use (California Environmental Protection Agency, Office of Environmental Health Hazard Assessment, 2005).
- USEPA regional screening levels (RSLs) for residential use for those compounds for which CHHSLs are unavailable or for which the existing CHHSLs are based on outdated toxicity factors (USEPA, 2009a).

- California Regional Water Quality Control Board, San Francisco Bay Region (Water Board, 2008) environmental screening levels for total petroleum hydrocarbons in the gasoline, diesel, and motor oil ranges for a residential exposure scenario for human health based on a hazard index of 1.0.
- Project-specific screening levels developed for COPCs/COPECs identified from Target Analyte List and Target Compound List (TAL/TCL) data, to be developed as needed.

The comparison values were used to assess the extent of contamination. The extent of contamination was defined to the lowest of the applicable comparison values, defined as the interim screening level. The soil interim screening level for most metals is equal to the corresponding BTV. Certain ECVs, USEPA RSLs, or DTSC CHHSLs for metals are lower than the BTV; in these cases, the BTV was used in lieu of the ECVs, USEPA RSLs, or DTSC CHHSLs when determining whether delineation is adequate. If a BTV is not available, then the interim screening value is usually the lesser of the DTSC CHHSLs or soil ECVs. As stated above, the USEPA RSL is used instead of the CHHSL in those instances where a CHHSL does not exist or where the toxicity values used in the CHHSL are outdated. The interim sediment screening level for most metals was the TEC. Where sediment TECs were not available for a given compound, the soil BTV was used as the interim screening level in a conservative estimate of sediment background values since background concentrations of metals in upland soil would be expected to be lower than background concentrations in sediment. The comparison values are shown in Tables 3-1 through 3-8. Exceedance of any comparison values does not indicate the presence or absence of unacceptable risk (potential site-related risks will be evaluated in the baseline risk assessment).

To assess dioxin/furan results, dioxin toxicity equivalence quotients (TEQs) were calculated and compared to the DTSC/Human Ecological Risk Department (HERD) dioxin TEQs remedial goals presented in *Remedial Goals for Dioxins and Dioxin-like Compounds for Consideration at California Hazardous Waste Site* (DTSC, 2009). The DTSC/HERD guidance provides the following dioxin TEQ remedial goals for sites in California:

- 50 nanograms per kilogram: residential exposure scenario (based on 10^{-6} risk level and adjusted by a factor of 10 to account for minimal contribution of soil and dust to dioxin body burden in a University of Michigan dioxin study).
- 200 to 1,000 nanograms per kilogram: commercial/industrial exposure scenario (a range is proposed from a concentration based on 10^{-6} cancer risk [adjusted by a factor of 10 as with the residential value] to a concentration based on a hazard index of 1).

For completeness, the data were also compared to commercial/industrial DTSC CHHSLs or USEPA RSLs. This comparison is for informational purposes only; the nature and extent delineation was not based on comparison to the commercial use values.

3.2 Nature and Extent Evaluation

As outlined in the decision process for Decision 1 in the Soil Part A DQO Tech Memo, the nature and extent evaluation consisted of:

- Identifying newly detected compounds (note that these constituents have not been formally designated as COPCs or COPECs).
- Conducting a point-by-point comparison of all detected compounds to the comparison values.
- Assessing lateral and vertical extent of detected compounds, as well as spatial concentration trends of detected compounds (i.e., changes in concentration laterally and vertically).
- Conducting a central tendency comparison between site and background data sets.

These steps are discussed in more detail below.

3.2.1 Identification of Newly Detected Compounds

The full inorganic and organic suite analyses included in the CERCLA TAL/TCL includes compounds that have not typically been included in analytical suites for the areas outside the fence line. At the request of DOI, 10 percent of all samples collected during the Soil Part A Phase 1 investigation were analyzed for the full TAL/TCL suite. The Part A Phase 1 data and existing data were combined and reviewed to assess whether, as a result of the full TAL/TCL analysis, any new compounds that qualify as COPCs/COPECs have been identified in the areas outside the compressor station. An evaluation of detected Part A CERCLA TAL/TCL constituents is included in Appendix C.

3.2.2 Point-by-Point Comparison with Comparison Values

The initial comparison of COPCs/COPECs was conducted on a point-by-point basis for all depths (i.e., a simultaneous lateral and vertical assessment). All data for a given area were compared to the comparison values described in Section 3.1.3. (Data tables by constituent group by individual unit are included in Appendix C.) Detected concentrations of a given chemical were flagged for each occurrence of a COPC or COPEC exceeding the interim screening level. It should be noted that the results from this point-by-point comparison were used in conjunction with the spatial trends analysis and central tendency comparison to assess whether a data gap existed at locations with one or more constituents exceeding the applicable BTV or risk-based comparison values. Other considerations included:

- The frequency and extent to which the lowest applicable comparison value was exceeded and, in the case of comparison to BTVs, the degree of exceedance of the lowest applicable risk-based comparison value (typically the ECV).
- The influence of topography on both the likely direction of COPC or COPEC movement and the ability to collect additional samples.
- The proximity of other relevant sample locations to the sample location exceeding the interim screening level.

For example, at AOC 9, copper was detected in samples at concentrations exceeding the BTV. One of these samples is located at the perimeter of the sampling area. However, none of the detected concentrations exceeded ECV and residential or commercial/industrial

CHHSLs (20.6 milligrams per kilogram [mg/kg], 3,000 mg/kg, and 38,000 mg/kg, respectively). Consequently, no further sampling for copper was recommended for AOC 9.

Statistical summary tables were also created for each area and are included in the Appendix C sub-appendices. The statistical summary tables present the frequency of detection for each COPC and COPEC detected in soil, the maximum detected concentration, and the number of exceedances of each comparison value described in Section 3.1.3. Soil sample counts presented in the statistical summary tables do not include duplicate (quality control) soil samples. At locations where duplicate samples were collected, the higher of the two values were included in the statistical summary tables. The number of exceedances is the number of detections that are equal to or exceed the respective screening/comparison values. For the BTV, exceedances are the number of detections exceeding the BTV (i.e., if a detected concentration is equal to the BTV, it is considered to be within background).

Eight metals (antimony, beryllium, cadmium, mercury, molybdenum, silver, selenium, and thallium) were commonly not detected in Part A Phase 1 soil samples at concentrations above laboratory reporting limits; however, the respective reporting limits were higher than the respective ECVs and/or BTVs. The laboratory reporting limits are equal to the laboratory's practical quantitation levels—the minimum concentration at which a laboratory can accurately determine the concentration of a substance. For these eight metals, the practical quantitation levels are at or below the USEPA Superfund Analytical Services/ Contract Laboratory Program required quantitation limits and are the lowest concentration the laboratory can accurately achieve.

The fact that reporting limits for these metals exceeded the respective ECVs and/or BTVs is not considered a data gap because of the following reasons:

- Antimony was not detected in background samples; therefore, a BTV was not calculated for antimony. The reporting limits for background samples are similar to the reporting limits for Part A Phase 1. Although the reporting limits exceeded the ECV, the limits are well below the residential CHHSL of 30 mg/kg , and no known source of antimony exists at Topock Compressor Station.
- The reporting limits for beryllium exceeded the BTV but were well below the ECV and residential CHHSL. The reporting limits were generally only two to three times the BTV, indicating that beryllium was not highly elevated above the BTV in any of the samples, and no known source of beryllium exists at Topock Compressor Station.
- The reporting limits for cadmium, silver, selenium, and thallium rarely exceeded ECVs and/or BTVs. The majority of the reporting limits for these metals were below or equal to the applicable comparison values.
- The reporting limits for mercury exceeded the ECV but were well below the residential CHHSL. Mercury was not detected in the background samples; therefore, a BTV was not calculated. The reporting limits for the background samples were similar to the reporting limits for the Part A Phase 1 soil investigation. The ECV is below the capability of laboratory instrumentation to detect mercury, which is a recognized common issue with mercury analyses in ecological risk assessment. Furthermore, the ECV developed for the Part A soil investigation is intentionally very conservative (i.e., the lowest value).

Ecological risk from mercury and the uncertainty associated with the reporting limits will be addressed during the ecological risk assessment.

- The reporting limits for molybdenum sometimes exceeded the BTV but rarely exceeded the ECV. All reporting limits were well below the residential CHHSL. The reporting limits were typically no more than two times the BTV, indicating that molybdenum was not highly elevated above the BTV in any of the samples.

3.2.3 Evaluation of Lateral and Vertical Extents and Spatial Trends

The lateral and vertical extents of each COPC/COPEC were evaluated by assessing whether constituent concentrations in the samples were below the applicable interim screening level toward the edge of the unit or affected area. Potential hot spots, if any, were identified through the presence of clusters of elevated concentrations of COPCs/COPECs.

In addition, spatial trends were evaluated for those COPCs/COPECs identified by the point-by-point comparison as having concentrations exceeding the interim screening level. Figures with posted concentrations were created for those COPCs/COPECs that were detected four or more times above respective interim screening levels to assist with the evaluation of lateral and vertical extents and spatial trends. These figures are presented for each unit in the Appendix C sub-appendices.

Spatial trends were evaluated both laterally and vertically. For lateral delineation, concentration trends toward the perimeter of each area were reviewed to ensure that concentrations are generally decreasing toward the perimeter. Vertical concentration trends were also reviewed for each boring showing concentrations of COPCs/ COPECs. Evaluation of spatial trends included:

- Lateral concentration trends toward the edge of a unit or affected area (i.e., potential hot spot) within a unit.
- Vertical concentration trends in each boring and throughout a given unit or area.
- Distribution of detections and non-detections of each constituent within a unit.
- Where applicable, concentrations trends at an upstream/upslope unit or area.

The specific areas where COPC/COPEC lateral or vertical boundaries are not adequately defined or where concentration trends are not decreasing were identified as locations where data gaps exist. The identified data gaps provided the basis for further sampling recommendations for Decision 1. If additional data collection was feasible (i.e., no structures, topography, or cultural resources preventing step-out sampling or deeper sampling vertically), then additional sampling locations, depths, and/or analytical suites were proposed for Phase 2 soil based on Step 7 of the DQO process. The additional sampling recommendations for each unit are included in the Appendix C sub-appendices.

3.2.4 Central Tendency Comparison

A population (central tendency) comparison was conducted for those metals detected in soil at concentrations exceeding the respective BTVs. The central tendency comparison assesses whether there is an overall shift of concentrations between the site data versus the background data (i.e., if the site concentrations are higher relative to the background concentrations than random variability could explain). The comparison helps to determine whether an overall shift exists between the background and the combined soil data set for each area.

The comparison was conducted using the approved *Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California Technical Memorandum* (CH2M HILL, 2009a). Because comparison to the BTV offers information only on the upper tail of the site concentration distribution, in cases where single point exceedances of the BTV exist, the central tendency comparison offers an opportunity to statistically address whether there is an overall shift of site concentrations relative to background concentrations. This overall shift may be identified as a data gap, and additional sampling may be proposed, if appropriate.

The Gehan test and Wilcoxon Rank Sum test are commonly used to conduct central tendency comparisons. These central tendency tests are discussed both in USEPA and Navy literature (USEPA, 2009b; Navy, 2002). These central tendency tests provide a calculated probability, which was compared to a significance level of 0.05. If the probability was below 0.05, it was concluded that a significant exceedance over background is present.

Both tests are nonparametric approaches based upon the ranks of the data; however, they handle ties in these ranks differently. For that reason, the Gehan test is recommended when the percent of nondetects is greater than 40 percent or when multiple detection limits exist for a given metal, both of which were frequently the case. These joint reasons led to the use of the Gehan test for all cases. (Using these rules, the Wilcoxon Rank Sum test could have been performed for one case, but the calculated probability only differed by a single thousandth between the two tests, thus not impacting the conclusion of the test and allowing use of the Gehan test to be a more consistent approach.)

The central tendency test was not performed if a metal was infrequently detected (less than five detects) in either the unit data or background data set or had a limited number of results (less than eight). Using these rules, a central tendency comparison for hexavalent chromium could not be conducted at any unit because there were insufficient detections of hexavalent chromium in the background data set.

Central tendency comparison box-and-whisker and scatter plots are shown in Figure 3-1, and results for each area are discussed in detail in the Appendix C sub-appendices.

Notes:

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

[2] USEPA residential regional screening level from April 2009 is used.

[3] Mercury: mercury, inorganic salts

[4] The oral reference dose (RfD) used for the vanadium screening level is derived from the IRIS oral RfD for vanadium pentoxide by factoring out the molecular weight of the oxide ion.

QAPP RL = quality assurance procedures plan reporting limit
DTSC CHHSL = California Department of Toxic Substances Control; California human health screening levels (OEHHA, 2005)
Background = CH2M HILL. 2009. "Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California". May.
--- = data not collected, available or applicable
x = indicates analytes from the Contract Laboratory Program Target Compound and Target Analyte Lists (TCL/TALs)
USEPA = United States Environmental Protection Agency

SL = USEPA regional screening level (USEPA, December 2009)
mg/kg = milligrams per kilogram
NE = regulatory standard not established
NC = not calculated
NA = not available
* = California modified preliminary remediation goal (USEPA 2004)

Notes:

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

[2] Calculated using California toxicity values. The EPA Regional SL for Benzo(a)anthracene, Benzo(b)fluoranthene and Indeno (1,2,3-c,d)pyrene residential is 150 µg/kg, commercial is 2100 µg/kg; Dibenzo(a,h)anthracene residential is 15 µg/kg, commercial is 210 µg/kg.

[S] Pyrene is used as a surrogate

QAPP RL = quality assurance procedures plan reporting limit

DTSC CHHSL = California Department of Toxic Substances Control; California human health screening levels (OEHHA, 2005)

SL = USEPA regional screening level, (USEPA, December 2009)

µg/kg = micrograms per kilogram

NE = regulatory standard not established

--- = background concentration could not be established because all background samples were non-detect for this constituent

(sat) = concentration may exceed saturation value

* = California modified preliminary remediation goal (USEPA 2004)

NA = not available

USEPA = United States Environmental Protection Agency

Pyrene	129-00-0	330[3]	NE	NE	1,700,000	17,000,000	---	See note 2	No	1,700,000	No

Notes:

All soil sample results will be reported in dry weight unless otherwise specified in the SAP.

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

[2] ECVs were calculated as needed for constituents detected during the Part A Phase 1 sampling.

[3] Analytes were analyzed by SW8270SIM to achieve a lower reporting limit.

[4] Calculated using California toxicity values. The EPA Regional SL for Benzo(a)anthracene, Benzo(b)fluoranthene and Indeno (1,2,3-c,d)pyrene residential is 150 µg/kg, commercial is 2100 µg/kg; Dibenzo(a,h)anthracene residential is 15 µg/kg, commercial is 210 µg/kg.

QAPP RL = quality assurance procedures plan reporting limit
DTSC CHHSL = California Department of Toxic Substances Control; California human health screening levels (OEHHA, 2005)
µg/kg = micrograms per kilogram
SL = USEPA regional screening level, (USEPA, December 2009)
NE = regulatory standard not established
(sat) = concentration may exceed saturation value
s1 = pyrene is used as a surrogate.
(max) = ceiling limit, not a risk-based value
^ = preliminary remediation goal, (USEPA, 2004)
--- = data not collected, available or applicable
x = indicates analytes from the Contract Laboratory Program Target Compound and Target Analyte Lists (TCL/TALs)
* = California modified preliminary remediation goal, (USEPA, 2004)
USEPA = United States Environmental Protection Agency

Notes:

All soil samples are reported in dry weight unless otherwise specified.

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

[2] ECVs to be calculated as needed based on analytical results from Part A Phase 1 soil sampling.

QAPP RL = quality assurance procedures plan reporting limit

DTSC CHHSL = California Department of Toxic Substances Control; California human health screening levels (OEHHA, 2005)

µg/kg = micrograms per kilogram

SL = USEPA regional screening level, (USEPA, December 2009)

s1 = 1,3-dichloropropene is used as a surrogate

s2 = 1,2-dichloropropane is used as a surrogate

s3 = isoproylbenzene is used as a surrogate

s4 = bromodichloromethane is used as a surrogate

s5 = m-xylene is used as a surrogate

* = California modified preliminary remediation goal (USEPA, 2004)

x = indicates analytes from the Contract Laboratory Program Target Compound and Target Analyte Lists (TCL/TALs)

NE = regulatory standard not established

(sat) = concentration may exceed saturated value

^(sat) = preliminary remediation goal, (UPEPA 2004); saturation concentration, not a risk based value

^ = preliminary remediation goal, (UPEPA 2004)

USEPA = United States Environmental Protection Agency

4.0 Decision 2 – Data Sufficiency to Estimate Representative Exposure Point Concentrations

This section presents the process used to evaluate Decision 2 – Data Sufficiency to Calculate Exposure Point Concentrations at the Part A SWMU, AOCs, and UAs. Results of the Decision 2 – Data Sufficiency to Calculate Exposure Point Concentrations by individual unit, including proposed Phase 2 sample locations if recommended, are provided in the Appendix C sub-appendices.

4.1 Inputs to Decision 2

The inputs required for Decision 2 include COPC and COPEC concentrations in soil within the exposure areas and depth categories defined in the RAWP (ARCADIS, 2008a). In addition, COPEC concentrations in sediment were evaluated using the following preliminary ecological exposure intervals: 0 to 0.5 foot below sediment surface (bss), 0 to 2 feet bss, and 0 to 3 feet bss. Only COPC and COPEC data meeting data quality Category 1 standards will be used for the risk assessment. A Data Usability Matrix for Soil Risk Assessment was developed to aid in evaluating data usability and adequacy for risk assessment purposes and was used as a Decision 2 input tool (the matrix is provided in Appendix A, Table A-1). The matrix lists the total number of existing and newly collected samples per AOC and sub-AOC areas, identifying horizontal and vertical coverage, exposure depths as defined in the RAWP, analytical suites, data quality, representativeness, and comparability. The inputs to Decision 2 also include comparison values described in Section 3.1.3.

4.2 Data Sufficiency to Estimate Representative Exposure Point Concentrations Evaluation

Existing soil and sediment data were evaluated for sufficiency to estimate a representative EPC by:

- Detected compound
- SWMU, AOCs, or UA
- Exposure depth interval

The evaluation assumes the existing data adequately represent the nature and extent of contamination; this assumption will be verified after Phase 2 data have been collected. Additional sampling was recommended if data were insufficient estimate a representative EPC for any constituent in any defined exposure interval at each unit. The technical approach used to evaluate the data to address Decision 2 is described below.

All soil Category 1 data were evaluated for each of the exposure intervals defined in the RAWP (ARCADIS, 2008a) and RAWP Addendum (ARCADIS, 2009a) for potential contact by both human populations and ecological receptors. In addition, as stated above, Category 1 data from sediment were evaluated using the following preliminary ecological exposure intervals: 0 to 0.5 foot bss, 0 to 2 feet bss, and 0 to 3 feet bss. The sediment exposure area defined for this evaluation extends from the east margin of the Tamarisk thicket near the mouth of Bat Cave Wash to the easternmost end of the wash. Samples from both the west and east side of National Trails Highway at the mouth of Bat Cave Wash were included. Data for each detected compound in each AOC-specific exposure interval were evaluated for:

- Frequency of detection.
- Maximum result.
- Number of detections above comparison values.
- Human health comparison values—residential criteria or background, whichever is higher.
- Soil ECVs previously submitted in technical memoranda (ARCADIS, 2008b 2009a-b) or background, whichever is higher.
- Sediment TECs from MacDonald, et. al. (2000) or soil background (as a conservative estimate of sediment background) if sediment TECs are not available.

Frequency of detections and maximum results were evaluated to understand whether the minimum data necessary are available to calculate a representative EPC to be used in the human and ecological risk assessment. A representative EPC could be either: (1) a 95 percent upper confidence limit of the mean (95%UCL) where at least eight results were reported with a minimum of five detections or (2) the maximum concentration reported, if data were not adequate for a 95%UCL and the following criteria were met:

- The maximum was less than or equal to approximately two times the comparison value for human health or ecological risk screening, and/or
- Additional data collection appeared unlikely to yield additional detections to support the calculation of a 95%UCL.

The Appendix C sub-appendices present data tables that summarize key information for each detected COPC/COPEC in each unit. For each detected COPC/COPEC, the tables in Appendix C indicate, for each relevant exposure depth interval, the total number of samples collected, the number of detections, the maximum detected value, and whether there is sufficient information to calculate a representative EPC for that particular COPC/COPEC at that particular unit.

As described in detail in Appendix C, in general the soil and sediment data for each COPC/COPEC detected at the individual units are adequate to support the calculation of an EPC for use in the human health and ecological risk assessment.

5.0 Decision 3 – Threat to Groundwater from Residual Soil Concentrations

This section presents the inputs and process used to evaluate Decision 3 – Threat to Groundwater from Residual Soil Concentrations at the Part A SWMU, AOCs, and UAs. Results of the Decision 3 evaluation, including proposed Phase 2 sample locations if recommended, are provided in Appendix C.

5.1 Inputs to Decision 3

The inputs required for Decision 3 consist of the nature and extent of soil data from Decision 1, site-specific information required to calculate SSLs protective of groundwater, and screening-level groundwater modeling results, where necessary.

Existing and new soil data provide information on the nature and extent of COPCs. Key site-specific information required to calculate the SSLs include:

- Soil BTVs for metals and inorganic compounds, discussed in the *Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California* (CH2M HILL, 2009a) and in Appendix E to this report.
- Groundwater background values for inorganics, calculated as 95 percent upper tolerance limits and presented in *Groundwater Background Study Steps 3 and 4: Revised Final Report of Results, PG&E Topock Compressor Station* (CH2M HILL, 2009b). For organics, groundwater maximum contaminant levels and/or applicable drinking water standards were used.
- Volume and cross-sectional area of the potential source (i.e., unit or area).
- Site-specific recharge and groundwater flow characteristics at each unit.
- Depth to groundwater, geochemical, and hydraulic characteristics of the vadose zone soil.

Inputs required for the screening-level groundwater modeling are the same as those for the SSL calculation, with the addition of transport parameters (dispersion, soil-water partition coefficients). USEPA literature and other technical literature served as the source for these parameters (USEPA, 2005; Xu M. and Y. Eckstein, 1995).

5.2 Threat to Groundwater from Residual Soil Concentrations Evaluation

A preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, is needed to resolve Decision 3. Data collected to satisfy Decision 1 – Nature and

Extent Evaluation – will provide the representative data set that will be used to assess the threat to groundwater. Additional evaluations will be performed as appropriate as data are collected to resolve Decision 1.

A conservative, three-tiered approach was used in the evaluation to assess which units may present a potential current or future threat to groundwater from COPCs in the vadose zone. The approach was presented in technical memorandum entitled *Calculation of Soil Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station* (CH2M HILL, 2008d) and includes:

- **Step 1.** The initial step in the evaluation process was to compare the metals concentrations in soil samples from each investigation area to the soil BTV to assess whether the concentrations are at or below background. If no individual COPC concentration from samples collected within a unit is greater than the BTV, or if the central tendency comparison evaluation concluded the COPC concentration in the sample population within a unit is not statistically greater than the COPC concentration in the background population, then no further analysis was required to assess the potential for leaching into groundwater for that COPC within the unit. This evaluation was completed for all metals detected in a given unit. If the deepest sample(s) in a boring or area exceeded the BTV, a data gap may have been identified for Decision 3.[1]

  Because organic compounds (polychlorinated biphenyls, pesticides, volatile organic compounds, semivolatile organic compounds) do not have a soil BTV to compare to, all organic compounds were evaluated in Step 3 (see detailed discussion in Appendix C).

- **Step 2.** For detected COPCs with concentrations above BTVs, the detected concentrations were compared to the unit-specific SSL. The SSLs were calculated in accordance with USEPA (1996) and New Mexico Environment Department (2006) guidance, among others. A detailed example SSL calculation was provided in the technical memorandum entitled *Calculation of Soil Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station* (CH2M HILL, 2008d). The SSLs were calculated using highly conservative assumptions so that COPCs that are eliminated from further consideration in this step are eliminated with high confidence. If sample concentrations are at or below the SSL, then no further analysis is required to assess the potential for leaching into groundwater for those COPCs.

  If samples concentrations were above SSLs, the data were evaluated to assess whether the sample results indicated a potential current threat to groundwater. A potential current threat to groundwater was identified if one or both of the following conditions existed:

  - Vertical concentration trends of COPC increased with depth.
  - Soil data indicated elevated concentrations of compounds (as compared to the BTVs) in samples throughout the boring <u>*and*</u> at the depth of the soil/groundwater interface.

---

[1] Note that this may also represent a data gap for Decision 1. However, if concentrations are declining with depth and/or the concentration detected in the lowest sample collected is near the BTV, the available data may be considered adequate for Decision 1.

If the evaluation did not indicate a potential current threat to groundwater, then the evaluation continued with Step 3.

- **Step 3.** If sample concentrations exceeded the SSL but did not indicate a potential current threat to groundwater, a vadose zone flow and transport model was used to evaluate the potential for leaching into groundwater. Modeling was performed using the HYDRUS-1D software package (Simunek et al., 1998) and is intended as a screening process using highly conservative assumptions. If the modeling results showed no exceedance of the groundwater background values, then no further evaluation was required. If the modeling results showed a COPC in groundwater at a concentration exceeding groundwater background values, the need for model refinement and possible additional data collection and/or development of a plan for a groundwater assessment was evaluated

The Step 3 modeling approach, model inputs, and assumptions provided in Appendix C. Results of the modeling evaluation, and data gaps identified with regard to Decision 3 are discussed in detail in the Appendix C sub-appendices.

Additional modeling and model refinement, if needed, will be performed after new Phase 2 soil data are collected.

6.0 Decision 4 – Data Sufficiency to Support Corrective Measures Study/Feasibility Study

6.1 Inputs to Decision 4

Inputs to Decision 4 consist of soil property and contaminant distribution data (validated Phase 1 data and existing Category 1 data) and other information needed to support the CMS/FS decisions and remedial design. Inputs to Decision 4 include volumes of debris; specific soil physical and chemical properties that could influence the performance of certain remedial technologies (e.g., porosity, grain size, density, organic carbon content, soil chemical properties); waste characterization parameters for any soils that may need to be transported and disposed of offsite; and potential physical limitations on implementation of various technologies (surface or subsurface structures).

6.2 Data Sufficiency to Support Corrective Measures Study/Feasibility Study Evaluation

A preliminary assessment of potential remedial technologies and presumptive remedies guided identification of the data needs to support the CMS/FS and remedial design. An initial list of suitable remedial technologies was presented in the approved *Final Corrective Measures/Feasibility Study Work Plan, Topock Compressor Station, Needles, California* (CH2M HILL, 2008e), referred to as the CMS/FS Work Plan. The following is a summary of the initial technologies presented in the CMS/FS Work Plan:

- **Excavation and Offsite Disposal:** involves excavation, transportation, and disposal of contaminated material from the Topock site to a permitted offsite disposal facility. Pretreatment may be required to meet disposal requirements of the offsite facility.
- **Excavation and Onsite Treatment:** is an *ex-situ* method that involves excavation of contaminated soil and treatment onsite by either soil washing or chemical reduction.
- **Soil Flushing:** is an *in-situ* method that involves application of water or additive-containing water to soil to enhance contaminant solubility. Soil flushing is used in combination with a groundwater remedial method. Contaminants are leached from soil into the groundwater, which is then remediated.
- **Solidification/Stabilization:** can be either *ex-situ* or *in-situ* and involves use of various chemical additives to physically bind or enclose contaminants within a stabilized mass (solidification) or to chemically reduce the contaminants' mobility by inducing chemical reaction between the stabilizing agent and the contaminants (stabilization).
- ***In-Situ* Chemical Reduction:** involves addition of reagents to react with targeted constituents in soil to chemically convert hazardous contaminants to non-hazardous or

less toxic compounds that are more stable, less mobile, and/or inert. Reductants could be applied to soil by infiltrating a liquid reductant from the surface, injecting a liquid reductant through wells, or injecting a gaseous reductant through wells.

- **Phytoremediation**: involves planting vegetation on contaminated soils. Contaminants are removed from soil through geochemical reactions in the root zone or through uptake by the roots and incorporation into the plant tissue. If contaminants become incorporated into the plants, the plant material may be periodically harvested and removed to a hazardous waste disposal facility. Phytoremediation is generally effective only for contaminants that are soluble in water and located at shallow depths that can be reached by the plant roots, or in combination with other measures, where it is used to reduce the amount of surface water infiltration to a deeper contaminated zone or to lower local groundwater levels to prevent contact with contaminated soils.
- **Capping in Place:** involves construction of a capping system on top of the contaminated area to contain and minimize exposure of the contaminants to the environment.
- **Soil Vapor Extraction:** involves application of a vacuum through a network of wells to remove contaminated vapor from the soil. Volatile contaminants are removed with the vapor stream. A treatment system is typically incorporated to remove the contaminants before the soil vapor is vented to the atmosphere.
- **Thermal Desorption:** involves heating the subsurface to accelerate the movement of contaminants from the soil into the soil vapor. It is typically combined with soil vapor extraction to remove the contaminants from the subsurface. By heating the subsurface, soil vapor extraction can be used for a wider range of contaminants with lower volatility. Heating can also speed up the removal of volatile contaminants, particularly if contaminants are present in the form of non-aqueous phase liquids. Heating can be accomplished by injection of hot air or steam, or through use of electric current.
- ***In-situ* Vitrification**: involves intensive heating of the subsurface to completely melt the soil, which then cools into a glassy, vitrified block. Most organic contaminants are driven off or broken down during the heating. Inorganic contaminants are driven off or incorporated into the vitrified block and sequestered from the surrounding soil or groundwater.
- **Incineration:** involves burning excavated soil at high temperatures in a kiln or furnace. Incinerators are carefully designed to capture and treat the gases generated during combustion. Due to difficulties in permitting incinerators, most incineration is accomplished in offsite hazardous waste treatment facilities rather than with onsite incinerators. Depending on the contaminants present, the ash remaining may require disposal as a hazardous waste.

Treatability studies to collect data on technologies identified during the alternative development process are conducted, as appropriate, to provide additional information for evaluating technologies during the preparation of the CMS/FS.

The evaluation of data sufficiency to support the CMS/FS (i.e., data requirements for the initial list of suitable remedial technologies listed above) was conducted by assessing the following for each individual unit:

- Lateral and vertical extents of COPCs and COPECs potentially posing an excess human health and/or ecological risk. The lateral and vertical extent information will be used to estimate required remediation volumes to determine the most appropriate and cost-effective remedial approach for each area potentially requiring remediation. This step cannot be completed until the baseline risk assessment is completed; however, if the nature and extent of contamination are sufficiently defined to satisfy Decision 1, sufficient data would be expected to be available to allow the completion of this portion of the evaluation for Decision 4 once the risk assessment has been completed.
- Waste characterization parameters for any soils that may be transported offsite for disposal (i.e., total threshold limit concentrations [TTLC], soluble threshold limit concentrations [STLC], and toxicity characteristic leaching procedure [TCLP]). The TTLC and STLC are waste characterization criteria in the State of California. The TTLC simply requires standard chemical analysis of samples to determine total concentrations of COPCs using published USEPA methods. The detected concentrations are compared to the TTLCs to determine whether total COPC concentrations exceed the hazardous waste criteria. Total chemical concentrations are also compared to a concentration of 10 times the STLC (10 x STLC) and 20 times the TCLP (20 x TCLP) to determine whether leachability testing is required to determine if leachable concentrations of COPCs may exceed hazardous waste criteria. To evaluate COPC leachability relative to the SLTC, samples are subjected to the Waste Extraction Test specified in the Title 26 of the California Code of Regulations. The TCLP determination is a federal criterion for RCRA waste; leachable concentrations of COPCs using the TCLP are compared to applicable RCRA criteria. The Waste Extraction Test uses a tenfold dilution/extraction of the sample, and the TCLP uses a twentyfold dilution/extraction. Consequently, total sample concentrations below 10 times STLC and 20 times TLCP cannot exceed the applicable hazardous waste criteria.
- Specific soil physical properties that may affect the performance of the various technologies (i.e., porosity, grain size, density, organic carbon content). Table 6-1 provides specific soil physical properties that are needed for applicable remedial technologies.
- Existing surface and subsurface features (i.e., vegetation, nearby roads and road structures, culverts, subsurface utilities, bedrock, topography) that may affect the implementability of various technologies.
- White powder and debris mapping to estimate the extent, volumes, and type of debris. This information will be used to estimate required removal and/or remediation volumes to determine the most appropriate and cost-effective approach for each area containing white powder or debris.

The evaluation of data sufficiency to support the CMS/FS for each area was completed by evaluating the data summary for Decision 1 (presented in Appendix C) and by comparing the available data to the list presented above and in Table 6-1 to determine if any data gaps exist. The data gaps and additional sampling recommendations for each unit are included in the Appendix C sub-appendices.

- Reactivity - Title 22, Division 4.5, Chapter 11, Article 3, Section 66261.23
- Ignitability - SW-846 1010/1020
- Corrosivity - SW-846 9040

7.0 Data Quality Objectives Steps 6 and 7

This section summarizes DQO Steps 6 and 7. The completed DQO Steps 1 through 7 for the 10 Part A SWMU, AOCs, and UAs included in this report are presented in Table 7-1.

7.1 Step 6: Acceptable Limits on Decision Error

Step 6 is intended to define acceptable limits on decision errors. A decision error would occur if, based on the available data, the project team chooses the wrong response action in the sense that a different response action would have been chosen if the project team had access "perfect data" or absolute truth. COPC concentrations are estimated using data that are subject to different variabilities at different stages of development, from field collection to sample analysis. The combination of all these errors is called "total study error." In some cases, total study error may lead to a decision error. Total study error is composed of two main components:

- **Sampling design error**. This error (variability) is influenced by the sample collection design, the number of samples, and the actual variability of the COPC concentration over space and time. Sampling must necessarily be limited to specific locations within a potentially impacted area, and this limited sampling may miss some features of the existing variation of the constituent concentration levels. Sampling design error occurs when the data collection design does not capture the complete variability within the media to the extent appropriate for the decision of interest.
- **Measurement error**. This error (variability) is influenced by imperfections in the measurement and analysis system. Random and systematic measurement errors may be introduced in the measurement process during physical sample collection, sample handling, sample preparation, sample analysis, and data reduction.

Potential decision errors can be evaluated quantitatively or qualitatively. For sites such as Topock, where the most appropriate sampling design is non-probabilistic, potential decision errors are evaluated qualitatively. Sample design errors are controlled through use of the CSM. Measurement error is controlled to an acceptable level by implementation of the Quality Assurance Project Plan and by rejection of data that do not meet the criteria specified in the Quality Assurance Project Plan.

Limits on decision error for the Part A soil investigation were reduced by ensuring with the highest level of confidence feasible that the Part A soil investigation sample locations were located in the appropriate areas. Appropriate areas consist of areas with known impacts or areas likely to have been impacted. These areas were identified based on site history information and current site conditions (i.e., to identify the release point) and transport pathways (to identify likely contaminant locations). Site-specific CSMs were developed for each of the SWMU, AOCs, and UAs to assess whether or not the Part A soil investigation samples are located in the areas of impact or likely to have been impacted. During the development of the CSMs and completion of Step 6, uncertainties at each individual unit were assessed for:

- Source of contamination, including release point.
- Potential release mechanisms and transport pathways.
- Topographic conditions and constraints.

Site-specific CSMs are presented in Appendix C. The completed DQO Step 6 for the AOCs included in this report are presented in Table 7-1.

7.1.1 Step 7: Optimize the Sampling Design for Obtaining Data

The purpose of Step 7 is to "identify a resource-effective data collection design for generating data that are expected to satisfy the DQOs" (USEPA, 2000) in the context of site-specific constraints. The output of this step is the Phase 2 sampling design discussed with the stakeholders during the Part A Phase 1 data gaps evaluation process. This step documents the applicable activities of the sample design process to describe the reasons for selecting a sampling scheme, the reasons for selecting specific sampling locations, and the expected performance of the data collection design with respect to qualitative DQOs only, as was done for the Part A Phase 1 soil investigation.

Phase 2 sample locations were chosen to address specific data gaps identified based on specific DQO rules. The Phase 2 locations also reflect input from stakeholders during the two-day workshops and the joint DTSC and DOI February 2011 direction letter. In order to reduce the number of samples and disturbances to sensitive cultural resources, DOI and DTSC evaluated each originally proposed Phase 2 sample location to determine which, if any, sample locations could be eliminated. Approximately 50 sample locations were eliminated based on the following assumptions:

- Defining edges or detailed distribution of contamination in the wash channels is not necessary for technology assessment or risk evaluation. It is assumed that known contaminant concentrations measured at previous sample points extend between the points and to the wash boundaries.

- It is unlikely that significantly higher concentrations of contaminants exist in the areas that have not been sampled.

- It is unlikely that different types of contaminants exist in the areas that have not been sampled.

- Where vertical extent of contamination is defined, sufficient data are available to support modeling.

The Soil Part A Phase 2 proposed sample locations shown on figures and tables in Appendix C of this report are considered the Soil Part A Phase 2 sampling program for the Soil RFI/RI Work Plan.

TABLE 7-1
Data Quality Objectives – Part A Soil Investigation
PG&E Topock Compressor Station, Needles, California

STEP 1 Problem Statement	**STEP 2 Decision Statement**	**STEP 3 Inputs to the Decision[1]**	**STEP 4 Study Area Boundaries**	**STEP 5 Decision Rules**
Contaminants in soil in AOCs/UAs outside the compressor station fence line resulting from historical compressor station practices may pose an unacceptable risk to humans or the environment, or threaten groundwater. Site-specific information is needed to: • Determine the nature and extent of soil and sediment contamination. • Estimate representative EPCs to support human health and ecological risk assessment being conducted separately from the Part A soil study. • Determine whether residual soil concentrations pose a threat to groundwater. • Estimate soil properties and contaminant distribution in support of the CMS/FS and/or remedial design.	**<u>Decision 1</u>** Determine the nature and extent of residual soil and/or sediment concentrations resulting from historic compressor station practices. If determination of the full nature and extent of contamination based on sample data is not feasible or is not warranted, address uncertainties in the risk assessment or CMS/FS.	COPCs and COPECs by AOC/SWMU/UA Part A and representative Category 1 and 2 historic RFI/RI COPC and COPEC data grouped by AOC/SWMU/UA and medium Data Usability Matrix for Soil and/or sediment (Appendix A) Comparison/screening values (background, risk-based, and regulatory screening values) CSMs Geologic/hydrogeologic/hydrologic information Topographic information Soil physical and chemical property information AOC/SWMU/UA location and use history information Cultural and historic information by AOC/SWMU/UA Infrastructure information by AOC/SWMU/UA	**Lateral Extent** Initially the same as the currently defined boundaries of each SWMU, AOC, and UA: • SWMU1/AOC 1: Within Bat Cave Wash from mouth of Debris Ravine north to the riparian area at mouth of bat cave wash. • AOC 4: Within the ravine from a point directly south of the water tanks to the junction with Bat Cave Wash; north slope of ravine directly south from end of small access road west to west side of storage area. • AOC 9: Within the potential drainage path to the East Ravine from the break in the former storm drain; initially estimated to be from facility fence line 2/3 of the way east down the slope to the East Ravine; approximately 100 feet north to south centered on the alignment of the former storm drain. • AOC 10: Within the East Ravine from its head at the compressor station to its downstream mouth. Low areas, former discharge and outfall locations (where known), and/or former retention areas (as indicated by presence of vegetation or sedimentation) are of particular emphasis. • AOC 11: Within the drainage from its head at the compressor station to the low areas and/or former retention areas (as indicated by presence of vegetation or sedimentation) northwest of the compressor station access road, south of I-40, and east of the compressor station fence line. • AOC 12: Areas indicated by former employees as sites of potential waste disposal. • AOC 14: The area north of I-40 bounded by Bat Cave Wash to the west, the former plant road to the east, and the railroad tracks to the north. • UA-1 (Potential Pipeline Disposal Area): An area approximately 20 feet wide by 100 feet long, encompassing an area indicated by a former employee as the site for burial of asbestos-wrapped pipes. • UA-2 (Former 300B Pipeline Liquids Tank):Area immediately surrounding the former location of a 900-gallon-capacity aboveground drip tank located southeast of the compressor station on a shelf in the hill next to a section of old Route 66. **Vertical Extent** Vertical study area boundaries extend from the ground surface to the water table. **Analytical Parameters [a]** *Chemical Parameters* (COPCs and COPECs) Title 22 metals, hexavalent chromium, total petroleum hydrocarbons, volatile organic compounds, semivolatile organic compounds, and PAHs for all areas outside the fence line except UA-2. Volatile organic compounds and total petroleum hydrocarbons-purgeable will not be analyzed in the surface (0.0 to 0.5 foot) soil samples. Dioxins and furans are COPCs/COPECs at AOC-4. Asbestos is a COPC for AOC 4, AOC-14, and UA-1. COPCs/COPECs at UA-2 are limited to total petroleum hydrocarbons and PAHs. Dioxins/furans, asbestos, and PCBs will be analyzed in samples collected from the upper end of AOC 1 where AOC 4 enters AOC 1. Ten percent of the samples collected in all AOCs will be analyzed for the full inorganic and organic analysis suites per the CERCLA Target Analyte List and Target Compound List. During Phase 1, select samples were analyzed to characterize the soluble fraction of compounds present at concentrations exceeding 10 x TTLC or 20 x TCLP values. Samples were selected after Title 22 metals data had been received. PG&E performed SPLP on approximately two soil samples per AOC and analyzed the samples for Cr(VI) and Cr(T). These data were validated. **Temporal Boundaries** Validated Part A soil sampling data and representative Category 1 and Category 2 historic RFI/RI data (based on the final Data Usability Assessment).	See Figure A-1 in Appendix A for the Decision 1 decision rule.

TABLE 7-1
Data Quality Objectives – Part A Soil Investigation
PG&E Topock Compressor Station, Needles, California

STEP 1 Problem Statement	STEP 2 Decision Statement	STEP 3 Inputs to the Decision[1]	STEP 4 Study Area Boundaries	STEP 5 Decision Rules
	Decision 2 Determine representative EPCs for residual soil and/or sediment contamination resulting from historic compressor station practices. If determination of representative EPCs based on sample data is not feasible, address uncertainties in the risk assessment or CMS/FS.	Nature and extent of contamination assessment from Decision 1 Part A and representative Category 1 historic RFI/RI COPC and COPEC data grouped by exposure area and depth interval Data Usability Matrix for soil and/or sediment (Appendix A) RAWP CSMs Geologic/hydrogeologic/hydrologic information Topographic information Soil physical and chemical property information AOC/SWMU/UA location and use history information Cultural and historic information by AOC/SWMU/UA Infrastructure information by AOC/SWMU/UA	**Lateral Extent** Same as for Decision 1. **Vertical Extent** Vertical study area boundaries for Decision 2 are defined by potential maximum exposure depths. For human health risk assessment, the maximum exposure depth is 10 feet for all AOCs/SWMUs/UAs except for Bat Cave Wash (SWMU 1/AOC 1), which is 15 feet to account for possible scouring of the surface during runoff events. For ecological risk assessment, the maximum depth is 6 feet, except in Bat Cave Wash, where the maximum exposure depth for ecological receptors is 11 feet to account for possible scouring during run-off events. **Analytical Parameters** Same as for Decision 1. **Temporal Boundaries** Validated Part A soil sampling data and representative Category 1 historic RFI/RI data (based on the final Data Usability Assessment).	See Figure A-2 in Appendix A for the Decision 2 decision rule.
	Decision 3 Determine whether residual soil concentrations resulting from historic compressor station practices may threaten groundwater. If so, conduct additional site-specific assessment of the threat, or implement response actions to mitigate the threat. If not, no further assessment or response actions are necessary to address threat to groundwater.	Nature and extent of contamination assessment from Decision 1 COPCs by AOC/SWMU/UA Part A and representative Category 1 and 2 historic RFI/RI COPC and COPEC data grouped by AOC/SWMU/UA Data Usability Matrix for soil and/or sediment (Appendix A) Comparison/screening values (SSLs and groundwater/ drinking water ARARs) CSMs Geologic/hydrogeologic/hydrologic information Topographic information Soil physical and chemical property information AOC/SWMU/UA location and use history information Cultural and historic information by AOC/SWMU/UA Infrastructure information by AOC/SWMU/UA	**Lateral Extent** Those portions of each AOC/SWMU/UA where COPC concentrations exceed SSLs. **Vertical Extent** Same as for Decision 1. **Analytical Parameters** *Chemical Parameters (COPCs/COPECs)* Same as for Decision 1. *Soil Characteristics* (to support modeling) Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes. **Temporal Boundaries** Same as for Decision 1.	See Figure A-3in Appendix A for the Decision 3 decision rule.
	Decision 4 Determine the site-specific soil property and contaminant distribution information necessary to support the CMS/FS decisions and remedial action design. If full determination of site-specific soil property and contaminant distribution information based on sample data is not feasible, address uncertainties in the CMS/FS and remedial design.	Nature and extent of contamination assessment from Decision 1 COCs from human health and ecological risk assessments Remedial action objectives and ARARs Risk-based and regulatory soil and/or sediment cleanup levels Estimated soil and debris volumes Waste classification testing results for soil, sediment, and/or debris as required	**Lateral Extent** Initially same as for Decision 1, to be refined based on results of risk assessments and threat to groundwater assessments. **Vertical Extent** Initially same as for Decision 1, to be refined based on results of risk assessments, threat to groundwater assessments, and remedial alternative practical constraints. **Analytical Parameters** *Chemical Parameters (COCs)* Initially same as COPCs/COPECs for Decision 1, to be refined to specific COCs based on results of risk	See Figure A-4 in Appendix A for the Decision 4 decision rule.

		Waste comparison/screening levels (TTLC, STLC, RCRA toxicity) Soil physical and chemical property information Geologic/hydrogeologic/hydrologic information Topographic information AOC/SWMU/UA location and use history information Cultural and historic information by AOC/SWMU/UA Infrastructure information by AOC/SWMU/UA	assessments and threat to groundwater assessments. *Soil Characteristics* (to support remedial technology selection and feasibility evaluation) Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes. **Temporal Boundaries** Same as for Decision 1.	

Notes:

[a] A comprehensive planned sample table, specifying analytes for all proposed samples, was provided in Appendix B of the Part A Soil Work Plan.

The list of analytical parameters is based on CSM and will be refined after each round of investigation/data evaluation. COCs will be selected based on the risk assessment.

ARARs = applicable or relevant and appropriate requirements.
PAH = polycyclic aromatic hydrocarbon.

8.0 Data Gaps Evaluation Summary

This section presents a summary of the data gaps evaluation described in Appendix C for SWMU1, AOC 1, AOC 4, AOC 9, AOC 10, AOC 11, AOC 12, AOC 14, UA 1, and UA 2. As described above, the combined Category 1 historical data and validated Part A Phase 1 data were used in evaluating whether sufficient data exist to make each of the four decisions. The data gaps evaluation concluded:

- **Decision 1**. Additional sampling to more precisely delineate the nature and extent of COPCs/COPECs and/or newly-identified compounds is proposed at SWMU 1, AOC 1, AOCs 4, 9, 10, 11, and 14. In addition, sampling is proposed to characterize the newly identified areas (debris, historic burn, and white powder areas) as part of AOCs 10 and 14.
- **Decision 2**. No further data are required to calculate EPCs for COPCs/COPECs and newly identified compounds exceeding interim screening levels.
- **Decision 3**. The initial conservative screening evaluation indicated that certain metals in soil could not be eliminated as a potential threat to groundwater at two AOCs 9 and 10. Additional sampling is proposed at these AOCs; in addition, more refined modeling is proposed at these two units. Additional vertical extent data collected in the remaining areas (SWMU 1, AOCs 1, 4, and AOC 11) for Decision 1 will also be used to refine modeling.
- **Decision 4**. As described in Section 6.0, certain waste characterization data and soil physical properties data are needed at all units. To minimize additional borings, soil physical property data are proposed to be collected only at those locations where borings are proposed for other purposes (two to three samples from each unit to be sampled during the Phase 2 investigation). The remaining information will be collected after the risk assessment has been completed, and the precise areas potentially requiring remediation have been defined.

Table 8-1 provides a summary of the proposed additional sampling to address the data gaps identified during this evaluation.

After collection of the Phase 2 samples presented in Appendix C, the data will be evaluated to assess if the data gaps have been resolved and identify remaining uncertainties to be addressed in the risk assessment or CMS/FS.

Dear Ms. Meeks:

Subject: PG&E Topock Compressor Station Remediation Site – *Topock Soil Investigation Part A Phase 1 Data Gaps Evaluation Report – Proposed Sample Locations, PG&E Topock Compressor Station, Needles, California*.

The Department of the Interior, on behalf of itself and the Bureau of Land Management, the U.S. Fish and Wildlife Service, and the Bureau of Reclamation (collectively referred to as "DOI") and the California Department of Toxic Substances Control (DTSC) are providing direction to Pacific Gas and Electric (PG&E) regarding the Topock Soil Investigation Part A Phase 1 Data Gaps Evaluation Report and the proposed sampling locations provided therein.

The Data Gaps Evaluation Report was prepared to address supplemental soil characterization activities at the Solid Waste Management Units (SWMUs), Areas of Concern (AOCs), and other undesignated areas (UAs) identified in the Revised Final RCRA Facility Investigation/Remedial Investigation Report, Volume 1 – Site Background and History (referred to as the RFI/RI Volume 1) located outside the compressor station fence line. Through a series of meetings held with the agencies, Tribes, PG&E, and other stakeholders in 2010, sample locations were identified to address data gaps in the SWMUs and AOCs.

In response to concerns raised by the Tribes through letters provided by the Fort Mohave Indian Tribe (FMIT) consultant (Hargis + Associates, November 22, 2010) and the Hualapai Department of Cultural Resources (December 3, 2010) and as a result of tribal meetings held December 7, 2010, and January 13, 2011, DOI and DTSC have had several discussions regarding the possibility of reducing the number of samples proposed at the various SWMUs and AOCs. To reduce the number of samples and disturbances to sensitive cultural resources, the agencies evaluated each sample location to determine which, if any, sample locations could be eliminated based on the following factors:

- Is future evaluation of the nature and extent of contamination necessary to assess the risk to human health and the environment, assess the threat to groundwater and/or evaluate and select a remedy?
- Is further data collection necessary to capture maximum concentrations or additional contaminants that could drive risk, threat to groundwater, or remedy technology assessment?
- Are contaminants of a type or concentration that could pose a potential threat to groundwater present?
- Are additional data needed to evaluate technology screening or assessment?

Based on this evaluation, the agencies have identified sample locations that we believe should be eliminated or relocated from those presented in the Data Gaps Analysis and carried forward in the development of the Soil Work Plan.

Our willingness to eliminate these sample locations is based on evaluation of existing data and some basic assumptions applicable to the SWMUs/AOCs identified in the attached table:

- Defining edges or detailed distribution of contamination in the wash channels is not necessary for technology assessment or risk evaluation. It is assumed that known contaminant concentrations measured at previous sample points extend between the points and to the wash boundaries.
- It is unlikely that significantly higher concentrations of contaminants exist in the areas that have not been sampled.
- It is unlikely that different types of contaminants exist in the areas that have not been sampled.
- Where vertical extent of contamination is defined, sufficient data are available to support modeling.

A major premise of this approach is that the nature and extent of contamination, where not currently fully defined, can and will be further defined, as necessary, during remedial design and/or remedial action implementation. Therefore, the decision to exclude an area from additional sampling at this time is not to be construed as a determination that the area is not contaminated or that the full extent of contamination is precisely defined.

The agencies also note that the focus was on reducing numbers of samples. PG&E should carefully review the proposed reduced sample set and evaluate whether revisions, beyond those specified here, are necessary to meet previously defined data quality objectives. Examples of the potential data gaps include whether the elimination of certain points has inadvertently eliminated necessary sampling for TAL/TCL-related characterization data or collection of samples for physical parameter data that may be necessary to assess the overall threat to groundwater or for remedy assessment. For efficiency, PG&E should also determine if a groundwater well should be installed at any of the planned deep soil boring locations in support of the groundwater remedy.

During the series of data gap evaluation meetings between the Tribes, agencies, PG&E and stakeholders in October and November 2010 and January 2011, revisions were discussed, proposed, and agreed upon for the various investigation areas. PG&E should incorporate these revisions into the Soil Work Plan. These include, but are not limited to, relocating sample locations based on field observations (e.g., AOC 9, AOC-11, etc.) and a proposal to investigate AOC 14 south of Interstate 40 (MW-24 Bench). PG&E should also incorporate the grid-based sampling of the mouth of Bat Cave Wash as proposed by DOI in our December 15, 2010 email to PG&E.

As part of our evaluation, we are also proposing the use of an X-ray fluorescence (XRF) analyzer in debris areas to screen for the presence of metal contamination associated with the debris. This method is a non-intrusive method that can provide chemical data in debris areas to help guide the need for actions or further investigation. As part of the Soil Work Plan, PG&E should propose an evaluation of debris areas using non-intrusive XRF technology.

Ultimately, it is PG&E's responsibility to ensure that the necessary data are collected in order to move forward with assessing risk and the development of a corrective measures study/feasibility study. PG&E should, therefore, carefully evaluate the proposals described in this letter and submit a comprehensive Soil Work Plan that will satisfy the data quality objectives (DQOs) specified in the Soil Part A and Part B DQO documents and the stipulations described in the 1996 Corrective Action Consent Agreement between DTSC and PG&E.

If you have any questions, please contact me at (303) 445-2502 or Jose Marcos (DTSC) at (714) 484-5492, at your convenience.

Sincerely,

Pamela S. Innis

FINAL DOI-DTSC REVISIONS TO SOIL PART A DATA GAP TABLE

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Rationale/Comments
SWMU 1				
SWMU1-18	0, 2, 5, 9, 14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gaps #1, #3, and #4 - Define lateral and vertical extent in southern part of AOC 1 and support CMS/FS	Hexavalent chromium, Title 22 metals, PCBs[a]; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Defining the vertical extent of contamination in this primary source area is a critical data gap. This location is retained to define the vertical extent of contamination in the southern portion of the former percolation beds area. Move this location due east approximately 25 feet so that it is located within the boundaries of the white powder area. Significantly elevated chromium concentrations are detected in this former impoundment area and is noted more often in aerial photos than the "blue line" impoundment.
SWMU1-19	0, 2, 5, 9, 14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gap #1, #3, and #4 - Define lateral and vertical extent in bottom of Bat Cave Wash	Hexavalent chromium, Title 22 metals, PCBs[a]; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Defining the vertical extent of contamination in this primary source area is a critical data gap. This location is retained to define the vertical extent of contamination in the central portion of the former percolation beds area.
SWMU1-20	14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gaps #1 and #3 - Define vertical extent at previous sample location SWU1-2	Hexavalent chromium, Title 22 metals, PCBs[a]	Defining the vertical extent of contamination in this primary source area is a critical data gap. This location is retained to define the vertical extent of contamination in the northern portion of the former percolation beds area.
SWMU1-21	14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gaps #1 and #3 - Define vertical extent at previous sample location SWU1-1	Hexavalent chromium, Title 22 metals, PCBs[a]	Defining the vertical extent of contamination in this primary source area is a critical data gap. This location is retained to define the vertical extent of contamination in the northern portion of the former percolation beds area.
SWMU1-22	None – pothole sample location	To resolve Data Gap #2 – Define lateral extent of white powder area and collect a sample of the white powder material and soil	Hexavalent chromium, Title 22 metals, PCBs[a], SPLP[b] and general chemistry analyses[b]	This location is retained to address the nature and extent of contamination associated with a previously uncharacterized potential pathway for site-related contamination to have migrated to Bat Cave Wash.
SWMU1-23	None – pothole sample location	To resolve Data Gap #2 – Define lateral extent of white powder area and collect a sample of the white powder material and soil	Hexavalent chromium, Title 22 metals, PCBs[a], SPLP[b] and general chemistry analyses[b]	This location is retained to address the nature and extent of contamination associated with a previously uncharacterized potential pathway for site-related contamination to have migrated to Bat Cave Wash.
SWMU1-24	None – pothole sample location	To resolve Data Gap #2 – Define lateral extent of white powder area and collect a sample of the white powder material and soil	Hexavalent chromium, Title 22 metals, PCBs[a], SPLP[b] and general chemistry analyses[b]	This location is retained to address the nature and extent of contamination associated with a previously uncharacterized potential pathway for site-related contamination to have migrated to Bat Cave Wash.

AOC1-T5d	0, 2, 5, 9, 14, and 20	To resolve Data Gaps #1 and #5- Define lateral extent near sample transect AOC1-T5 and support CMS/FS	Hexavalent chromium, Title 22 metals, PAHs, PCBs[a] ; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – 3 samples from boring	This location is retained to characterize this long-term terminal endpoint for sediment deposition.
~~AOC1-T5e~~	~~0, 2, 5, 9, and 14~~	~~To resolve Data Gap #1 - Define lateral extent near sample transect AOC1-T5.~~	~~Copper, PAHs, PCBs[a]~~	Existing data for this portion of wash are adequate for remedial action decision making. It is unlikely that significantly higher concentrations exist in this portion of the wash.

FINAL DOI-DTSC REVISIONS TO SOIL PART A DATA GAP TABLE

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Rationale/Comments
New Point	0, 2, 5, 9, 14, and 20	Located at potential impoundment area where flow enters the culvert under the railroad bridge	Hexavalent chromium, Title 22 metals, PAHs, PCBs[a] ; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – 3 samples from boring	This location is retained to characterize this potential long-term terminal endpoint for sediment deposition.
New Point	0, 2, 5, 9, 14, and 20	Located at potential impoundment area at IM-3 road crossing	Hexavalent chromium, Title 22 metals, PAHs, PCBsa ; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – 3 samples from boring	This location is retained to characterize this potential long-term terminal endpoint for sediment deposition.
AOC 4				
AOC4-BCW1	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs and dioxins/furans	This data point is necessary to address the down stream extent of contamination potentially migrating into Bat Cave Wash from the Debris Ravine.
~~AOC4-BCW2~~	~~0, 2, 5, and 9~~	~~To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).~~	~~Title 22 metals, hexavalent chromium , PCBs and dioxins/furans~~	This data point is not critical to remedial action decision making for this portion of the wash
AOC4-BCW3	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs and dioxins/furans	These data points are retained as two transects to assess the potential for contamination migrating into Bat Cave Wash from the Debris Ravine. The specific migration pathway of contaminants emanating from the Debris Ravine is unknown.
AOC4-BCW4	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs and dioxins/furans	

FINAL DOI-DTSC REVISIONS TO SOIL PART A DATA GAP TABLE

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Rationale/Comments
AOC4-BCW5	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs and dioxins/furans	
AOC4-BCW6	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs and dioxins/furans, asbestos (surface soil sample only)	
AOC4-BCW7	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs and dioxins/furans	This data point is retained to assess the influence of upstream conditions to distinguish Debris Ravine effects on soil in Bat Cave Wash.
AOC 9				
AOC10a-2	0, 2, 5 and 9	To resolve Data Gaps #3 and #4 - Define lateral and vertical extent downslope of AOC 9 and Subarea AOC 10a and support model refinement for Decision 3	Hexavalent chromium, Title 22 metals, PAHs, PCBs, pesticides	This data point is retained to assess the nature and extent of contamination within the surface drainage leading from the base of the slope at the primary pipe break release area.
AOC10a-3	0, 2, 5 and 9	To resolve Data Gap #3 - Define lateral and vertical extent downslope of AOC 9 and Subarea AOC 10a	Hexavalent chromium, Titl2 22, PAHs, PCBs, pesticides	This data point is retained to assess the downstream nature and extent of contamination within the surface drainage leading from AOC 9, and other surface discharges along the slope east of AOC 9.
AOC9-15	0, 2, 5 and 9	To resolve Data Gap #3 - Define lateral extent downslope of AOC 9	Hexavalent chromium, Title 22 metals, PAHs, PCBs, pesticides	This data point is retained to assess the nature and extent of contamination at a runoff pathway across the dirt road at the base of the slope beneath the primary pipe break release area.
AOC9-16	0, 2, 5 and 9	To resolve Data Gaps #3 and #5 - Define lateral extent and support CMS/FS	Hexavalent chromium, Title 22 metals, PAHs, PCBs, pesticides; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	This data point is retained to assess the nature and extent of contamination at the base of the slope at the primary pipe break release area.

FINAL DOI-DTSC REVISIONS TO SOIL PART A DATA GAP TABLE

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Rationale/Comments
AOC9-17	9 and 14	To resolve Data Gaps #1 and #4 - Define vertical extent at cluster of previous sample locations (#4 through #9 and AOC9-8) and support model refinement for Decision 3	Hexavalent chromium	This data point is retained to verify the efficacy of the previous removal action and assess the vertical extent of contamination at the primary pipe break release area.
AOC9-18	5, 9, and 14	To resolve Data Gaps # 2 and 4 - Define vertical extent at previous sample location AOC9-5, and support model refinement for Decision 3	Hexavalent chromium, Title 22 metals, PAHs	This data point is retained to assess the vertical extent of contamination where the vertical extent was undefined based on previous sampling.
~~AOC9-19~~	~~5, 9, and 14~~	~~To resolve Data Gaps #3 and 4 - Define vertical extent at previous sample location AOC9-3 and support modeling for Decision 3~~	~~Lead, zinc~~	Lead and zinc are unlikely to result in groundwater contamination or drive risk
~~AOC9-20~~	~~5, 9, and 14~~	~~To resolve Data Gaps #2 and 4 - Define vertical extent at previous sample location AOC9-10~~	~~Title 22 metals, PAHs~~	This location is in close proximity to AOC 9-18, which is adequate to define the vertical extent of contamination
AOC9-21	0, 2, 5 and 9	To resolve Data Gaps #3 and #5 - Define lateral and vertical extent and support CMS/FS	Title 22 metals, PAHs, pesticides, PCBs; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	This data point is retained to assess the nature and extent of contamination downslope of the primary pipe break release area.
AOC9-22	0, 2, 5 and 9	To resolve Data Gap #3 - Define lateral extent associated with AOC9-13	Mercury, lead, PAHs, pesticides, PCBs	This data point is retained to assess the influence of upstream conditions to distinguish AOC 9 effects on soil in surface drainage.
AOC 10				
AOC10-9	0, 2, 5,and 9	To resolve data gap #2 – Assess nature and extent associated with runoff from station access road to the low point north of Subarea 10d	Hexavalent chromium, Title 22 metals, PAHs	This point is retained to assess the potential for contamination entering the East Ravine from runoff
AOC10-10	0, 2, 5, and 9	To resolve data gap #1- Assess lateral extent associated with PS-21and nature and extent of potential impact from soil down slope from the outfall	Hexavalent chromium, Title 22 metals	This data point is retained to assess the potential for contaminated surface runoff entering the East Ravine from an outfall from the facility

FINAL DOI-DTSC REVISIONS TO SOIL PART A DATA GAP TABLE

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Rationale/Comments
~~AOC10-11~~	~~0, 2, 5, and 9~~	~~To resolve data gap #3 -Assess lateral extent between Subareas 10c and 10d~~	~~Hexavalent chromium, Title 22 metals, PAHs~~	Existing data and stream configuration adequately define and constrain lateral extent of contamination for remedial action decision making purposes
~~AOC10-12~~	~~0, 2, 5, and 9~~	~~To resolve data gap #4 - Assess potential impact from debris on northern slope (may not be technically feasible to get to proposed depth)~~	~~Hexavalent chromium, Title 22 metals, PAHs~~	This location is in close proximity to AOC 10-20
AOC10-13	0, 2, 5, 9~~ and 14~~	~~To resolve data gaps #1, 4, and 7 -~~ Assess potential impacts from debris on south slope~~ and support CMS/FS, and the lateral extent between Subareas 10b and 10c~~	Hexavalent chromium, Title 22 metals, PAHs; pH, TPH, SVOCs, dioxins and furans (if burn material present), PCBs, soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution))	Move this location to immediately adjacent to debris pile to assess potential impact from debris. This is an unknown debris site and should be tested for all potential contaminants. Existing data are adequate to define the lateral extent of contamination in the main part of the wash. May want to consider another location for soil physical parameter data sample.
AOC10-14	0, 2, 5, and 9	To resolve data gap #4 -Assess potential impacts from debris on south slope (may not be technically feasible to get to proposed depth)	Hexavalent chromium, Title 22 metals, PAHs	This data point is retained to assess the potential for contamination entering the East Ravine from a debris pile
AOC10-15	~~0, 2, 5, and 9~~ White Powder Only	To resolve data gap #4 - Assess white powder material on north slope ~~(may not be technically feasible to get to proposed depth)~~	Hexavalent chromium, PAHs, pH, Title 22 metals,	Insufficient basis on which to drill boring at this location pending determination if white powder is contaminated
AOC10-16	~~0 and 2[a]~~ White Powder ~~Only~~ and discolored soil	To resolve data gap #4 -Assess white powder material and discolored soil on north slope ~~(may not be technically feasible to get to proposed depth)~~	Hexavalent chromium, PAHs, pH, Title 22 metals	Insufficient basis on which to drill boring at this location pending determination if white powder is contaminated
AOC10-17	0, 2, 5, and 9	To resolve data gap #4 – Assess potential impact from debris (dirt pile with green-colored wood)	Hexavalent chromium, pH, Title 22 metals	This data point is retained to assess potential contamination from the debris, including green-colored wood possibly indicative of chromium contamination
AOC10-18	0 and 2[a]	To resolve data gap #1 – Assess nature and extent of soil down slope from the potential outfall of the former trench drain	Hexavalent chromium, Title 22 metals, PAHs	This data point is retained to assess the potential for contaminated surface runoff entering the East Ravine from an outfall from the facility

FINAL DOI-DTSC REVISIONS TO SOIL PART A DATA GAP TABLE

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Rationale/Comments
AOC10-19	0, 2, 5, and 9	To resolve data gap #4 - Assess debris on north slope (may not be technically feasible to get to proposed depth)	Hexavalent chromium, Title 22 metals, PAHs, pH, TPH, SVOCs, dioxins and furans (if burn material present), PCBs	This is an unknown debris site and should be tested for all potential contaminants
AOC10-20	~~0, 2, 5, and 9~~ White Powder and discolored soil	To resolve data gap #4 -Assess white powder material and discolored soil on north slope (may not be technically feasible to get to proposed depth)	Hexavalent chromium, PAHs, pH, Title 22 metals	Insufficient basis on which to drill boring at this location pending determination if white powder is contaminated
AOC10a-2	0, 2, 5, and 9	To resolve data gaps # 1 and 6 - Assess vertical and lateral extent and collect data to assess current threat to groundwater.	Hexavalent chromium, Title 22 metals, PAHs	This data point is retained to assess the potential for contaminated surface runoff in the surface drainage leading from the compressor station and AOC 9.
AOC10a-3	0, 2, 5, and 9	To resolve data gap #1 -Assess lateral extent (down slope of AOC9 and Subarea 10a)	Hexavalent chromium, Title 22 metals, PAHs	This data point is retained to assess the potential for contaminated surface runoff in the surface drainage leading from the compressor station and AOC 9.
~~AOC10b-5~~	~~0, 2, 5, and 9~~	~~To resolve data gap # 3 - Assess lateral extent up slope from AOC 10b-3~~	~~Hexavalent chromium, Title 22 metals~~	Existing data and stream configuration adequately define and constrain lateral extent of contamination for remedial action decision making purposes
~~AOC10c-6~~	~~14 To Groundwater~~	~~To resolve data gaps # 3 and 6 - Assess vertical extent at previous sample location AOC10c-1 and assess current threat to groundwater~~	~~Hexavalent chromium, total chromium~~	Dropping this sample location is contingent on the sampling of East Ravine Well Site H.
~~AOC10c-7~~	~~14~~	~~To resolve data gap #3 - Assess vertical extent at previous sample location AOC10c-4~~	~~Title 22 metals, PAHs~~	In close proximity to MW-58BR that adequately defined vertical extent of contamination.
AOC10d-9	0, 2, 5, and 9	To resolve data gap #3 -Assess lateral extent associated with AOC 10d-3 and L-3	Hexavalent chromium, Title 22 metals, PAHs	This data point is retained to assess the potential for contaminated surface runoff into the East Ravine.
~~AOC10d-10~~	~~0, 2, 5, 9 and 14~~	~~To resolve data gaps #3 and 7 - Assess lateral and vertical (Zinc only) extent collect soil parameter information to support CMS/FS~~	~~Hexavalent chromium, Title 22 metals, PAHs; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring~~	Existing data and stream configuration adequately define and constrain lateral extent of contamination for remedial action decision making purposes. May want to consider another location for soil physical parameter data sample.

Subject: RCRA Facility Investigation/Remedial Investigation
Soil Investigation Work Plan, Part A, Data Quality Objectives Steps 1 through 5
Technical Memorandum
PG&E Topock Compressor Station, Needles, California

Dear Mr. Marcos, Ms. Innis:

This letter transmits the Final Data Quality Objectives (DQOs) – Part A Soil Investigation Technical Memorandum (TM) for the PG&E Topock Compressor Station RCRA Facility Investigation/Remedial Investigation (RFI/RI). The technical memorandum addresses Steps 1 through 5 of the DQO process for the Part A Soil program. Steps 6 and 7 will be developed through discussions with the agencies and stakeholders during the Soil Part A data gaps evaluation, scheduled for Spring 2010.

This TM incorporates revisions made to the December 15, 2009 report based on comments received from DOI on January 22, 2010 and March 10, 2010, and DTSC on January 11, 2010, and from both agencies during a February 4, 2010 meeting. No additional changes have been made to the report.

The attached Response to Comments Table provides responses to specific comments provided by DOI in its January 22, 1010 cover letter and comments table. In addition, the Response to Comments Table provides a response to the DTSC comment provided by email.

If you have any questions regarding RFI/RI activities, please contact me at (805) 234-2257.

Very truly yours,

Yvonne Meeks

DOI Comments – January 22, 2010

Comment Number	Location	Type[a]	Comment	Comment Response
1	General	M	There are several inconsistencies between statements in the text and Table 1 and the figures. Examples include Decision Statement 3, Box 2 decision on Figure 7, and the vertical boundaries for Decision 1. In general, Table 1 better reflects DOI's preferences. Please revise the text and figures for consistency with Table 1.	Text and Figures will be revised to be consistent with language in Table 1.
2	Section 2.1.3.1, CSM discussion	M	The CSM discussion includes statements regarding appropriate sampling that are premature for Step 1 of the DQOs. The whole point of the DQOs is to lay out a stepwise process for assessing what are appropriate and adequate samples to resolve the decisions. This section should focus strictly on describing the CSMs, as was proposed in DOI's suggested language. Refrain from offering statements about sampling at this point in the document.	Reference to sampling has been removed from the CSM discussion.
3	Section 2.1.3.1, groundwater discussions	E	This section refers to the groundwater CMS/FS in the future tense. This should be revised to reflect the final nature of the CMS/FS.	Text revised as requested.
4	Section 2.1.3.1, groundwater discussions	A	While DOI agrees that the focus of the DQOs is on soil, additional focused groundwater assessment may be warranted if soil investigations indicate a potential current threat to groundwater.	Modifications made to text as agreed upon during February 4, 2010 meeting with Agencies.

---

DOI Comments – January 22, 2010

Comment Number	Location	Type[a]	Comment	Comment Response
5	Sections 2.1.3.2 and 2.1.3.3,	A	It is noted that PG&E chose not to include DOI recommended language acknowledging the contaminant distribution uncertainties resulting from unpredictable scouring and re-deposition processes in washes and ravines. DOI contends it is not possible to predict with confidence the distribution of contamination in the washes and ravines except where impoundments or temporally stable depressions exist. PG&E's reluctance to explicitly acknowledge this point cannot serve as a basis for assuming a higher degree of sampling confidence in the upcoming Steps 6 and 7 than is warranted.	As agreed upon during the February 4, 2010 meeting with the Agencies, this comment will be addressed in Step 6 of the DQOs.
6	Section 2.1.3.3, 4th full paragraph on Page 7	M	The statement that the COPCs for transport to groundwater are primarily hexavalent and total chromium is speculative pending the results of the soil investigations. Remove the sentence.	Text revised as requested.
7	Section 2.1.3.4, second to the last sentence, VOCs in burrows	M	The CSM figure 5 shows the VOC pathway as a potentially complete route "not significant or not directly assessed." The work plan on page 3-13 states that "If complete pathways are identified based on upcoming sampling for VOCs, then the inhalation of burrow air will be evaluated for burrowing receptors. This pathway will be further evaluated and if found to be complete and significant, will be quantitatively evaluated and presented in the ERA." PG&E should not speculate at this point that this pathway is incomplete or insignificant. Remove the statement.	Text revised as requested.

[a] Comment Types: A = Advisory comment, M = Mandatory Revision, P = Proposed Revision, C = Clarification Request, E = Editorial Revision recommended

DOI Comments – January 22, 2010

Comment Number	Location	Type[a]	Comment	Comment Response
8	Section 2.4	M	The decision statements in the text should precisely match the decision statements on Table 1. In the case of Decision Statement 3, the phase "if warranted" was added to the text (as well as other modifications). This phrase is not in the decision statement on Table 1 and is not necessary since the decision is already that additional assessment or a response action is warranted. DOI prefers that the statements in Table 1 be used for all cases.	Text revised as requested.
9	Section 2.5.2, page 14, 3rd full paragraph	C	What is meant by "the identification of hot spots will be made through visual examination of the data"? How does this differ from evaluation for outliers?	Visual examination of the data is a qualitative assessment that includes consideration of relative concentrations in relation to nearest neighboring sampling locations (both horizontally and vertically), field observations of staining or debris, and topography. Outlier evaluation, if conducted, will be done quantitatively using applicable statistical tests. The text has been revised to include this clarification.
10	Section 2.5.4 and Table 1	C	Why were soil and waste volumes deleted as inputs for Decision 4? Estimation of soil and waste volumes would be critical for assessing removal alternatives in the CMS/FS.	Soil and waste volumes have been added back as inputs to Decision 4.
11	Section 2.6.1.1,	A	Maximum exposure depths are only applicable to Decision 2 (EPC estimation), not for Decision 1 (nature and extent). DOI will expect a high burden of proof of low permeability if bedrock is to be considered a barrier to vertical migration and sampling.	The text has been modified as agreed upon during February 4, 2010 meeting.
12	Section 2.6.1.2	M	Dioxins/furans and asbestos should be added for the upper portions of AOC-1 near the point where AOC-4 enters. Dioxins/furans and asbestos are COPCs for AOC-4 that could have migrated to the upper reaches of AOC-1.Total PCBs should be added as well.	Dioxins/furans, asbestos, and total PCBs will be analyzed in samples collected from AOC 1 near confluence of AOC 4.

DOI Comments – January 22, 2010

Comment Number	Location	Type[a]	Comment	Comment Response
13	2.7.1.2 and Figure 6	M	The decision rule for Decision 1 does not appropriately consider the process for determining the nature of contamination associated with TAL/TCL detections (whether they are COPCs). Specifically, PG&E proposes to assess whether or not detected TAL/TCL constituents are COPCs based on the very limited (10%) data set, and proposes to consider factors such as frequency of detection, concentrations, and distribution in making the determination. With only 10% of the samples being analyzed for TAL/TCL constituents, reliable estimates of frequency, maximum concentrations, and distribution cannot be made without additional sampling. In DOI's proposed decision rule, TAL/TCL constituents are first identified as potential COPCs by being detected. This then leads to additional sampling necessary to adequately assess their nature (e.g., using frequency of detection, concentrations, and distribution as determining factors in their selection as COPCs). Moreover, PG&E's decision rule does not provide for assessment of the extent of TAL/TCL COPCs. Rather it leads to the risk assessment to evaluate the nature of contamination. DOI requires that TAL/TCL constituents detected in the 10% of samples either be considered COPCs and then assessed for nature and extent along with the other COPCs (including collection of additional samples necessary to characterize the nature and extent), or be investigated further with additional sampling before any argument can be made to exclude them as COPCs.	The text and Figure 6 has been modified as agreed upon during the February 4, 2010 meeting.

[a] Comment Types: A = Advisory comment, M = Mandatory Revision, P = Proposed Revision, C = Clarification Request, E = Editorial Revision recommended

DOI Comments – January 22, 2010

Comment Number	Location	Type[a]	Comment	Comment Response
14	Section 2.7.1.2	C	The issue of screening level development and its purported complexity as discussed in this section is unclear to DOI. For many TAL/TCL constituents, soil screening levels are already available from EPA (RSLs) and California (CHHSLs). For TAL/TCL COPCs without existing screening levels, risk based assessment might be necessary to determine whether they have the potential to be risk drivers. However, this could only be accomplished once the nature of the COPCs has been assessed through an appropriate level of sampling, as discussed above.	The text has been modified as agreed upon during February 4, 2010 meeting.
15	Section 2.7.1.2	C	EPA has recently (December 2009) updated its RSLs. In some cases, the updated RSLs are lower than the CHHSLs. Screening should be conducted against the most stringent of the RSL and CHHSL levels. Also, neither the RSLs nor the CHHSLs have screening levels for petroleum compounds, which are PCOCs for some AOCs. The California Regional Water Quality Control Board-San Francisco Bay Region has published soil ESLs for TPH-gasoline, diesel, and motor oil (residual range) that are commonly used in California as screening levels. What is PG&E's intent with regard to screening of petroleum compounds?	The hierarchy of screening values, as presented in the Draft Part A Soil Sampling Workplan was to use California values (i.e., CHHSLs) where they exist over EPA RSLs, as they incorporate California-specific assumptions regarding toxicity and exposure (e.g., dermal absorption). Screening is not conducted specifically against the most stringent of the RSL and CHHSL levels. The RSL is only used, instead of the CHHSL, in those instances where the toxicity values used in the CHHSLs are outdated. Specifically, the following exceptions to the general hierarchy are as follows: • PCBs (use RSL, which incorporates more recent updated oral cancer slope factor, consistent with the AOC 4 discussions); • cadmium (calculate a 'modified' CHHSL, because consistent with USEPA, CA no longer considers cadmium to be carcinogenic via oral exposure. Calculated a 'modified'

DOI Comments – January 22, 2010

Comment Number	Location	Type[a]	Comment	Comment Response
				CHHSL (as opposed to using the RSL), because CA has a more conservative inhalation potency factor than USEPA (0.0042 versus 0.0018 (ug/m3$^{)-1}$); • cobalt (use RSL, because the toxicity value for cobalt has been updated); and • vanadium (use RSL, because the toxicity value has been updated). Based on discussions with DOI and DTSC, and because the RSLs and CHHSLs do not have screening levels for petroleum compounds, the Environmental Screening Levels (ESLs) developed by staff of the California Regional Water Quality Control Board-San Francisco Bay Region will be used to screen soil samples analyzed for TPH-gasoline, diesel, and motor oil. It is important to note that the use of ESLs will be limited only for petroleum hydrocarbons defined as TPH-gasoline, diesel, and motor oil. Individual hydrocarbon compounds that comprise TPH, such benzene, toluene, ethyl benzene, xylenes, and polycyclic aromatic hydrocarbons will be screened based on appropriate RSLs or CHHSLs. The Regional Board has developed several TPH ESLs based on different end points, such as leaching to groundwater, human health (ESLs are developed for both a

Comment Number	Location	Type[a]	Comment	Comment Response
				Hazard Index of 0.2 and 1.0), and gross contamination. TPH ESLs for the protection of terrestrial species are not available. PG&E proposes to use the ESLs developed for a residential exposure scenario for human health, based on a Hazard Index of 1.0. Using screening levels that are based on a Hazard Index of 1.0 is consistent with the CHHSLs and RSLs, which for noncancer endpoints are based on an HI of 1.0. Leaching of TPH to groundwater will be evaluated by assessing leaching of the individual hydrocarbon compounds that comprise TPH. From ESL Table K-1, the following TPH Screening levels are proposed: TPH-G = 540 mg/kg TPG-D = 540 mg/kg TPH-MO = 1,800 mg/kg
16	Section 2.7.1.3 and Figure 6	M	Box 8, which includes the statement that nature and extent have been adequately defined, is not a suitable endpoint if additional sampling is judged to be warranted but infeasible (i.e., path from Box 13). All that can be said in that case is that no further data collection is required. DOI's recommended Decision Rule appropriately addressed this condition by adding the phrase "no further data collection is necessary to resolve Decision 1" to the equivalent of Box 13.	Comment noted - Figure will be modified.
17	Section 2.7.2.2, 1st bullet	E	There is a typo in the 1st bullet. Should read "… at a given unit, combination <u>of</u> units, or portion …"	Text revised as suggested.

Data Quality Objectives Steps 1 through 5 – Part A Soil Investigation at the Pacific Gas and Electric Company Topock Compressor Station, Needles, California

PREPARED FOR:	Pacific Gas and Electric Company
PREPARED BY:	CH2M HILL
DATE:	December 14, 2009
	Revised: March 12, 2010

1.0 Introduction

The purpose of this technical memorandum is to document the results of Steps 1 through 5 of the data quality objectives (DQO) process for Phase 2 of the soil investigation outside the fence line of the Topock Compressor Station (referred to as Phase 2 of the Soil Part A program). The California Department of Toxic Substances Control's (DTSC's) August 10, 2007 conditional approval letter for the Soil Part A Work Plan specifically rejected the DQO sections in that workplan while directing PG&E to implement Phase 1 of the soil sampling program in accordance with the work plan. DTSC, the United States Department of the Interior (DOI), and Pacific Gas and Electric Company (PG&E) then convened a series of meetings to collaboratively develop the DQOs for evaluating Phase 1 data and identifying sampling needs for Phase 2 of the soil Part A program. Steps 1 through 5 were addressed during several meetings held from June through September 2008. Steps 6 and 7 will be addressed during meetings to be held in the first half of 2010.

The Soil Part A program addresses 9 Solid Waste Management Units (SWMUs), Areas of Concern (AOCs), and other undesignated areas (UAs) outside the Topock Compressor Station fence line. These areas are SWMU 1/AOC 1, AOCs 4, 9, 10, 11, 12, and 14; Undesignated Area (UA) 1 -- the Potential Pipeline Disposal Area; and UA 2 -- the Former 300B Pipeline Liquids Tank. These units are shown in Figure 1. (All figures are provided at the end of this technical memorandum).

The DQO process is a recognized procedure for defining project objectives and decisions, and optimizing sampling and other information-gathering programs to balance uncertainty, site disturbances, and cost in an acceptable manner. The goal of the DQO process is to ensure that data collected at each stage of the investigation process are of sufficient quantity and quality to enable the specified decisions to be made.

The United States Environmental Protection Agency (USEPA) has issued detailed guidance for the DQO process (USEPA, 2000, 2006a-b). The DQO process consists of seven steps:

- **Step 1: State the Problem.** Concisely describe the problem to be studied. Review prior studies and existing information to gain a sufficient understanding to define the problem. Identify resources available to resolve the problem, and develop the conceptual site model.
- **Step 2: Identify the Decision(s)**. Identify the principal study questions that require new environmental data to address the contamination problem and what actions may result to resolve the problem statement.
- **Step 3: Identify the Inputs to the Decision**. Identify the information and environmental measurements that are needed to resolve principal study questions
- **Step 4: Define the Study Boundaries**. Specify the spatial and temporal aspects of the environmental media that the data must represent to support the decision.
- **Step 5: Develop a Decision Rule**. For each principal study question, define the statistical parameter(s) of interest, specify action levels, and integrate the previous DQO outputs into "if…then" statements that describe the logical basis for choosing among alternative actions.
- **Step 6: Specify Tolerable Limits on Decision Errors**. Define the decision makers' tolerable decision error rates based on the consequences of making an incorrect decision.
- **Step 7: Optimize the Design**. Evaluate information from the previous steps and generate alternative data collection designs. Choose the most resource-effective design that meets all DQOs.

While the steps of the DQO process are described sequentially above, the iterative nature of the DQO process allows one or more of these steps to be revisited as more information on the problem is obtained. Detailed DQOs for the subsequent phases of the soil investigation will be developed during those phases.

This technical memorandum addresses Steps 1 through 5 of the DQO process for Phase 2 of the Soil Part A program. DTSC, DOI, and PG&E agreed to defer Steps 6 and 7 pending completion of Phase 1 sampling and analysis, and to address those two steps once validated data from the Phase 1 Part A site investigation are available for each of the AOCs. An understanding of the characteristics of the Phase 1 data is necessary to guide decisions on the tolerable limits on decision errors for Phase 2 data.

2.0 Data Quality Objectives

Steps 1 through 5 of the DQO process for Phase 2 were completed collaboratively by DTSC, DOI, and PG&E for all of the investigation areas included in the Soil Part A Work Plan. This section provides a detailed description of the assumptions for each step and the process for implementing each step. A summary of the DQOs for Steps 1 through 5 is provided in Table 1.

2.1 Step 1: Problem Statement

Step 1 consists of defining the problem and includes review of existing information; identification of the planning team; development of a conceptual model of the environmental hazard to be investigated (site conceptual model); identification of available resources, constraints, and deadlines; and a brief discussion of potential remedial/closure options. These components are described in detail below.

2.1.1 Problem Definition

Historic practices at the Topock Compressor Station have resulted in known and potential releases of constituents of potential concern (COPCs) and constituents of potential ecological concern (COPECs) in several locations in the vicinity of the station. These locations are defined in the approved *Revised Final RCRA Facility Investigation/Remedial Investigation Report, Volume 1 – Site Background and History* (Revised Final RFI/RI Volume 1) (CH2M HILL, 2007). The Soil Part A program addresses SWMU 1/AOC 1, AOCs 4, 9, 10, 11, 12, and 14; UA 1, the Potential Pipeline Disposal Area; and UA 2, the Former 300B Pipeline Liquids Tank. The existing data regarding these units have been documented in the Soil Part A Work Plan.

The overall problem statement for the Soil Part A program is:

Contaminants in soil in AOCs/UAs outside the compressor station fence line resulting from historical compressor station practices may pose an unacceptable risk to humans or the environment, or threaten groundwater. Additional site-specific information is needed to:

- *Determine the nature and extent of soil and sediment contamination*
- *Estimate representative exposure point concentrations (EPCs) to support human health and ecological risk assessment being conducted separately from the Part A soil study*
- *Determine whether residual soil concentrations pose a threat to groundwater*
- *Estimate soil properties and contaminant distribution in support of the Corrective Measures Study/Feasibility Study (CMS/FS) and/or remedial design*

The nature and extent of soil COPCs and soil COPECs associated with former compressor station practices at or affecting these units must be defined to determine whether unacceptable risks or impacts to groundwater occur currently or could occur in the future, and whether soil remediation is required and should be implemented. The extent of the soil COPCs and COPECs must be understood in sufficient detail laterally and vertically to allow risk assessment to be conducted and remedial decisions to be made.

2.1.2 Conceptual Site Models

The conceptual site model (CSM) is a schematic representation of how constituents released from a source may be transported to the surrounding environmental media and ultimately may come into contact with human or ecological receptors. The CSM includes known and suspected sources of contamination, types of constituents and affected media, known and potential routes of migration, and known or potential human and environmental receptors.

The CSMs provide the framework for where and to what depths investigations should occur and the factors that must be considered in developing screening values. The CSMs also support the identification of potential remedial technologies. Information on contaminant transport and migration mechanisms and potentially exposed receptors helps guide the necessary investigation of the lateral and vertical extent of contamination. Detailed investigation-area-specific CSMs were developed for the *Human Health and Ecological Risk Assessment Work Plan, Topock Compressor Station, Needles, California* (RAWP; ARCADIS, 2008a). The CSMs originally presented in the RAWP were based on knowledge from historical data. Those CSMs have been updated to incorporate the findings of the Groundwater Risk Assessment (GWRA; ARCADIS 2009), and included herein as Figures 2 through 5. The focus of the CSMs is on evaluating potential exposure pathways to human and ecological receptors.

The CSMs rely on the detailed information on the physical characteristics and setting of the study area, including surface features, meteorology, site geology, surface water hydrology, site hydrogeology, land use, cultural resources, and ecology presented in Appendix A of the Part A Work Plan.

2.1.3 Constituent Release, Migration, and Potential Exposure Pathways

Figures 2 through 5 depict the conceptual contaminant release, migration, and potential exposure pathways for the following areas and receptors:

- Figure 2 - Bat Cave Wash: recreational, tribal, worker, and hypothetical future groundwater uses
- Figure 3 - AOCs 4, 9, 10, 11, 12, and 14, and UA-1 and UA-2: recreational, tribal, worker, and hypothetical future groundwater uses
- Figure 4 - Bat Cave Wash: future hypothetical residential user north of the railroad
- Figure 5 - Bat Cave Wash and other areas outside the compressor station: ecological receptors

2.1.3.1 Overview of Release and Migration Pathways

For simplicity, this discussion addresses the common features of the four CSMs. All CSMs have surface soil as the primary source medium. All CSMs also include the release mechanism where COPCs in surface soil may be eroded and entrained in stormwater/ surface water runoff and subsequently re-deposited as contaminated soil in other areas within a wash or ravine. Entrained soil may be transported to areas of standing or flowing water and then be deposited in downstream areas. Soil that is inundated with water even in the absence of storm events is considered sediment. When entrained soil is deposited in these areas, it is considered sediment, and may result in the presence of contaminated sediment.

In order for soil to be entrained in run-off, it must be scoured from another portion of the project area. Such potential 'scouring' events were discussed with the agencies, and various hypothetical soil scouring depths were agreed upon in order to identify Phase 2 sampling needs and the relevant exposure depth intervals that would be used to assess the potential significance of chemical impacts (ARCADIS, 2008a).

Contaminated surface soil or sediment resulting from entrainment of affected soils are secondary source media or exposure media and may be ingested or contacted directly. COPCs/COPECs may also be entrained as dust in ambient air, leading to potential inhalation exposure and/or surface re-deposition (ARCADIS, 2008a).

All CSMs also show that contaminants in surface soil may also percolate or infiltrate into the subsurface to affect subsurface soil and groundwater as secondary source media. Contaminated subsurface soil may be ingested, contacted directly, or inhaled as dust during intrusive events.

Historical data show that volatile organic compounds (VOCs) have been infrequently detected at very low concentrations in soil; therefore, historical data suggest that volatilization is an insignificant secondary release mechanism. However, as indicated in Table 1, additional soil sampling is proposed to further evaluate the presence of compounds that may volatilize and affect ambient air, potentially leading to inhalation exposure. As shown on the CSMs, if VOCs are present in groundwater, the VOCs may also be volatilized to affect ambient air, leading to inhalation exposure. However, the GWRA concluded that VOCs were infrequently detected at low levels in groundwater. Therefore, the GWRA concluded that volatilization from pumped groundwater and subsequent inhalation of VOCs was an insignificant pathway.

The CSMs all include a migration pathway showing groundwater potentially impacted by subsurface soil contamination, with subsequent migration of contaminated groundwater to extraction wells and discharge to surface water, leading to potential ingestion and dermal contact exposure routes. These potential exposure pathways were the subject of the GWRA (ARCADIS, 2009) for releases to SWMU 1/AOC 1. The GWRA concluded that hexavalent chromium is the only risk-related chemical of concern (COC) for the groundwater CMS/FS (CH2M HILL, 2009)[1]. The GWRA also concluded that discharge of chemically-affected groundwater to surface water is an insignificant pathway based on a review of site-specific groundwater and surface water data. Accordingly, the GWRA (ARCADIS, 2009) concluded that quantitative surface water human health and ecological risk assessments are not warranted.

The focus of this technical memorandum is to develop DQOs for: (1) guiding the soil sampling activities and (2) evaluating soil data (e.g., evaluating the potential for previously unidentified soil contamination to impact groundwater quality). Therefore, surface and subsurface soil are the primary media of interest for data collection and evaluation.

2.1.3.2 Human Health Potential Migration and Exposure Pathways for Bat Cave Wash

In Bat Cave Wash, the primary source of contamination for the surface soil is historic direct discharge of untreated wastewater at SWMU 1, the Former Percolation Bed (see Figures 2 and 4). Topography generally limits surface runoff pathways in Bat Cave Wash to the floor

---

[1] Because there is no current direct human exposure pathway for contact with impacted site groundwater, there is no human or population currently at risk of adverse health effects due to the presence of chemicals in the groundwater. Further, because there is no significant ecological exposure pathway for contact with impacted site groundwater, there is no ecological population currently at risk of adverse effects due to the presence of COPCs in the groundwater

of the wash. Periodic runoff and flash flood events may disturb the soil bed, resulting in rapid erosion, movement, and re-deposition of material down wash. These events can cover surface soil and expose subsurface soil, and are referred to as scouring events.

Windblown contamination from the wash may not be fully constrained within the bed of the wash. While it is possible for surface soil contaminants eroded and dispersed by wind to potentially affect areas outside the wash limits, aerial deposition of windblown contamination is generally expected to follow a pattern of decreasing concentrations with increasing distance from Bat Cave Wash.

North of the railroad, future residential use of the wash is hypothesized by DOI (see Figure 4). Residential activities hypothesized by DOI include eating homegrown produce and poultry. Garden produce and poultry could contact contaminants directly from contaminated surface soil, or could contact contaminants through irrigation with impacted groundwater. The GWRA has already evaluated irrigation with contaminated groundwater, and concluded that potential human exposure to produce and poultry irrigated with impacted groundwater is insignificant relative to the potential exposure resulting from direct ingestion and dermal contact with impacted groundwater (ARCADIS, 2009). Soil data proposed for collection in Part A will be used to evaluate the potential significance of contact of homegrown produce and poultry with contaminants in soil. Therefore, for this pathway, surface and subsurface soil (depths consistent with garden produce root growth) are the media of interest for soil sampling north of the railroad.

Soil data for Bat Cave Wash will be used to evaluate potential risk from contaminated surface and subsurface soil that may be ingested or contacted directly, or soil particles that may be entrained as dust in ambient air, leading to potential inhalation exposure. The hypothetical future resident and maintenance worker both are assumed to participate in intrusive activities as described in the RAWP (ARCADIS, 2008a).

2.1.3.3 Human Health Potential Migration and Exposure Pathways for AOCs 4, 9, 10, 11, 12, and 14, and UA-1 and UA-2

This section addresses other areas (i.e., AOCs 4,9,10,11, and 14 and UA-1 and UA-2) besides Bat Cave Wash where contaminants may be present due to the migration pathways shown on Figure 3 and described above (see Section 2.1.3.1). The primary sources for release to surface soil in these areas include: discharges/runoff from the compressor station, disposal of debris, leaking above ground tank, and potential pipe disposal area. Constituents known to have been released at the Topock Compressor Station consist of non-volatile compounds. These constituents were released primarily as liquids. Some constituents may also have been released as dust on the station (i.e., from sand blasting) and would have been deposited onto the ground surface. These constituents would also have been transported outside the facility fence line via stormwater runoff.

Local topography is the primary feature to consider when examining releases of constituents from the Topock Compressor Station to areas outside the fence line via surface runoff. The compressor station is located on a ridgeline bordered by low areas (washes and ravines) on the north, east, west, and southwest sides of the station. Higher-elevation terrain is located to the south and southeast. In the past, runoff from the compressor station would have preferentially entered and/or accumulated in low-lying areas, including the Debris

Ravine (AOC 4), the East Ravine (AOC 10), and other topographic low areas (AOC 11) contiguous with the compressor station fence line, potentially contaminating surface soil.

Topography generally limits surface runoff pathways in the ravines to the floor of the ravines. Within the East Ravine, several impoundment berms were constructed across the ravine in the past. Within the Debris Ravine and AOC 11, periodic runoff events disturb the soil bed, resulting in rapid erosion, movement, and re-deposition of material downstream. Impoundment areas and stable low-lying areas are most likely to contain contaminated soil.

Potential groundwater contamination extent and migration is not restricted by topography. Contaminated groundwater originating from the ravines, if present, could migrate in directions different from the topographic slope. The groundwater impact of discharges to AOC 1/SWMU 1 were thoroughly evaluated outside the boundaries of Bat Cave Wash by the RFI/RI and the GWRA.

Prior investigation results indicate that COPCs released to SWMU 1 (Former Percolation Bed) have also entered groundwater. While soluble constituents have the potential to have been transported to groundwater at other locations outside the compressor station, the quantity of liquids released and the frequency of release would only be a small fraction of the volume of liquid released to SWMU 1.

Solid materials and debris have been disposed of at the Debris Ravine (AOC 4) and the Railroad Debris Site (AOC 14). Debris may have been disposed of at the Fill Area (AOC 12) and UA 1 (Potential Pipeline Disposal Area). In these locations, debris of various types was physically placed into the unit. In many cases, the debris was subsequently covered with soil. In addition, white powdery material is present in SWMU 1, within the bank of Bat Cave Wash below the compressor station.

COPCs associated with the debris located in these areas and the white powder in Bat Cave Wash could be located in the immediate vicinity of the debris or powder and in surrounding and underlying soil. In some cases, stormwater runoff could transport debris, powder, and contaminated soil to lower-lying areas.

Soil data for each area will be used to evaluate potential risk from contaminated surface and subsurface soil that may be ingested or contacted directly, or soil particles that may be entrained as dust in ambient air, leading to potential inhalation exposure.

2.1.3.4 Ecological Potential Exposure and Migration Pathways for Bat Cave Wash and Other Areas

Figure 5 depicts the ecological CSM for Bat Cave Wash and AOCs 4, 9, 10, 11, 12, and 14, and UA-1 and UA-2. The primary sources and primary source medium (surface soil) are the same as depicted for human exposure. The ecological CSM differs from the human CSMs in the receptors and the distinction between shallow soil and deeper soil, reflecting the potential for exposure of plants, invertebrates, and burrowing mammals in shallow soil but not deeper soil. Potential exposure media include surface soil, shallow soil, and sediment, as well as aquatic and terrestrial biota tissue (which can lead to exposure via ingestion), direct contact, root uptake, or inhalation of particulates.

2.1.4 Potentially Exposed Receptors

The investigation areas are located in and adjacent to public lands, including the Havasu National Wildlife Refuge and land owned by United States Bureau of Reclamation (managed by United States Bureau of Land Management [BLM]). Access limitations are due primarily to topography and climate. There is no active effort to limit human access to the area. Thus, there are both potential human and ecological receptors for soil. Potential exposures to groundwater from SWMU 1 (Former Percolation Bed) and AOC 1 (Bat Cave Wash) have been addressed in Final RFI/RI Volume 2 (Groundwater) and the GWRA (ARCADIS, 2009).

2.1.4.1 Potential Human Receptors

The human receptor populations are grouped as follows:

- Bat Cave Wash – recreational user, tribal user, maintenance worker, hypothetical future groundwater user, and hypothetical future resident (north of the railroad only)
- Other AOCs/UAs outside the compressor station fence line – recreational user, tribal user, maintenance worker, and hypothetical future groundwater user

Recreational users hiking in or visiting the wildlife refuge would be expected potentially to come into contact with soil intervals (see below) defined as: surface (0 to 0.5 ft bgs) and shallow (0 to 3 ft bgs). Maintenance workers may come into contact with subsurface soils as deep as 10 feet (bgs) if a gas pipeline has to be fully exposed for maintenance work (defined as subsurface II). PG&E is working with tribal representatives to develop a tribal use scenario and to define the specific land-use locations and exposure assumptions that would be representative of tribal use of the land.

The GWRA (ARCADIS, 2009) evaluated the potential groundwater impacts associated with Bat Cave Wash, as well as any potential groundwater impacts located outside the wash. The assumption was made that the groundwater, in the future, could be hypothetically used as a potable source of water across any site location, even if residential use is not planned for that area. Therefore, the hypothetical future groundwater user is included on CSM Figures 2 through 4 since the groundwater was evaluated in the GWRA for all areas sampled regardless of well location.

It is unlikely in the foreseeable future that the land currently occupied by the Havasu National Wildlife Refuge and managed by the United States Fish and Wildlife Service will become residential. However, BLM has specifically requested an evaluation of a future residential use on its property. Therefore, although future residential land use is a highly unlikely scenario, a future hypothetical residential land use scenario will be evaluated for BLM property in Bat Cave Wash north of the railroad. PG&E plans to continue owning and operating the associated property outside the fence line as supporting areas for the compressor station for the foreseeable future. Accordingly, the reasonably anticipated future use of the PG&E-owned land is for ongoing industrial operations.

Federal workers may be engaged in land management activities on Refuge and BLM land, such as sampling, fire suppression, or various types of foliage or wildlife maintenance. The recreational and maintenance worker receptors are expected to be protective of the federal worker receptor.

2.1.4.2 Potential Ecological Receptors

Ecological receptors outside the compressor station may include terrestrial flora and fauna associated with Mojave Creosote scrub, Mojave wash scrub, Desert Riparian, and Tamarisk Thicket habitats. Representative animal receptors present in the vicinity of the site include birds such as raptors, songbirds, ground-nesting birds, and species tolerant of human disturbance (e.g., dove and raven). Snakes, lizards, small mammals, larger herbivores, and larger carnivorous mammals such as the desert kit fox are also present. Representative terrestrial receptors include larger burrowing animals (e.g., kit fox) capable of burrowing to depths of several feet bgs and deep-rooted plants such as mesquite. Other representative terrestrial plant species include creosote bush and associated species such as spineflower (*Chorizanthe brevicornu*) and cheesebush (*Hymenoclea salsola*).

2.1.4.3 Leaching to Groundwater

A potential indirect exposure route associated with soil is the potential for residual COPCs in soil to leach to groundwater. If the rate of leaching is sufficiently high, concentrations of COPCs in groundwater could potentially pose a risk if receptors are exposed to groundwater or groundwater migrates to a location where it can affect surface water. There are no current uses of the groundwater near the facility. As indicated above, potential risks associated with groundwater affected by SWMU 1/AOC 1 are being addressed separately.

2.1.4.4 Potential Exposure Depth Intervals

Based on the types of receptors likely to be found in the investigation areas and nearby areas, the types of activities likely to occur, and the nature of the soils in the area, four exposure depth intervals are of interest; surface soil, shallow soil, subsurface soil to 6 ft bgs and subsurface soil to 10 ft bgs. For human health, exposure intervals for soil are surface soil (0 to 0.5 foot bgs), shallow soil (0 to 3 feet bgs), subsurface soil I (0 to 6 feet bgs), and subsurface soil II (0 to 10 feet bgs). For ecological receptors, exposure intervals for soil are surface soil (0 to 0.5 foot bgs), shallow soil (0 to 3 feet bgs), and subsurface soil I (0 to 6 feet bgs).

2.2 Planning Team

The planning team for the Soil Part A program consists of PG&E, DTSC, DOI, and the tribes. Designated representatives from these organizations will meet to evaluate data and determine whether each of the decisions to be made can be made with a sufficient level of certainty.

2.3 Constraints, Resources, and Deadlines

Resources available to complete the soil RFI/RI and subsequent steps in the RCRA corrective action and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) programs consist of PG&E staff and consultants, DTSC and DOI staff and consultants, and tribal staff and consultants. Resources are limited in terms of available knowledgeable staff and project deadlines (as outlined in the project "rainbow" schedule). The Soil Part A program is on the critical path to determining and implementing the final soil remedy for the project.

There are physical, cultural, and biological constraints on the site investigation and remediation effort. Physical constraints outside the fence line consist of challenging topography, limited access, and possible presence of high-pressure gas lines and other utilities. The remote location of the compressor station also makes certain investigation and remediation activities more difficult. In addition, the site is located in and around sensitive habitat areas. The site is also located in an area rich in cultural and historical resources. Several federally recognized tribes have identified areas of traditional, religious, and cultural importance in the vicinity of the Topock Compressor Station..

The physical constraints and the types of COPCs and COPECs released limit the potential remedial actions that could be employed to address constituents posing an unacceptable risk to human health and the environment or threat to groundwater. For the purposes of developing these DQOs, the potential remedial actions fall into three categories: (1) no further action, (2) institutional controls, and (3) certain remedial technologies and will be further defined in the CMS/FS workplan.

2.4 Step 2: Identify the Decisions

Step 2 consists of identifying the decisions to be made in the Part A soil study. Activities completed in this step consist of identifying the principal study questions, defining the alternative actions that may be taken based upon the range of possible outcomes , and combining the alternative actions and the principal study questions into decision statements.

The Part A soil investigation sampling and analysis activities are intended to provide site-specific information to:

- Determine the nature and extent of soil and sediment contamination
- Estimate representative exposure point concentrations (EPCs) to support human health and ecological risk assessment being conducted separately from the Part A soil study
- Determine whether residual soil concentrations pose a potential threat to groundwater
- Estimate soil properties and contaminant distribution in support of the Corrective Measures Study/Feasibility Study (CMS/FS) and/or remedial design

Based on these objectives, four principal study questions were identified. The principal study questions and alternative outcomes of the questions are discussed below. A decision statement is provided for each. Decision statements are summarized in Table 1.

1. What are the nature and extent of residual soil and/or sediment COPC and/or COPEC concentrations resulting from historic compressor station practices?

   The alternative outcomes of this question are: (a) the nature and extent of residual soil and/or sediment concentrations are fully defined based on sample data; or (b) it is infeasible or unwarranted to fully define the nature and extent of soil and/or sediment concentrations based on sample data, and uncertainties will be addressed in the risk assessment and/or CMS/FS.

   Decision Statement: Determine the nature and extent of residual soil and/or sediment concentrations resulting from historic compressor station practices. If determination of the full nature and extent of soil and/or sediment concentrations based on sample data is not feasible or is not warranted, address uncertainties in the risk assessment and/or CMS/FS.

2. What are representative EPCs for residual soil and/or sediment contamination resulting from historic compressor station practices?

   The alternative outcomes of this question are: (a) representative EPCs can be determined based on sample data; or (b) it is infeasible to determine representative EPCs based on sample data, and uncertainties will be addressed in the risk assessment.

   Decision Statement: Determine representative EPCs for residual soil and/or sediment contamination resulting from historic compressor station practices that may pose unacceptable risks to current or future human or ecological receptors. If determination of representative EPCs based on sample data is not feasible, address uncertainties in the risk assessment or CMS/FS.

3. Do residual soil concentrations resulting from historic compressor station practices pose a potential threat to groundwater?

   The alternative outcomes of this question are: (a) conclude a threat to groundwater may exist, warranting either further site investigation or remedial action to protect groundwater, or (b) conclude no threat to groundwater exists and no further action is needed to protect groundwater.

   Decision Statement: Determine whether residual soil concentrations resulting from historic compressor station practices may threaten groundwater. If so, conduct additional site-specific assessment of the threat, or implement response actions to mitigate the threat. If not, no further assessment or response actions are necessary to address potential threats to groundwater.

4. What are the site-specific soil properties and contaminant distribution relative to CMS/FS decisions and/or remedial design, if remediation is anticipated?

   The alternative outcomes of this question are: (a) site-specific soil property and contaminant distribution information can be fully determined based on sample data to support the CMS/FS and remedial design; or (b) it is infeasible to fully determine site-specific soil property and contaminant distribution information based on sample data, and uncertainties will be addressed in the CMS/FS decisions and remedial design.

   Decision Statement: Determine the site-specific soil property and contaminant distribution information necessary to support the CMS/FS decisions and remedial design. If full determination of site-specific soil property and contaminant distribution information based on sample data is not feasible, address uncertainties in the CMS/FS and remedial design.

2.5 Step 3: Inputs to the Decision

Once the necessary decisions have been determined, the next step is to identify the inputs required to make the decisions. While there may be significant overlap between the inputs required for the various decisions, the inputs for each decision are defined separately, to ensure all required inputs have been identified. Inputs for each decision are also listed on Table 1.

2.5.1 Inputs to Decision 1 – Nature and Extent of COPCs/COPECs

Three types of information have to be available and considered when assessing whether the nature and extent of contamination at a site are adequately understood: (1) usable COPC and COPEC concentration data, (2) potential contaminant fate and transport mechanisms, and (3) screening and comparison values.

Both existing and new data may provide usable COPC and COPEC concentrations for soil and sediment. Newly collected COPC and COPEC concentration data must meet data quality criteria (including reporting limits and other criteria) set forth in the *Draft PG&E Program Quality Assurance Project Plan* (QAPP) (CH2M HILL, 2008a) to be considered usable. Existing data were evaluated in the *Final Soil and Sediment Data Usability Assessment Technical Memorandum, PG&E Topock Compressor Station* (CH2M HILL, 2008b). Category 1 and 2 data will be used to delineate the nature and extent of contamination. Collectively, new data meeting the criteria set forth in the QAPP and Category 1 and 2 data identified in the Data Usability Assessment are considered usable COPC and COPEC data for Decision 1. Sufficient usable data must be available for each unit. These usable COPC and COPEC concentration data must be compared to background and other screening levels to assess whether the delineation of nature and extent is adequate.

As described in the Revised Final RFI/RI Volume 1 (CH2M HILL, 2007), five phases of data collection have been completed to date to support characterization of SWMUs and AOCs at the Topock Compressor Station. Data collected from implementation of the Part A Work Plan will be combined with the usable data from the existing data set.

The CSMs are an input to Decision 1 because they describe the potential transport mechanisms and fate of COPCs and COPECs potentially released into the environment. This ensures that site data are collected in the appropriate locations.

Six types of comparison/screening levels were identified for this study: background soil concentrations (CH2M HILL 2009), ecological comparison values (ECVs) that are calculated to be protective of the species potentially present in the area outside the fence line, DTSC California human health screening levels (CHHSLs) for residential use (OEHHA, 2005), USEPA regional screening levels (RSLs) for residential use for those compounds for which CHHSLs are unavailable (USEPA, 2008), Environmental Screening Levels (ESLs) developed by staff of the California Regional Water Quality Control Board-San Francisco Bay Region for screening soil samples analyzed for total petroleum hydrocarbons (TPH) gasoline, diesel, and motor oil (RWQCBSF, 2008), and project specific screening levels developed for COPCs/COPECs identified from TAL/TCL data. All six types of screening levels will be specifically used to assess the extent of contamination, and do not necessarily indicate the presence of unacceptable risk (which will be evaluated in the Baseline Risk Assessment). Ideally, the extent of contamination will be defined to the lowest of the applicable delineation action levels. As noted in the discussion for Step 1, physical, cultural, and biological constraints may limit the feasibility of sampling in certain areas.

The background soil study determined that background metals concentrations are generally consistent throughout the study area and the soil column, and that there are no ambient levels of polycyclic aromatic hydrocarbons (PAHs) or pesticides. The results of the background soil study and the statistical analyses describing the characteristics, uses, and limitations of the background soils dataset will be submitted separately as a technical memorandum for review and approval by DTSC and the federal agencies. A series of statistical tests will be conducted to assess whether concentrations of constituents detected in the soil at the various units are elevated above background. There is no single statistical test that can be used to determine when concentrations in soil represent background levels. Rather, there are several tests that may be used to support this determination. To evaluate whether the concentrations of constituents across the exposure area are comparable to background concentrations, the use of both point estimates (e.g., the 95 percent upper tolerance limit) and statistical distributional tests (comparisons of means and medians) may be used to compare the concentrations of constituents detected to background concentrations.

ECVs have been developed for metals and those organic constituents encountered in the top 6 feet of soil. ECVs will be used to a maximum depth of 6 feet bgs, consistent with DTSC guidance for ecological risk assessment (CalEPA, 1998) and as agreed for burrowing animals in the RAWP (ARCADIS, 2008a). CHHSLs, RSLs, ESLs, and project specific screening levels developed for TAL/TCL COPCs/COPECs will be used to a maximum depth of 10 feet bgs, consistent with the RAWP for human health risk assessment for exposure to soil (ARCADIS, 2008a).

2.5.2 Inputs to Decision 2 – Data to Support EPC Calculations

The inputs required for Decision 2 include COPC and COPEC concentrations in soil and sediment within the exposure areas and depth categories defined in the RAWP (ARCADIS, 2008a). Only COPC and COPEC data meeting data quality Category 1 standards may be used for the risk assessment. A Data Usability Matrix for Soil Risk Assessment has been developed to aid in evaluating data usability and adequacy for risk assessment purposes and will be used as a Decision 2 input tool (See Table A-1, Appendix A). The matrix lists the total number of existing and newly collected samples per AOC and sub AOC areas, identifying horizontal and vertical coverages, exposure depths as defined in the RAWP (ARCADIS, 2008a), analytical suites, data quality, representativeness and comparability.

Approaches for developing the human health and ecological risk assessments and estimating representative EPCs are specified in the RAWP (ARCADIS, 2008a). The EPC is a conservative estimate of the average chemical concentration in an environmental medium to which a receptor may be exposed. The EPC is constituent-specific and is estimated for each individual exposure area within a site. The risk assessments will calculate EPCs based on specific data groupings and depth categories, as discussed below. Therefore, it is critical to consider those data groupings and depth categories when determining the inputs needed for estimation of representative EPCs.

For the human health risk assessment, the exposure areas outside the fence line consist of: (1) Bat Cave Wash (which includes SWMU 1/AOC 1 and the portion of the drainage feature extending north to the river); (2) the remaining AOCs/UAs located outside the compressor station fence line; and (3) 1/8-acre parcels within Bat Cave Wash north of the railroad (for the hypothetical future residential user only). Once data are available from the soil sampling activities, additional refinements to the exposure areas may occur.

The EPCs for direct soil contact (i.e., soil ingestion, dermal contact, and inhalation of particulates) will be estimated based on separate data groups for each of the exposure areas and will consider the following separate depth categories for each receptor: 0 to 0.5 foot bgs, 0 to 3 foot bgs, 0 to 6 foot bgs, and 0 to 10 foot bgs. Typically, the soil EPCs will be the 95% upper confidence limit (UCL) on the arithmetic mean for the exposure area and depth category being considered. Additionally, specific areas of hot spots may warrant specific assessment. In general, the identification of hot spots will be conducted through visual examination of the data. Visual examination of the data is a qualitative assessment that includes consideration of relative concentrations in relation to nearest neighboring sampling locations (both horizontally and vertically), field observations of staining or debris, and topography. Additional assessment may consist of evaluating the site data for outliers, which if conducted, will be done quantitatively using applicable statistical tests and may require additional and/or alternative statistical evaluations for identifying the appropriate EPCs.

EPCs in air from dust will be modeled from soil data by dividing the concentration of each constituent in the soil by a particulate emission factor. As stated in the preceding paragraph, the EPCs for direct contact pathways, including particulate inhalation, will be estimated using data from the four listed depth intervals, as appropriate, for the receptor as identified in the RAWP. EPCs in air from VOCs, if present, will be modeled from soil data based on a volatilization factor equation.

For the ecological risk assessment, the exposure areas for the large home range receptors consist of Bat Cave Wash and AOC 4 as one exposure area, and AOCs 9, 10, 11, 12, and 14 and UA-1 as another single exposure area. For the small home range receptors, the ecological risk assessment will initially include each individual AOC/UA as a separate exposure area. Once data are available from the soil sampling activities, additional refinements to the exposure areas may occur.

For direct exposure, the ecological risk assessment will evaluate representative EPCs from soils within the depth categories of 0 to 0.5 foot bgs, 0 to 3 foot bgs, and 0 to 6 foot bgs, which are consistent with three of the categories specified for the human health risk assessment. Therefore, soil data needed to address direct exposure for the ecological risk assessment conform to data needs for the human health risk assessment.

Typically, the EPCs for soil and sediment COPECs will be the 95% UCL on the arithmetic mean. The maximum detected concentration may be selected if the data do not support a valid UCL calculation. Additionally, specific areas of hot spots may warrant specific assessment.

If a potentially complete pathway from soil to burrow air for VOCs is identified based on the Part A investigation results, transport modeling, active soil gas sampling and analysis, and sampling and analyzing burrow air are all alternatives that could be considered. If transport modeling is conducted, burrow air concentrations will be estimated using soil data from the 0 to 6 feet interval.

Exposure modeling will be used to estimate representative EPCs for biota tissue from soil concentrations from the same depth categories as for the soil EPCs.

2.5.3 Inputs to Decision 3 – Impacts to Groundwater

The inputs required for Decision 3 consist of information that is required to calculate soil screening levels (SSLs) protective of groundwater and to conduct modeling, where necessary. These inputs are shown in Table 1. Soil background concentrations are also an input to this decision because SSLs will only be calculated for metals where soil concentrations exceed background. SSLs consider the volume and cross-sectional area of the potential source and will thus be developed on a unit-specific basis. Groundwater maximum contaminant levels and groundwater background values will define the maximum allowable concentrations of COPCs in groundwater. USEPA literature and other technical literature will serve as the source for modeling parameters. Existing and new site data will provide information on the nature and extent of COPCs, depth to groundwater, and geotechnical, geochemical, and hydraulic characteristics of the vadose zone soil.

2.5.4 Inputs to Decision 4 – Data for CMS/FS

Inputs to Decision 4 consist of soil property and contaminant distribution data and other information needed to estimate required remediation volumes and to determine the most appropriate and cost-effective remedial approach for each area potentially requiring remediation. Inputs to Decision 4 include volumes of soil and debris, specific soil physical and chemical properties that could influence the performance of certain remedial technologies (e.g., porosity, grain size, density, organic carbon content, soil chemical properties), and waste characterization parameters for any soils that may need to be transported offsite.

New and existing analytical data will provide information regarding chemical and physical soil characteristics and waste characterization parameters. New and existing data regarding the nature and extent of COPCs and COPECs, coupled with results of the human health and ecological risk assessments will provide the volumes of soil potentially requiring remediation. New and existing data will be supplemented by USEPA and other technical literature regarding physical and chemical properties of COPCs and soils and the performance and requirements of specific remedial technologies. Debris mapping will be conducted to estimate the types and volumes of debris present in areas where solid materials were discarded.

2.6 Step 4: Study Boundaries

Study boundaries include spatial (lateral and vertical), temporal, and analytical boundaries for each unit or group of units, as appropriate. Constraints that could interfere with sampling are also identified in this step and are reflected in the definition of the boundaries. Boundaries must be defined for each decision individually, as the scale at which data will be evaluated and the data populations of interest may vary for each decision. Temporal boundaries are required because a given medium or unit may change over time. Practical constraints may limit the spatial and/or temporal boundaries or regions that will be included in the study. Practical constraints associated with the Topock RCRA corrective action/CERCLA program consist primarily of access limitations (physical, cultural, historical, or biological constraints) but may also include other factors such as soil characteristics and the presence of bedrock. Study boundaries, especially the lateral and vertical study boundaries, are subject to change as additional data are collected. The study boundaries associated with each of the decisions are summarized in Table 1.

2.6.1 Decision 1 Study Boundaries – Nature and Extent of COPCs and COPECs

Lateral Boundaries

Lateral boundaries for Decision 1 are initially estimated based on the current boundaries of each individual unit as estimated in the Revised Final RFI/RI Volume 1 (CH2M HILL, 2007). For AOCs within drainages, such as AOC 1, AOC 4, AOC 9, AOC 10, and AOC 11, the lateral boundaries are expected to be constrained by topography in the up-drainage and cross-drainage directions. The down-drainage extent is not constrained and remains to be defined through sampling and analysis.

For AOC14, the lateral boundary is initially estimated to be bounded by Bat Cave Wash to the west, the former plant road and historic Route 66 to the east, Interstate 40 to the south, and the railroad tracks to the north. For AOC-12 and UA-1, the locations and extents of the AOCs are estimated based on anecdotal information on past waste disposal, and are shown on Figure 1, and as described in the Revised Final RFI/RI Volume 1 (CH2M HILL 2007).

For UA-2, the lateral boundary is the area surrounding the location of the former aboveground drip tank.

Where units are adjacent, the lateral study boundaries are defined at a clear physical demarcation to the extent feasible. For example, the western lateral study boundary for AOC 4 is at the mouth of the Debris Ravine where it joins Bat Cave Wash.

The specific lateral boundaries for each unit are shown in Table 1.

2.6.1.1 Vertical Boundaries

The vertical boundary of the soil investigation for Decision 1 extends from the ground surface to the water table.

2.6.1.2 Analytical Boundaries

Analytical boundaries for Decision 1 include both chemical (COPCs, COPECs, and general chemistry) parameters and soil physical characteristics. Sample location tables were included in the Part A Soil Workplan (a separate table was provided for each AOC). In addition, a comprehensive planned sample table, specifying analytes for all proposed samples, was provided in Appendix B of the workplan. Similar tables will be provided for the Phase 2 sampling program.

Chemical Parameters

Chemical parameters were defined for each individual unit and may be refined following completion of the Phase 1 sampling program. The list of analytical parameters at each unit is based on the site use and release history described in the Revised Final RFI/RI Volume 1 (CH2M HILL, 2007) and fate and transport mechanisms, as documented in the CSMs. Based on the available information, it was determined Title 22 metals, hexavalent chromium, total petroleum hydrocarbons, volatile organic compounds, semivolatile organic compounds, and PAHs are COPCs/COPECs for all areas outside the fence line except UA-2. VOCs are not considered COPCs/COPECs for surface soil. Dioxins and furans are COPCs/COPECs at AOC-4. Asbestos is a COPC for AOC 4, AOC-14, and UA 1 (asbestos is not a COPEC).

COPCs/COPECs at UA-2 are limited to total petroleum hydrocarbons and PAHs. Dioxins/furans, asbestos, and PCBs will be analyzed in samples collected from the upper end of AOC 1 where AOC 4 enters AOC 1. Ten percent of the samples collected in all AOCs will be analyzed for the full suite of inorganic and organic analyses per the CERCLA Target Analyte List (TAL) and Target Compound List (TCL). Select samples were analyzed to characterize the soluble fraction of compounds present at concentrations exceeding 10 times the total threshold limit concentration or 20 times the toxicity characteristic leaching procedure values. The samples selected will be determined based on the Title 22 metals analysis results.

2.6.1.3 Temporal Boundaries

All historic RFI/RI and new Part A soil sampling Category 1 data and acceptable Category 2 data (based on the final Data Usability Assessment) will be evaluated for determination of the nature and extent of contamination.

2.6.2 Decision 2 Study Boundaries – Data to Support Calculation of EPCs

2.6.2.1 Lateral Boundaries

The lateral study boundaries for Decision 2 are the same as for Decision 1.

2.6.2.2 Vertical Boundaries

Vertical study area boundaries for Decision 2 are defined by potential maximum exposure depths. Based on the types of receptors likely to be found in the investigation areas and nearby areas, the types of activities likely to occur, and the nature of the soils in the area, four exposure depth intervals are of interest; surface soil, shallow soil, subsurface soil to 6 feet bgs and subsurface soil to 10 feet bgs. For human health, exposure intervals for soil are surface soil (0 to 0.5 foot bgs), shallow soil (0 to 3 feet bgs), subsurface soil I (0 to 6 feet bgs), and subsurface soil II (0 to 10 feet bgs). Depths up to 10 feet bgs are appropriate for maintenance workers. Depths up to 3 feet bgs are appropriate for all human receptor populations being evaluated including: recreational users, tribal users, maintenance workers, and hypothetical future residents. Depths of 0 to 6 feet bgs and 0 to 10 feet bgs apply only to the maintenance worker and the hypothetical future resident (north of the railroad). For ecological receptors, exposure intervals for soil are surface soil (0 to 0.5 foot bgs), shallow soil (0 to 3 feet bgs), and subsurface soil I (0 to 6 feet bgs). Thus, the vertical study boundary for Decision 2 is 10 feet bgs, except at SWMU 1/AOC 1 where scouring scenarios will be considered. For SWMU 1/AOC 1, the vertical study boundary for Decision 2 is 15 feet bgs. This additional 5 feet of sampling depth (10 to 15 feet bgs) is needed to account for potential exposure 10 feet below the surface AFTER a 5 foot scouring event has occurred.

2.6.2.3 Analytical Boundaries

The same analytical boundaries for chemical parameters that apply to Decision 1 apply to Decision 2.

2.6.2.4 Temporal Boundaries

The same temporal boundaries that apply to Decision 1 apply to Decision 2; however, only existing Category 1 data will be considered for use in the risk assessment.

The Data Usability Matrix for Soil Risk Assessment lists the various Risk Assessment study boundaries for existing and newly collected data (Appendix A – Table A-1).

2.6.3 Decision 3 Study Boundaries - Impacts to Groundwater

2.6.3.1 Lateral Boundaries

The definition of lateral study boundaries for Decision 3 will be an iterative process. Initially, the lateral study boundaries for Decision 3 will be the same as for Decision 1. Following completion of the Phase 1 data evaluation, Decision 3 study boundaries will be refined to consist of those areas with COPC/COPEC concentrations exceeding the SSLs.

2.6.3.2 Vertical Boundaries

The vertical study area boundaries for Decision 3 are the same as for Decision 1.

2.6.3.3 Analytical Boundaries

The same analytical boundaries for chemical parameters that apply to Decision 1 also apply to Decision 3. Additional data regarding soil characteristics may be collected if needed to complete any required modeling. Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes.

2.6.3.4 Temporal Boundaries

The temporal boundaries for Decision 3 are the same as for Decision 1.

2.6.4 Decision 4 Study Boundaries – Inputs to CMS/FS

2.6.4.1 Lateral Boundaries

Initially, human health screening levels (RSLs, CHHSLs, and ESLs), ecological comparison values, and project specific screening levels developed for TAL/TCL COPCs/COPECs developed for this project will be used to define the lateral study boundaries for Decision 4. Results of the human health and ecological risk assessments will refine the lateral boundaries for remedial actions.

2.6.4.2 Vertical Boundaries

The vertical study area boundary for Decision 4 is the maximum depth for which remedial actions may be taken at the site to achieve remedial action objectives. The maximum depth for which soil remedial actions may be taken is determined by a combination of feasible technology types as defined in the CMS/FS workplan and physical or other constraints on soil remediation.

2.6.4.3 Analytical Boundaries

The same analytical boundaries for chemical parameters and soil characteristics that apply to Decision 1 also apply to Decision 4. Additional data regarding physical soil characteristics may be collected if needed to complete any required modeling and to support remedial technology selection and feasibility evaluation.

2.6.4.4 Temporal Boundaries

The temporal boundaries for Decision 4 are the same as for Decision 1.

2.7 Step 5: Decision Rule

Decision rules are "if…, then…" statements that describe the actions to be taken depending on the site-specific findings. A decision flow chart was developed for each of the four decisions identified in these DQOs. The decision process depicted on Figures 6 through 9 is described below.

2.7.1 Decision 1 - Nature and Extent of COPCs - Decision Rules and Decision Process

Refer to Figure 6 for the following discussion of the decision rule for Decision 1. The decision rule is applied separately for each AOC, SWMU, and UA.

2.7.1.1 Boxes 1 through 3

Once the Part A Phase 1 soil samples have been collected and the data have been validated (Boxes 1 and 2), the Phase 1 data and existing historic RFI/RI data sets for each AOC/SWMU/UA will be combined.

The data collected during the Phase 1 investigation will be validated as described in the QAPP (CH2M HILL, 2008a) and the *Draft Soil Addendum for the Topock Compressor Station, RCRA Facility Investigation/Remedial Investigation* (CH2M HILL, 2008c). The validated data will then be combined with existing data. Existing data were evaluated in the Data Usability Assessment (CH2M HILL, 2008b), and only data meeting data quality Category 1 or 2 requirements will be used to assess the nature and extent of COPCs and COPECs.

During this step, the existing data will also be reviewed to assess whether they are still considered reliable. If site conditions have changed substantially (e.g., as in Bat Cave Wash following the 2006 high runoff events), the data will be assessed to determine whether it is likely that the changes in site conditions have altered the conditions at that particular location. This data assessment process will be limited to surface and near-surface samples, as deeper samples would not be expected to be affected. Any surface or near-surface data for organic COPCs and COPECs will also be noted, as organic constituents located in surface and near-surface soils may have degraded under the influence of high surface temperatures and/or light. Older data for organic compounds will be compared to newer data for organics in the same vicinity.

2.7.1.2 Boxes 4 through 8

Once the new and existing data sets have been combined and reviewed, the combined data set for each unit will be first be reviewed to assess whether, as a result of the TAL/TCL analysis, any new compounds that qualify as COPCs/COPECs have been identified in the areas outside the compressor station (Box 4). Box 4 consists of the following decision:

Are any new COPCs/COPECs identified as a result of the TCL/TAL analysis?

If new compounds have been identified, a decision will be made in conjunction with DTSC and DOI to determine whether the detected compound represents a new COPC or COPEC. The decision whether any newly identified compounds may represent new COPCs and/or COPECs will be based on multiple factors including:

- Potential for the compound to be related to the compressor station (e.g., potential for the compound to be associated with past activities at the compressor station and/or to be a breakdown product of constituents known to have originated at the compressor station)
- Frequency of detection
- Concentrations detected, and
- Distribution of detections.

The outcome of Box 4 can be

> ***Yes**: new COPCs/COPECs have been identified, or*
>
> ***No**: no new COPCs/COPECs have been identified.*

It should be noted that it is possible for new compounds to be detected without these compounds necessarily being designated as COPCs/COPECs. Additional sampling may be warranted in order to make this decision.

If the outcome from the decision in Box 4 is yes, the next step is to determine whether screening values will be required for the newly-identified COPCs/COPECs (Box 5A). If the outcome from Box 4 is no, the decision process moves to Box 5C, and the decision process continues with comparison to screening levels (see discussion below).

The decision for Box 5A is:

Is development of screening value for new COPCs/COPECs required?

The possible outcomes for this decision step are:

> ***No**: Screening values are not required.*
>
> ***Yes**: Screening values are required.*

Screening levels may not need to be developed because they already exist. If screening levels do not need to be developed, the process moves to Box 7, evaluation of lateral and vertical extent. Screening may not be required because the frequency of detection and/or detected concentrations of these compounds are too low to merit the likely complex effort of developing screening levels. The decision to develop additional screening levels will be made in conjunction with DTSC and DOI. If screening levels are not developed the significance of the new COPCs and any associated uncertainties would be addressed in the risk assessment (Box 6A).

If screening levels will be required for any new COPCs/COPECs they will be developed by PG&E and require concurrence from DTSC and DOI (Box 5B). Once appropriate screening levels are available for all COPCs/COPECs the lateral and vertical extent of these compounds can be evaluated.

Following the identification of potential new COPCs/COPECs, all data will then be compared to screening criteria (Box 5C). The combined data tables will flag each occurrence of a COPC or COPEC exceeding one or more of the screening criteria. The following sets of screening values will be used:

- Background soil concentrations of metals (CH2M HILL, 2008d).
- CHHSLs for residential use, where available (OEHHA, 2005).
- RSLs for residential use for constituents for which CHHSLs are not available (USEPA, 2008).
- ESLs for residential use for petroleum hydrocarbon compounds TPH-gasoline, diesel, and motor oil.
- Preliminary ECVs developed by ARCADIS for PG&E (ARCADIS, 2008b)

- Project specific screening levels developed for COPCs/COPECs identified from TAL/TCL data.

ECVs have been developed for metals and select organics. ECVs have only been developed for organic COPECs that have been detected. Certain ECVs for metals are lower than the background soil concentrations and/or method quantitation limits; in these cases, the background concentration or method quantitation limit will be used in lieu of the ECV when determining whether delineation is adequate.

The initial comparison will be on a point-by-point basis for all depths (i.e., a simultaneous lateral and vertical assessment). The detected concentrations at each unit will first be compared to either the background concentrations (for metals) or the lowest applicable screening criterion for organic compounds. The lowest applicable organic screening value may differ depending on depth (ECVs are applicable to a maximum depth of 6 feet bgs; CHHSLs/RSLs are applicable to a depth of 10 feet bgs).

As a further check for metals, a population (central tendency) comparison such as the Wilcoxon Rank Sum Test will be performed for the population of detected concentrations to the applicable background data set, provided there are sufficient detections of the metal in question to allow a meaningful statistical comparison to be made.

If any COPCs or COPECs are present above background concentrations or the lowest applicable screening criterion for organic compounds, the locations of the COPC or COPEC concentrations exceeding the initial screening will be examined to determine whether nearby samples provide an adequate perimeter (lateral) or base (vertical) of samples to meet the initial screening criteria. In addition to point by point comparisons of site data to screening levels, spatial trends will be reviewed graphically (Box 6B).

Spatial trends will be evaluated both laterally and vertically. For lateral delineation, for samples potentially containing elevated levels of COPCs or COPECs, concentration trends toward the perimeter of the unit will be reviewed to ensure that concentrations are generally decreasing toward the perimeter. Vertical concentration trends will also be reviewed for each boring showing elevated concentrations of COPCs or COPECs. Potential hot spots will be identified through the presence of clusters of elevated concentrations of COPCs/COPECs. Evaluation of spatial trends will include the following considerations:

- Lateral concentration trends toward the edge of a unit or affected area (i.e., potential hot spot) within a unit
- Vertical concentration trends in each boring, and throughout a given unit or area
- Distribution of detections and non-detections of each constituent within a unit, and
- Where applicable, concentrations trends at the upstream unit.

For ease of evaluation, COPC and COPEC concentrations exceeding the screening criteria will be presented in different colors on the figures, according to the lowest concentration screening criterion exceeded.

The spatial trends analysis will used to make the decision identified in Box 7:

Are lateral and vertical boundaries of COPCs/COPECs including hot spots, if applicable, defined?

The possible outcomes of Box 7 are:

> ***Yes:*** *the lateral and vertical extent of COPCs/COPECs including any hot spots are defined, or*
>
> ***No:*** *the lateral and vertical extent of COPCs/COPECs including any hot spots are not fully defined*

This evaluation will be conducted for each compound, and may indicate that the boundaries of some but not all compounds at a given unit are adequately defined. If all boundaries are defined for a given unit, no further data are required to resolve Decision 1 (Box 8). The determination that COPC/COPEC boundaries have been adequately defined at a specific unit will be made in consultation with DTSC and DOI.

2.7.1.3 Boxes 10 through 13

If the determination is made that the boundaries have not been adequately defined, additional sampling of specific compounds may be required to complete the delineation of the lateral and vertical extent of contamination and/or hot spots. The specific areas where COPC/COPEC boundaries are not adequately defined will provide the basis for further sampling recommendations (Box 10). The information developed pursuant to Box 9 will be used to define the additional sampling needed to delineate a chemical boundary or define potential hot spots in each area identified as needing further delineation. The extent of additional sampling recommended will be defined in consultation with DTSC, and DOI. Once the additional sampling necessary to create a complete delineation has been defined (Box 10), Box 11 requires the following decision:

Would additional sampling significantly improve data quality, or risk assessment or site remediation decisions, and is the additional sampling feasible?

The possible outcomes for the decision in Box 11 are as follows:

> ***Yes****: Additional data would significantly improve data quality and/or risk assessments and site remediation decisions, and the additional data collection is feasible*
>
> ***No*** *The additional data would not significantly improve data quality and/or risk assessments and site remediation decisions, and is therefore not necessary; or, while additional data would significantly improve data quality and/or risk assessments and site remediation decisions, the additional data collection is not feasible due to physical or institutional constraints*

Data quality may be improved if existing sample results for the COPC or COPEC in question at the given unit are for older samples that may no longer represent current conditions (e.g., surface soil results in Bat Cave Wash collected prior to 2006 high runoff events), or have data flags that could limit the reliability of the data.

The risk assessment team will review the value of the additional sampling for improving the risk characterization for the specific COPC/COPEC at the given unit. Risk characterization may be improved by additional sampling if: the existing number of samples for an exposure area or designated hot spot is low; the detection limits did not achieve adequate concentrations for risk assessment purposes; the total number of samples in a given exposure depth interval is low; or the lateral or vertical distribution is uncertain at a level significant to the risk decisions.

Remedial decision making may be improved if the area or volume of potentially-impacted soil could be defined more precisely. Thus, additional sampling in areas where samples are spaced relatively far apart and/or where vertical characterization is limited might be considered to improve remedial decision making. If there are remaining uncertainties regarding soil physical properties in areas where remediation may be required, remedial decision-making could also be improved through the collection of additional data pertaining to the physical characteristics of interest.

If it is concluded in Box 11 that additional sampling is not feasible or warranted, then no further sampling is required and remaining uncertainties would be addressed in the risk assessment or CMS/FS (Box 13), and no further sampling is required to resolve Decision 1. The agencies will be consulted prior to concluding additional sampling is not feasible or warranted.

If additional data collection is desirable and feasible, the additional sampling needs will be defined, the sampling will be conducted and the new data will be validated (Box 12). After the data are validated, the flowchart leads back to Box 3 to reinitiate the data evaluation process.

2.7.1.4 Box 14

Once it has been determined that the nature and extent of contamination have been adequately defined and no further data collection is necessary to resolve Decision 1, the flow chart leads to Boxes 14A through 14C that refer to the decision rules for Decisions 2, 3, and 4. Those decision rules (Figures 7, 8, and 9) address data sufficiency for estimating EPCs, assessment of threat to groundwater, and data sufficiency for estimating soil properties and contaminant distribution to support the CMS/FS and remedial design.

2.7.2 Decision 2 – Data to Support Calculation of EPCs- Decision Rules and Decision Process

Refer to Figure 7 for the following discussion of the decision rule for Decision 2. This decision rule follows from the decision rule for Decision 1.

2.7.2.1 Box 1

The first step in addressing Decision 2 is to group all Part A soil investigation and Category 1 historic RFI/RI soil and sediment data by exposure area and depth category defined in the Risk Assessment Work Plan (ARCADIS, 2008a),as discussed below.

2.7.2.2 Boxes 2 through 4

Boxes 2 though 4 consist of the evaluation of data adequacy and additional data needs, if warranted. Box 2 addresses the following decision:

> *Are sufficient Category 1 data available to calculate representative EPCs for each exposure area and applicable depth interval (as defined in the Risk Assessment Work Plan)?*

The outcomes of the decision in Box 2 are:

- **Yes** – If sufficient Category 1 data exist to calculate representative EPCs for each exposure area and depth interval, the flow chart leads to Box 3, which concludes no further data collection is necessary to resolve Decision 2, and Box 9, for the calculation of representative EPCs and conduct of the risk assessments. The RAWP defines the process to be used to calculate EPC, assess risk and determine whether chemicals present at a given unit, combination of units, of portion of a unit potentially pose an unacceptable risk. The risk assessment will recommend which chemicals for which areas should be carried into the CMS to provide information for risk management decisions

- **No** - If the Category 1 data are not sufficient to calculate representative EPCs for each exposure area and depth interval, the flow chart leads to Box 4 to determine what additional samples are necessary to allow calculation of representative EPCs. In this step, PG&E, in consultation with DOI and DTSC, will define specific sampling needs.

The Box 2 decision will be resolved by comparing the existing medium-specific data for each exposure area and depth interval with the data requirements imposed by the acceptable limits on decision errors to be developed for Step 6 of the DQOs, coupled with professional judgment from the risk assessment experts. Box 4 will also consider the Step 6 requirements when defining the additional samples needed.

2.7.2.3 Box 5

Box 5 addresses the feasibility of collecting the additional samples identified as desirable in Box 4. As discussed for Decision 1, there are significant physical and other practical limitations on sampling in the areas outside the fence line. The proposed additional sampling effort will be evaluated by PG&E in consultation with DOI, DTSC and the stakeholders to determine if implementation of the sampling effort is feasible. The outcomes of Box 5 are:

- **No** – Further sampling is not feasible. The flow chart leads to Box 8 (EPC uncertainties are addressed in the risk assessment), and no further sampling is necessary to resolve Decision 2 (Box 3).
- **Yes** – Further sampling is feasible. The flow chart leads to Box 6. Additional sample collection is conducted and the data are validated. The flow chart then leads to Box 7 to combine the newly collected data with the previous Category 1 and Part A Phase 1 data set, and from there back to Box 2 to restart the decision rule with the new data set.

2.7.3 Decision 3 – Threat to Groundwater - Decision Rules and Decision Process

Refer to Figure 8 for the following discussion of the decision rule for Decision 3. This decision rule follows from the decision rule for Decision 1.

2.7.3.1 Boxes 1 through 5

The same data set used for Decision 1 will be used for Decision 3. The combined data set will be compared against soil screening levels. The combined data tables will flag each occurrence of a COPC exceeding the relevant SSL.

Box 3 addresses whether the screening level assessment based on SSLs indicates a threat to groundwater.

The potential outcomes of Box 3 are:

- **Yes** – A potential threat to groundwater exists from residual soil contamination at this AOC/UA based on the screening level assessment. Additional assessment is warranted. The flow chart leads to Box 5 to assess whether data indicate a potential current threat to groundwater exists.
- **No** – No threat to groundwater is indicated by the screening level assessment for this AOC/SWMU/UA. The flowchart leads to Box 4; no further sampling is required to resolve Decision 3.

The decision criteria used for this decision are the SSLs. The development of SSLs is described in the *Calculation of Soil Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station Technical Memorandum* dated August 1, 2008 (CH2M HILL, 2008e). SSLs will be calculated for each unit. COPC concentrations within each unit will first be compared to the SSLs developed for that unit. If COPC concentrations are all below SSLs, then soil within that unit does not pose a potential threat to groundwater.

SSLs are highly conservative screening concentrations; SSLs were chosen as the first step in evaluating the potential threat of leaching to groundwater because they are a simple, conservative screening tool. The calculation process for SSLs does not take into consideration changes in concentration with depth but assumes that the maximum concentration detected at any point in the soil column is present at the groundwater interface and that all constituents are completely leachable. If SSLs are exceeded for any COPC at any unit, it does not mean that that particular COPC in soil in that particular unit necessarily poses a potential threat of leaching to groundwater; rather, it is an indication of a potential threat. More site-specific and detailed evaluation (modeling) may be appropriate to better assess the potential threat of leaching to groundwater for that specific compound at that unit.

Box 5 addresses whether data indicate a potential current threat to groundwater exists.

Box 5 addresses the following decision:

Do data indicate a potential current groundwater impact?

Outcomes of Box 5 are:

- **Yes** – Soil data indicate a current groundwater impact. The flowchart leads to Box 12, which requires either the development of a plan for an AOC-specific groundwater assessment and/or inclusion of the potential source area in the CMS/FS and characterization of any uncertainties in the CMS/FS.
- **No** – A potential future threat to groundwater exists from residual soil contamination at this AOC/UA based on the screening level assessment. Additional assessment is warranted. The flow chart leads to Box 6 to conduct vadose zone modeling to further assess the potential impact.

The criteria for resolving this decision are vertical concentration trends of compounds in each boring, and throughout a given unit or area location. If soil data indicates elevated concentrations of compounds (as compared to screening criteria) in samples throughout the boring and at the depth of the soil/groundwater interface, a potential for a current impact to groundwater exists.

Boxes 6 and 7 address quantitative vadose zone modeling to assess whether residual soil concentrations could affect groundwater in the future even if current groundwater impacts are not indicated. The HYDRUS-1D (Simunek et al., 1998) vadose zone model will be used. HYDRUS is a finite-element model for one-dimensional solute fate and transport simulations that incorporates sorption along with dispersion in the vadose zone. Critical input to the model will be an estimate of the mass of the COPC(s) present in soil, based on soil sample data. Box 7 addresses the following decision:

Does modeling indicate the potential for soil-related impacts to groundwater?

Outcomes of Box 7 are:

- **Yes** – Modeling indicates the potential for future impacts to groundwater from the residual soil contamination at the AOC/SWMU/UA. The flowchart leads to Box 8 to assess whether additional site-specific refinement of the model is warranted to better simulate site conditions.
- **No** – Modeling does not indicate a potential impact to groundwater. The flowchart leads to Box 4; no further sampling is required to resolve Decision 3.

The criteria for resolving this decision are the simulated groundwater concentrations relative to groundwater chemical-specific Applicable or Relevant and Appropriate Requirements (ARARs) for COPCs. The target groundwater concentrations used to assess potential impacts to groundwater are the California State groundwater maximum contaminant levels (MCLs), both primary and secondary. The MCLs have been defined as chemical-specific ARARs)in Volume 2 of the Resource Conservation & Recovery Act (RCRA) facility investigation (RFI) and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) remedial investigation (RI) Revised Final Report (CH2M HILL, 2009).

2.7.3.2 Boxes 8 and 9

Boxes 8 and 9 address the need for collecting additional data in support of model refinement. Box 6 addresses the following decision:

Is further site-specific refinement of the model warranted?

The primary consideration for this decision is the evaluation of the potential uncertainty in the refined model results (i.e., would the refined model be significantly more reliable?). The decision to pursue a more refined model on which to base decision making will be made PG&E in consultation with DTSC and DOI.

The outcomes of Box 8 are:

- **Yes** – Further refinement is warranted. The flow chart leads to Box 9 to assess whether additional data collection is necessary to support the model refinement.
- **No** – Further refinement of the model is not warranted. The flowchart leads to Box 12, which requires either the development of a plan for an AOC-specific groundwater assessment or inclusion of the potential source area in the CMS/FS and characterization of any uncertainties in the CMS/FS.

If further refinement is warranted, the next decision is a determination of whether additional data collection is required to refine the model. Refinements would not necessarily require additional sampling, because refinements may also be achieved through further literature research regarding physical and chemical characteristics, more detailed modeling of the area of interest (i.e., smaller "cells"), and/or use of a model more specifically targeted at the compound in question. Box 9 states:

Is additional data collection required to refine the model?

The outcomes of Box 9 are:

- **Yes** – Additional sampling is required. The flow chart leads to Box 10 to determine additional data collection needs.
- **No** – Further data collected is not required. The flowchart leads to Box 14, and the model is refined without additional sample collection.

The need for additional data collection may be due to a variety of factors. It is likely that a number of assumptions will have had to be made as part of the initial modeling effort; for example site-specific leaching data (soluble threshold limits concentration and/or toxicity characteristic leaching procedure data) may not be available for all compounds of interest. It may also be determined that, rather than this type of waste characterization analysis, a DI-WET or similar modified testing method would have been more appropriate to characterize the in-situ leaching potential in the areas outside the fence line.

2.7.3.3 Boxes 10 and 11

Boxes 10 through 11 define the additional data needed and the feasibility of collecting the desired data. Following the decision in Box 9 that additional data collection is required to refine the model, the data to be collected are determined in Box 10. From Box 10, the process flows to Box 11, which addresses the following decision:

Is additional data collection feasible?

Considerations for this decision are the types of data that need to be collected to refine the model and the feasibility of collecting additional samples. Feasibility of sample collection may be limited by physical, cultural/historical, and/or biological factors. The decision regarding the feasibility of additional data collection will be made by PG&E in consultation with DTSC and DOI.

Outcomes of Box 11 are:

- **Yes** – Additional data collection is feasible. The flow chart leads to Box 13 to collect the additional samples and validate the newly collected data. From there, the flowchart leads to Box 14 to refine the model, and then to back Box 6 to conduct the refined modeling.
- **No** – Additional data collection is not feasible. The flowchart leads to Box 12, which requires either the development of a plan for groundwater assessment or inclusion of the potential source area in the CMS/FS and characterization of any uncertainties in the CMS/FS.

2.7.4 Decision 4 – Inputs to CMS/FS and Remedial Design - Decision Rules and Decision Process

Refer to Figure 9 for the following discussion of the decision rule for Decision 4. This decision rule follows from the decision rule for Decision 1.

2.7.4.1 Box 1

The first step in addressing Decision 4 is to compile Part A soil investigation and historic RFI/RI soil property data and nature and extent of contamination information from Decision 1.

2.7.4.2 Box 2

Box 2 addresses the following decision:

Are soil property and contaminant distribution data (see Decision) sufficient to support the CMS/FS and/or remedial design?

The outcomes of the decision in Box 2 are:

- **Yes** – If sufficient soil property and contaminant distribution information is available to support the CMS/FS and/or remedial design, the flow chart leads to Box 3, which concludes no further sampling is necessary to resolve Decision 4, and Box 9, for conduct of the CMS/FS and remedial design.
- **No** - Available soil property and contaminant distribution information is insufficient to support the CMS/FS and/or remedial design, the flow chart leads to Box 4 to determine what additional samples are necessary to support the CMS/FS and/or remedial design.

Considerations for this decision are the availability of site-specific soil property data, such as porosity, grain size, Atterberg limits, organic carbon content, and chemical makeup, and contaminant distribution information. Once the delineation of the nature and extent of COPCs and COPECs at each unit is complete as defined for Decision 1, areas and volumes of soil potentially requiring remediation can be calculated. Consequently, sufficient data on contaminant distribution are available when the Decision 1 data needs are met. The actual volumes of soil ultimately requiring remediation will be determined based on the results of the risk assessment and other factors considered in developing remediation action objectives.

A preliminary assessment of potential remedial technologies and presumptive remedies will guide identification of the data needs to support the CMS/FS and remedial design. Once an initial list of suitable remedial technologies has been agreed upon the approved CMS/FS workplan, soil property data requirements will be identified and will be compared to the available soil property data to assess whether sufficient data are available to support remedy alternative evaluation and selection, and/or remedial design.

2.7.4.3 Boxes 5 through 8

Box 5 addresses the feasibility of collecting the additional samples. As discussed for Decision 1, there are significant physical and other practical limitations on sampling in the areas outside the fence line. The proposed additional sampling effort will be evaluated by PG&E in consultation with DOI, DTSC, and the stakeholders to determine if implementation of the sampling effort is feasible. The outcomes of Box 5 are:

- **No** – Further sampling is not feasible. The flow chart leads to Box 6 (uncertainties are addressed in the CMS/FS and/or remedial design), and no further data collection is necessary to resolve Decision 4 (Box 3).
- **Yes** – Further sampling is feasible. The flow chart leads to Box 7. Additional data collection is conducted, the data are validated as appropriate, and the new and existing data are combined (Box 8). The flow chart then leads back to Box 2 to restart the decision rule with the expanded data set.

2.8 Steps 6 and 7: Acceptable Limits on Decision Error and Optimize Sampling Design

Step 6 is intended to define acceptable limits on decision errors. A decision error would occur if, based on the available data, the project team chooses the wrong response action in the sense that a different response action would have been chosen if the project team had access "perfect data" or absolute truth. The purpose of Step 7 is to *"identify a resource-effective data collection design for generating data that are expected to satisfy the DQOs"* (USEPA 2000). The output of this step will be the Phase 2 sampling design agreed upon by the stakeholders during the Part A Phase 1 data gaps evaluation process. Following compilation of and initial assessment of the Phase 1 soil data, DOI, DTSC and PG&E, in consultation with stakeholders, will reconvene to develop Steps 6 and 7 of the DQO process.

Data Quality Objectives – Part A Soil Investigation
PG&E Topock Compressor Station, Needles, California

STEP 1 Problem Statement	**STEP 2 Decision Statement**	**STEP 3 Inputs to the Decision[1]**	**STEP 4 Study Area Boundaries**	**STEP 5 Decision Rules**
Contaminants in soil in AOCs/UAs outside the compressor station fence line resulting from historical compressor station practices may pose an unacceptable risk to humans or the environment, or threaten groundwater. Site-specific information is needed to: Determine the nature and extent of soil and sediment contamination Estimate representative exposure point concentrations (EPCs) to support human health and ecological risk assessment being conducted separately from the Part A soil study Determine whether residual soil concentrations pose a threat to groundwater Estimate soil properties and contaminant distribution in support of the Corrective Measures Study/Feasibility Study (CMS/FS) and/or remedial design	**<u>Decision 1</u>** Determine the nature and extent of residual soil and/or sediment concentrations resulting from historic compressor station practices. If determination of the full nature and extent of contamination based on sample data is not feasible or is not warranted, address uncertainties in the risk assessment or CMS/FS.	COPCs and COPECs by AOC/SWMU/UA Part A and representative Category 1 and 2 historic RFI/RI COPC and COPEC data grouped by AOC/SWMU/UA and medium Data Usability Matrix for Soil and/or sediment (Appendix A) Comparison/screening values (background, risk-based, and regulatory screening values) Conceptual Site Models (CSMs) Geologic/hydrogeologic/hydrologic information Topographic information Soil physical and chemical property information AOC/SWMU/UA location and use history information Cultural and historic information by AOC/SWMU/UA Infrastructure information by AOC/SWMU/UA	<u>Lateral Extent</u> Initially the same as the currently defined boundaries of each SWMU, AOC and UA: SWMU1/AOC 1: Within Bat Cave Wash from mouth of Debris Ravine north to the riparian area at mouth of bat cave wash. AOC 4: Within the ravine from a point directly south of the water tanks to the junction with Bat Cave Wash; north slope of ravine directly south from end of small access road west to west side of storage area. AOC 9: Within the potential drainage path to the East Ravine from the break in the former storm drain; initially estimated to be from facility fence line 2/3 of the way east down the slope to the East Ravine; approximately 100 feet north to south centered on the alignment of the former storm drain. AOC 10: Within the East Ravine from its head at the compressor station to its downstream mouth. Low areas, former discharge and outfall locations (where known), and/or former retention areas (as indicated by presence of vegetation or sedimentation) are of particular emphasis. AOC 11: Within the drainage from its head at the compressor station to the low areas and/or former retention areas (as indicated by presence of vegetation or sedimentation) northwest of the compressor station access road, south of I-40, and east of the compressor station fence line. AOC 12: Areas indicated by former employees as sites of potential waste disposal. AOC 14: The area north of I-40 bounded by Bat Cave Wash to the west, the former plant road to the east, and the railroad tracks to the north. UA-1 (Potential Pipeline Disposal Area): An area approximately 20 feet wide by 100 feet long, encompassing an area indicated by a former employee as the site for burial of asbestos wrapped pipes. UA-2 (Former 300B Pipeline Liquids Tank): Area immediately surrounding the former location of a 900-gallon-capacity aboveground drip tank located southeast of the compressor station on a shelf in the hill next to a section of old Route 66. <u>Vertical Extent</u> Vertical study area boundaries extend from the ground surface to the water table. <u>Analytical Parameters</u>[1] *Chemical Parameters* (COPCs and COPECs) Title 22 metals, hexavalent chromium, total petroleum hydrocarbons, VOCs, SVOCs, and PAHs for all areas outside the fence line except UA-2. VOCs and TPH-purgeable will not be analyzed in the surface (0.0 – 0.5 foot) soil samples. Dioxins and furans are COPCs/COPECs at AOC-4. Asbestos is a COPC for AOC 4, AOC-14, and UA-1. COPCs/COPECs at UA-2 are limited to total petroleum hydrocarbons and PAHs. Dioxins/furans, asbestos, and PCBs will be analyzed in samples collected from the upper end of AOC 1 where AOC 4 enters AOC 1.Ten percent of the samples collected in all AOCs will be analyzed for the full inorganic and organic analysis suites per the CERCLA Target Analyte List and Target Compound List.	See Figure 6 for the Decision 1 decision rule

---

[1] A comprehensive planned sample table, specifying analytes for all proposed samples, was provided in Appendix B of the Part A Soil Workplan.

TABLE 1
Data Quality Objectives – Part A Soil Investigation
PG&E Topock Compressor Station, Needles, California

STEP 1 Problem Statement	STEP 2 Decision Statement	STEP 3 Inputs to the Decision[1]	STEP 4 Study Area Boundaries	STEP 5 Decision Rules
			During Phase 1, select samples were analyzed to characterize the soluble fraction of compounds present at concentrations exceeding 10 x TTLC or 20 x TCLP values. Samples were selected after Title 22 metals data had been received. PG&E performed SPLP on approximately 2 soil samples per AOC and analyzed for Cr(VI) and Cr(T). These data were validated. Temporal Boundaries Validated Part A soil sampling data and representative Category 1 and Category 2 historic RFI/RI data (based on the final Data Usability Assessment) .	
	Decision 2 Determine representative EPCs for residual soil and/or sediment contamination resulting from historic compressor station practices that may pose unacceptable risks to current or future human or ecological receptors. If determination of representative EPCs based on sample data is not feasible, address uncertainties in the risk assessment or CMS/FS.	Nature and extent of contamination assessment from Decision 1 Part A and representative Category 1 historic RFI/RI COPC and COPEC data grouped by exposure area and depth interval Data Usability Matrix for soil and/or sediment (Appendix A) RAWP CSMs Geologic/hydrogeologic/hydrologic information Topographic information Soil physical and chemical property information AOC/SWMU/UA location and use history information Cultural and historic information by AOC/SWMU/UA Infrastructure information by AOC/SWMU/UA	Lateral Extent Same as for Decision 1. Vertical Extent Vertical study area boundaries for Decision 2 are defined by potential maximum exposure depths. For human health risk assessment, the maximum exposure depth is 10 feet for all AOCs/SWMUs/UAs except for Bat Cave Wash (SWMU 1/AOC 1), which is 15 feet to account for possible scouring of the surface during runoff events. For ecological risk assessment, the maximum depth is 6 feet, except in Bat Cave Wash, where the maximum exposure depth for ecological receptors is 11 feet to account for possible scouring during run-off events. Analytical Parameters Same as for Decision 1 Temporal Boundaries Validated Part A soil sampling data and representative Category 1 historic RFI/RI data (based on the final Data Usability Assessment)	See Figure 7 for the Decision 2 decision rule
	Decision 3 Determine whether residual soil concentrations resulting from historic compressor station practices may threaten groundwater. If so, conduct additional site-specific assessment of the threat, or implement response actions to mitigate the threat. If not, no further assessment or response actions are necessary to address threat to groundwater.	Nature and extent of contamination assessment from Decision 1 COPCs by AOC/SWMU/UA Part A and representative Category 1 and 2 historic RFI/RI COPC and COPEC data grouped by AOC/SWMU/UA Data Usability Matrix for soil and/or sediment (Appendix A) Comparison/screening values (SSLs and groundwater/ drinking water ARARs) CSMs Geologic/hydrogeologic/hydrologic information Topographic information Soil physical and chemical property information AOC/SWMU/UA location and use history information Cultural and historic information by AOC/SWMU/UA Infrastructure information by AOC/SWMU/UA	Lateral Extent Those portions of each AOC/SWMU/UA where COPC concentrations exceed SSLs Vertical Extent Same as for Decision 1. Analytical Parameters *Chemical Parameters (COPCs/COPECs)* Same as for Decision 1. *Soil Characteristics* (to support modeling) Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes. Temporal Boundaries Same as for Decision 1	See Figure 8 for the Decision 3 decision rule

TABLE 1
Data Quality Objectives – Part A Soil Investigation
PG&E Topock Compressor Station, Needles, California

STEP 1 Problem Statement	STEP 2 Decision Statement	STEP 3 Inputs to the Decision[1]	STEP 4 Study Area Boundaries	STEP 5 Decision Rules
	Decision 4 Determine the site-specific soil property and contaminant distribution information necessary to support the CMS/FS decisions and remedial action design. If full determination of site-specific soil property and contaminant distribution information based on sample data is not feasible, address uncertainties in the CMS/FS and remedial design.	Nature and extent of contamination assessment from Decision 1 COCs from human health and ecological risk assessments Remedial action objectives and ARARs Risk-based and regulatory soil and/or sediment cleanup levels Estimated soil and debris volumes Waste classification testing results for soil, sediment, and/or debris as required Waste comparison/screening levels (TTLC, STLC, RCRA toxicity) Soil physical and chemical property information Geologic/hydrogeologic/hydrologic information Topographic information AOC/SWMU/UA location and use history information Cultural and historic information by AOC/SWMU/UA Infrastructure information by AOC/SWMU/UA	Lateral Extent Initially same as for Decision 1, to be refined based on results of risk assessments and threat to groundwater assessments Vertical Extent Initially same as for Decision 1, to be refined based on results of risk assessments and threat to groundwater assessments, and remedial alternative practical constraints Analytical Parameters *Chemical Parameters (COCs)* Initially same as COPCs/COPeCs for Decision 1, to be refined to specific COCs based on results of risk assessments and threat to groundwater assessments *Soil Characteristics* (to support remedial technology selection and feasibility evaluation) Select samples will be analyzed for organic carbon content, grain size, Atterberg limits, gradation, and washes. Temporal Boundaries Same as for Decision 1	See Figure 9 for the Decision 4 decision rule

Notes:

1) The list of analytical parameters is based on CSM and will be refined after each round of investigation/data evaluation. COCs will be selected based on the risk assessment.

VOCs - Volatile Organic Compounds
SVOCs - Semi-Volatile Organic Compounds
TPH - Total Petroleum Hydrocarbons
CSMs - Conceptual Site Models
ARARs - Applicable or Relevant and Appropriate Requirements
mg/kg - milligrams per kilogram
CMS/FS – Corrective Measures Study/Feasibility Study
PAHs – Polycyclic Aromatic Hydrocarbons

NOTES:

[1]	Conceptual site model (CSM) from the Topock Final Human Health and Ecological Risk Assessment Work Plan (RAWP; ARCADIS, 2008) and updated with information based on the Topock Groundwater Risk Assessment (GWRA; ARCADIS, 2009a).
[2]	Applicable to AOC 1 and AOC 10 only.
a	As requested by California's Department of Toxic Substances Control (DTSC), the groundwater-to-phreatophytes pathway and consumption of phreatophytes by herbivores were evaluated in the GWRA (ARCADIS, 2009a) and exposure and risk were found to be insignificant.
——▶	Potentially complete exposure pathway
- - - -▶	Soil/sediment potential pathway under evaluation (separate assessment)
- - - -▶	Insignificant transport pathway as evaluated in the GWRA (ARCADIS, 2009a). Part A Phase I data will be reviewed in the data gaps assessment to evaluate potential future impacts or current localized impacts to groundwater from soil.
*	Soil/sediment exposure route under evaluation (separate assessment)
*	Insignificant exposure route as evaluated in the GWRA (ARCADIS, 2009a).
X	Potentially complete exposure route
O	Potentially complete exposure route not significant or not directly assessed
AOC	Area of concern
PPDA	Potential Pipeline Disposal Area

a. The Former 300B Pipeline Liquids Tank area has already been closed (CH2M HILL, 2007), but DTSC has requested additional investigation (CalEPA, 2007). If complete pathways are identified based on the results, the Former 300B Pipeline Liquids Tank area will be included in the Ecological Risk Assessment (ERA).

b. For the large home range ecological receptors, two exposure areas will be evaluated: (i) BCW (AOC 1) and AOC 4 and (ii) all other remaining AOCs outside the compressor station (AOCs 9, 10, 11, 12, 14, Potential Pipeline Disposal Area).
For small home range ecological receptors, the Potential Pipeline Disposal Area and each AOC outside the compressor station (AOCs 4, 9, 10, 11, 12, 14) will be evaluated as separate exposure areas (See Section 3 of the RAWP; ARCADIS, 2008).
All exposure pathways inside the compressor station are considered incomplete and will not be evaluated for ecological receptors.

c. Potential inhalation exposure in burrows was included for the Former 300B Pipeline Liquids Tank area only based on the potential presence of volatile organic compounds (VOCs).

d. For applicable soil exposure depth, please see Fig 3-1 in the RAWP Addendum (ARCADIS, 2009b).

e. Applicable soil depth is 0-6 feet below ground surface (bgs) for volatilization to burrow air.

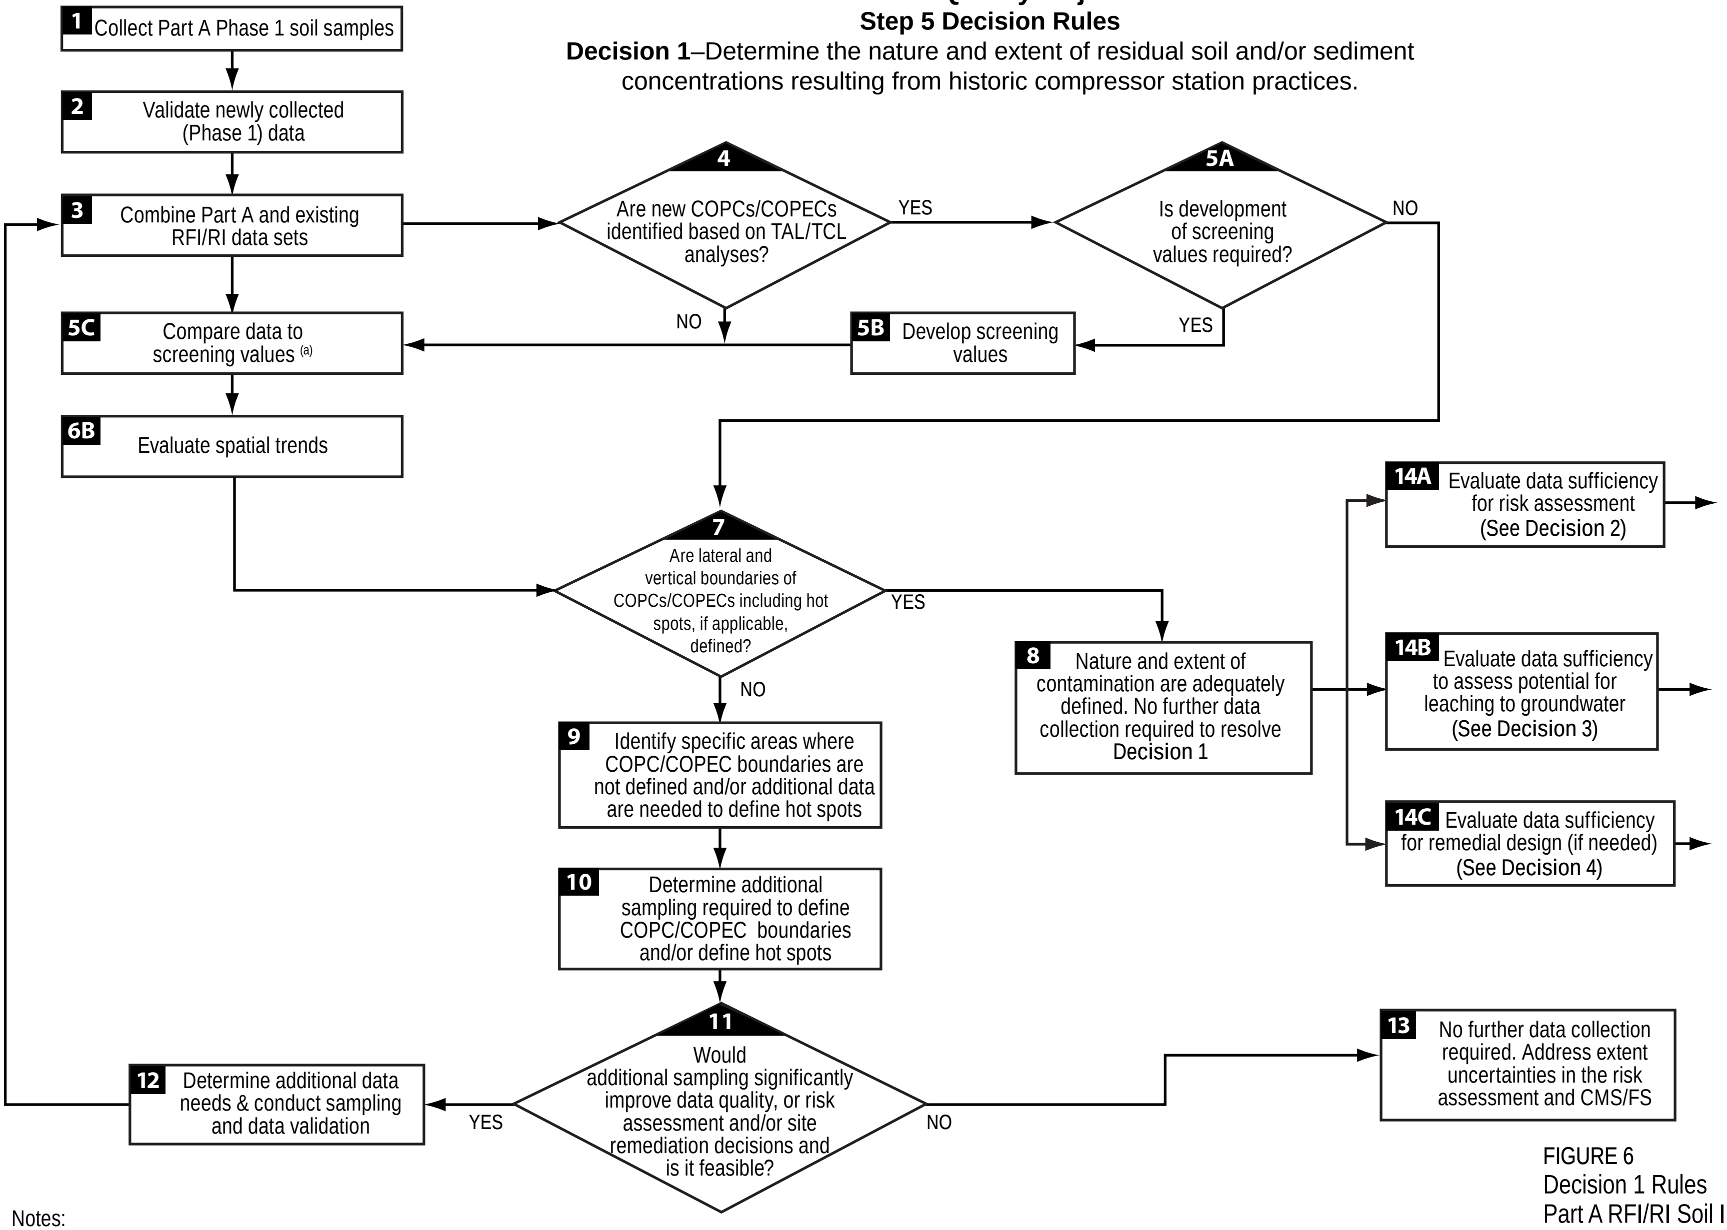
Draft Data Quality Objectives

Step 5 Decision Rules

Decision 1–Determine the nature and extent of residual soil and/or sediment concentrations resulting from historic compressor station practices.



Notes:
– Steps are for each unit (SWMU, AOC, or UA)
– (a) Screening levels will include background (for metals), CHHSLs, ECVs, and Soil Screening Levels for protection of groundwater

Table A-1
Data Usability Matrix for Soil Risk Assessment
PG&E Topock
Needles, California

Notes: Information for this table was obtained from Part A Soil Investigation Work Plan (CH2M HILL, 2006a) and the updated figures for Part A Soil Investigation Work Plan posted on the DTSC website: http://www.dtsc-topock.com . Information presented in this table is current as of December 15, 2008 and includes historical sampling and Part A Phase I sampling information. The conclusions regarding representativeness and data adequacy will be based on the outcome of Step 6 of the data quality objectives (Table 1), which has yet to be performed. The intent of the matrix, when finalized, is to summarize all the relevant information pertaining to data usability and adequacy for determining EPCs.

a. This matrix includes soil sampling information only for areas outside the compressor station. For HHRA, the soil sampling presented in this matrix will be used to evaluate two exposure areas (ARCADIS, 2008): (i) BCW, and (ii) the rest of the AOCs/subareas outside the compressor station. BCW includes a sub area of USBLM land north of the railroad (north of AOC 1) to be evaluated separately for potential future residential use. For the ERA, for small home ranging receptors, each AOC or subarea will be evaluated as separate exposure areas; for large home range receptors, two exposure areas will be evaluated: (i) BCW and AOC4 and (ii) the rest of the AOCs/subareas outside the compressor station.

b. Assumption is that horizontal and vertical extent will be characterized to background regardless of risk assessment needs. If a background value is not available then the lesser of the soil ecological comparison value, the USEPA Regional Screening level, or DTSC CHHSL will be used. Horizontal coverage refers to the adequacy of the number of locations to support EPCs for the exposure area. The horizontal coverage was based on all the sample locations in the Work Plans (all sample locations indicated at least some surface interval [0/0.5/1/3/6/10 feet bgs]). Vertical coverage refers to the adequacy of sampling depth intervals to provide information to support calculation of EPCs for the four exposure intervals and the number of samples at each depth interval was reported. For calculation of EPCs, a minimum of 8 samples and 5 detects are required for the ERA, depths evaluated will include 0 to 0.5, 0 to 3, and 0 to 6 foot/feet bgs. For the HHRA, depths evaluated will include 0 to 0.5, 0 to 3, 0 to 6, and 0 to 10 foot/feet bgs. Vertical coverage for Phase I sampling was obtained from Part A Work Plan (CH2M HILL, 2006a) and confirmed with the Soil Investigation team. The 0.5 foot bgs sample were collected from 0 to 0.5 feet bgs; the 3 feet bgs samples were collected from 2 to 3 feet bgs; the 6 feet bgs samples were collected from 5 to 6 feet bgs; and the 10 feet bgs samples were collected from 9 to 10 feet bgs.

c. Full suite of analytes and TAL/TCL analytes are listed in the Draft QAPP (CH2M HILL, 2008a,b); analyte classes include metals, PAHs, SVOCs, VOCs, TPH, PCBs, and pesticides.

d. Limited VOC and TPH data from the surface interval does not compromise the assessment to evaluate potential risks to human health or burrowing receptors.

e. Only Category 1 data which are considered suitable for risk assessment were included in the horizontal and vertical coverage evaluation in this matrix (CH2M HILL, 2006a).

f. Site-specific background concentrations are not yet final; preliminary site-specific background concentrations were estimated for metals with available data and reported in the QAPP (CH2M HILL, 2006a). The reporting limits were less than preliminary site-specific background concentrations for all metals (Draft QAPP; CH2M HILL, 2008a,b). For metals with no site-specific preliminary background concentrations, reporting limits were compared to California regional background concentrations (Bradford et al., 1996); the reporting limits for these metals were less than the regional background concentrations.

g. Human health screening values were based on the lesser of the CHHSLs and USEPA Regional Screening Levels. The reporting limits were less than the final human health screening values for most of the chemicals (Draft QAPP; CH2M HILL, 2008a,b).

h. ECVs were calculated for metals and PAHs (ARCADIS, 2008). The reporting limits were less than the ECVs for PAHs and for most of the metals except antimony, cadmium, lead, mercury, nickel, selenium, and zinc (Draft QAPP; CH2M HILL, 2008a,b). ECVs for the rest of the analytes have not yet been developed.

i. “Yes” indicates that data are considered representative; this is optimized by the appropriate placement of Phase I sample locations in areas suspected to have been impacted by site releases. Further, the analyte list captures those chemicals assumed to be associated with a potential release. Adequacy of the representativeness will be re-assessed once Phase I data are obtained. [Representativeness is defined as the degree to which sample data accurately reflect the characteristics of a population of samples. It is achieved through a well-designed sampling program and by using standardized sampling strategies and techniques and analytical procedures (DUA; CH2M HILL, 2008c)].

j. “Yes” indicates, as stated in the DUA Technical Memorandum (CH2M HILL, 2008c), that existing datasets were reported which consistent units and reporting limits for soil and sediment data were equivalent to those required by the QAPP Addendum (CH2M HILL, 2006b). The existing datasets with are considered usable for risk assessment, and will be supplemented with additional data that meet the overall requirements of the Draft QAPP (CH2M HILL, 2008a,b) and thus, the existing Category 1 data should be very comparable to the data that will be generated during Phase I sampling. [Comparability is defined as the confidence in which one dataset can be compared to another. It is achieved by maintaining standard techniques and procedures for collecting and analyzing samples and reporting the analytical results in standard units].

k. Data considered sufficient to calculate EPCs assumes validation of Phase I soil data will not result in data unsuitable for risk assessment (e.g., “R” or reject qualified).

UA	undesignated area
UU	undifferentiated utility
VOC	volatile organic compound
Water Board	California Regional Water Quality Control Board
XRF	X-ray fluorescence

APPENDIX B

Investigation Procedures and Field Methodology

B.1 Introduction

This appendix describes field activities performed as part of the Resource Conservation and Recovery Act (RCRA) Facility Investigation/Remedial Investigation (RFI/RI) Soil Investigation Part A, Phase 1. The following sections summarize field methodology, debris and white powder material mapping, trenching observations, and any deviations from the *RCRA Facility Investigation/Remedial Investigation Soil Investigation Part A Work Plan* (CH2M HILL, 2006) pertaining to the field activities performed in 2008. The primary objectives of this soil investigation were to determine the nature and extent of contamination and to collect sufficient data for the purposes of performing human and ecological risk assessments and evaluating remedial action alternatives.

B.1.1 Approvals and Authorizations

The Part A Phase 1 soil investigation was executed in conformance with the following approvals and authorizations:

- DTSC and DOI conditionally approved the Soil Part A Work Plan on August 10, 2007 (DTSC, 2007) and June 4, 2008 (DOI, 2008), respectively.
- Clarification of DTSC's conditional approval was documented in the "Clarification to Responses to PG&E Topock Compressor Station Soil Investigation Part A Work Plan August 10, 2007 Conditional Approval Letter" (CH2M HILL, 2007a).
- Pre-construction and post-construction biological surveys were conducted in compliance with the *Programmatic Biological Assessment for the Pacific Gas and Electric Topock Compressor Station Remedial and Investigative Action* (CH2M HILL, 2007b).

B.2 Field Methodology

This section describes the methods used in field activities related to embankment modification; X-ray fluorescence (XRF) analyzer field screening; installation of soil boreholes; and collection of soil, debris, and white powder material samples.

B.2.1 Embankment Modification

An existing embankment within Area of Concern 10 (AOC 10) was modified to provide access for soil sampling equipment to subareas AOC 10b and -10c. Excavation equipment was used to re-grade the material comprising the upper one-half of the embankment such that the slope of a portion of the embankment was shallower. The material that was displaced during grading was moved to the east and west of the existing embankment slope to create shallower sloping “ramps.” The lower half of the embankment was not disturbed such that surface water flow in the upper portion of AOC 10 would not flow freely to the lower portion.

Prior to conducting the embankment modification, an XRF threshold value for total chromium (300 milligrams per kilogram) was developed jointly with United States Department of the Interior to determine if implementation of erosion control measures was needed during this work (CH2M HILL, 2008). As the total height of the embankment was lowered during modification, soil samples were collected within the embankment from the excavated surface from three locations equally spaced along the length of the feature. Samples collected were analyzed for screening analysis of total chromium using a portable XRF analyzer (Section B.2.2) and one confirmation soil sample was collected and analyzed for total chromium and hexavalent chromium using an off-site laboratory. The results of the analyses were compared to the XRF threshold value. Based on results of the analyses it was determined that erosion control measures were not required. However, temporary silt fence was installed downstream of the embankment to impede the migration of sediments as a Best Management Practice (BMP).

B.2.2 X-ray Fluorescence Field Screening

A portable XRF analyzer was used to assist with identifying sample and trench locations in AOC 4 and to determine if erosion controls were necessary during the AOC 10 embankment modification by field screening soil samples for total chromium. The XRF analyzer was calibrated daily in the field with standards provided by the XRF manufacturer. Soil samples were collected using a clean stainless-steel trowel, placed in clean zip-top bags, and analyzed in the field for total chromium using the XRF analyzer. XRF analyzer results were recorded in the field notebook.

B.2.3 Installation of Boreholes and Soil Sample Collection

Four methods of subsurface soil collection were used during the RFI/RI Soil Investigation Part A, Phase 1. Methods for collecting soil samples included drilling, excavation, trenching, and hand sampling. Attachment B1 contains boring logs and trench logs associated with the RFI/RI Soil Investigation Part A, Phase 1.

B.2.3.1 Drilling

Boreholes were drilled using rotosonic and direct-push methods. A limited access (track mounted), “mini” rotosonic drill rig was used to install the rotosonic boreholes. Boreholes were advanced with a 4-inch-inner-diameter core barrel and then over-drilled with 5-inch- or 6-inch-outer-diameter drill pipe (drive casing), as necessary. Continuous cores were collected via a core barrel attached to the end of the 4-inch drive casing advanced ahead of the outer casing, generally in 5-foot intervals. The cores were placed in plastic sample bags.

A limited access (track-mounted) direct-push rig (Marl M5T), also capable of hollow-stem auger drilling, was used to install the direct-push boreholes. Continuous direct-push cores were collected using a hydraulic hammer to advance a 4-foot-long, 1.5-inch-diameter, hollow core stainless-steel sampler lined with a dedicated acetate liner into the ground. If borehole advancement by direct-push was impeded due to adverse subsurface conditions, hollow-stem augers were used to displace gravels or cobbles, and then direct-push coring was continued.

Soil samples were collected from drilled boreholes at pre-designated depth intervals in accordance with the sample collection and handling procedures described in Section B.2.4. Once drilling and sampling activities were complete, each borehole was backfilled with a mixture of clean sand and bentonite chips, and hydrated.

B.2.3.2 Trenching and Potholing

An excavator or backhoe was used to install trenches and potholes to evaluate the presence, nature, and extent of buried debris, and collect soil samples in areas where site conditions were unsuitable for drilling. Trenches and potholes were deepened gradually so that subtle changes in lithology and buried debris could be documented. Soil samples for laboratory analysis were collected directly from the excavator or backhoe bucket from soils that were not in contact with the bucket. Soil samples were collected at pre-designated depth intervals in accordance with the sample collection and handling procedures described in Section B.2.4.

Excavated material was used to backfill the excavation from which it originated.

B.2.3.3 Hand Tools

Hand tools, which include stainless-steel trowels, slide hammers, and hand augers, were used for samples collected between 0 and 3 feet below ground surface (bgs) in areas that could not be accessed by drilling or excavation equipment. Soil samples collected in the depth interval from 0 to 1 foot bgs were collected using a stainless-steel trowel. Soil samples collected in the depth interval from 1 to 3 feet bgs were collected using a hand auger or a slide hammer to drive a core sampler into the undisturbed soil to the desired sampling depth. Soil samples were collected at pre-designated depth intervals in accordance with the sample collection and handling procedures described in Section B.2.4.

Each hole created using hand tools was backfilled using the material removed from that hole.

B.2.4 Sample Collection and Handling

This section describes the procedures for the collection and handling of soil, debris, and white powder material samples.

B.2.4.1 Soil, White Powder Material, and Debris Sample Collection for Inorganic, Semivolatile Organic Compounds, Pesticides, and Polychlorinated Biphenyls Analyses

Upon retrieval of the soil from the drilling cores or excavations, the soil was logged for lithology in accordance with the Unified Soil Classification System by or under the supervision of a California Professional Geologist. Soil and white powder samples requiring inorganic, semivolatile organic compounds, pesticides, and polychlorinated biphenyls analyses were collected directly from the drilling core or backhoe/excavator bucket using stainless-steel trowels. The collected material was then put through a stainless-steel sieve to remove any rocks and other debris from the soil sample prior to being homogenized in a stainless-steel bowl. After homogenization, the soil was transferred to unpreserved glass sample jars.

Debris (e.g., wood, dry wall, etc.) samples were collected using stainless-steel trowels, as appropriate, and depending on the size of the debris, either placed into glass sample jars or large plastic zip-top bags. Samples of white powder material were collected using stainless-steel trowels and were placed directly into glass jars; these samples were not homogenized.

B.2.4.2 Soil Sample Collection for VOC and TPH-gasoline Analyses

Soil sample aliquots designated for VOC and TPH-gasoline analyses were collected immediately upon opening the relatively undisturbed drilling core, or recovery from an excavation, (i.e., before geologic logging or the collection of other soil sample aliquots) to minimize the potential for volatilization of compounds to the atmosphere. VOC and TPH-gasoline aliquots were collected using dedicated plastic syringes. Using the syringes, a specific volume of sample, which correlates to an approximate target mass, was transferred directly from the drilling core or backhoe/excavator bucket into pre-preserved sample vials. The sample vials were chilled prior to use to minimize evaporation of the preservative when opened. Syringes could not be used to collect sample from soils consisting of loose sand and gravel. In this case, stainless-steel trowels were used to transfer the soil into the vials for volume measurement prior to preservation.

B.2.4.3 Sample Management and Storage

Samples were placed immediately into field coolers with ice; VOC and TPH-gasoline containers were arranged in the sample cooler standing upright. The field coolers were taken to the sample management area, where the samples were transferred into a refrigerator and/or freezer. If transport of a sample to the laboratory was scheduled for a pickup more than 24 hours after sampling, samples were stored in the freezer.

B.2.4.4 Shipping

Samples collected for chemical analysis were transported to the laboratory via courier, generally on a daily basis. Samples collected for geotechnical analyses were shipped via Federal Express. Chains-of-custody accompanied all samples to the laboratory.

B.2.5 Decontamination and Management of Investigation-derived Waste

This section discusses procedures for decontamination of the soil sampling equipment and the management of investigation-derived waste (IDW).

B.2.5.1 Decontamination

Drilling and excavation equipment (i.e., drilling rig, backhoe/excavator tracks, etc.) was cleaned prior to mobilization to the Pacific Gas and Electric Company (PG&E) Topock Compressor Station and were cleaned between investigation areas as determined necessary by the field team leader. When appropriate, equipment was transported to the designated decontamination area (Figure B-1) and steam cleaned. If necessary, equipment was cleaned using dry methods prior to leaving an excavation area to prevent the tracking of material out of the area. Equipment blanks were collected at a frequency of one per sampling crew per day where non-dedicated equipment was used. Results of equipment blanks are discussed in Appendix D.

Rotosonic and direct-push drilling pipe and core barrels were steam cleaned at the designated decontamination area between boreholes. The direct-push core barrels were fitted with dedicated acetate liners for each core. Backhoe/excavator buckets were steam cleaned before work began and between sampling locations using a dry brush.

All hand tools were cleaned between sample locations. Each field team established a mobile decontamination unit in each sample area. The mobile decontamination units included three containers: one with Liquinox soap and two with rinse water. After each sample, the stainless-steel mixing bowl, stainless-steel sieve, and trowel were cleaned thoroughly in the Liquinox soap mixture with a brush and then rinsed twice in each of the consecutive rinse buckets.

B.2.5.2 Management of Investigation-derived Waste

Drill cuttings were contained at the drilling location in a receptacle (i.e., skid hopper or equivalent) that could be safely moved with a forklift or loader. As necessary, the hopper was emptied into roll-off bins located in the decontamination area. For the duration of the field event, approximately 15 yards of soil were contained in one bin. A composite soil sample, comprising four sub-samples, was used to characterize the IDW prior to offsite disposal. Refer to Attachment B2 for soil manifest and complete analytical results.

Liquid IDW was contained at the decontamination area in a tank that could be safely moved by a forklift or loader. As necessary, the tank was emptied at the Topock Compressor Station Interim Measures 3(IM No. 3) onsite treatment facility. Waste characterization for the liquid IDW disposed at the IM No. 3 treatment facility was not required per approval from the California Regional Water Quality Control Board (Water Board, 2006).

B.3 Debris and White Powder Material Mapping

The following section describes the mapping process and results for debris and/or white powder material mapping at AOC 4, AOC 10, Solid Waste Management Unit (SWMU) 1, and AOC 14. Due to the varying nature of site topography in each of these areas, methods of documentation and inventory of the debris and/or white powder material varied.

B.3.1 Debris Mapping and Results in AOC 4 – Debris Ravine

Debris mapping within AOC 4 was performed by creating a grid to accurately capture the extent of debris in and on the slopes of the steep ravine (Figure B-2). The grid was placed in over areas of containing the most extensive debris within AOC 4 and captured most of the debris in and on the slopes of the steep ravine. The ravine was sectioned off in 20-foot by 10-foot grid squares using rope and stakes. Global positioning system (GPS) coordinates were taken near the stakes at the top and bottom of each rope line. The debris was then noted and each grid section was photo documented, and described below.

Debris observed at AOC 4 generally consisted of broken glass, wooden slats, miscellaneous industrial debris, concrete slabs, rebar, scrap metal, and miscellaneous burned debris, as shown in Attachment B3, Photographs 1 through 4. The most extensive debris was observed along the western portion of the primary ravine slope of AOC 4 and included three large pieces of concrete, wooden slats, white powder material, scrap metal, and piping, as shown in Attachment B3, Photographs 5 and 6. Debris is also observed to the east along the ravine floor, as shown in Attachment B3, Photograph 7. Two samples of the wooden slats were collected (AOC4-Wood1 and AOC4-Wood2) and were sent to the laboratory for analyses, as listed in Table B-1.

Debris observed in grid section B, shown in Figure B-2, consisted of a large piece of concrete and wood debris, as shown in Attachment B3, Photograph 8. White powder material, shown in Attachment B3, Photograph 9, was found in quadrant B30, shown in Figure B-2. A sample of the white powder material was collected (AOC4-B30) and sent to the laboratory for analyses, as listed in Table B-1.

A pile of wooden slats was observed in grid sections C and D near the bottom of the ravine, as shown in Attachment B3, Photographs 10 through 12. No other debris was observed in these grid sections; however, green stained soil was observed near the top of grid section D.

No debris was observed in grid sections E through I, shown in Attachment B3, Photograph 13. Green stained soil was observed in section G, as shown in Attachment B3, Photograph 14.

B.3.2 White Powder and Debris Mapping in AOC 10 – East Ravine

As part of the conditional approval of the RCRA Facility Investigation/Remedial Investigation, Soil Investigation Work Plan, Part A, DTSC requested that the white powder and metal debris observed in AOC 10 be mapped. PG&E conducted a site walk at AOC 10 in May 2009 to map the white powder and debris areas. White powder was observed in the ravine bottom within subarea 10d and between subareas 10c and 10d. Several areas of miscellaneous debris were identified, as shown on Figure B-3. Miscellaneous debris consisted of pieces of metal, cans, tires, concrete rubble, tiles, and bricks. A small dirt pile with small pieces of green wood was observed near the access road adjacent to subarea 10d, this debris pile is being evaluated as part of AOC 10 (see Appendix C, Attachment C-4). Two areas of discolored soil were observed in the debris areas located on northern ravine wall, as shown on Figures C4-1 through C4-10. Following recent heavy rainfall in January 2010, an additional white powder area was discovered on the slope near the station access road north and slightly west of subarea 10b; these areas are also shown Figures C4-1 through C4-10.

B.3.3 White Powder Material and Debris Mapping in SWMU 1 – Former Percolation Bed

Several areas of surficial white powder material were identified in SWMU 1 during previous investigations and site visits. The surficial extent of the white powder material quantified by various methods, as described below, and was plotted on a figure.

In SWMU 1, the white powder material was visually documented, photographed, and plotted in Figure B-4. White powder material was observed in the slope near sample locations SWMU1-WP8 and SWMU1-WP10, as shown in Figure B-4. A white powder lens was also observed at the toe of the slope near the floor of Bat Cave Wash beginning at sample location SWMU1-WP6a and tapering off at 10 feet south of sample location

SWMU1-WP7, as shown in Figure B-4. These observations are further investigated and discussed in Section B.5.1.

B.3.4 White Powder Material and Debris Mapping AOC 14 – Railroad Debris Site

Several areas of surficial white powder material were identified in AOC 14 during previous investigations and site visits. The surficial extent of the white powder material was quantified by various methods, as described below, and was plotted on a figure.

The extent of the white powder material in six areas of AOC 14 (AOC14-WP1 through AOC14-WP6) was documented by walking the perimeter of the visible white powder material, recording the GPS coordinates, and plotting those areas on a figure. The seventh area (AOC14-WP7) was located from a photograph of the I-40 road cut. The seven areas of white powder material observed are shown in Figure B-5. Sampling locations AOC14-1, AOC14-2, AOC14-11, AOC14-12, and AOC14-13 were collocated within white powder areas. White powder material areas AOC14-WP2, AOC14-WP5, and AOC13-WP6 were the only areas that had no sampling locations in the immediate proximity. During drilling activities at AOC 14, white powder material and/or debris were encountered in borings AOC14-2 (at 0.5 foot bgs) and AOC14-3 (at 2-3 feet bgs). Samples of the white powder material and debris were collected at these two locations and were sent to the laboratory for analyses, as shown in Table B-1.

In May 2009 PG&E conducted a site walk at AOC 14 in to map the debris areas. Debris was observed on the hill above AOC 14 towards the east. The debris consisted of concrete rubble, transite, cans, and miscellaneous trash; these debris areas are shown on Figures C7-1 to C7-7. No sampling has occurred in these debris areas. Nature and extent of contamination in these debris areas has not been defined. Section 8 presents the proposed Part A, Phase 2 sample locations within these debris areas.

Additional debris and burned debris was also identified on the west side of AOC 14, near a small drainage feature in the western wall of Bat Cave Wash near the northwestern edges of AOC 14 (see Figures C7-1 to C7-7). Some debris was noted on the side of the wash. The nature and extent of the debris toward Bat Cave Wash have not been defined.

B.4 Newly Identified Debris, Historic Burn, and White Powder Areas

In a letter dated May 15, 2009, DTSC directed PG&E to, among other items, to submit a formal description of historic burning operations, and of any previously undocumented disposal practices, at the Topock Compressor Station. PG&E has gathered information from interviews with current and former PG&E employees regarding historic burn activities on or near the PG&E Topock Compressor Station, as well as waste disposal activities that were not previously documented. PG&E attempted to contact many former PG&E employees and was successful in interviewing a total of twelve current and former PG&E employees on these topics, in addition to the fourteen interviewed during 2006. The information derived from the majority of the employee interviews and documentation of previously unidentified disposal practices was submitted to DTSC and DOI in a letter dated August 14, 2009 (PG&E 2009a). Supplemental information was provided in letters dated October 15, 2009 (PG&E

2009b), January 15, 2010 (PG&E 2010a), and January 29, 2010 (PG&E 2010b). All employee interviews were completed in time for the January 29, 2010 information submittal.

In addition, the major storm event in January 2010 exposed five new white powder areas (one in Bat Cave Wash, three in East Ravine, and one in AOC 11). These newly-identified areas are shown on Figure B-6 and are also included in the individual AOC data gaps evaluations in Appendix C.

B.5 Trenching

This section summarizes observations made during trenching activities at SWMU 1, AOC 4, and AOC 12. Soil and debris samples were collected from the trenches, as listed in Table B-1. Soil lithology and debris were logged by, or under the direction of a California Professional Geologist; the trench logs are located in Attachment B1.

B.5.1 SWMU 1 – Former Percolation Bed

Eight trenches were advanced into the eastern slope of Bat Cave Wash within SWMU 1 between October 5, 2008 and October 7, 2008 to assess the extent of white powder material. The locations of the eight trenches (SWMU1 WP1h, SWMU1 WP2h, SWMU1 WP3h, SWMU1 WP5h,[1] SWMU1 WP6h, SWMU1 WP7, SWMU1 WP8, and SWMU1 WP10) are shown in Figure B-4 and in Attachment B4, Photograph 1. Trench logs for these trenches are included in Attachment B1, B-1 through B-7.Trench dimensions were determined in the field to characterize extent while retaining slope integrity. Soil and white powder samples were collected from the trenches, as listed in Table B-1. Sample intervals are discussed below. Trench SWMU1 WP1h is located near the northern end of the white powder material and was approximately 4.5 feet long by 3 feet wide and extended approximately 7.5 feet into the slope, as shown in Attachment B4, Photograph 2. White powder material was not observed in this trench, shown in Attachment B4, Photographs 3 through 6. However, debris and green stained soil was observed in the north sidewall near the surface, as shown in Attachment B4, Photographs 7 and 8. Samples were collected at 0-0.5, 2-3, 5-6, and 9-10 feet bgs.

Trench SWMU1 WP3h was approximately 6.5 feet long by 3 feet wide and extended approximately 5 feet into the slope. A 1-foot-thick layer of white powder material was observed in the sidewalls of this trench, as shown in Attachment B4, Photographs 9 through 11. Due to the white powder observations in the sidewalls of this trench, a step-out trench (SWMU1 WP2h) was advanced approximately 3 feet north of trench SWMU1 WP3h, as shown in Figure B-4 and in Attachment B4, Photograph 12. A thin white powder material lens was observed on the south wall of this step-out trench. Samples were collected at 0-0.5, 2-3, and 5-6 feet bgs.

Trench SWMU1 WP5h was approximately 6 feet long by 3 feet wide and extended 10 feet into the slope. Only a small lens of white powder material was observed in the southern sidewall of the trench, as shown in Attachment B4, Photographs 13 through 16. Samples were collected at 0-0.5, 2-3, and 5-6 feet bgs. A sample of the white powder material (SWMU1 WP5h at 2-3 feet bgs) was collected and sent to the laboratory of analyses, as listed

---

[1] Because sample locations were named relative to prior sample locations, there is no location 4.

in Table B-1. Trench SWMU1 WP6h was approximately 4 feet long by 3 feet wide and extended approximately 10 feet into the slope. Two small white powder material lenses were observed in this trench, and small outcrops of white powder material were also observed in the back wall and north sidewall of the trench at approximately 2 feet bgs, as shown in Attachment B4, Photograph 17. Samples were collected at 0-0.5, 2-3, 5-6, and 9-10 feet bgs. A sample of the white powder material (SWMU1 WP6h at 0-0.5 foot bgs) was collected and sent to the laboratory of analyses, as listed in Table B-1.

Trench SWMU1 WP7 was approximately 9 feet long by 3 feet wide and extended approximately 11 feet into the slope. A 2-foot-thick layer of consolidated white chalky material was observed in the trench, as shown in Attachment B4, Photographs 18 through 20. Samples were collected at 0-0.5, 2-3, 5-6, and 9-10 feet bgs. A sample of the white powder material (SWMU1 WP7 at 2-3 feet bgs) was collected and sent to the laboratory of analyses, as listed in Table B-1. The white chalky material layer had a small area of red staining, shown in Attachment B4, Photograph 21. Under the layer of consolidated chalky material, a 1-foot layer of green stained soil was observed. In addition, a surficial layer of white powder material was observed at the toe of the slope beginning at sample location SWMU1 WP6a and tapering off 10 feet south of trench SWMU1 WP7, as shown in Figure B-4. Based on this observation, a small trench was advanced into the slope approximately 3 feet above the surficial layer. The horizontal lens of white powder material was observed beneath the surficial rock and rubble layer, as shown in Attachment B4, Photograph 22.

Trench SWMU1 WP8 was approximately 7 feet long by 3 feet wide and extended 10 feet into the slope, as shown in Attachment B4, Photograph 23. A 6-inch layer of green stained soil was observed beneath a surficial rock and rubble layer. Under the green stained soil layer, a layer of white powder material approximately 1 foot thick, followed by a second layer of green stained soil approximately 1 foot thick, were observed in this trench, as shown in Attachment B4, Photographs 24 through 26. Samples were collected at 0-0.5, 2-3, 5-6, and 9-10 feet bgs.

Trench SWMU1 WP10 was approximately 10 feet long by 3 feet wide and extended 9 feet into the slope, as shown in Attachment B4, Photograph 27. A layer of green stained soil approximately 6 inches thick was observed beneath a surficial rock and rubble layer. Under the green stained soil layer, a layer of white powder material approximately 6 inches thick, followed by a second layer of green stained soil approximately 6 inches thick, and followed by a second layer of white powder material approximately 1 foot thick, were observed in this trench, as shown in Attachment B4, Photographs 28 through 30. A sample of the white powder material (SWMU1 WP10 at 2-3 feet bgs) was collected and sent to the laboratory of analyses, as listed in Table B-1. Samples were collected at 0-0.5, 2-3, 5-6, and 9-10 feet bgs.

B.5.2 AOC 4 – Debris Ravine

Four trenches (AOC4-T1 through AOC4-T4) were advanced in AOC 4 between October 22, 2008 and October 24, 2008 to determine the nature and extent of buried debris. Trench locations were chosen based on visual observations of debris and on XRF analyzer field screening results for total chromium. Trench locations are shown in Figure B-2. Trench logs for these trenches are included in Attachment B1, B-8 through B-11.

Trench AOC4-T1 was installed slightly east of the established debris mapping grid, as shown in Figure B-2. The trench was approximately 8 feet by 2 feet and extended to 4 feet bgs, as shown in Attachment B5, Photograph 1. No significant debris was observed in this trench, with the exception of a metal wire in the east sidewall, shown in Attachment B5, Photograph 2. AOC4-T1a was collected in the center of the trench at 0.5 and 3 feet bgs.

Trench AOC4-T2 was installed to determine the extent of fill in the eastern portion of the ravine. The trench was approximately 20 feet by 2 feet and extended to 6 feet bgs, as shown in Attachment B5, Photograph 3. Trench AOC4-T2 extended into the undisturbed interior of the ravine, which was approximately 1 foot of fill. Debris observed in this trench included trash, household burned trash, laboratory glassware, tiles, and rope, as shown in Attachment B5, Photographs 4 and 5. There were three sampling locations in this trench: AOC4-T2a (3-4 feet bgs), AOC4-T2b (2-3 and 7-8 feet bgs), and AOC4-T2c (0-0.5 and 2-3 feet bgs).

Trench AOC4-T3 was installed at the top of the primary ravine slope, as shown in Attachment B5, Photograph 6. This trench was approximately 25 feet long by 3 feet wide and extended to 4.5 feet bgs, as shown in Attachment B5, Photograph 7. A rusted pipe was observed in the west sidewall, shown in Attachment B5, Photograph 8. There was also green stained soil and a yellow coated rock found in this trench. There were three sampling locations in this trench: AOC4-T3a (2-3 feet bgs), AOC4-T3b (2-3 feet bgs), and AOC4-T3c (2-3 feet bgs).

Trench AOC4-T4 was also located at the top of the primary ravine slope, west of trench AOC4-T3 (Attachment B5, Photograph 9). This trench was approximately 25 feet long by 3 feet wide and extended to 4.5 feet bgs. No debris or discolored soil was observed in this trench. There were three sampling locations in this trench: AOC4-T4a (2-3 feet bgs), AOC4-T4b (2-3 feet bgs), and AOC4-T4c (2-3 feet bgs).

B.5.3 AOC 12 – Fill Area

Five trenches were proposed in AOC 12 to assess three potential debris disposal areas (AOC 12a, AOC 12b, and AOC 12c), as shown on Figure B-1. Trench logs for these trenches are included in Attachment B1, Figures B-12 through B-16. Prior to trenching activities at AOC 12, a geophysical survey was performed at each trench location to attempt to locate buried debris and to identify the location of underground utility infrastructure. The results of the surveys identified two alignments crossing AOC 12a, which were positively identified by PG&E via hand digging as a PG&E gas pipeline and associated cathodic protection wire. In AOC 12b and AOC 12c, geophysical results indicated two undifferentiated utilities (UUs) extending east from aboveground storage tank bunker pipe stub-outs.

The trenches were advanced in AOC 12 at the locations specified in the work plan between September 20, 2008 and September 22, 2008. Aside from the underground utility structures, anomalies that may be attributable to buried debris were not observed. Complete geophysical survey results are presented in Attachment B6.

Trench AOC12a-T1, located in potential disposal area AOC 12a, was approximately 18 feet long by 2.5 feet wide and extended to 8 feet bgs. There were two sampling locations in this trench: AOC12a-T1a (0-0.5, 2-3, and 7-8 feet bgs) and AOC12a-T1c (7-8 feet bgs). Trench AOC12a-T2 is perpendicular to and intersects trench AOC12a-T1, as shown on Figure B-1.

Trench AOC12a-T2 was approximately 12 feet long by 2.5 feet wide and extended to 8 feet bgs to native material, as shown in Attachment B7, Photograph 1. There were two sampling locations in this trench: AOC12a-T2a (6-7 feet bgs) and AOC12a-T2b (7-8 feet bgs). No debris was observed in either of these trenches.

Trench AOC12b-T1, located in potential disposal area AOC 12b, was approximately 35 feet long by 2.5 feet wide and extended to 3 feet bgs to native material, as shown in Attachment B7, Photographs 2 and 3. There were two sampling locations in this trench: AOC12b-T1a (2-3 feet bgs) and AOC12b-T1b (2-3 feet bgs). No debris was observed in the trench.

In area AOC 12c, two trenches were advanced (AOC12c-T1 and AOC12c-T2). Trench AOC12c-T1 was approximately 20 feet long by 2.5 feet wide and extended to 11 feet bgs, as shown in Attachment B7, Photograph 4. There were three sampling locations in this trench: AOC12c-T1a (0-0.5, 2-3, and 10-11 feet bgs), AOC12c-T1b (2-3, 3-4, and 10-11 feet bgs), and AOC12c-T1c (10-11 feet bgs).

Trench AOC12c-T2 intersects trench AOC12c-T1, as shown in Figure B-1. Trench AOC12c-T2 was approximately 20 feet long by 2.5 feet wide and extended to 8 feet bgs, as shown in Attachment B7, Photographs 5 and 6. There were two sampling locations in this trench: AOC12c-T2a (7-8 feet bgs) and AOC12c-T2b (7-8 feet bgs). A large piece of concrete (at approximately 1.5 feet bgs), small piece of wire (at approximately 5 feet bgs), an 18-inch wooden slat, plastic debris, and a bung cover from a polyethylene drum were observed in trench AOC12c-T1, as shown in Attachment B7, Photographs 7 and 8.

B.6 Geophysical Survey - UA 1 – Potential Pipeline Disposal Area

A geophysical survey was performed in UA 1 to evaluate the potential presence of buried asbestos-wrapped metal pipes in this area and to identify the location of underground utility infrastructure. Results of the geophysical survey did not suggest the presence of buried pipes in this area; however, several small metallic anomalies and two UUs were observed sporadically across the UA 1 area. One UU was truncated in the north and extended out of the survey area in the south, and the other UU was located in the southern portion of the survey area trending east-west. Complete geophysical survey results are presented in Attachment B6.

Following the geophysical survey, further visual assessment of the area in the vicinity of UA 1 identified miscellaneous pipe band clamps and small quantities of insulation to the east of UA 1. A pronounced soil mound approximately 100 feet long by 25 feet wide is also observed in this area. The initial location of UA 1 was based on tentative identification by a former employee; due to the long period of time that had elapsed since the disposal activities allegedly took place, it is possible that the area initially identified was off-set from the actual location.

B.7 Deviations from the Draft Work Plan

Table B-1 lists deviations from the Draft Work Plan. Deviations to the workplan fall into two categories:

1. Additional samples or locations added based on agency comments
2. Collection of proposed samples not possible due encountering refusal or groundwater

Notes:

[a] Agencies requested that 10 percent of all soil samples collected in an AOC/SWMU be analyzed for the United States Environmental Protection Agency CLP TAL/TCL analytical suite.

AOC	Area of Concern
CLP TAL	United States Environmental Protection Agency Contract Laboratory Program Target Analyte List
CLP TCL	United States Environmental Protection Agency Contract Laboratory Program Target Compound List
ft bgs	feet below ground surface
NA	not applicable
PAH	polycyclic aromatic hydrocarbon
PCB	polychlorinated biphenyl
SPLP	synthetic precipitation leaching procedure
SVOC	semivolatile organic compounds

	SILTY GRAVEL (GM): yellowish brown (10YR 5/4), (50% gravel/10% sand/40% fines), poorly graded, subangular to angular, no dominant mineralogy, sand is fine-grained only, loose to medium density to five ft bgs, moderate to dense sand to 10 ft bgs, loose to medium density to 28 ft bgs, clast-or-matrix supported (varied), dry, max clast size =50mm.	Purpose of boring is to establish lithology to groundwater and/or to bedrock, not to exceed 100 ft bgs. Drill rates varied but met refusal at 90 feet bgs. Borehole integrity supplemented by 6" steel casing. Casing advanced to 70 ft bgs by end of 9/22/08 while boring advanced to 80 feet bgs by end of 9/22/08. Borehole caved in below 70 ft bgs by start of day 9/23/08. Water encountered at 80 ft bgs. Nearby well yielded groundwater level of 78 ft bgs. No presence of dark reddish-brown miocene conglomerate at this location. bedrock is granitic in nature.

INTERVAL (ft) RECOVERY (ft) SAMPLE INTERVAL	SOIL NAME, USCS GROUP SYMBOL, COLOR, MOISTURE CONTENT, RELATIVE DENSITY OR CONSISTENCY, SOIL STRUCTURE, MINERALOGY	DEPTH OF CASING, DRILLING RATE, DRILLING FLUID LOSS, TESTS, AND INSTRUMENTATION

GRAVELLY SILT with sand (ML) pale brown (7.5YR 6/3), dry, no odor, poorly sorted (30% gravel/20% sand/50% fines) max diameter=6 cm, angular to subangular, metamorphic.

Refusal at 10 ft. bgs. Will direct sonic rig to drill this location to collect entire sample set. Backfilled with hydrated bentonite chips.

Total Depth at 10 ft below ground surface

RE: PG&E Topock

Attention: Shawn P. Duffy

Enclosed are the results for sample(s) received on December 12, 2008 by Advanced Technology Laboratories - Las Vegas . The sample(s) are tested for the parameters as indicated in the enclosed chain of custody in accordance with the applicable laboratory certifications.

The attached report is the final hard copy pertaining to the subcontracted tests for the above project.

Thank you for the opportunity to service the needs of your company.

Please feel free to call me at (702) 307-2659 if I can be of further assistance to your company.

Sincerely,

Jose Tenorio Jr.
Laboratory Director

This cover letter is an integral part of this analytical report.

CLIENT: Advanced Technology Laboratory-Las Vega
Project:
Lab Order: 103157

CASE NARRATIVE

Sample Receiving/General Comments

1. All sample containers were received intact with proper chain of custody documentation.
2. Information on sample receipt conditions including discrepancies can be found in attached Sample Receipt Checklist Form.
3. Sample preservation were verified upon receipt of samples, if applicable.
4. All samples were analyzed within method holding times.

Analytical Comments for Method 6010B

1. For sample 103157-001A, dilution was necessary due to sample matrix.

RE: PG&E Topock

Attention: Shawn P. Duffy

Enclosed are the results for sample(s) received on December 12, 2008 by Advanced Technology Laboratories - Las Vegas . The sample(s) are tested for the parameters as indicated in the enclosed chain of custody in accordance with the applicable laboratory certifications.

Thank you for the opportunity to service the needs of your company.

Please feel free to call me at (702) 307-2659 if I can be of further assistance to your company.

Sincerely,

Jose Tenorio Jr.
Laboratory Director

Advanced Technology Laboratories - Las Vega **Date:** *29-Dec-08*

CLIENT: CH2M HILL
Project: PG&E Topock
Lab Order: N002424

CASE NARRATIVE

SAMPLE RECEIVING/GENERAL COMMENTS

All sample containers were received intact with proper chain of custody documentation.

Information on sample receipt conditions including discrepancies can be found in attached Sample Receipt Checklist Form.

Cooler temperature and sample preservation were verified upon receipt of samples if applicable.

Samples were analyzed within method holding time.

Subcontracted Analysis:

Mercury (EPA 7471A), SVOC (EPA 8270C), Pesticides (EPA 8081A) and PCBs (EPA 8082) were subcontracted to Advanced Technology Laboratories-Signal Hill, CA.

Analytical Comments for EPA 6010B:

Matrix Spike Duplicate (MSD) recovery for Chromium was out of recovery criteria for sample N002424-001AMSD possibly due to matrix interference. A post digestion spike was performed on the sample and demonstrated recoveries within acceptance limits. Laboratory Control Sample (LCS) and Laboratory Control Sample Duplicate (LCSD) were within acceptance crtieria.

RE:

Attention: Marlon Cartin

Enclosed are the results for sample(s) received on December 13, 2008 by Advanced Technology Laboratories . The sample(s) are tested for the parameters as indicated in the enclosed chain of custody in accordance with the applicable laboratory certifications.

Thank you for the opportunity to service the needs of your company.

Please feel free to call me at (562)989-4045 if I can be of further assistance to your company.

Sincerely,

Eddie F. Rodriguez
Laboratory Director

CASE NARRATIVE

Sample Receiving/General Comments

1. All sample containers were received intact with proper chain of custody documentation.
2. Information on sample receipt conditions including discrepancies can be found in attached Sample Receipt Checklist Form.
3. Sample preservation were verified upon receipt of samples, if applicable.
4. All samples were analyzed within method holding times.

Analytical Comments for EPA 8270C

1. For samples 102700-003AMS and 102700-003AMSD, LCS-51263 and LCSD-51263, 4-Bromophenyl-phenylether recovery was biased high. Sample results were non-detects (ND) for these analytes therefore reanalysis of the sample was not necessary.

Geophysical Results

NORCAL GEOPHYSICAL CONSULTANTS, INC.

October 1, 2008

Mr. Mike Cavaliere
CH2M Hill Inc.
155 Grand Avenue, Suite 1000
Oakland, CA 94612

Subject: Geophysical Survey
PG&E Topock Compressor Station, Needles, CA
NORCAL Job Number 08-106.47

Dear Mr. Cavaliere:

This letter presents the findings of a geophysical investigation performed by NORCAL Geophysical Consultants, Inc. on the property located at the PG&E Topock Compressor Station, Needles, CA. The field survey was conducted on September 4 - 5, 2008 by NORCAL Professional Geophysicist Sierra Boyd and Geophysical Technician Travis Black. Logistical support and background information were provided by Mike Cavaliere, CH2M Hill Inc., and Barry Collum, Site Coordinator/On-Site Safety Officer, Topock Compressor Station.

SITE DESCRIPTION

The PG&E Topock Compressor Station is located off of Highway 40, west of the Colorado River, California/Arizona border, approximately 14 miles southeast of Needles, CA. The facility provides pressure to natural gas which is piped from Texas to central and northern California. The Compressor Station is located in dry rocky terrain with sparse desert vegetation.

The geophysical survey was conducted in several regions known as Areas of Concern (AOC), as shown on Plates 1 and 2. The regions include AOC–12A, AOC-12B and AOC-12C in the vicinity of the Transwestern Gas Pipeline Intertie. An additional survey area, called AOC UA-1 Potential Pipe Disposal Area, is located approximately 2600 feet to the southwest from the Transwestern Gas Pipeline Intertie. Details of each survey area are described below.

AOC-12A

The area of concern is located in a small ravine northeast of the Transwestern Gas Pipeline Intertie, as shown on Plate 1. The terrain is rocky and uneven with a steep slope in the southern portion of the survey area. Site features include several bushes and pin flags delineating two suspected pipelines crossing the region.

AOC-12B&C

These two small areas are located along the western perimeter of the Transwestern Gas Pipeline Intertie, as shown on Plate 1. To simplify data acquisition, these two areas were combined into AOC-12B & C. There is a steep drop-off to the west and an earthen mound to the north which create an irregularly shaped survey area. The facility is surrounded by chain link fencing which was removed in the vicinity of the survey area. The metal fence posts surrounding the former Above-ground Storage Tank (AST) pad and AST bunker were left in place, as shown on Plate 1.The AST pad and bunker are enclosed by cement retaining walls. In the south there is a large metal container with miscellaneous pipes and rolls of chain link fencing stored nearby.

AOC UA-1 Potential Pipe Disposal Area

This area is located approximately 2600 feet to the southwest of the Transwestern Gas Pipeline Intertie. The region is flat and bordered by a dirt road to the south, a steep drop-off to the west and a steep slope to the east, as shown on Plate 2. There are two monitoring wells surrounded by metal bollards located in the southeast and southwest as well as several large bushes. The surface appears uneven, perhaps due to differences in fill materials.

PURPOSE

Future plans for AOC-12A, AOC-12B and AOC-12C include trenching. The purpose of the geophysical surveys is to locate detectable utilities and buried metallic debris in the vicinity of the proposed trenching sites. The purpose of the survey in AOC UA-1 is to locate possible buried pipes, utilities and buried metallic debris.

FIELD INVESTIGATIONS

Methodology

We used vertical magnetic gradient (VMG), electromagnetic (EM), metal detection-electromagnetic line locating (MD-EMLL) and ground penetrating radar (GPR) methods to investigate for detectable subsurface features and debris.

The VMG method is used to determine the presence of buried ferrous metal objects. These objects could include various metallic debris and utilities. We used a Geometrics G-858 cesium vapor magnetometer to obtain the vertical magnetic gradient data, since it provides high sensitivity and rapid data acquisition.

The EM instrument records terrain conductivity (TC). TC values represent the electrical conductivity of the subsurface to a depth of approximately 12 to 15 feet. These values can be affected by both metallic and nonmetallic debris. The effect that ferrous or nonferrous metal will have on the TC readings is dependent upon the depth and size of the metal object. In addition, subsurface properties such as differences in soil compaction, composition and water content of fill materials can also affect TC values. We performed the TC survey using a Geonics EM31-DL ground conductivity meter connected to an Omnidata recorder.

The MD-EMLL methods are used to scan for near surface metal objects and the presence of metallic utilities. We used the Fischer TW-6 M-Scope to perform the MD survey and the Radio Detection 4000 for the EMLL portion of the survey.

The GPR method is used to aid in further characterizing the source of detected VMG, TC and MD-EMLL anomalies or for additional information where these methods experienced interference from above ground sources. We used a Geophysical Survey Systems, Inc. SIR-3000 Subsurface Interface Radar System equipped with a 400 megaHertz (MHz) transducer. This transducer is near the center of the available frequency range and is used to provide high resolution at shallow depths. Descriptions of the VMG, TC, MD-EMLL, and GPR methods are provided in Appendix A.

Geophysical Surveys

Prior to proceeding with the geophysical work, we established a survey grid to provide horizontal control for each of the areas. The grids are based on a rectangular coordinate system with the origin (0E, 0N) located in the southwest corner of the survey areas. We established the grid in the field using a fiberglass measuring tape and wooden survey lath. The lath was used in lieu of spray paint at the request of CH2M Hill. The grids were then used to guide the VMG, TC, MD-EMLL and GPR surveys.

VMG and TC data were obtained at 5-ft. intervals along south-north trending traverses spaced 5 feet apart. Following data acquisition, we transferred the VMG and TC data to a personal computer and contoured the respective data sets to produce VMG and TC contour maps. Each contour map was analyzed to determine potential locations of buried metallic debris, utilities and other subsurface features. Further processing was completed at our Cotati office.

We also scanned each of the survey areas with the MD-EMLL equipment to further characterize detectable subsurface features. Further investigations over suspect VMG, TC and MD-EMLL anomalies were conducted using GPR along south-north and/or west-east trending traverses. The GPR records were examined for reflection patterns characteristic of buried pipes and other subsurface features.

Following the geophysical data acquisition, we used a Trimble GeoExplorer 2005 Series global positioning system (GPS) to survey selected grid nodes and site features. The limits of the survey areas are shown on Plates 1 and 2.

RESULTS and INTERPRETATION

The results of the geophysical investigation of the respective survey areas are presented on Plates 3, 4 and 5. These plates show pertinent site features, limits of the VMG-TC survey areas, and the respective VMG Contour and TC Color Image Maps. The VMG Contour Map shows variations of the VMG values. Typically, closely spaced contours or contours forming localized contour closures are normally caused by specific metallic sources. Variations that can not be associated with known above or below ground features are considered anomalous. The TC

Color Image Map shows variations in terrain conductivity ranging from low values (blue shades) to high values (red shades), as indicated by the color scale shown with the map. Also shown are the lateral extents of suspected MD-EMLL anomalies that are typically caused by near surface metallic sources.

AOC–12A Geophysical Results, Plate 3

Magnetic Survey

The VMG results show numerous closely spaced contour closures extending across the central portion of the survey area, as shown on Plate 3. This anomalous zone is approximately 30 feet wide and consists of an alignment of densely spaced contour closures with both positive and negative peaks. The areal extent of the contour closures is large, and the peaks have extreme high and low values, suggesting a large source buried near the surface. There is an alignment of less intense, loosely spaced contour closures to the north, suggestive of a possible additional metallic source. Due to the linearity, these anomalies may represent pipelines.

Terrain Conductivity Survey

The TC Color Image Map shows two linear features, extending across the central portion of the survey area, which correlates with the VMG results. One linear feature is shaded yellow and is located between 15 and 25 feet north of another linear feature shaded blue. The difference in color corresponds to a difference in conductivity values. Blue shades correspond to extreme negative conductivity values and yellows correspond to mid-range conductivity values. The southern linear anomaly is larger and has more extreme conductivity values, suggestive of a larger source buried closer to the surface in relation to the northern anomaly.

Metal Detector – Electromagnetic Line Locating Survey

The MD emitted a strong continuous tone in the vicinity of the southern linear anomaly, suggestive of a metallic pipeline. There was no audible signal in the vicinity of the suspected anomaly to the north. The EMLL equipment detected both linear anomalies that appear to be due to pipelines or tracer lines associated with possible pipelines.

Ground Penetrating Radar Survey

Four GPR profiles were collected across the suspected pipelines, as shown on Plate 1. The profiles over the southern pipeline display characteristics typical of a large buried pipe with an approximate diameter of 3.0 to 4.0 ft., buried less than one foot below the surface. There were no indications of a buried pipeline to the north.

AOC–12B & C Geophysical Results, Plate 4

Magnetic Survey

The VMG contour map shows numerous closely spaced contour closures throughout the area. They correlate with above ground surface features as shown on Plate 4. There is a north-south trending linear alignment of closely spaced circular contour closures that correlates with the north-south equally-spaced fence posts. Additional fence posts extending to the east and remnants of the chain link fence stored nearby also contribute to the numerous contour closures in the north and south.

Terrain Conductivity Survey

The TC Color Image Map shows very uniform conductivity variations over the site. The only color variations are caused by the former AST pad and the AST bunker. There appears to be no evidence of UST's or buried debris.

Metal Detector-Electromagnetic Line Locating Survey

Two suspected undifferentiated utilities (UU's) extending east from two AST pipe stub-outs were detected.

AOC UA-1 Potential Pipe Disposal Area Geophysical Results, Plate 5

Magnetic Survey

The VMG Contour Map shows numerous closely spaced contour closures throughout the site. The strongest variations are associated with the two monitoring wells, and along the southern boundary. Additional scattered anomalies appear to be related to small scattered debris observed on the ground surface.

Terrain Conductivity Survey

The TC Color Image Map shows subtle TC variations throughout the site. Lower conductivity values are shown along the eastern and western boundaries where there are steep elevation changes. High conductivities are shown along the southern boundary bordering the dirt road.

Metal Detector – Electromagnetic Line Locating Survey

The MD-EMLL survey delineated two linear anomalies suspected to be pipelines, as shown on Plate 5. The north trending pipeline bends to the east where it appears to be truncated, and extends out of the survey area in the south. The EMLL depth estimate for the north-south trending portion is shallow, ranging from 11 to 16 inches below the surface. The east-west trending pipeline along the southern boundary of the site may truncate to the east and west as shown. There is no evidence for additional pipelines within the survey area.

SUMMARY

Several geophysical methods including vertical magnetic gradient, terrain conductivity, metal detection, electromagnetic line locating and ground penetrating radar were used to investigate portions of the PG&E Topock Compressor Station (Plates 1 and 2) for buried debris, undifferentiated utilities (UU's) and buried pipes.

- The results of the geophysical surveys found two alignments crossing AOC-12A, as shown on Plate 3. The southern alignment is an interpreted large pipeline, approximately 3 to 4 feet in diameter, buried within the upper 1 foot of the surface. The northern alignment is a suspected pipeline or UU, buried deeper, within 3 to 4 feet below the surface.
- In AOC-12B&C, the geophysical results indicate two suspected UU's extending east from two AST Bunker pipe stub outs, as shown on Plate 4. There is no evidence for additional buried debris within this survey area.
- In AOC UA-1 two suspected UU's were detected, as shown on Plate 5. The north to south trending UU appears to be buried within 1.5 ft. below the surface. The suspected UU appears to be truncated in the north and extends out of the survey area in the south. Another suspected UU is located in the southern portion of the survey area and trends east-west. The ends appear to be truncated. There were no indications of buried debris or pipes other than those mentioned above.

STANDARD CARE AND WARRANTY

Please note that all geophysical methods have limitations that may not allow for the detection of certain subsurface features or targets. These limitations may be related to the target being deeper than instrument detection capabilities; target not providing sufficient contrast with the surrounding materials; or other features or structures causing instrumental interference that masks the detection of a target of interest. Therefore it is possible that not all subsurface features/targets may be located or characterized.

The scope of NORCAL's services for this project consisted of using geophysical methods to characterize the shallow subsurface. The accuracy of our findings is subject to specific site conditions and limitations inherent to the techniques used. We performed our services in a manner consistent with the standard of care ordinarily exercised by members of the profession currently employing similar methods. No warranty, with respect to the performance of services or products delivered under this agreement, expressed or implied, is made by NORCAL.

We appreciate having the opportunity to provide our services to CH2M Hill Inc. for this investigation.

Respectfully,

NORCAL Geophysical Consultants, Inc.

O. Sierra Boyd

GEOPHYSICAL METHODOLOGY, INSTRUMENTATION, DATA ANALYSIS and LIMITATIONS

VERTICAL MAGNETIC GRADIENT (VMG)

VMG Methodology

Vertical magnetic gradient surveys are used to determine the presence of buried ferrous objects. A magnetic gradiometer measures the vertical gradient of the earth's magnetic field. It consists of two total field magnetic sensors separated vertically by one-half meter. The magnetic field strength is measured simultaneously at both of these sensors. The difference in magnetic intensity between these measurements is proportional to the vertical gradient of the earth's magnetic field. Because the vertical gradient is constant with respect to time, the effect of diurnal variations is eliminated. Therefore, a gradiometer provides higher sensitivity and better resolution of near surface sources than total field magnetometers. Areas with significant amounts of buried metal typically produce anomalously steep magnetic gradients. Since it is sensitive to ferrous metal sources both above and below ground, site and vicinity surface conditions can affect survey results.

We typically use a Geometrics G-858 cesium vapor magnetometer to obtain vertical magnetic gradient data. This instrument features a built-in memory that stores the vertical magnetic gradient and survey grid information. The information can be down loaded to a computer for further processing.

Data Analysis

Computer Processing

The VMG data are down loaded to a lap-top computer and converted it into a format for contouring. The contouring program (SURFER Version 8.0 by Golden Software) calculates an evenly spaced array of values (grid) based on the observed field data. Finally, these gridded values are contoured to produce a VMG contour map.

Contour Map Interpretation

The VMG contour map illustrates the variations in the vertical magnetic gradient across the site. Areas without below or above ground ferrous metal are characterized by very low magnetic gradients. In these areas, there are very few contours. In areas with above or below ground ferrous metal, the magnetic gradient is relatively steep. These areas are characterized by numerous closely spaced contours and are considered anomalous. If the source of the anomaly is linear (e.g. underground utilities or fence lines), then the contours tend to be parallel and evenly distributed. If the source of the anomaly is localized (e.g. sign post, buried drum, etc.), then the contours tend to form circular or elliptical closures proportional to the size of the object. The larger the object and the closer it is to the magnetometer, the denser the concentrations of contours. Magnetic anomalies that cannot be attributed to above ground objects (fences, vehicles, buildings, etc.) are probably caused by buried objects.

USTs are often characterized by circular to elliptical contour closures. These closures have magnitudes ranging from several hundred to several thousand nano-Tesla per meter (nT/m) depending on the size and depth of the tank. If the UST is cylindrical and lying horizontally, it will often produce a bi-polar VMG anomaly. This consists of two adjacent contour closures. One has VMG values that increase towards the center of the closure and is referred to as a positive lobe. The second has VMG values that decrease towards the center of the closure and is referred to as a negative lobe. Typically, the positive lobe is situated directly above the UST and the negative lobe is to the north of the UST. Utilities and scattered metal debris, on the other hand, are generally characterized by single circular or irregular shaped negative lobes, or a group of alternating positive and negative lobes (closures). These closures typically have magnitudes ranging from less than fifty to several hundred nano-Tesla per meter (nT/m) depending on the size, depth, and amount of utilities and debris in a given area.

Limitations

Below ground metal ferrous objects produce localized variations in the earth's magnetic field. The magnetic intensity associated with buried metal depends on the mass of the metal and the distance the metal object is from the magnetometer sensor. As the distance between the object and the magnetometer sensor increases, the intensity of the associated field decreases, thereby making detection more difficult. In addition, the ability to detect a buried metal object is based on the intensity of these variations versus the intensity of the background variations. Background variations can be caused by other nearby above or below ground metallic sources. Cultural features such as chain link fences, buildings, debris, railroad spurs, utilities, above ground electric lines, etc. typically produce numerous magnetic variations with high intensities. These variations may mask effects from buried metal objects, or make it very difficult to determine whether the magnetic variations are associated with below ground metal or above/below ground cultural features.

ELECTROMAGNETIC (EM)

EM Methodology

The electromagnetic method is used to measure variations in subsurface electrical conductivity that may be due to buried foreign objects or changes in subsurface materials. The electromagnetic system utilizes two coils separated by a specified distance. One of these coils transmits a time-varying electromagnetic signal (primary magnetic field) which induces current flow in the earth. This in turn creates a secondary magnetic field which is detected by the receiver coil. The secondary signal is complex and has both quadrature and in-phase components. The amplitude of the quadrature component is proportional to the electrical conductivity of the subsurface materials. The in-phase component is proportional to conductivity, but is also affected by electrical properties associated with metal objects. The instrument displays the quadrature component in units of milliSiemens/meter (mS/m). Since this measurement represents the conductivity of the volume of material sampled, rather than individual layers, it is an apparent value and is referred to as terrain conductivity (TC). The instrument displays the in-phase component (IPC) value in units of parts per thousand (ppt).

Electromagnetic surveys are typically conducted using a Geonics EM31-DL ground conductivity meter connected to an Omnidata data recorder. The EM31 has a fixed coil separation of 12 feet, which results in a total depth of investigation of approximately 10 to 15 feet depending upon local site conditions. The data recorder automatically stores the EM values as well as station locations and annotations regarding cultural features.

Data Analysis:

Computer Processing

The EM data are downloaded to a lap-top computer and converted into a format for contouring. The contouring program (SURFER Version 8.0 by Golden Software) calculates an evenly spaced array of values (grid) based on the observed field data. Finally, these gridded values are contoured to produce TC and IPC contour maps.

Contour Map Interpretation

The TC and IPC contour maps show the variations in the electromagnetic terrain conductivity and in-phase component values within the survey area. The contour map is characterized by a series of contour lines that represent specific values. Areas that lack contour lines, or where the contours are spaced far apart, indicate a minimal change or variation in the respective values. This is indicative of relatively uniform conditions. Areas where contours are closely spaced indicate variations that are not uniform and probably caused by local sources.

In areas where there are significant quantities of above or below ground metal objects, the measured values are relatively large. These areas are characterized by numerous closely spaced contours. If the source of the anomaly is linear (e.g. underground utilities, railroad spurs, culvert, etc.), then the contours tend to parallel the object, and are closely spaced in close proximity to the object. If the below ground source is localized (e.g. UST, buried drum, isolated metal debris, etc.), then the contours tend to form circular or elliptical closures that enclose the object. The larger the object and the closer it is to the geophysical instrument, the more contours there are in a given area.

Buried landfill material is often characterized by circular to elliptical contour closures. These closures can vary from large circular closures that cover broad areas, to clusters of small closures that occur in zones. If the composition of the landfill is generally homogenous and nonmetallic, the contours tend to form large closures representing a decrease in value. If the fill material consists of both nonmetallic and metallic debris that varies significantly throughout the landfill, the contours tend to occur as numerous small closures representing both high and low values.

Limitations

There are inherent limitations associated with EM techniques that may not allow for the detection of all subsurface features of interest. These limitations are related to the composition of the subsurface feature, its size and depth of burial, and its proximity to other above or below ground features. In general, as the distance between a subsurface object and the respective geophysical instrument increases, the intensity of the associated field decreases, thereby making detection more difficult. In addition, above and below ground objects, such as buildings, debris, utilities, above ground electric lines, etc., typically produce interference that may mask effects from nearby buried features (targets).

Apart from the physical limitations of the instrument and the unwanted effects from secondary objects, the ability to detect subsurface features is also dependent upon the density of data acquisition points. If the distance between data acquisition points is significantly larger than the size of the subsurface feature, then this object may not be detectable.

METAL DETECTION (MD)

MD Methodology

This method uses the principle of electromagnetic induction to detect shallowly buried metal objects such as USTs, metal utility conduits, rebar in concrete, manhole covers, and various metallic debris. This is done by carrying a hand-held radio transmitter-receiver unit above the ground and continuously scanning the surface. A primary coil broadcasts a radio signal from a transmitter which induces secondary electrical currents in metal objects. These secondary currents in turn produce a magnetic field which is detected by the receiver.

Instrumentation

The MD instrument that we typically use for shallow subsurface investigations is a Fisher TW-6 pipe and cable locator. This instrument is expressly designed to detect metallic pipes, cables, USTs, manhole covers, and other large, shallowly buried metallic objects. The instrument operates by generating both a meter reading (unitless) and an audible response when near a metal object. The peak instrument response usually occurs when the unit is directly over the object. The TW-6 does not provide a recordable data output that can be used for later computer processing. Results are generally limited to marking the interpreted outlines of detected objects in the field and mapping their locations.

Limitations

In general, the response of the MD instrument is roughly proportional to the horizontal surface area of near surface buried objects (typically in the upper three or four feet). This relationship can be used to advantage in discriminating between metal debris, reinforced concrete pads, and pipelines. However, in the presence of above ground metal objects such as fences, walls, parked cars, and metal debris, this is no longer valid. In some instances, the presence of such objects can make it very difficult to determine whether the instrument responses are associated with below ground targets or above ground cultural features. When multiple sources are present it may not be possible to identify individual targets. Also, relatively large objects that have a limited horizontal cross-section such as well casing and fence posts are sometimes difficult to detect.

GROUND PENETRATING RADAR (GPR)

GPR Methodology

Ground penetrating radar is a method that provides a continuous, high resolution graphical cross-section of the shallow subsurface. The method entails repeatedly radiating an electromagnetic pulse into the ground from an antenna as it is moved along a traverse. Reflected signals are received by an antenna (often the same one used to generate the signal) and sent to a control unit for processing. The control unit then converts the varying amplitude of reflected radar signals as a function of time into a cross-sectional image showing signal amplitude as a function of depth.

GPR is particularly sensitive to variations of two electrical properties. One property is conductivity (the ability of a material to conduct a charge when a field is applied) and the other is permittivity (the ability of a material to hold a charge when a field is applied). These two properties determine how far a signal can propagate. They also determine the strength of reflected signals that can be generated at material boundaries. Most soil and earthen-like materials such as concrete are electrically resistive and have a relatively low permittivity. As a result, they are relatively transparent to electromagnetic energy. This means that only a portion of the radar signal incident upon them is reflected back to the surface. On the other hand, when the signal encounters an object composed of a material that has the opposite electrical properties, especially one with a high permittivity (such as metal) much of the incident energy is reflected.

Instrumentation

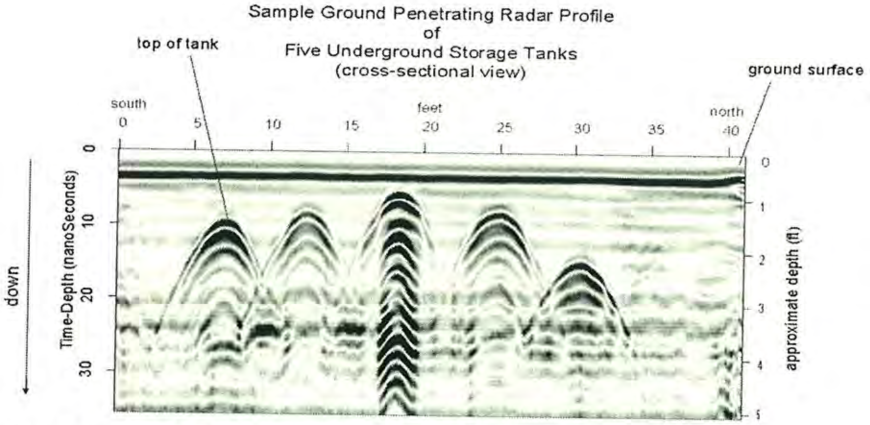
We typically perform GPR surveys using a Geophysical Survey Systems, Inc. SIR-3000 Subsurface Interface Radar System equipped with a 500 megahertz (MHz) transducer. This unit is comprised of a combined control/data recording console that is connected by a telemetry cable to the antenna. This system is often chosen for investigating environmental sites since it usually provides both the resolution and depth penetration needed for characterizing the upper three to four feet of the subsurface.

Data Interpretation

The interpretation of GPR data involves examining the graphical records for reflections from buried objects. GPR records display changes in reflected signal strength and arrival time with changes in horizontal position. Strong signals appear dark and weak reflections appear light. Reflections that arrive earlier in time are placed in the upper portions of the record and reflections that arrive later are placed lower, towards the bottom of the records. Horizontal position is across the top of the record.

In areas with relatively uniform conditions, with no buried objects producing reflections, the records typically appear as a series of alternating dark and light horizontal bands. In areas where there are subsurface objects producing reflections, the horizontal banding is disrupted. Discrete objects typically produce reflections having the appearance of inverted "U"s, forming what are known as "hyperbolic reflections". Metallic objects often produce markedly strong reflections, in many cases forming multiple reflections appearing as a series of inverted U's cascading down the record. Non-metallic objects can produce similar reflections, but the multiples are typically much weaker.

A sample profile from a different site with five adjacent steel USTs is presented below:



Sample Ground Penetrating Radar Profile
of
Five Underground Storage Tanks
(cross-sectional view)

Note: the "Time Depth" of 35 nanoSeconds at the bottom of this profile corresponds to a true depth of approximately 5 feet for this example only. Actual depth to bottom of other profiles may be different.

An object's burial depth may also be estimated from GPR profiles. As mentioned above, GPR measures signal amplitude as a function of time. However, the translation of the radar signal's travel time (technically known as time-depth) to an actual distance (true depth) is not always a simple one. Strictly speaking, in order to translate from time-depth to true depth the signal velocity within each time interval must be known. Since this is not routinely determined in the field, estimated velocities are often used for determining the approximate depth to a reflector. The empirical values for GPR signal propagation velocities within commonly encountered soils are obtained from published tables.

Limitations

The ability to detect subsurface targets is dependent on specific site conditions. These conditions include depth of burial, the size or diameter of the target, the condition of the specific target in question, the type of backfill material associated with the target, and the surface conditions over the target. Typically, the depth of detection will be reduced as the clay and/or moisture content in the subsurface increases. As a result, depths of detection (using a 500 Mhz antenna) typically range from as deep as six feet to as little as a few inches.

APPENDIX C

Part A Phase 1 Soil Investigation Data Gaps Evaluation Results

This appendix presents the results of the Part A Phase 1 Data Gaps Evaluation for the following areas:

- Solid Waste Management Unit (SWMU) 1 – Former Percolation Bed
- Area of Concern (AOC) 1 – Area Around Former Percolation Bed
- AOC 4 – Debris Ravine
- AOC 9 – Southeast Fence Line
- AOC 10 – East Ravine
- AOC 11 – Topographic Low Areas
- AOC 12 – Fill Area
- AOC 14 – Railroad Debris Area
- Undesignated Area (UA) 1 – Potential Pipeline Disposal Area
- UA 2 – Former 300B Pipeline Liquids Tank Area

In addition, at the California Environmental Protection Agency, Department of Toxic Substances (DTSC) and the United States Department of Interior's direction, the data gaps evaluation incorporated the newly identified debris, historic burn, and white powder areas. The evaluation and agreed upon sampling for these new areas is integrated into the sections regarding the appropriate SWMU/AOC.

C.1 Organization of Appendix C

The data gaps evaluation is presented in sub-appendices to this appendix. One sub-appendix is provided for each unit (i.e., there are 10 sub-appendices, covering SWMU 1, AOC 1, AOC 4, AOC 9, AOC 10, AOC 11, AOC 12, AOC 14, UA 1, and UA 2).

Each sub-appendix is organized as follows:

- **Section 1.0, Introduction and Background,** contains background, history, and a summary of the combined data set.
- **Section 2.0, Decision 1 – Nature and Extent,** presents an evaluation of the nature and extent of chemicals of potential concern/chemicals of potential ecological concern (COPCs/COPECs) and a description of data gaps associated with the nature and extent of COPCs/COPECs. Soil results are discussed first, followed by data for any debris or white powder material, if present and sampled at that unit.
- **Section 3.0, Decision 2 – Data Sufficiency to Estimate Representative Exposure Point Concentrations,** presents the results of the data sufficiency evaluation with regard to estimation of representative exposure point concentrations for use in the human health and ecological risk assessments.

- **Section 4.0, Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations,** presents the results of the assessment of current and potential impacts to groundwater from contaminants in soils.
- **Section 5.0, Data Summary for Decision 4 – Data Sufficiency to Support the Corrective Measure Study/Feasibility Study,** presents the evaluation data needs for the corrective measures study/feasibility study for each specific unit.
- **Section 6.0, Potential Part A Phase 2 Sample Locations,** presents agreed upon Part A Phase 2 sample locations and rationale. This includes the specific samples to be analyzed for soil physical properties. In addition, this section also identifies any access restrictions that may impact sample collection.
- **Section 7.0, References,** presents a list of works cited during preparation of these documents.

Section C.2 evaluates if newly detected Part A Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) Contract Laboratory Program Target Analyte List/Target Compound List (TAL/TCL) constituents should be considered COPCs and/or COPECs for the purposes of Decision 1. A separate evaluation of COPCs/COPECs will be conducted in the soil risk assessment as described in the approved Risk Assessment Work Plan (ARCADIS, 2008). In accordance with the Risk Assessment Work Plan, all detected chemicals (including TAL/TCL constituents) will be considered in the data evaluation for the risk assessment. Therefore, detections of TAL/TCL constituents were retained for evaluation of Decision 2, regardless of the outcome of Decision 1.

Section C.3, discusses the distribution of lead and polycyclic aromatic hydrocarbons (PAHs) across the Part A SWMU, AOCs, and UAs.

Section C.4, provides additional detail regarding the modeling approach used to support Decision 3. References are provided in Section C.5.

C.2 Identification of Newly Detected Compounds

At the United States Department of the Interior's direction, 10 percent of Part A Phase 1 soil samples were analyzed for the full inorganic and organic suites per the CERCLA TAL/TCL. Sample collected in AOC 4 for TAL/TCL constituents were removed during the AOC 4 2010 Time-Critical Removal Action, except location AOC 4-1 which has been included in the discussion below. Table C-1, presented at the end of this appendix, presents a statistical summary of the soil samples analyzed for TAL/TCL constituents. As shown in Table C-1, the TAL/TCL constituents detected include:

- Seven inorganic compounds: aluminum, calcium, iron, magnesium, manganese, potassium, and sodium.
- Three semivolatile organic compounds (SVOCs): 4-methylphenol, bis(2-ethylhexyl)phthalate, and di-n-butyl phthalate.
- One volatile organic compound: methyl acetate.

- Two polychlorinated biphenyls (PCBs): Aroclor 1254 and Aroclor 1260. Total PCBs were also calculated.
- Five pesticides: 4,4-dichlorodiphenyldichloroethylene [4,4-DDE], 4,4-dichlorodiphenyl trichloroethane [4,4-DDT], alpha-chlordane, gamma-chlordane, and dieldrin.

Of the detected compounds listed above, aluminum, the three SVOCs, methyl acetate, the two PCBs, and the five pesticides are newly detected compounds resulting from the TAL/TCL analysis.

As described in the Soil Part A Data Quality Objectives Technical Memorandum (Appendix A of this Report), the decision about whether a detected compound may represent a new COPC and/or COPEC for the purposes of defining nature and extent in Decision 1 will be based on multiple factors, including:

- Potential for the compound to be related to the compressor station (e.g., potential for the compound to be associated with past activities at the compressor station and/or to be a breakdown product of constituents known to have originated at the compressor station).
- Frequency of detection.
- Concentration detected.
- Distribution of detections.

The evaluation of the detected TAL/TCL compounds is presented below.

C.2.1 Inorganic Compounds

As described above, aluminum, calcium, iron, magnesium, manganese, potassium, and sodium were detected in the Part A Phase 1 and historical soil samples analyzed for the complete TAL/TCL suite of compounds. These inorganic compounds are discussed below.

- Aluminum was detected in 59 of 59 samples collected during the Part A Phase 1 soil investigation. Detected concentrations slightly exceeded the interim screening level (background threshold value [BTV]) of 16,400 milligrams per kilogram (mg/kg) in one soil sample (18,000 mg/kg) collected in AOC 10 and in two soil samples (19,000 and 20,000 mg/kg) collected in AOC 11. None of the detected concentrations exceeded the residential and commercial/industrial California human health screening levels (CHHSLs) (77,000 mg/kg and 990,000 mg/kg, respectively). A numerical ecological comparison value (ECV) was not established for aluminum; however, aluminum is identified as a COPEC only for those soils with a soil pH less than 5.5 (ARCADIS, 2008; United States Environmental Protection Agency [USEPA], 2003). Soil pH results for the Part A SWMU, AOCs, and UAs range from 7.48 to 10.49. Soil pH results for the units included in Part A are presented in the individual sub-appendices to this appendix.
- Calcium was detected in 64 of 64 samples collected as part of Part A Phase 1. Detected concentrations of calcium exceeded the interim screening level of 66,500 mg/kg (BTV) in four soil samples collected in SWMU 1 and in one soil sample collected in AOC 10. The maximum detected concentration of calcium was 280,000 mg/kg collected in SWMU 1. There are no residential and commercial/industrial CHHSLs or USEPA regional

screening levels (RSLs) for calcium. An ECV has not been established for calcium. Although ecological toxicity data are available for essential nutrients (e.g., for calcium), the likelihood of calcium and other inorganic constituents that are essential nutrients (iron, magnesium, potassium, and sodium) being risk ecological drivers at the site is remote. Therefore, based on agency agreement, ECVs were not developed for iron, calcium, magnesium, potassium, and sodium (ARCADIS, 2009).

- Iron was detected in 91 of 91 samples collected as part of Part A Phase 1. The maximum detected concentration of iron was 32,000 mg/kg, which is below the interim screening level of 55,000 mg/kg (residential RSL). There are no residential and commercial/ industrial CHHSLs or USEPA RSLs for iron, and a BTV has not been established.
- Magnesium was detected in 64 of 64 samples collected as part of Part A Phase 1. Detected concentrations of magnesium slightly exceeded the interim screening level of 12,100 mg/kg (BTV) in two soil samples collected in SWMU 1 and in one soil sample collected in AOC 10. The maximum detection of magnesium was 14,700 mg/kg collected in SWMU 1. There are no residential and commercial/industrial CHHSLs or USEPA RSLs for magnesium. An ECV has not been established for magnesium.
- Manganese was detected in 89 of 89 samples collected as part of Part A Phase 1. Detected concentrations of manganese exceeded the interim screening level of 402 mg/kg (BTV/ECV) in one soil sample collected in each in SWMU 1, AOC1, and AOC 11; in two soil samples collected in AOC 10; and in two soil samples collected from UA 2. The maximum detected concentration of manganese was 1,300 mg/kg collected in AOC 10. None of the detected concentrations exceeded the residential and commercial/ industrial CHHSLs (1,800 mg/kg and 23,000 mg/kg, respectively).
- Potassium was detected in 63 of 63 samples collected as part of Part A Phase 1. Detected concentrations of potassium slightly exceeded the interim screening level of 4,400 mg/kg (BTV) in one soil sample collected in SWMU 1 and in two soil samples collected from AOC 11. The maximum detected concentration of potassium was 5,300 mg/kg collected in AOC 11. There are no residential and commercial/industrial CHHSLs or USEPA RSLs for potassium. An ECV has not been established for potassium.
- Sodium was detected in 52 of 64 samples collected as part of Part A Phase 1. The maximum detected concentration of sodium was 1,800 mg/kg in one soil sample collected in SWMU 1, which is below the interim screening level of 2,070 mg/kg (BTV). Residential and commercial/industrial CHHSLs and an ECV have not been established for sodium.

As expected, except for sodium, these naturally occurring inorganic compounds were detected in all soil samples collected as part of the Part A soil investigation. These compounds are among the most common elements that make up the rocks in Earth's crust. Elevated manganese is also common in desert soils and rock surfaces in the form of desert varnish (Dorn, 2007). Based on chemical inventory lists presented in the *Revised Final RCRA Investigation/Remedial Investigation Report, Volume 1 - Site Background and History, PG&E Topock Compressor Station, Needles, California*, there is no current indication that manganese-containing compounds were used at the Topock Compressor Station (CH2M HILL, 2007).

Dehydrated lime sludge from the Permutit® water-conditioning system was produced at the compressor station (Pacific Gas and Electric Company [PG&E], 1962, 1968). Elevated levels of calcium may have been present in this sludge.

Based on the reasons stated above, PG&E does not recommend that these inorganic compounds be identified as new COPCs/COPECs. The distribution of these compounds at each unit is also discussed in the individual sub-appendices to this appendix.

C.2.2 Semivolatile Organic Compounds

Three SVOCs (4-methylphenol, bis(2-ethylhexyl)phthalate, and di-n-butyl phthalate) were detected in the Part A Phase 1 soil and historical samples analyzed for the complete TAL/TCL suite of constituents, as shown in Table C-1. These SVOCs are discussed below.

- 4-methylphenol was detected in two of 518 soil samples collected during the Part A soil investigation: 430 micrograms per kilogram (µg/kg) at AOC14-2 at 0 to 0.5 feet below ground surface (bgs) and 460 µg/kg at UA2-300B-1 at 2.5 to 3 feet bgs. The two detected concentrations are below the interim screening level of 500 µg/kg (ECV) and well below the residential and commercial/industrial RSLs (310,000 µg/kg and 3,100,000 µg/kg, respectively).
- Bis(2-ehtylhexyl)phthalate was detected in four of 518 soil samples collected during the Part A soil investigation. The maximum detected concentration was 1,300 µg/kg at UA2-300B-1 at 2.5 to 3 feet bgs, which is below the interim screening level of 2,870 µg/kg and well below the residential and commercial/industrial RSLs (35,000 µg/kg and 120,000 µg/kg, respectively). Bis(2-ehtylhexyl)phthalate was also detected at AOC1-T3c at 5 to 6 feet bgs (370 µg/kg), AOC4-1 at 2 to 3 feet bgs (810 µg/kg), and AOC14-3 at 0 to 0.5 foot bgs (640 µg/kg), which are also below the interim screening level.
- Di-n-butyl phthalate was only detected in one of 518 soil samples collected at a concentration of 1,100 µg/kg in AOC12c-T1c at 10 to 11 feet bgs. The detected concentration of di-n-butyl phthalate exceeded the interim screening level (46.9 µg/kg) (ECV). The basis for the ECV was potential risk to the cactus wren using a no observed adverse effect level (NOAEL) and a home range of 4.8 acres; di-n-butyl phthalate screening levels for other ecological receptors were not exceeded (ARCADIS, 2009). The single detection of di-n-butyl phthalate does not appear significant when the range of ecological screening values and the basis for the ECV is considered. The detected di-n-butyl phthalate concentration is several orders of magnitude below the residential and commercial/industrial RSLs (6,100,000 µg/kg and 62,000,000 µg/kg, respectively).

The above SVOCs were detected in soil samples collected at sample locations AOC1-T3c, AOC4-1, AOC12c-T1c, AOC14-2, AOC14-3, and UA2-300B-1. To evaluate whether the detections of these SVOCs can be correlated with the presence of other constituents detected in these samples, PG&E considered all compounds detected in each of these six samples. The following is a summary of all compounds detected in these samples:

- AOC1-T3c (collected at 2 to 3 feet bgs): bis(2-ehtylhexyl)phthalate, total petroleum hydrocarbon (TPH) as motor oil, arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, and zinc. Of these detected compounds, total chromium (89 mg/kg), hexavalent chromium (1.65 mg/kg), molybdenum (1.4 mg/kg), and zinc (65 mg/kg) were detected at concentrations exceeding their respective interim screening levels.

- AOC4-1 (collected at 2 to 3 feet bgs): bis(2-ehtylhexyl)phthalate, methyl acetate, arsenic, barium, total chromium, cobalt, copper, lead, nickel, vanadium, zinc, and Aroclor 1254. Of the detected compounds, lead (17 mg/kg) was the only compound detected above respective interim screening levels.
- AOC12c-T1c (collected at 10 to 11 feet bgs): bis (2-ethylhexyl) phthalate, TPH-motor oil, arsenic, barium, total chromium, cobalt, copper, lead, nickel, vanadium, and zinc. Only bis(2-ehtylhexyl)phthalate was detected at a concentration exceeding the interim screening level.
- AOC14-2 (surface soil sample): 4,4-DDE, 4,4-DDT, 4-methylphenol, TPH-diesel, TPH-motor oil, arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, nickel, vanadium, zinc, and PAHs. Of the detected compounds, 4,4-DDE (2.0 µg/kg), 4,4-DDT (3 µg/kg), copper (44 mg/kg), and lead (18 mg/kg) were detected at concentrations exceeding their respective interim screening levels.
- AOC14-3 (surface soil sample): bis (2ethylhexyl) phthalate, TPH-motor oil, arsenic, barium, total chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, zinc, and PAHs. Of the detected compounds, only lead (8.4 mg/kg), and molybdenum (1.6 mg/kg) were detected at concentrations exceeding their respective interim screening levels.
- UA2-300B-1 (collected at 2.5 to 3 feet bgs): 4-methylphenol, bis(2-ethylhexyl)phthalate, TPH-diesel, TPH-motor oil, arsenic, barium, total chromium, cobalt, copper, lead, nickel, vanadium, zinc, and PAHs. Of the detected compounds, only arsenic (16 mg/kg) and zinc (59 mg/kg) were detected at concentrations exceeding respective interim screening levels.

After review of other compounds detected in the soil samples where SVOCs were detected, there does not appear to be a discernable pattern or correlation between the other compounds detected at these locations and the detected SVOCs. Phthalates, including di-n-butyl phthalate and bis (2-ethylhexyl) phthalate are common ingredients in polyvinyl chloride plastics. Phthalates are used to make common items such as carpets, paints, glue, insect repellents, hair spray, and nail polish (United States Department of Human Health Services, 2001).

4-methylphenol is a very common chemical and is a component in everyday items, such as cleaning and disinfectant products (i.e., Lysol), wood preservatives, road tar, and tobacco smoke.

For the above reasons, PG&E does not recommend that any of these three SVOCs be identified as a new COPC/COPEC. These compounds are also discussed in the individual SWMU, AOCs, and UAs discussions in the sub-appendices to this appendix.

C.2.3 Volatile Organic Compounds

As described above, methyl acetate was the only VOC detected in the Part A Phase 1 soil samples analyzed for the complete TAL/TCL suite of compounds, as shown in Table C-1.

During the Part A soil investigation, methyl acetate was detected in three of 56 soil samples collected at 2 to 3 feet bgs at sample locations AOC1-T3a, AOC4-1 and AOC11e-2 at concentrations of 6.6 µg/kg, 12 µg/kg, and 17 µg/kg, respectively. The detected concentrations are six orders of magnitude below the interim screening level of 22,000,000 µg/kg (residential RSL).

Other compounds present in samples containing methyl acetate were evaluated as for the samples containing SVOCs. The following is a summary of other compounds detected in these samples:

- AOC1-T3a (collected at 2 to 3 feet bgs): bis (2-ethylhexyl) phthalate, TPH as motor oil, arsenic, barium, total chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, and zinc. None of the detected compounds were detected at concentrations exceeding their respective interim screening levels.
- AOC4-1 (collected at 2 to 3 feet bgs): bis (2-ehtylhexyl) phthalate, arsenic, barium, total chromium, cobalt, copper, lead, nickel, vanadium, zinc, and Aroclor 1254. Of the detected compounds, lead (17 mg/kg) was the only compound detected above respective interim screening levels.
- AOC11e-2 (collected at 2 to 3 feet bgs): TPH-motor oil, arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, zinc, PAHs, and Aroclor 1254. Of these detected concentrations, total chromium (130 mg/kg), hexavalent chromium (3.78 mg/kg), copper (19 mg/kg), lead (11 mg/kg), molybdenum (2.9 mg/kg), and zinc (120 mg/kg) were detected at concentrations exceeding their respective interim screening levels.

After review of other compounds detected in the soil samples where methyl acetate was detected, there does not appear to be a discernable pattern or correlation between the other compounds detected at these locations and the detected VOCs.

Methyl acetate is infrequently detected at extremely low concentrations and is also a common laboratory contaminant; therefore, PG&E does not recommend that this VOC be identified as a COPC/COPEC.

C.2.4 Polychlorinated Biphenyls

As described above, Aroclor 1254 and Aroclor 1260 were detected above interim screening levels in the Part A Phase 1 soil samples analyzed for the complete TAL/TCL suite of compounds, as shown in Table C-1.

- Aroclor 1254 was detected in 36 of 104 soil samples collected as part of Part A Phase 1. Aroclor 1254 was detected in SWMU 1, AOC 1, AOC 4, AOC 9, AOC 10, AOC 11, and AOC 12. Detected concentrations of Aroclor 1254 only exceeded the interim screening level (220 µg/kg) (residential RSL) in three soil samples collected near the mouth of AOC 4 – Debris Ravine where it drains into Bat Cave Wash, as shown in Figure C-1 provided at the end of this appendix. These samples were collected as part of the time-critical removal action currently being implemented at AOC 4 to stabilize and mitigate the threat of release of contaminated material that was historically disposed of in AOC 4. The maximum detected concentration of Aroclor 1254 was 900 µg/kg, exceeding the commercial/industrial RSL (740 µg/kg).

- Aroclor 1260 was detected in only one of 104 soil samples (in AOC 11) collected as part of Part A Phase 1 at a concentration of 240 µg/kg, slightly exceeding the interim screening level (220 µg/kg) (residential RSL), as shown in Figure C-1. The detected concentration did not exceed the commercial/industrial RSL (740 µg/kg).

To assist with evaluation of PCBs for Decision 2, total PCB values were calculated.[1] Total PCBs were detected in 37 of 105 soil samples collected as part of Part A Phase 1. The total PCB concentrations exceeded the interim screening level of 204 µg/kg (ECV) in three soil samples collected near the mouth of AOC 4 where it drains into Bat Cave Wash and in one soil sample collected in AOC 11, as shown in Table C-2. The maximum calculated concentration of total PCBs was 900 µg/kg collected in AOC 4.

There were four types of equipment within the compressor station in which PCBs may have been present at the Topock Compressor Station in the past. The types of equipment were the Natural Gas Transmission Line 300,[2] gas scrubbers, former compressor and generator engine oil bath air filters, and former electrical equipment (e.g., transformers and capacitors), which may have contained PCB fluids. Transformers are identifiable at the compressor station in several historical aerial photographs (DTSC, 2008) but are no longer in use, and no historical analyses of the former transformer contents are available. PCBs were not detected in soil samples collected directly beneath the former oil bath air filters.

Of the equipment at the Topock Compressor Station described in the above paragraph, the presence of PCBs has been detected in the past inside Natural Gas Line 300 and the scrubbers. PCBs, which were detected within Line 300 in the past, are known to be the result of contamination originating from Transwestern Pipeline Company in the late 1990s. PCBs were also detected in the liquid released from the gas transmission line 300A scrubbers during the annual blowdown event in March 2004 (CH2M HILL, 2007). Approximately 200 pounds of soil were removed during excavation and cleanup of this release.

PCBs have been added to the analyte lists for those AOCs and areas within the compressor station where used transformers or used oil may have been stored or in unpaved areas where pipeline liquids may have been applied to the ground surface. Information obtained from employees suggests that pipeline liquids historically may have been sprayed on unpaved areas for dust control (Russell, 2006). Based on available information, this practice ceased by 1975 and waste oil, including pipeline liquids, was sent offsite for reuse starting in 1975 (PG&E, 1980).

PCBs have been detected in all units, with the exception of AOC 14 and UA 2. Potential sources of the PCBs in AOC 1, AOC 9, AOC 10, AOC 11, and AOC 12 are runoff from the unpaved areas in the compressor station. Sources for the PCBs in Bat Cave Wash near the

---

[1] Total PCB exposure point concentrations will be estimated for the ecological risk assessment.

[2] Only a small portion of Line 300 is located at the Topock Compressor Station; Line 300 is a linear facility which runs from the Arizona border to the San Francisco Bay Area.

mouth of AOC 4 are most likely a result of disposal activities in AOC 4. PCBs are discussed further in the individual SWMU, AOCs, and UAs discussions in the sub-appendices to this appendix.

C.2.5 Pesticides

4,4-DDE, 4,4-DDT, alpha-chlordane, gamma-chlordane, and dieldrin were detected in Part A Phase 1 soil samples analyzed for the complete TAL/TCL suite of compounds, as shown in Table C-1. These pesticides are discussed below:

- 4,4-DDT was detected at a concentration of 3 µg/kg in one of 59 soil samples collected as part of Part A Phase 1. The detected concentration of 4,4-DDT exceeded the interim screening level of 2.1 µg/kg (ECV) in one soil sample collected at AOC14-2 at 0 to 0.5 foot bgs. The basis for the ECV was potential reproductive risk to the red-tailed hawk using a NOAEL and a home range of 2,471 acres. The preliminary NOAEL-based ECV that was calculated for the cactus wren was also exceeded; the cactus wren home range is 4.8 acres. Screening levels for non-avian ecological receptors were not exceeded (ARCADIS, 2009). The detection of 4,4-DDT does not appear significant when the range of ecological screening values and the basis for the ECV is considered. When DDT and metabolites are combined and compared with the ECV, the detections are also not significant when the basis of the ECV and the range of potential risk estimates (i.e., other representative receptors and the range of available toxicity reference values) are considered. The detected concentration did not exceed the residential or commercial/ industrial CHHSLs (1,600 µg/kg and 6,300 µg/kg, respectively).

- 4,4-DDE, the daughter product of 4,4-DDT, was detected in three of 59 soil samples (3.2 µg/kg at AOC9-11 at 0 to 0.5 foot bgs, 6.1 µg/kg at AOC11d-1 at 0 to 0.5 foot bgs, and 2.9 µg/kg at AOC14-2 at 0 to 0.5 foot bgs) collected as part of Part A Phase 1. The three detected concentrations of 4,4-DDE exceeded the interim screening level of 2.1 µg/kg (ECV). The maximum detected concentration of 4,4-DDE is 6.1 µg/kg. As discussed above for 4,4-DDT, the three sporadic detections of 4,4-DDE do not appear significant when the range of ecological screening values and the basis for the ECV are considered. The detected concentration did not exceed the residential or commercial/ industrial CHHSLs (1,600 µg/kg and 6,300 µg/kg, respectively).

- Alpha-chlordane was detected in one of 59 soil samples collected as part of Part A Phase 1 at a concentration of 12J µg/kg collected at AOC11d-1 at 0 to 0.5 foot bgs, which is well below the interim screening level of 430 µg/kg (residential CHHSL) and the ECV of 470 µg/kg.

- Gamma-chlordane was detected in one of 59 soil samples collected as part of Part A Phase 1 at a concentration of 13J µg/kg collected at AOC11d-1 at 0 to 0.5 foot bgs, which is well below the interim screening level of 430 µg/kg (residential CHHSL) and the ECV of 470 µg/kg.

- Dieldrin was detected in one of 59 soil samples collected as part of Part A Phase 1 at a concentration of 6.7 µg/kg. The detected concentration of dieldrin exceeded the interim screening level (5 µg/kg) (ECV) and was collected at AOC11d-1 at 0 to 0.5 foot bgs. The basis for the ECV was potential risk to the desert shrew estimated using a geometric mean NOAEL for growth and reproduction and a home range of 0.1 acre; screening levels for other ecological receptors were not exceeded (ARCADIS, 2009). The single detection of dieldrin sitewide does not appear significant when the range of ecological screening values and the basis for the ECV are considered. The detected concentration did not exceed the residential or commercial/industrial CHHSLs (35 µg/kg and 130 µg/kg, respectively).

Pesticides were detected in the surface soil samples at sample locations AOC9-11, AOC11d-1 and AOC14-2. To assess potential patterns of compounds detected in association with pesticides, all other detected compounds in these three samples were also reviewed. The following is a summary of all compounds detected in these samples:

- AOC9-11 (surface soil sample): 4,4-DDE, TPH-motor oil, PAHs, arsenic, barium, total chromium, cobalt, copper, lead, mercury, nickel, vanadium, and zinc were detected. Only mercury (0.13 mg/kg) was detected at a concentration above its interim screening level.
- AOC11d-1 (surface soil sample): 4,4-DDE, alpha-chlordane, gamma-chlordane, dieldrin, arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, nickel, vanadium, zinc, PAHs, TPH-motor oil, and Aroclor 1254. Of the detected compounds, 4,4-DDE, dieldrin, copper (19 mg/kg), lead (16 mg/kg), zinc (73 mg/kg), benzo(a)pyrene (44 µg/kg) and PAHs as benzo(a)pyrene equivalents (66 µg/kg) were detected at concentrations exceeding their respective interim screening levels.
- AOC14-2 (surface soil sample): 4,4-DDE, 4,4-DDT, 4-methylphenol, TPH-diesel, TPH-motor oil, arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, nickel, vanadium, zinc, and PAHs. Of the detected compounds, 4,4-DDE, 4,4-DDT, copper (44 mg/kg), and lead (18 mg/kg) were detected at concentrations exceeding their respective interim screening levels.

Several pesticides (4,4-DDE, alpha-chlordane, gamma-chlordane, and dieldrin) are collocated in the surface soil sample collected at location AOC11d-1. After review of other compounds detected in the soil samples where pesticides were detected, there does not appear to be a discernable pattern or correlation between the other compounds detected at these locations and the detected pesticides.

The only possible historical source of 4,4-DDT and its daughter products and dieldrin in the area would have been pest (insect) control.

The distribution of pesticides at each unit where detected is also discussed in the individual SWMU, AOCs, and UAs discussions in the sub-appendices to this appendix. Based on the reasons presented above, PG&E does not recommend that 4,4-DDE, 4,4-DDT, and dieldrin be identified as new COPCs/COPECs.

C.3 Lead and Polycyclic Aromatic Hydrocarbon Distribution

Lead and PAHs have been detected in soil samples collected across the Part A SWMU, AOCs, and UAs. Many of these detections exceed the interim screening levels; these exceedances are discussed in the individual sub-appendices to this appendix. Lead and

PAHs are found primarily in the surface and shallow soil samples, and exceedances in soil are not consistent with the conceptual site models developed for these sites (i.e., these exceedances are not found in areas where other elevated COPCs/COPECs are found or in areas with known or suspected contamination).

Many natural and anthropogenic sources of lead and PAHs exist. Particulate lead is commonly found in surface soil near roadways as a result of leaded gasoline use in vehicles until the 1970s. Former Route 66 and California Interstate Highway 40 are near most of the Part A sites. The site-specific background concentration of lead in soil is 8.39 mg/kg.

PAHs are ubiquitous in both urban and rural environments. The most notable natural and anthropogenic sources of PAHs are from combustion of fossil fuels, wild fires, volcanic activities, industrial facilities, petroleum oils, asphalt binders, and vehicle exhaust. However, because PAHs were not detected in site-specific background samples, a Topock site-specific background value was not calculated. Therefore, an interim screening level of 38 µg/kg benzo(a)pyrene (BaP) equivalents is based on the CHHSL. The Topock background samples were collected from areas away from the compressor station, Interstate 40, former Route 66, and the Burlington Northern Santa Fe railroad tracks, all of which are potential sources of PAHs.

To aid in the cleanup process at manufactured gas plant sites, DTSC developed the advisory *Use of the Northern and Southern California Polynuclear Aromatic Hydrocarbon (PAH) Studies in the Manufactured Gas Plant Site Cleanup Process* (DTSC, 2009). The advisory describes how ambient concentrations of PAHs identified by the southern and northern California background PAH studies can be used to help guide the cleanup process at manufactured gas plant sites. The advisory is to be used on a case-by-case basis for those sites that are similar to the sites that were used in the southern and northern California background PAH studies. The DTSC advisory suggests that for similar sites, a value of 900 µg/kg in BaP equivalents can be used as a pragmatic target for guiding soil excavation/remediation because 900 µg/kg BaP equivalents corresponds to the upper bounds of the southern and northern California ambient/background data sets. While anthropogenic sources of PAHs in the vicinity of the Compressor Station are likely less substantial than for some locations included in the Northern and Southern California PAH studies, some anthropogenic contribution of PAHs is likely due to the proximity of roads and railroad tracks.

Although lead and PAH detection distribution in soil are generally not consistent with the conceptual site models developed for the site and may be to the result of activities unrelated to the compressor station, soil samples collected during the Part A Phase 2 soil investigation will be analyzed for lead and PAHs in those areas where data gaps have been identified. The Part A Phase 2 proposed sample locations are presented in the sub-appendices to this appendix.

C.4 Additional Details on Modeling Approach (Decision 3)

This section presents the development and application of the models and assumptions used to simulate variably unsaturated flow and solute transport in the vadose zone associated with the third tier of the screening assessment of potential future threat to groundwater from COPCs in vadose zone.[3] Only those units where inorganic COPCs/COPECs exceeded the soil screening levels (Step 2 of the threat to groundwater screening process) and organics were simulated. The objective of the initial model simulations is intended as a conservative screening process to evaluate which COPCs can be ruled out as having the potential to leach to groundwater. The models were developed using conservative assumptions regarding infiltration rates and initial COPC/COPEC concentrations.

The analyses were performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, is needed to resolve Decision 3. Additional evaluations will be performed as appropriate as data are collected to resolve Decision 1. The HYDRUS-1D code version 4.14 (Simunek et al., 1998) was selected for the modeling effort because it can numerically solve the variably saturated flow equation (i.e., Richards Equation) and transport equations in one dimension (i.e., from the COPC/COPEC source area near land surface downward through the vadose zone to the top of the water table).

The mathematical model design is the result of converting the conceptual site model into a form that is suitable for numerical modeling. The following steps were associated with the mathematical model design:

1. Establish the vertical extent of the model.
2. Spatially distribute the subsurface hydraulic parameter values.
3. Spatially distribute the transport parameter values and initial COPC concentrations.
4. Select a time discretization approach appropriate for evaluating the field problem and fulfilling the modeling objectives.
5. Establish boundary conditions for flow (i.e., water budget terms through time).

The total thickness of the simulated vadose zone profiles in the HYDRUS-1D models was variable and was based on the depth to groundwater beneath each area. Profile depths ranged from 30 feet to 100 feet bgs and, except for AOC 1, SMWU 1, and AOC 11, were estimated from the groundwater flow model developed for the Topock site. AOC 1, SMWU 1, and AOC 11 are near wells MW-11, MW-10, and MW-12, respectively, and profile thicknesses were determined based on groundwater level data at those locations. Numerical models require the area being simulated to be discretized into separate cells or nodes. For this evaluation, all models comprised of 200 model nodes, resulting in a maximum cell thickness of 8 inches. The model simulated of 100 years of transport.

Boundary conditions are mathematical statements (i.e., rules) that specify water elevation, water flux, solute concentration, and solute flux at particular locations within the model domain, which can vary in time. The upper boundary condition for water flow in the HYDRUS-1D model was set as a specified-flux boundary equal to 0.1 inch of infiltration per year to simulate the estimated percolation rate, except for AOC 10a, AOC 10b, and AOC 10c, as discussed in Section C.4.1. The bottom boundary was set as a specified-pressure head

---

[3] The details provided herein on the approach and assumptions of the vadose zone model were not included in the technical memorandum entitled *Calculation of Soil Screening Levels for Protection of Groundwater at the PG&E Topock Compressor Station* (CH2M HILL, 2008).

equal to 0 feet, representing the water table. The model was initially run in transient mode until a steady-state moisture profile was achieved. The resulting equilibrium vertical moisture profile was then used for the initial moisture conditions for the transport simulation.

C.4.1 Model Parameters

HYDRUS-1D was set up to numerically solve the Richards equation using the van Genuchten (1980) model of soil hydraulic properties. The models were parameterized using the soil catalog (Carsel and Parrish, 1988). The soil catalog provides values for the van Genuchten parameters for a number of different soil types. For the current set of models for the Topock site, the soil texture was assumed to be a loamy sand. Table C-2 presents the van Genuchten parameters defined by the soil catalog for this type of soil that were used in all of the HYDRUS-1D models.

Except for models of AOC 10a, AOC 10b, and AOC 10c, a deep percolation rate of 0.1 inch per year was used. Diffuse natural recharge rates are assumed to be very low (< 0.1 inch per year) across the Mohave Desert at the elevation range of the Topock site, based on literature from similar terrain (Hevesi et al., 2003). The United States Geological Survey estimated recharge rates of Bat Cave Wash in an unpublished study following similar methods of Hevesi et al. (2003). The United States Geological Survey recharge rate estimate for Bat Cave Wash was 0.005 inch per year. This is the recharge rate estimated for the bottom of the wash where runoff is concentrated and surface water flows occur a few times per year. Recharge rates for upland sites would be considerably less than in Bat Cave Wash. PG&E chose to use a conservatively high rate of recharge of 0.1 inch per year in the screening model simulations.

At AOC 10a, AOC 10b, and AOC 10c, deep percolation rates were likely higher because of annual Topock Compressor Station fire pump tests, which reportedly discharged into East Ravine. Visual observations of soil wetness by site personnel following these tests suggest that areas AOC 10a, AOC 10b, and AOC 10c receive water from the fire pump test discharges. As a conservative estimate, the deep percolation rate for Areas AOC 10a, AOC 10b and AOC 10c was set at 1.3 inches per year, disregarding the effects of evapotranspiration. AOC 10d was not impacted by the fire pump tests.

Solute transport parameters used in the HYDRUS-1D model are shown in Table C-3. Dispersivity was a model-specific parameter and was calculated using the model of Xu and Eckstein (1995), in which dispersivity is correlated to the length of the flowpath (i.e., deeper soil profiles experience greater dispersion). The distribution coefficient (K_d) was COPC/COPEC-specific. K_d values used in the models were the mean value for each COPC/COPEC presented in United States Environmental Protection Agency (2005), except for hexavalent chromium. The K_d value used for hexavalent chromium was a Topock site-specific value of 0.318 milliliters per gram estimated by ARCADIS during the upland *in-situ* pilot test (Gillow, personal communication, 2009).

A conservative approach was used to establish the initial soil concentration profiles for the HYDRUS-1D simulations. For each modeled COPC/COPEC, soil samples at each unit or subarea were pooled. The initial concentration profile was established such that the maximum concentration detected within the unit or subarea over a given depth interval was assigned across the entire interval. For each modeled COPC/COPEC, the maximum concentration at the deepest sample depth was assigned from that depth to the water table. In cases where the maximum concentration for a given depth interval was a non-detect, a value equal to half of the maximum reporting limit was used. This highly conservative approach was used to remove COPCs in soil as a threat to groundwater with a high degree of confidence. If all sample results for a given COPC were nondetects at a specific unit or subarea, the COPC/COPEC was not modeled.

C.4.2 Model Application

HYDRUS-1D output is in the form of time-series COPC/COPEC concentration at the model's bottom boundary (i.e., the water table). To calculate the groundwater concentration projected to result from vadose zone leaching, the HYDRUS-1D output was input into a spreadsheet-based mixing-cell model. The mixing cell accounts for the mixing of the pore water leaching from the vadose zone as it enters the top 10 feet of the saturated zone. The mixing cell calculation accounts for fluxes of water and COPCs/COPECs from the vadose zone and the flux of groundwater through the uppermost 10 feet of the aquifer below each unit. Allowing mixing to occur only in the top 10 feet of aquifer is an additional conservative approach because COPCs at Topock are mixed across the entire thickness of the aquifer.

The calculation includes the following assumptions:

- The COPCs/COPECs leaching from the vadose zone will mix only in the uppermost 10 feet of the aquifer.
- Instantaneous mixing occurs within the mixing cell.
- Saturated conditions exist within the mixing cell.
- No decay or vapor-phase exchange occurs within the mixing cell.

Figure C-2 shows the dimensions of each mixing cell. Mixing cells were oriented such that they encompassed the entire unit or subarea of interest and so that they were orthogonal to the primary direction of groundwater flow as determined by the current Topock groundwater flow model. The water flux value representing subsurface inflow into the mixing cell was estimated using the current Topock groundwater flow model representing pre-pumping conditions. The upgradient concentration and initial concentration in the mixing cell were set to zero so that inputs from the vadose zone of the modeled unit only could be evaluated. An impact to groundwater by a COPC/COPEC was defined as a concentration in the mixing cell in excess of the groundwater upper tolerance limit (UTL) at any time during the 100-year simulation time. Groundwater UTLs are shown in Table C-4.

The results of the modeling effort for each unit are presented in the sub-appendices to this appendix.

C.4.3 Model Application for Organic Compounds

As shown in Table C-5, detected SVOCs, volatile organic compounds, Aroclor 1254, and dioxins/furans were modeled using the HYDRUS-1D model code as described above; however, the model for organics was constructed assuming a hypothetical worst-case scenario using a set of extremely conservative input parameters. For example, the distance to groundwater assumed the shortest distance observed across all SWMUs/AOCs or UAs (30 feet) and the highest infiltration rate (1.3 inches/year), and the initial concentration profile assumed the highest concentration detected at each depth interval, regardless of in which AOC the compound was detected. The analysis was conducted in this manner to show that even when an unrealistically conservative set of input parameters was used, organic compounds do not cause a significant increase in groundwater concentration when compared to regulatory standards.

Naphthalene was modeled as a conservative proxy for all PAHs because it is the most mobile of this class of chemicals. Similarly, Aroclor 1254 was modeled for all PCBs, and dioxin TCDD, 2,3,7,8- was modeled for dioxin/furans.

Table C-5 presents results of this analysis. Even using ultraconservative assumptions, none of the organic compounds detected in soil is a threat to groundwater.

APPENDIX C1

Solid Waste Management Unit 1 Data Gaps Evaluation Results

1.0 Introduction and Background

This sub-appendix presents the results of the Data Gaps Evaluation and the Part A Phase 2 Sampling Program for Solid Waste Management Unit (SWMU) 1 – Former Percolation Beds at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the Data Gaps Evaluation is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report.

1.1 Background

SWMU 1, the Former Percolation Bed, is located outside the facility fence line in the bed of Bat Cave Wash, as depicted in Figure C1-1. (All tables and figures appear at the end of the sub-appendix.) SWMU 1 is located on both PG&E property and property owned by the Havasu National Wildlife Refuge and managed by the United States Fish and Wildlife Service. The southern boundary of SWMU 1 is roughly in line with the water treatment system in the lower yard of the compressor station, and the northern boundary of SWMU 1 is in the vicinity of the access road leading from the lower yard into Bat Cave Wash. PG&E completed closure of the former water treatment system that consisted of the sludge-drying beds (SWMU 5), chromate reduction tank (SWMU 6), process pump tank (SWMU 8), transfer sump (SWMU 9), transfer piping (Area of Concern [AOC] 18), the oil/water holding tank (Unit 4.3), the oil/water separator (Unit 4.4), and the portable waste oil storage tank (Unit 4.5). In the 1955 aerial photograph, an apparent round impoundment area with white powder material is located in the lower yard of the compressor station, south of the sludge-drying beds (SWMU 5). This area has been identified as potential new investigation area in Figure C1-2.

Based on historical aerial photographs, it appears that during the 1950s, the facility discharged wastewater containing chromium (cooling tower blowdown) wastewater into Bat Cave Wash without any impoundment. Wastewater was released to the wash through two pipes that ran from the sludge-drying beds (SWMU 5) area in the lower yard down the slope into Bat Cave Wash. These pipes are shown in Figure C1-2 as “historical discharge piping.” From about 1964 to approximately 1971, the facility discharged wastewater containing chromium to a percolation bed and allowed water to percolate into the ground and/or evaporate. The chromium-containing wastewater was combined with a small quantity (approximately 5 percent) of treated water from the oily waste treatment system discharged from the station.

Periodic storm (high runoff) events occur in Bat Cave Wash, making it difficult to assess the precise nature of erosion and deposition patterns. A 2006 storm event resulted in substantial erosion and deposition in portions of the wash in SWMU 1, and a January 2010 storm event resulted in the movement of large gravel and cobbles from south of SWMU 1/AOC 1 to the area near where the Debris Ravine (AOC 4) enters Bat Cave Wash and as far north as the pipeline overcrossing (in the vicinity of SSB-1). While there was considerable movement of rock south of SWMU 1, there appeared to be limited scouring in the wash and erosion of the wash walls within SWMU 1 during the January 2010 storm event. Although there was damage to well MW-38, (installed within Bat Cave Wash), most of the sample location survey markers (1/8-inch lathe stakes) were still in place following the 2010 run-off event. MW-38 is also located immediately downstream of a sizable feeder wash on the west side of Bat Cave Wash. Based on this visual reconnaissance of Bat Cave Wash, most of the soil samples collected during the Phase 1 sample locations and former sample locations included in the Soil Part A Work Plan are still considered to be representative. Surficial samples collected from locations within areas of highest energy during the 2010 event may not be representative of current conditions.

1.2 Conceptual Site Model

A graphical conceptual site model for SWMU 1 has been developed based on the above site history and background, as shown in Figure C1-2. Table C1-1 presents the primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for SWMU 1. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the Soil Part A Data Quality Objectives (DQO) Tech Memo, which is presented as Appendix A to the Data Gaps Evaluation Report.

For SWMU 1, the primary source of contamination is historical direct discharge of untreated wastewater into Bat Cave Wash and the Former Percolation Bed. Therefore, surface soil in SWMU 1 was the primary source medium. Contaminated wastewater infiltrated and impacted subsurface soil and groundwater, as evidenced by hexavalent chromium contamination in groundwater. From surface soil, soluble contaminants could have migrated to subsurface soils. Subsurface soil may act as a secondary source medium to groundwater.

Historically, chemicals of potential concern (COPCs) in surface soil in SWMU 1 may have been eroded and entrained in stormwater/surface water runoff during flow events and may have been subsequently re-deposited downstream in Bat Cave Wash (AOC 1). The thick vegetation, widening of the channel near the end of Bat Cave Wash, and blockage of flow by National Trails Highway greatly reduces the energy of flow during runoff events, resulting in deposition of entrained soil within the vegetated area in AOC 1 (downstream migration of contamination from SWMU 1 is addressed in AOC 1). Repeated erosion and deposition of soil at SWMU 1 may have resulted in mixing of surface and near-surface soils at SWMU 1. If released, volatile organic compounds (VOCs) in surface soils would be expected to have been degraded by heat and light and are likely no longer present.

Because chromium-containing wastewater from the facility was discharged to Bat Cave Wash and topography surrounding the wash confined wastewater and surface water flows to the bed of the wash, the potential lateral extent of soil contamination associated with SWMU 1 is constrained within the boundaries of SWMU 1 (contamination outside of SWMU 1 is addressed in AOC 1). The vertical extent of soil contamination within SWMU 1 is not defined.

Contamination associated with SWMU 1 may also exist on the eastern sidewall of Bat Cave Wash east of SWMU 1 based on results of samples collected from white powder material observed on the eastern sidewall. Two possible sources of white powder material in SWMU 1 are residual mineral salts from the percolation pond and water conditioning (lime treatment) sludge from the sludge-drying beds. Lime treatment is a chemically simple process involving the addition of lime (calcium hydroxide), sometimes soda ash (Na_2CO_3), and sometimes other flocculants or caustic chemicals to remove hardness (calcium and magnesium ions) from water. Both lime and soda ash were used at the compressor station. The lime treatment sludge produced is primarily calcium carbonate with smaller quantities of magnesium hydroxide, both of which are poorly soluble at normal pH (American Water Works Association, 1981). Lime treatment sludge is generally low in contaminant concentrations, whereas residual mineral salts from the percolation bed may contain higher concentrations of chromium.

Windblown contamination from SWMU 1 is influenced by wash topography. Windblown contaminant deposition, if any, is expected to be limited to surface soils. Windblown contaminant deposition, if any, outside of SWMU 1 is addressed in AOC 1.

Based on the site history and background and conceptual site models, Part A Phase 1 and historical soil samples were collected within areas of historical discharge of chromium-containing wastewater from the facility. Similarly, trench samples in the eastern wall of Bat Cave Wash were located in areas where white powder material was present.

1.3 SWMU 1 Data

Forty-four historical soil samples were collected from 15 locations (MW-9, SSB-2 through SSB-5, WP-1 through WP-6, WP-Blank1, WP-Blank2, T-3-B, and P-2) in SWMU 1, as shown in Figure C1-1. Samples were generally collected from 0 to 10 feet below ground surface (bgs); however, the MW-9 samples were collected to 87 feet bgs. Historical soil samples were analyzed for five constituents: total chromium, hexavalent chromium, copper, nickel, and zinc. A few historical samples were also analyzed for barium, lead, molybdenum, and vanadium.

During the 2008 Soil Part A Phase 1 investigation, 142 soil samples were collected from 29 sample locations (SWMU1-1 through SWMU1-17, SWMU1-SP-1h, SWMU1-WP-3a, SWMU1-WP-3h, SWMU1-WP-5a, SWMU1-WP-5h, SWMU1-WP-6a, SWMU1-WP-6h, SWMU1-WP-7, SWMU1-WP-8, SWMU1-WP-9, SWMU1-WP-10, and SWMU1-WP-T3a), as shown in Figure C1-1. The samples were generally collected at sample depths of 0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet bgs, with SWMU1-3 sampled down to 80 feet, and SWMU1-15 sampled down to 90 feet. Soil Part A Phase 1 soil samples were analyzed for Title 22 metals, hexavalent chromium, VOCs, semivolatile organic compounds (SVOCs), polycyclic aromatic hydrocarbons (PAHs), total petroleum hydrocarbons (TPH), pH, pesticides, and polychlorinated biphenyls (PCBs). Surface soil samples were not analyzed for VOCs. Ten percent of the Phase 1 soil samples collected in SWMU 1 (16 soil samples) were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL). In addition, synthetic precipitation leaching procedure (SPLP) extraction was performed on a soil sample collected at 2 to 3 feet bgs at location SWMU1-8 and soil samples collected at 5 to 6 feet bgs at sample locations SWMU1-1 and SWMU1-3, as shown in Table C1-2. The leachate from the SPLP extractions was analyzed for total and hexavalent chromium. Phase 1 data were validated and the data quality evaluation is included Appendix D to the Data Gaps Evaluation Report.

In addition, nine trenches (SWMU1-WP-1h, SWMU1-WP-2h, SWMU1-WP-3h, SWMU1-WP-5h, SWMU1-WP-6h, SWMU1-WP-7, SWMU1-WP-8, SWMU1-WP-9, and SWMU1-WP-10) were excavated on the eastern side of SWMU 1 to evaluate the extent of white powder, as shown in the inset of Figures C1-1 and C1-3 through C1-10. A photo log of the trenches is included as Appendix B4 of Appendix B to the Data Gaps Evaluation Report. Four samples of white powder material were collected from four trenches: SWMU1-WP-5h (collected at 2 to 3 feet bgs), SWMU1-WP-6h (collected at the surface [0 to 0.5 foot bgs]), SWMU1-WP-7 (collected at 2 to 3 feet bgs), and SWMU1-WP-10 (collected at 2 to 3 feet bgs). The white powder samples were analyzed for Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, and pH. One white powder material sample was also analyzed for the full inorganic and organic suites per TAL/TCL.

All historical and Part A Phase 1 data considered Category 1 were used as inputs to the four data quality objective decisions for SWMU 1.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of COPCs and chemicals of potential ecological concern (COPECs) at SWMU 1. Laboratory analytical results for historical and Part A Phase 1 soil samples at SWMU 1 are presented in Tables C1-2 through C1-8. Suites of constituents that were 100 percent non-detect (SVOCs and VOCs) are not presented in the tables. Tables C1-2 through C1-8 also include data for white powder samples. Table C1-9 presents a statistical summary of soil analytical results for COPCs and COPECs that were detected in soil samples, as well as COPCs and COPECs which were all non-detect but for which one or more reporting limits exceeded the interim screening level. The white powder samples are not included in the statistical summary presented in Table C1-9. The results of the nature and extent evaluation for the white powder samples are presented separately below (see Section 2.3).

2.1 Summary of SWMU 1 Soil Data

Pesticides, SVOCs, VOCs, TPH-gasoline, antimony, beryllium, cadmium, mercury, silver, thallium, cyanide, several PAHs, and several congeners of PCBs were not detected in soil samples collected in SWMU 1.

Table C1-9 lists the 37 constituents detected at SWMU 1. These include four calculated quantities (benzo(a)pyrene equivalents, total low molecular weight PAHs, total high molecular weight PAHs, and total PCBs). Nine of these constituents (aluminum, calcium, iron, magnesium, manganese, potassium, sodium, Aroclor-1254, and total PCBs) were detected in the TAL/TCL samples.

Twenty-one of these constituents (aluminum, iron, sodium, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, fluoranthene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, pyrene, total low molecular weight PAHs, total high molecular weight PAHs, benzo(a)pyrene equivalent, Aroclor-1254, total PCBs, TPH-diesel, and TPH-motor-oil) were detected at concentrations below their respective interim screening levels. Sixteen constituents (arsenic, barium, calcium, total chromium, hexavalent chromium, cobalt, copper, lead, magnesium, manganese, molybdenum, nickel, potassium, selenium, vanadium, and zinc) were detected one or more times at concentrations exceeding the interim screening levels and are discussed below.

Nine constituents (total chromium, hexavalent chromium, cobalt, copper, molybdenum, nickel, vanadium, zinc, and calcium) were detected at concentrations exceeding the interim screening level four or more times; the distributions of these constituents are shown in Figures C1-1 and C1-3 to C1-9. A figure has not been created for calcium since it is considered an essential nutrient, and residential and commercial/industrial California human health screening levels (CHHSLs) and an ecological comparison value (ECV) have not been established for this compound.

2.2 Nature and Extent Evaluation

This section describes the nature and extent of residual soil concentrations of COPCs and COPECs at SWMU 1. Laboratory analytical results for historical and Part A Phase 1 soil samples and the white powder samples at SWMU 1 are presented in Tables C1-2 through C1-8. Table C1-9 presents a statistical summary of soil analytical results for COPCs and COPECs that were either detected above the laboratory reporting limits or not detected but where the reporting limits for one more samples was greater than the interim screening value. White powder data are not included in this soil data statistical summary. Soil data are discussed first, followed by a discussion of the white powder sample data.

As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Section 2.5 of this sub-appendix summarizes the constituents that may require further evaluation and Section 6.0 of this sub-appendix provides the rationale for proposed Phase 2 sample locations to fill identified data gaps.

2.2.1 Arsenic

Arsenic was detected in 134 of 141 soil samples collected at SWMU 1. At two locations (SWMU1-WP-3A at 9 to 10 feet bgs and SWMU1-WP-5a at 5 to 6 feet bgs), the detected concentrations of arsenic (12 milligrams per kilogram [mg/kg]) slightly exceeded the interim screening level of 11 mg/kg (background threshold value [BTV]) , as shown in Tables C1-3 and C1-9. The same two samples also exceeded the ECV of 11.4 mg/kg. These locations are located along the center of SWMU 1. Samples with concentrations below the screening levels surround these two locations laterally. At each location, concentrations in deeper samples are below the screening levels.

2.2.2 Barium

Barium was detected in 149 of 149 soil samples collected from SWMU 1. At two locations, the detected concentrations of barium exceeded the interim screening level of 410 mg/kg (BTV/ECV) (SWMU1-15 [560 mg/kg at 89 to 90 feet bgs] and SWMU1-WP-9 [1,900J mg/kg at 2 to 3 feet bgs]), as shown in Tables C1-3 and C1-9. None of the detected concentrations exceeded the residential and commercial/industrial CHHSL of 5,200 mg/kg and 63,000 mg/kg, respectively. The two locations with exceedances of the BTV/ECV are in the southwestern portion of SWMU 1. Samples with concentrations below the interim screening level are located to the north, east, and south of these locations, but not the west. At SWMU1-WP-9, concentrations in deeper samples are well below the interim screening level. At SWMU1-15, all other samples were located above 89 to 90 feet bgs. All of these samples had barium concentrations well below the BTV. Therefore, because the elevated concentration of barium detected at depth does not appear to be related to a surface release, no further characterization is needed for barium in this area. Also, while the concentration of barium in the deepest sample exceeds the BTV, it is well below the CHHSL.

2.2.3 Total Chromium

Total chromium was detected in 185 of 185 soil samples collected at SWMU 1. Detected concentrations of total chromium exceeded the interim screening level of 39.8 mg/kg (BTV/ECV) 73 times (with a maximum detected concentration of 3,200 mg/kg at SWMU1-1 at 5 to 6 feet bgs), as shown in Tables C1-3 and C1-9 and Figure C1-1. Twenty-six of the detected concentrations of total chromium exceeded the United States Environmental Protection Agency residential regional screening level (RSL) for residential use (280 mg/kg), and seven of the detected concentrations exceeded the RSL for commercial use (1,400 mg/kg). The lateral extent of samples with concentrations exceeding the BTV encompasses all of SWMU 1. At fifteen locations, the deepest samples have concentrations exceeding the BTV. Seven of these locations are along the eastern bank of Bat Cave Wash. In addition, five locations where only surface soil samples were collected (T-B-3, WP-1, WP-2, WP-Bank-1, and WP-Bank-2) showed concentrations above the BTV (three of these surface soil samples also exceeded the residential RSL). Samples with concentrations exceeding the residential RSL are located in the northern portion of SWMU 1 and the eastern bank of Bat Cave Wash. Exceedances of the residential RSL are generally vertically bounded, except at the three surface soil locations described above, and at location WP-6, where the deepest sample was collected at 2 feet bgs.

2.2.4 Hexavalent Chromium

Hexavalent chromium was detected in 48 of 185 soil samples collected at SWMU 1. Detected concentrations of hexavalent chromium exceeded the interim screening level of 0.83 mg/kg (BTV) 34 times (with a maximum detected concentration of 47.5 mg/kg at WP-1 at 0 feet bgs), as shown in Tables C1-3 and C1-9 and Figure C1-3. Four of the detected concentrations of hexavalent chromium exceeded the residential CHHSL (17 mg/kg), and one detected concentration exceeded the commercial/industrial CHHSL (37 mg/kg). None of the detected concentrations exceeded the ECV (139.6 mg/kg). The lateral extent of samples with hexavalent chromium concentrations exceeding the screening levels exist primarily along the northern portion of SWMU 1 and the eastern bank of Bat Cave Wash. At four subsurface locations, the deepest samples have concentrations exceeding screening levels. In addition, five surface soil samples (T-B-3, WP-1, WP-4, WP-Bank-1, and WP-Bank-2) and one shallow sample (WP-6 at 2 feet bgs) exceed the BTV, and deeper samples were not collected in these locations.

2.2.5 Cobalt

Cobalt was detected in 141 of 141 soil samples collected from SWMU 1. Detected concentrations of cobalt slightly exceeded the interim screening level of 12.7 mg/kg (BTV) 20 times and the ECV of 13 mg/kg 14 times (with a maximum detected concentration of 19 mg/kg at SWMU1-WP-6h), as shown in Table C1-3 and C1-9 and Figure C1-4. None of the detected concentrations exceeded residential or commercial/industrial RSLs (23 mg/kg and 300 mg/kg, respectively). The lateral extent of samples with concentrations exceeding screening levels appears to be limited to the southern half of SWMU 1. At five locations, the deepest samples have concentrations that slightly exceed the BTV and the ECV (the highest concentration is 16 mg/kg), but all detections are below the residential RSL.

2.2.6 Copper

Copper was detected in 184 of 185 soil samples collected at SWMU 1. Detected concentrations of copper exceeded the interim screening level of 16.8 mg/kg (BTV) 41 times (with a maximum detected concentrations of 61 mg/kg at SWMU1-WP-6h at 2 to 3 feet bgs), as shown in Tables C1-3 and C1-9 and Figure C1-5. Twenty-five detected concentrations exceeded the ECV (20.6 mg/kg), and no detected concentrations of copper exceeded the residential or commercial/industrial CHHSLs (3,000 mg/kg, and 38,000 mg/kg, respectively). The lateral extent of samples with concentrations exceeding the screening levels appears to be limited primarily to the southern half of SWMU 1, although one slight exceedance (22 mg/kg) of the ECV was identified at SWMU1-2 in the northern portion of SWMU 1. At seven locations, the deepest samples have concentrations exceeding the BTV and ECV. In addition, three surface samples (T-3-B, WP-2, and WP-BANK 2) have concentrations exceeding the BTV, and deeper samples were not collected at these locations.

2.2.7 Lead

Lead was detected in 148 of 149 soil samples collected at SWMU 1. Detected concentrations of lead exceeded the interim screening level of 8.39 mg/kg (BTV/ECV) at two locations (MW-9 [8.4 mg/kg at 87 feet] and SWMU1-WP-7 [13 mg/kg at the surface]), as shown in Tables C1-3 and C1-9. None of the detected concentrations exceeded the residential or commercial/industrial CHHSLs (80 mg/kg and 320 mg/kg, respectively). These locations are located in the southern portion of SWMU 1. Samples with concentrations below screening levels surround each of these two locations laterally. At MW-9, the deepest sample contains lead at 8.4 mg/kg compared to the BTV of 8.39 mg/kg. At SWMU1-WP-7, concentrations in deeper samples are below screening levels.

2.2.8 Molybdenum

Molybdenum was detected in 31 of 149 soil samples collected form SWMU 1. Detected concentrations of molybdenum exceeded the interim screening level of 1.37 mg/kg (BTV) 22 times (with maximum detected concentration of 7.8 mg/kg at SWMU1-1), as shown in Table C1-3 and C1-9 and Figure C1-6. Eleven detected concentrations exceeded the ECV (2.25 mg/kg), and no detected concentrations of molybdenum exceeded residential and commercial/industrial CHHSL (380 mg/kg and 4,800 mg/kg, respectively). The lateral extent of samples with concentrations exceeding the BTV includes most of SWMU 1. At one location (2.8 mg/kg at SWMU1-2 at 9 to 10 feet bgs), the deepest samples have concentrations slightly exceeding the BTV. The concentration at SWMU1-2 also slightly exceeds the ECV.

2.2.9 Nickel

Nickel was detected in 185 of 185 soil samples collected from SWMU 1. Detected concentrations of nickel exceeded the interim screening level of 27.3 mg/kg (BTV/ECV) 20 times (with a maximum detected concentration of 51 mg/kg at SWMU1-WP-9 at 11 to

12 feet bgs), as shown in Tables C1-3 and C1-9 and Figure C1-7. None of the detected concentrations exceeded the residential or commercial/industrial CHHSLs (1,600 mg/kg and 16,000 mg/kg, respectively). The lateral extent of samples with concentrations exceeding screening levels appears to be limited to the southern portion of SWMU 1. At five locations, the deepest samples have concentrations exceeding the BTV. The vertical extent of nickel is not defined at SWMU1-WP-9 at 13 to 14 feet bgs.

2.2.10 Selenium

Selenium was detected in four of 141 soil samples collected from SWMU 1. Detected concentrations of selenium exceeded the interim screening level of 1.47 mg/kg (BTV/ECV) at two locations (1.6 mg/kg at SWMU1-16 at 5 to 6 feet bgs and 2.5 mg/kg at SWMU1-WP-9 at 2 to 3 feet bgs), as shown in Tables C1-3 and C1-9. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). These locations are located in the southern portion of SWMU 1. Samples with concentrations below screening levels surround each of these two locations laterally. At SWMU1-16, the deepest sample (5 to 6 feet bgs) slightly exceeds the screening level (1.6 mg/kg compared to the BTV of 1.47 mg/kg). At SWMU1-WP-9, concentrations in deeper samples are below screening levels.

2.2.11 Vanadium

Vanadium was detected in 149 of 149 soil samples collected from SWMU1. Detected concentrations of vanadium slightly exceeded the interim screening level of 52.2 mg/kg (BTV/ECV) nine times (with a maximum detected concentration of 57 mg/kg at SWMU1-15 at 40 to 50 feet bgs), as shown in Table C1-3 and C1-9 and Figure C1-8. None of the detected concentrations of vanadium exceeded residential and commercial RSLs (390 mg/kg and 5,200 mg/kg, respectively). The lateral extent of samples with concentrations exceeding screening levels appears to be limited to the southern half of SWMU 1. At three locations (SWMU1-T3a, SWMU1-WP-6a, and SWMU-WP-9), the deepest samples have concentrations slightly exceeding the BTV, with concentrations of 53 mg/kg, 55 mg/kg, and 56 mg/kg, respectively.

2.2.12 Zinc

Zinc was detected in 185 of 185 soil samples collected at SWMU 1. Detected concentrations of zinc exceeded the interim screening level of 58 mg/kg (BTV/ECV) 37 times (with a maximum detected concentration of 673 mg/kg [surface soil sample T-3-B]), as shown in Tables C1-3 and C1-9 and Figure C1-9. None of the detected concentrations exceeded residential and commercial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively). The lateral extent of samples with concentrations exceeding screening levels is generally limited to the northern portion of SWMU 1 and a portion of the east bank of Bat Cave Wash. At 10 locations, the deepest samples have concentrations exceeding screening levels. In addition, four surface samples (T-3-B, WP-2, WP-4, and WP-Bank-2) and one shallow soil sample (WP-6 at 2 feet bgs) have concentrations exceeding the BTV; deeper samples were not collected at these locations.

2.2.13 Target Analyte List/Target Compound List Constituents

Ten percent of the Phase 1 soil samples collected in SWMU 1 (16 soil samples) were analyzed for the full inorganic and organic suites per the CERCLA TAL/TCL. Aluminum, calcium, iron, magnesium, manganese, potassium, sodium, Aroclor-1254, and total PCBs were detected in the SWMU 1 soil samples analyzed for the complete TAL/TCL suite of compounds. These constituents are discussed below.

Aluminum was detected in 16 of 16 surface soil samples collected from SWMU 1. None of the detected concentrations exceeded the BTV (16,400 mg/kg). The maximum detected concentration was 12,000 mg/kg at SWMU1-11. Remaining detected concentrations of aluminum ranged from 5,900 to 11,000 mg/kg), as shown in Tables C1-4 and C1-9. None of the detected concentrations exceeded residential and commercial CHHSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in 19 of 19 surface soil samples collected from SWMU 1. Detected concentrations of calcium exceeded the interim screening level of 66,500 mg/kg (BTV) four times (with a maximum detected concentration of 280,000 mg/kg at WP-BANK 1), as shown in Tables C1-4 and C1-9. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium. The lateral extent of samples with concentrations exceeding the BTV appears to be limited primarily on the eastern slope of Bat Cave Wash in the white powder area, although one exceedance (255,000J mg/kg) of the BTV was identified at P-2Soil in the central portion of SWMU 1 along the western boundary.

Iron was detected in 27 of 27 soil samples collected from SWMU 1. The maximum detected concentration of iron was 25,000 mg/kg at both SWMU1-1 at 0 to 0.5 foot bgs and SWMU1-WP-7 also at 0 to 0.5 foot bgs. All detected concentrations are below the interim screening level of 55,000 mg/kg (residential RSL), as shown in Tables C1-4 and C1-9. Remaining detected concentrations of iron ranged from 4,760 to 24,000J mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for iron.

Magnesium was detected in 19 of 19 surface soil samples collected from SWMU 1. Detected concentrations of magnesium exceeded the interim screening level of 12,100 mg/kg (BTV) two times (at two sample locations; 14,700J mg/kg at P-2Soil at 3.5 feet bgs and 14,300 mg/kg at WP-BANK 2 at 0 to 0.5 foot bgs), as shown in Tables C1-4 and C1-9. Remaining detections ranged from 6,300 to 12,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium. The two samples with concentrations exceeding the BTV are located in the southern portion of SWMU 1.

Manganese was detected in 27 of 27 samples collected from SWMU 1. One detected concentration of magnesium slightly exceeded the interim screening level of 402 mg/kg (BTV/ECV) (detected concentration of 526 mg/kg at MW-9), as shown in Tables C1-4 and C1-9. The detected concentration did not exceed the residential and commercial/industrial CHHSLs (1,800 mg/kg and 23,000 mg/kg, respectively). This exceedance was detected in the deepest sample collected at this location (87 feet bgs), and concentrations in the overlying samples at this location were well below the BTV. Remaining detected concentrations ranged from 67.4 to 340 mg/kg. Therefore, because the elevated concentration of manganese detected at depth does not appear to be related to a surface release, no further characterization is needed for manganese in this area.

Potassium was detected in 19 of 19 surface soil samples collected from SWMU 1. One detected concentrations of potassium exceeded the interim screening level of 4,400 mg/kg (BTV) (detected concentration of 4,900 mg/kg at SWMU1-17), as shown in Tables C1-4 and

C1-9. The remaining detected concentrations ranged from 1,040 to 3,200 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for potassium.

Sodium was detected in 13 of 19 surface soil samples collected from SWMU 1. The maximum detected concentration of sodium was 1,800 mg/kg at WP-Bank-1) which is below the interim screening level of 2,070 mg/kg (BTV), as shown in Tables C1-4 and C1-9. Remaining detected concentrations of sodium ranged from 190 to 1,650 mg/kg. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for sodium.

The PCB Aroclor-1254 was detected in nine of 21 soil samples collected from SWMU 1; both surface (0 to 0.5 feet bgs) and shallow soil (2 to 3 feet bgs) samples were collected. The maximum detected concentration of Aroclor-1254 of 200 micrograms per kilogram (µg/kg) was detected at SWMU1-WP-7 at 0 to 0.5 foot bgs. Remaining detected concentration of Aroclor-1254 range from 18 to 96 µg/kg. None of the detected concentrations of Arcolor-1254 exceeded the interim screening level of 220 µg/kg (residential RSL), as shown in Table C1-8. To assist with evaluation of PCBs for ecological risk, detected concentrations of the Aroclors (only Aroclor-1254 at SWMU 1) were summed, and the total PCB values were compared to the ECV. The maximum calculated value for total PCBs was 200 µg/kg, which is below the total PCB ECV of 204 µg/kg, as shown in Table C1-8. The remaining calculated total PCB concentrations ranged from 18 to 96 µg/kg.

As discussed in Section C.2 of the main text of Appendix C, PG&E recommends that PCBs be evaluated further in SWMU 1. PG&E also recommends aluminum, calcium, iron, magnesium, manganese, potassium, and sodium not be considered COPCs/COPECs for this SWMU, and no further sampling is proposed for these constituents. These constituents have been fully discussed in Section C.2 of Appendix C.

2.3 White Powder Samples

As previously mentioned, eight trenches were excavated on the eastern side of SWMU 1 to evaluate the extent of white powder on the hillside, as shown in the inset of Figures C1-1 and C1-3 to C1-9. A photo log of the trenches is included as Appendix B4 of Appendix B to the Data Gaps Evaluation Report. Trench SWMU1-WP-2h defines the northern extent of the white powder, and the southern extent is defined by trench SWMU1-WP-10 and the topography just south of trench SWMU1-WP-10.

White powder material was encountered at several places in SWMU 1 during trenching activities into the eastern sidewall of Bat Cave Wash. Four samples of white powder material (sample locations SWMU1-WP-5h at 2 to 3 feet bgs, SWMU1-WP-6h at the surface (0 to 0.5 foot bgs), SWMU1-WP7 at 2 to 3 feet bgs, and SWMU1-WP-10 at 2 to 3 feet bgs) were collected and sent to the laboratory for analysis. The white powder material in SWMU 1 was mapped, and results of the mapping are presented in Appendix B to the Data Gaps Evaluation Report. In general, the following compounds were detected in the white powder material samples: arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, nickel, vanadium, and zinc. Molybdenum was detected in one of the white powder material samples. Of those compounds detected, total chromium, hexavalent chromium, molybdenum, and zinc were detected above their respective interim screening levels. The maximum detected concentrations of total chromium in the white powder samples was 1,400 mg/kg (exceeding the BTV and equal to the industrial RSL) collected at

SWMU1-WP-10 at 2 to 3 feet bgs; hexavalent chromium was 18.2 mg/kg (exceeding the BTV and residential CHHSL) collected at SWMU1-WP-7 at 2 to 3 feet bgs; molybdenum was 3.4 mg/kg (exceeding the BTV and ECV) collected at SWMU1-WP-7 at 2 to 3 feet bgs; and zinc was 360 mg/kg (exceeding the BTV and ECV) collected at SWMU1-WP-10 at 2 to 3 feet bgs.

The extent of white powder material in SWMU 1 has been defined to the north, south, and west of the white powder area; however, the extent of the white powder has not been defined to the east of the white powder area, on the slope leading up to the compressor station fence line.

2.4 Central Tendency Comparison to Background Threshold Values

Sixteen metals (arsenic, barium, calcium, total chromium, hexavalent chromium, cobalt, copper, lead, magnesium, manganese, molybdenum, potassium, nickel, selenium, vanadium, and zinc) were detected above their respective Topock site-specific BTVs in soil collected from SWMU 1, as shown in Table C1-9. A central tendency comparison was performed for 14 of these 16 metals (arsenic, barium, calcium, total chromium, cobalt, copper, lead, magnesium, manganese, molybdenum, potassium, nickel, vanadium, and zinc) to compare the SWMU 1 soil data set for these metals with the corresponding Topock soil background data set to determine whether a difference exists between the two populations and if additional sampling is required for a given metal (see Figure 3-1 in the Data Gaps Evaluation Report and Table C1-10 of this sub-appendix). Metals in either the SWMU 1 data or background data set that were detected infrequently (less than five detects) or had a limited number of results (less than eight) were not tested. There were insufficient detections of selenium at SWMU 1 to conduct the test, and there were insufficient detections of hexavalent chromium in the background data set to allow for a central tendency comparison; however, additional investigation is proposed to evaluate the lateral and vertical extent of hexavalent chromium at SWMU 1.

No statistical difference between the two populations was noted for arsenic, barium, calcium, lead, magnesium, manganese, molybdenum, potassium, nickel, and vanadium, as shown in Table C1-10. However, results from the Gehan test show that site concentrations for total chromium, cobalt, copper, and zinc may exceed background. The lateral and vertical extent of cobalt have been adequately defined, as discussed above, and additional sampling is proposed for total chromium, copper, and zinc. Although the Gehan test indicated that the distribution of nickel and molybdenum detections in the site data set is statistically comparable to background, additional sampling is also recommended to further evaluate the extent of nickel and molybdenum within SWMU 1.

2.5 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review indicates than decision error has been held to an acceptable level. Sufficient data of acceptable quality have been attained by the collection of historical Part A soil samples in areas most likely to have been impacted by the wastewater discharges to the Bat Cave Wash and the former percolation bed, white powder on the east bank of Bat Cave Wash, and potential stormwater runoff from the lower yard of the compressor station. Review of the nature and extent discussions above indicates that the lateral extent of samples with concentrations exceeding interim screening levels is variable, with the majority constituents exceeding screening levels located in the northern portion of SWMU 1 and along the eastern bank of Bat Cave Wash. Exceedances of total chromium and hexavalent chromium are present throughout this unit. Based on the review of the data for SWMU 1, the lateral extent of molybdenum extends to the SMWU 1 boundary. The vertical extent of chromium, hexavalent chromium, copper, molybdenum, nickel, and zinc has not been completely defined in the bottom of the wash.

Based on review of the data and the Part A DQOs, two data gaps were identified to resolve Decision 1 – Nature and Extent, and limited additional sampling is recommended in Phase 2 to fill the following data gap:

- Data Gap #1 – Vertical extent of contamination within the SWMU 1 boundary.
- Data Gap #2 – Lateral extent of white powder upslope from the white powder area to the compressor station boundary.

Proposed Phase 2 sample locations are presented in Section 6.0 of this sub-appendix.

3.0 Decision 2 – Data Sufficiency to Estimate Representative Exposure Point Concentrations

The principal consideration for Decision 2 was whether there were sufficient data to estimate a representative exposure point concentration (EPC) for the combined SWMU 1/AOC 1 area. For Decision 2, SWMU 1 data were combined with AOC 1 data to determine if SWMU 1/AOC 1 data are sufficient to conduct human health and ecological risk assessments based on the criteria described in Section 4.0 of the Data Gaps Evaluation Report. This is consistent with the approach to exposure assessment described in the Human Health and Ecological Risk Assessment Work Plan (ARCADIS, 2008). Category 1 soil sampling results and results from location AOC1-BCW-6, in an area of soil transitioning to sediment, were included in the combined SWMU 1/AOC 1 data set for the Decision 2 evaluation.

Table C2-10 in Appendix C2 summarizes the results of the evaluation to determine if data are sufficient to estimate representative EPCs. Table C2-10 documents the review of all combined AOC 1/SWMU 1 data. Data were reviewed for all chemicals that were detected in at least one sample and that exceeded at least one comparison value. The samples designated as “white powder” were included in the data reviewed as a conservative measure, assuming that exposure to white powder areas would not differ significantly from exposure to surrounding soil areas. In general, existing data are adequate to support soil EPC development for detected chemicals that exceeded one or more comparison values (twelve metals, three CLP inorganics, and PAHs) as described below. Phase 2 data will be added to the existing data set to calculate the final EPC (i.e., after Decision 1 is satisfied).

3.1 Metals

Sufficient data (numbers of samples and detections) are available to calculate EPCs for arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, and zinc using the ProUCL software, as shown in Table C2-10. For selenium, additional data collection is not expected to significantly change the results of the risk assessment because the compound is very infrequently detected (i.e., additional non-detects would be expected).

3.2 Inorganics

Sufficient data (numbers of samples and detections) are available to calculate EPCs for calcium, magnesium, and potassium using ProUCL, although additional data are not available for deeper locations associated with the scouring scenarios. No additional data collection appears warranted because it is reasonable to assume that the nature and extent of these inorganics in the shallow exposure intervals (0 to 0.5 foot bgs or 0 to 3 feet bgs) are representative of the deeper depths. In addition, maximum concentrations of calcium, magnesium, and potassium detected in the standard exposure intervals (0 to 0.5, 0 to 3, 0 to 6, and 0 to 10 feet bgs) are comparable to background (all detections were below the BTV, as discussed in Tables C1-4 and C1-9).

3.3 Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene toxicity equivalents and high molecular weight PAHs using ProUCL.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

A conservative, three-tiered approach was used in the evaluation to assess the potential impact to groundwater from source areas in the vadose zone. A full description of the three-tiered approach is provided in Section 5.0 of the Data Gaps Evaluation Report. Since the southern portion of AOC 1 encompasses SMWU 1, the data from these two areas were analyzed together for Decision 3. Figure C-1 in Appendix C shows the location of the combined SMWU 1/AOC 1 South subarea.

The following preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, are needed to resolve Decision 3. Additional evaluation will be performed as appropriate, as data are collected to resolve Decision 1. Data collected to satisfy Decision 1 – Nature and Extent evaluation will provide the final representative data set that will be used to assess the threat to groundwater. Table C1-11 presents the results of the tiered analysis for the SMWU 1/AOC 1 South subarea.

Twelve metals were detected at concentrations above the background threshold values. Of these 12 metals, only hexavalent chromium and molybdenum were detected at concentrations that exceeded the calculated soil screening levels, as shown in Table C1-12. Based on the initial screening model, the potential for hexavalent chromium and molybdenum to leach to groundwater was ruled out. Consequently, none of the metals detected in soil in subarea SWMU 1/AOC 1 South presents a threat to current or future groundwater, and no further sampling is required to address Decision 3 for SWMU 1/AOC 1 South.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Gaps Evaluation Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study (CMS/FS). The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fence line include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite).
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil washing technologies).
- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies).
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- If present, volumes of white powder and debris.

The following is a summary of data for SWMU 1 that are currently available to support CMS/FS. Data gaps identified for Decision 4 will be filled using samples being collected to fill data gaps identified for other decisions. Data will not be collected to solely fill Decision 4 data gaps.

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. The lateral and vertical extent of the COPCs and COPECs is discussed in Sections 2.2 and 2.3 of this sub-appendix. Data results for selected constituents are shown in Figures C1-1 and C1-3 through C1-9, and data gaps associated with lateral and vertical delineation are discussed in Section 6.0 of this sub-appendix.

5.2 Waste Characterization Parameters

Only partial waste characterization data are available to characterize the soil and other materials to be potentially removed for remedial action and disposed in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations (TTLC). The maximum concentrations of these metals for each of the units were compared to the TTLCs, and total chromium exceeded the TTLCs twice, as shown in Table C1-13. The maximum detected concentrations were also compared to the soluble threshold limit concentrations (STLCs). Concentrations of barium exceeded 10 times the STLC once, and total chromium exceeded 10 times the STLC 58 times, as shown in Table C1-13. In addition, total chromium also exceeded 20 times the toxicity characteristic leaching procedure (TCLP) in 37 samples, as indicated in Table C1-13. Because these metals have the potential to exceed STLC or TCLP thresholds, additional leachability testing for waste characterization purposes may be required if soil excavation and offsite disposal is chosen as a remedy. For the purposes of supporting the CMS/FS, the lack of STLC or TCLP analysis is not considered a data gap, for the existing total concentrations are sufficient for the purposes of evaluating various remedial alternatives. Additional data regarding potential COPC/ COPEC leachability include SPLP analysis for total and hexavalent chromium, as shown in Table C1-2. SPLP analysis was conducted only for soil samples (no white powder or debris samples were tested using SPLP). SPLP analysis of the white powder material is needed to support the CMS/FS.

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 soil investigation was limited to grain size analysis only. Specific soil physical properties data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 in the Data Gaps Evaluation Report. Additional soil physical parameter data are needed to support the CMS/FS.

5.4 Surface and Subsurface Features

While there is extensive information regarding surface and subsurface features at SWMU 1, additional information may be required once areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are known for SWMU 1. However, subsurface utilities, including gas transmission pipelines and any culverts or other features, may have to be more precisely defined to evaluate the feasibility and cost of certain remedial alternatives and to prepare construction specifications.

6.0 Summary of Data Gaps, Proposed Phase 2 Soil Sample Locations to Fill Identified Gaps, and Access Restrictions

Based on the Part A DQO, data gaps were identified for two of the four decisions and are summarized below by decisions:

- **Decision 1 – Nature and Extent**. The following data gaps were identified to resolve this decision:
  - Data Gap #1 – Vertical extent of contamination within SWMU 1 boundary.
  - Data Gap #2 – Lateral extent of white powder upslope from white powder area to the compressor station boundary.
- **Decision 2 (Data Sufficient to Estimate Representative Exposure Point Concentrations)**. No data gap was identified for this decision.
- **Decision 3 (Potential Threat to Groundwater from Residual Soil Concentrations).**
  - Data Gap #3 – Vertical extent of contamination within SWMU 1 boundary.

- **Decision 4 (Data Sufficient to Estimate Soil Properties and Contaminant Distribution in Support of the CMS/FS).** The following data gap was identified to resolve this decision**:**
  - Data Gap #4 – Soil physical parameters to support the CMS/FS. Three samples each from boring locations SWMU1-18 and SWMU1-19 are proposed to be analyzed for soil physical parameters.

Table C1-14 summarizes the proposed Phase 2 sample locations, depths, rationale for each location, and analytes. Proposed Phase 2 sample locations are also shown in Figure C1-1 and Figures C1-3 through C1-10.

6.1 Access Restrictions

Most of the potential SWMU 1 Phase 2 sample locations are located at the bottom of Bat Cave Wash; no access restrictions are apparent with the exception of potential subsurface boulders. The proposed Phase 2 sample locations not located in the wash are located near the compressor station fence line at the top of a very steep slope. A backhoe will need to be used to collect these samples. Slope stability may limit the amount of soil that can be removed for sampling.

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

TABLE C1-5

Sample Results: Polycyclic Aromatic Hydrocarbons

SWMU 1 - Former Percolation Bed (Former Holding Pond)

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

mg/kg	miligrams per kilogram
µg/kg	micrograms per kilogram
ng/kg	nanograms per kilogram

[1] Soil Screening Level (SSL) calculation was provided in the technical memorandum entitled "Calculation of Soil Screening Levels for Protection of Groundwater at the PGE Topock Compressor Station", CH2MHill 2008.

[2] CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

Cobalt has no MCL. EPA tapwater regional screening level (11 ug/L) was used in place of MCL.

Results greater than or equal to the SSL and greater than or equal to the background value are circled.

mg/kg	milligrams per kilogram
ft bgs	feet below ground surface
N	primary sample
FD	field duplicate
---	not analyzed
ND	not detected at the listed reporting limit
J	concentration or reporting limit estimated by laboratory or data validation

TABLE C1-13

Constituent Concentrations in Soil Compared to Total Threshold Limit Concentration (TTLC), Soluble Threshold Limit Concentration (STLC), and Toxic Characteristic Leaching Procedure (TCLP)
SWMU 1 - Former Percolation Bed (Former Holding Pond)
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Topock Compressor Station, Needles, California

			TTLC in mg/kg[1]		**STLC in mg/L**[1]			**TCLP in mg/L**[1]		
Parameter	**Frequency of detection**	**Maximum Detected Value (mg/kg)**	**# of Exceedences**	**TTLC**	**# of Exceedences of STLC x 10**	**STLC x 10**	**STLC**	**# of Exceedences of TCLP x 20**	**TCLP x 20**	**TCLP**

Notes:

[1] Code of Regulations, Title 22, Chapter 11, Article 3

mg/kg	miligrams per kilogram
mg/L	milligrams per liter
ND	not detected in any of the samples
NE	not established
‡	maximum reporting limit greater than or equal to the STLC x 10.

TABLE C1-14
Proposed Phase 2 Sampling Locations at SWMU 1
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Proposed Collection Method[c]
SWMU1-18	0, 2, 5, 9, 14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gaps #1, #3, and #4 - Define lateral and vertical extent in southern part of AOC 1 and support CMS/FS	Hexavalent chromium, Title 22 metals, PCBs[a]; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Rotosonic
SWMU1-19	0, 2, 5, 9, 14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gap #1, #3, and #4 - Define lateral and vertical extent in bottom of Bat Cave Wash	Hexavalent chromium, Title 22 metals, PCBs[a]; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Rotosonic
SWMU1-20	14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gaps #1 and #3 - Define vertical extent at previous sample location SWU1-2	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
SWMU1-21	14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gaps #1 and #3 - Define vertical extent at previous sample location SWU1-1	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
SWMU1-22	None – pothole sample location	To resolve Data Gap #2 – Define lateral extent of white powder area and collect a sample of the white powder material and soil	Hexavalent chromium, Title 22 metals, PCBs[a], SPLP[b] and general chemistry analyses[b]	Backhoe
SWMU1-23	None – pothole sample location	To resolve Data Gap #2 – Define lateral extent of white powder area and collect a sample of the white powder material and soil	Hexavalent chromium, Title 22 metals, PCBs[a], SPLP[b] and general chemistry analyses[b]	Backhoe
SWMU1-24	None – pothole sample location	To resolve Data Gap #2 – Define lateral extent of white powder area and collect a sample of the white powder material and soil	Hexavalent chromium, Title 22 metals, PCBs[a], SPLP[b] and general chemistry analyses[b]	Backhoe

Notes:

CMS/FS = corrective measures study/feasibility study.
ft bgs = feet below ground surface.

[a] PCB analysis only on soil samples collected at 0 and 2 feet bgs.

[b] White powder samples only.

[c] Proposed anticipated collection methods listed on this table are based on experience and knowledge of the site; actual collection method will be chosen in the field based on field conditions and site access restrictions.

Acronyms and Abbreviations

µg/kg	micrograms per kilogram
AOC	Area of Concern
bgs	below ground surface
BTV	background threshold value
CHHSL	California human health screening level
CMS/FS	corrective measures study/feasibility study
COPC	chemical of potential concern
COPEC	chemical of potential ecological concern
DQO	data quality objective
ECV	ecological comparison value
EPC	exposure point concentration
mg/kg	milligrams per kilogram
ng/kg	nanograms per kilogram
PAH	polycyclic aromatic hydrocarbon
PCB	polychlorinated biphenyl
PG&E	Pacific Gas and Electric Company
RSL	regional screening level
SPLP	synthetic precipitation leaching procedure
STLC	soluble threshold limit concentration
SWMU	Solid Waste Management Unit
TAL	Target Analyte List
TCL	Target Compound List
TCLP	toxicity characteristic leaching procedure
TPH	total petroleum hydrocarbons
TTLC	total threshold limit concentration
VOC	volatile organic compound

APPENDIX C2

Area of Concern 1 Data Gaps Evaluation Results

1.0 Introduction and Background

This sub-appendix presents the results of the Data Gaps Evaluation and the Part A Phase 2 Sampling Program for Area of Concern (AOC) 1 – Area Around Former Percolation Bed at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the data gaps evaluation is outlined in Sections 2.0 through 6.0 in the Data Gaps Evaluation Report.

1.1 Background

AOC 1 consists of the area that surrounds Solid Waste Management Unit (SWMU) 1, the former percolation bed. AOC 1 is located outside the facility fence line west of the compressor station within Bat Cave Wash, as shown in Figures C2-1 and C2-2. (All figures and tables appear at the end of this sub-appendix.) AOC 1 comprises a portion of Bat Cave Wash adjacent to the station and surrounding SWMU 1, as well as the portion of Bat Cave Wash extending to the north toward the Colorado River from SWMU 1. The investigation area is located partially on PG&E property, partially on the Havasu National Wildlife Refuge, partially on Bureau of Reclamation property (managed by Bureau of Land Management), partially on Burlington Northern Santa Fe Railroad land, and partially on Fort Mojave Indian Tribe property with PG&E as the easement holder.

From 1951 to approximately 1971, the facility discharged wastewater containing chromium (cooling tower blowdown) into Bat Cave Wash. Based on historical aerial photographs, it appears that during the 1950s, the facility discharged wastewater into the wash without any impoundment. Wastewater was released to the wash through two pipes that ran from the sludge-drying beds (SWMU 5) area in the lower yard down the slope into Bat Cave Wash. From about 1964 to 1971, wastewater was discharged to the former percolation bed (SWMU 1) which allowed water to percolate into the ground and/or evaporate. The chromium-containing wastewater was combined with a small quantity (approximately 5 percent) of treated water from the waste treatment system discharged from the station. PG&E completed closure of the former water treatment system that consisted of the sludge-drying beds (SWMU 5), chromate reduction tank (SWMU 6), process pump tank (SWMU 8), transfer pump (SWMU 9), transfer piping (AOC 18), the oil/water holding tank (Unit 4.3), the oil/water separator (Unit 4.4), and the portable waste oil storage tank (Unit 4.5). In the 1955 aerial photograph, an apparent round impoundment area with white powder material is located to the south of the sludge-drying beds (SWMU 5). This area has been identified as a new AOC (AOC 21) in the Part B investigation program (see Figure C2-2). Aerial photo review indicates that, prior to the establishment of the bermed percolation bed, discharges to Bat Cave Wash may have extended as far downstream as the railroad tracks.

Periodic storm (high runoff) events occur in Bat Cave Wash, making it difficult to assess the precise nature of erosion and deposition patterns. A 2006 storm event resulted in substantial erosion in portions of the wash in the vicinity of the compressor station, and a January 2010 storm event resulted in the movement of large gravel and cobbles from the southern area of Bat Cave Wash to the area near where AOC 4 enters Bat Cave Wash and as far north as the L-300A pipeline overcrossing (in the vicinity of SSB-1). North of the pipeline overcrossing, there appeared to be limited scouring and deposition in the wash and limited erosion of the wash walls within SWMU 1/AOC 1. Although there was damage to well MW-38, (installed in Bat Cave Wash), most of the sample location survey markers (1/8-inch lathe stakes) were still in place following the 2010 runoff event. MW-38 is also located immediately downstream of a sizable feeder wash on the west side of Bat Cave Wash. Based on this visual reconnaissance of Bat Cave Wash, most of the soil samples collected during Soil Part A Phase 1 are still considered to be representative. Surficial samples collected from locations within areas of highest energy during the 2010 event may not be representative of current conditions.

1.2 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 1 based on the above site history and background and is shown in Figures C2-3 and C2-4. Table C2-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 1. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the Soil Part A Data Quality Objective (DQO) Tech Memo, which is included as Appendix A to the Data Gaps Evaluation Report.

For AOC 1, the primary source of contamination is historical direct discharge of untreated wastewater into Bat Cave Wash and potential overflow or discharges from the SWMU 1 percolation bed. Therefore, surface soil in AOC 1 is the primary source medium. From surface soil, contaminants could have migrated to shallow and deeper soils. Shallow soils may act as a secondary source medium to subsurface soil, and subsurface soil may act as a secondary source medium to groundwater. Some of the contaminated wastewater may have infiltrated to affect subsurface soil and groundwater, as hexavalent chromium contamination is present in groundwater underneath AOC 1. If released, volatile organic compounds (VOCs) in surface soils would be expected to have been degraded by heat and light and are likely no longer present.

Other potential sources of contamination to AOC 1 are:

- Discharge from the Debris Ravine (AOC 4). Contaminants in fill/debris and surface soil in AOC 4 could have been entrained in surface water runoff and deposited in the southern portion of AOC 1 south of SWMU 1.
- Incidental spills and stormwater runoff from the western side of the compressor station (storm drains and/or sheet flow).
- Stormwater runoff from Interstate 40 and the railroad (from culverts discharging to Bat Cave Wash) could have resulted in the release of total petroleum hydrocarbons (TPH), polycyclic aromatic hydrocarbons (PAHs), lead, and wear metals (including barium, chromium, copper, nickel, and zinc) into AOC 1.

- Stormwater runoff from AOC 14, North of Interstate 40.
- Historical dumping and military activities in the vicinity of Bat Cave Wash.
- Runoff from the former "Workman's Roadhouse" and service station near the mouth of Bat Cave Wash.

Historically, chemicals of potential concern (COPCs) in surface soil in AOC 1 may have been eroded and entrained in stormwater/surface water runoff during flooding events and may have been subsequently re-deposited downstream (further north) in Bat Cave Wash. Repeated erosion and deposition of soil at AOC 1 may have resulted in mixing of surface and near-surface soils in this unit.

The thick vegetation, widening of the channel near the end of Bat Cave Wash, and blockage of flow by National Trails Highway, greatly reduces the energy of flow during runoff events, resulting in deposition of entrained soil within the vegetated area near the mouth of Bat Cave Wash. This heavily vegetated portion of Bat Cave Wash is a long-term depositional area that has existed since before the compressor station was built.

For AOC 1, windblown contamination from within the wash (in the southern portion of AOC 1 around SWMU 1), is influenced by the topography of the wash. Windblown contamination, if any, is expected to be limited to surface soils.

Part A Phase 1 and historical soil samples were collected in AOC 1 primarily from the bed of the wash, with six sample transects in the areas south of the Burlington Northern Santa Fe railroad tracks and in a linear pattern in center of the wash north of the railroad tracks to the south end of the vegetated area at the mouth of the wash.

Sixteen samples were collected from four locations on the upstream side of the vegetated area near the mouth of Bat Cave Wash, and two samples were collected from one location on the downstream side, as shown in Figure C2-2.

Additionally, six samples from four locations were collected south of SWMU 1, where AOC 4 Debris Ravine enters Bat Cave Wash, to assess potential impacts from AOC 4.

Based on the site history, background, and conceptual site models, Part A Phase 1 and historical soil samples were collected in areas within the wash expected to have been impacted by the discharge of chromium-containing wastewater from the facility runoff and transport of material from SWMU 1, as well as runoff from AOC 4, portions of the compressor station, and potentially AOC 14 and MW-24 bench.

Both soil and sediment data have been collected in AOC 1. These two data sets are discussed separately below.

1.3 AOC 1 Soil Sampling

1.3.1 AOC 1 Soil Data

There are 64 historical soil samples collected from 17 locations (MW-10, MW-11, MW-13, SS-1 through SS-8, SSB-1, SSB-6 through SSB-9, and XMW-9) in AOC 1, as shown in Figures C2-1 and C2-2. Samples were generally collected from 0 to 10 feet below ground surface (bgs); however, at XMW-9, MW-10, and MW-11, samples were collected from depths up to 82 feet bgs. Historical soil samples were analyzed for five constituents: total chromium, hexavalent chromium, copper, nickel, and zinc. The two samples from SS-1 were collected near the mouth of Bat Cave Wash in an area of soil transitioning to sediment. For the purposes of data evaluation, these two samples were included in both the soil and sediment data sets.

During the 2008 Soil Part A Phase 1 investigation, 105 soil samples (generally collected at sample depths of 0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet bgs) were collected from 26 sample locations (AOC1-BCW1 through 6 and AOC1-T1a-c, AOC1-T2a-e, AOC1-T3a-c, AOC1-T4a-c, AOC1-T5a-c and AOC1-T6a-c), as shown in Figures C2-1 and C2-2.

The two samples collected from location AOC1-BCW6 were collected where soil is transitioning into sediment near the mouth of Bat Cave Wash. As with the samples from SS-1, these two samples were included in both the soil and sediment data sets.

Soil Part A Phase 1 soil samples collected in AOC 1 were analyzed for Title 22 metals, hexavalent chromium, VOCs, semivolatile organic compounds, PAHs, TPH, pH, pesticides, and polychlorinated biphenyls (PCBs). Surface soil samples were not analyzed for VOCs. Ten percent of the Phase 1 soil samples collected in AOC 1 (11 soil samples) were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL). In addition, synthetic precipitation leaching procedure (SPLP) extraction was performed on soil samples collected at 2 to 3 feet bgs and 5 to 6 feet bgs at sample location AOC1-T2d, as shown in Table C2-2. The leachate from the SPLP extractions was analyzed for total and hexavalent chromium. Phase 1 data are included in Appendix D to the Data Gaps Evaluation Report.

All historical Category 1 and validated Phase 1 soil data were used as inputs to the four DQO decisions, this data is shown on Tables C2-3 through C2-10.

1.3.2 AOC 1 Sediment Data

In addition to the soil and soil-transitioning-to-sediment data discussed above, 18 historical sediment samples (collected at 1 and 2 feet bgs) were collected from 18 sample locations in the mouth of Bat Cave Wash and along the banks of the Colorado River upstream and downstream of the mouth of Bat Cave Wash (DrSed-1 through DrSed-3, SED-1 through SED-12, and SED-27 through SED-29). The sediment samples were analyzed for total chromium, hexavalent chromium, copper, nickel, and zinc. A few of the samples were also analyzed for the full suite of Title 22 metals. Arsenic, cadmium, barium, beryllium, total chromium, cobalt, copper, lead, mercury, molybdenum, nickel, silver, selenium, and thallium, vanadium, and zinc were detected in the sediment samples, as shown in Table C2-3.

1.3.3 Soil Data Collected in Bat Cave Wash near AOC 4

Soil sampling was recently conducted at the mouth of AOC 4 Debris Ravine where it enters Bat Cave Wash near the south end of AOC 1 as part of the AOC 4 time-critical removal action. The AOC 4 time-critical removal action is discussed in detail in Appendix C10. Twelve soil samples (AOC4-GB01 through AOC4-GB12) from seven sample locations were collected in this area at various depths, ranging from the surface to 5 feet bgs, and were analyzed for metals, PCBs, dioxins/furans, and PAHs. Prior to the AOC 4 time-critical removal action, three soil samples were collected in this area at sample location AOC4-1 at 0 to 0.5, 0.5 to 1, and 2 to 3 feet bgs, as shown in Figure C2-1. The AOC4-1 samples were analyzed for Title 22 metals, hexavalent chromium, PCBs, and PAHs. Barium, total chromium, hexavalent chromium, copper, lead, and zinc were detected in these soil samples above their respective soil background threshold values (BTVs). The maximum detected concentration of total PCBs was 2,400 micrograms per kilogram (µg/kg) in sample AOC4-GB05 collected at 4 to 5 feet bgs. The maximum detected concentration of dioxin/furan 2,3,7,8-TCDD toxic equivalency quotients (TEQs) was 950 nanograms per kilogram (ng/kg) in surface soil sample AOC4-GB03. All detected concentrations of benzo(a)pyrene equivalents were below screening levels.

During the installation of the gabions near the mouth of Debris Ravine, soil excavation was conducted, and soil was removed where samples AOC4-GB01 through AOC4-GB09 were collected. The soil samples collected at AOC4-GB10, AOC4-GB11, AOC4-GB12, and AOC4-1 are the only sample locations remaining, as shown in Figure C2-1. Results for these remaining samples are shown in Table C2-9. All historical Category 1, representative AOC 4 data (i.e., from samples collected following the installation of the gabions) and validated Phase 1 soil data were used as inputs to the four DQO decisions.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of COPCs and chemicals of potential ecological concern (COPECs) at AOC 1. Data for AOC 1 were divided into two media: soil and sediment. Laboratory analytical results for historical and Phase 1 soil samples at AOC 1 are presented in Tables C2-2 and C2-4 through C2-10. (As noted above, laboratory analytical results for historical sediment samples at AOC 1 are presented in Table C2-3.) Tables C2-4 through C2-10 also includes data for white powder samples. Table C2-11 presents a statistical summary of soil analytical results for COPCs and COPECs that were either (1) detected above the laboratory reporting limits or (2) not detected but where the reporting limits for one more samples was greater than the interim screening value. The soil statistical summary presented in Table C2-10 does not include white powder or sediment samples.

2.1 Summary of AOC 1 Sediment Data

The 2005 *RCRA Investigation/Remedial Investigation Report PG&E Topock Compressor Station, Needles, California* (CH2M HILL, 2005) recommended no further action for sediment in this AOC. Therefore, no additional sediment sampling was proposed as part of the Soil Part A Work Plan. However, since the completion of the Soil Part A Work Plan, consensus-based threshold effect concentrations (TECs) and consensus-based probable effects concentrations were identified in the *Human Health and Ecological Risk Assessment Work Plan, Topock Compressor Station, Needles, California* as potential screening values for sediment samples, as shown in Table C2-1 (ARCADIS, 2008). To confirm the previous assessment of historical sediment concentrations, the combined AOC 1 sediment data (historical sediment data and data from SS-1 and AOC1-BCW6) were compared to the newly-defined interim screening values for sediment.

TECs are the more conservative of the two screening criteria; therefore, the interim screening levels for metals in sediment were defined as the TEC, where available, and soil BTV where no TEC was available. TECs are available for arsenic, cadmium, total chromium, copper, lead, mercury, nickel, selenium, silver, and zinc. Soil BTVs are available for all but three of the remaining compounds (antimony, silver, and thallium).

All sediment data were below the applicable interim screening values, with exception of arsenic, chromium, and hexavalent chromium in the shallow sample (0 to 0.5 foot bgs) at AOC1-BCW6, as shown in Table C2-3 and Figures C2-5 through C2-7. In this sample, located in the soil-transitioning-to-sediment zone, arsenic and chromium exceeded the TECs and hexavalent chromium exceeded the soil BTV. Hexavalent chromium was not detected above laboratory reporting limits in any of the historical sediment samples; however, the reporting limits ranged from 0.05 to 6 milligrams per kilogram (mg/kg), some of which are above the soil BTV of 0.83 mg/kg.

A TEC or soil BTV was not available for antimony, silver, or thallium. Antimony was not detected above laboratory reporting limits. All detections of silver are estimated concentrations below or approximately equal to the reporting limits for the non-detect samples. Thallium was detected in only one sample at an estimated concentration below the reporting limit for all the other samples.

2.2 Summary of AOC 1 Soil Data

Pesticides, TPH-gasoline, antimony, beryllium, cadmium, mercury, selenium, silver, thallium, cyanide, and most species of PCBs were not detected in soil samples collected in AOC 1. Table C2-11 lists the 41 constituents detected at AOC 1, including four calculated quantities: benzo(a)pyrene equivalents, total low molecular weight PAHs, total high molecular weight PAHs, and total PCBs. Nine of these constituents (aluminum, calcium, iron, magnesium, manganese, potassium, sodium, Aroclor-1254, and total PCBs) were detected in the TAL/TCL samples.

Twenty-six of these constituents (cobalt, vanadium, aluminum, calcium, iron, magnesium, potassium, sodium, bis(2-ethylhexyl)phthalate, methyl acetate, 2-methyl naphthalene, anthracene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, phenanthrene, pyrene, total low molecular weight PAHs, TPH-diesel, TPH-motor-oil, Aroclor 1254, and total PCBs) were detected at concentrations below their respective interim screening levels. Fifteen constituents, including two calculated quantities, were detected one or more times at concentrations exceeding the interim screening levels. These constituents were arsenic, barium, total chromium, hexavalent chromium, copper, lead, manganese, molybdenum, nickel, zinc, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(a)pyrene equivalents, and total high molecular weight PAHs. Seven constituents (total chromium, hexavalent chromium, copper, lead, molybdenum, zinc, and benzo(a)pyrene equivalent) were detected at concentrations exceeding the interim screening level four or more times; the distribution of these constituents are shown in Figures C2-1, C2-2, and C2-8 through C2-19. For ease of review, the figures show the sample locations and results separately for the area south of the railroad tracks and the area north of the railroad tracks.

2.3 Nature and Extent Evaluation

The following subsection discusses the nature and extent of COPCs and COPECs detected in soil at concentrations exceeding the interim screening level. As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent have been adequately delineated. Section 2.4 of this sub-appendix summarizes the constituents that may require further evaluation, and Section 6.0 of this sub-appendix provides the recommended follow-up sampling for the Part A Phase 2 Soil Investigation.

2.3.1 Arsenic

Arsenic was detected in 106 of 111 soil samples collected at AOC 1. Only one detected concentration of arsenic (AOC1-BCW6 at 0 to 0.5 foot bgs) exceeded the interim screening level (11 mg/kg) (BTV); this same sample also exceeded the ecological comparison value (ECV) (11.4 mg/kg), as shown in Tables C2-4 and C2-11. This location is located at the mouth of Bat Cave Wash. No other samples in the vicinity of this location were analyzed for arsenic. At this location, the concentration in the deepest sample is below the screening level.

2.3.2 Barium

Barium was detected in 130 of 130 soil samples collected from AOC 1. Two detected concentration of barium in AOC 1 exceeded the interim screening level (410 mg/kg) (BTV/ECV), as shown in Table C2-4 and C2-11. The highest barium concentration was 1,580 mg/kg in sample XMW-9 at 70 feet bgs. The detected concentration is well below the residential and commercial/industrial California human health screening level (CHHSLs) (5,200 mg/kg and 63,000 mg/kg, respectively).

The detected concentration of barium exceeding the interim screening level is from the same sample in XMW-9 that also contained an elevated concentration of copper. As with the copper detection, there is a declining trend from 10 feet to 50 feet bgs, and barium concentrations in all samples above 70 feet bgs are below the interim screening level. The elevated concentration of barium detected at depth does not appear to be related to a surface release. Barium was also detected at 440 mg/kg in sample AOC4-1 at 0 to 0.5 foot bgs. This concentration is close to BTV.

2.3.3 Total Chromium

Total chromium was detected in 167 of 167 soil samples collected at AOC 1. Detected concentrations of total chromium exceeded the interim screening level (39.8 mg/kg) (BTV) 23 times (maximum detected concentration of 970 mg/kg at AOC1-T2d at 2 to 3 feet bgs), as shown in Tables C2-4 and C2-11 and Figures C2-1 and C2-2. Three of the detected concentrations of total chromium exceeded the United States Environmental Protection Agency residential regional screening level for residential use (280 mg/kg); none of the detected concentrations exceeded the residential regional screening level for commercial/industrial use (1,400 mg/kg). With the exception of the detection of total chromium at AOC 1-BCW6 and SSB-8, samples with concentrations exceeding the screening levels were located south of Interstate 40, primarily in the area immediately north of SWMU 1. The highest detected concentration south of SWMU 1 was 47 mg/kg (at AOC4-1 at 0 to 0.5 foot bgs), which is above the BTV (39.8 mg/kg). At all locations, the deepest samples have concentrations below the screening levels, with the exception of the deepest sample collected at AOC1-T1b; however, this sample contained only 42 mg/kg total chromium, which is very close to the BTV.

2.3.4 Hexavalent Chromium

Hexavalent chromium was detected in 28 of 173 soil samples collected at AOC 1. Detected concentrations of hexavalent chromium exceeded the interim screening level (0.83 mg/kg) (BTV) 12 times (with a maximum detected concentration of 5.73 mg/kg at AOC1-T2d at 2 to 3 feet bgs), as shown in Tables C2-4 and C2-11 and Figures C2-8 and C2-9. None of the detected concentrations of hexavalent chromium exceeded the residential or commercial/ industrial CHHSLs (17 mg/kg and 37 mg/kg, respectively) or the ECV (139.6 mg/kg). With the exception of AOC1-BCW4 at 0 to 0.5 foot bgs and AOC1-BCW6 at 0 to 0.5 foot bgs, AOC 1 samples with concentrations exceeding the screening levels were located south of Interstate 40; the highest concentrations are immediately north of SWMU 1, and concentrations decrease with distance from SWMU 1. All samples collected south of SWMU 1 had hexavalent chromium concentrations below the BTV. At all locations in AOC 1, hexavalent chromium concentrations in the deepest samples are below the screening levels.

2.3.5 Copper

Copper was detected in 166 of 167 soil samples collected at AOC 1. Detected concentrations of copper exceeded the interim screening level (16.8 mg/kg) (background value) 11 times (with a maximum detected concentration of 170 mg/kg at XMW-9 at 70 feet bgs), as shown in Tables C2-4 and C2-11 and Figures C2-10 and C2-11. Seven detected concentrations exceeded the ECV (20.6 mg/kg), and no detected concentrations of copper exceeded the residential or commercial/industrial CHHSLs (3,000 mg/kg and 38,000 mg/kg, respectively). With the exception of AOC1-BCW6 at 0 to 0.5 foot bgs, all AOC 1 samples with concentrations exceeding the screening levels were located south of Interstate 40. The locations of exceedances of the BTV and ECV were variable, with a slightly higher frequency of exceedance to the north of SWMU 1. With the exception of the deep sample from XMW-9, all detections were below 30 mg/kg. At all locations, concentrations in deepest samples are below the screening levels, with the exception of the deepest sample collected at XMW-9 (at 70 feet bgs). Copper concentrations in XMW-9 above this sample ranged from 12 to 19.7 mg/kg. There is an apparent declining trend from 10 feet bgs to 50 feet bgs, with a copper concentration in the 50 feet bgs sample of 15.6 mg/kg, which is below the background value. Therefore, because the elevated concentration of copper detected at depth does not appear to be related to a surface release, no further characterization is needed for copper in this area.

2.3.6 Lead

Lead was detected in 130 of 130 soil samples collected at AOC 1. Detected concentrations of lead exceeded the interim screening level (8.39 mg/kg) (BTV/ECV) 19 times (with a maximum detected concentration of 32J mg/kg at AOC1 T1c at 2 to 3 feet bgs), as shown in Tables C2-4 and C2-11 and Figures C2-12 and C2-13. None of the detected concentrations exceeded the residential or commercial/industrial CHHSLs (80 mg/kg and 320 mg/kg, respectively). The lateral extent of samples with lead concentrations exceeding the BTV consists of the portions of AOC 1 north and south of the tamarisk thicket, the area between the railroad tracks and sample Transect 3, and the samples collected at the mouth of the debris ravine (AOC 4 samples). With the exception of the samples from AOC1-T1c and AOC1-BCW6, exceedance concentrations were limited to no more than two times the BTV. At all locations except AOC1-T6b (concentration of 12 mg/kg at 9.5 feet bgs), concentrations in the deepest samples are below the BTV. Samples near AOC1-T6b collected at the same depth had concentrations equal to or below the BTV.

2.3.7 Molybdenum

Molybdenum was detected in 38 of 130 soil samples collected at AOC 1. Detected concentrations of molybdenum exceeded the interim screening level (1.37 mg/kg) (background value) 22 times (maximum detected concentration of 5.5 mg/kg at AOC1-T2b at 5 to 6 feet bgs), as shown in Tables C2-4 and C2-11 and Figures C2-14 and C2-15. Nine detected concentrations exceeded the ECV (2.25 mg/kg), and none of the detected concentrations of molybdenum exceeded residential and commercial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). The lateral extent of samples with concentrations exceeding the screening levels is limited to the central portions of AOC 1, just north of SWMU 1, with the exception of the exceedance at AOC1-T5a. Samples with concentrations below the screening levels surround the AOC1-T5a location. One sample each collected at locations AOC1-BCW2 (1.5 mg/kg at 5 to 6 feet bgs) and XMW-9 (1.8 mg/kg at 70 feet bgs) slightly exceeded the BTV. At all but three locations, concentrations in deepest samples are below the screening levels. The deepest samples at AOC1-T2d (at 69 to 70 feet bgs) and XMW-9 at (70 feet bgs) exceed the BTV but not the ECV. The deepest sample from AOC1-T1b (at 9 to 10 feet bgs) contains 5 mg/kg molybdenum.

2.3.8 Nickel

Nickel was detected in 167 of 167 soil samples collected from AOC 1. Detected concentrations of nickel exceeded the interim screening level (27.3 mg/kg) (BTV/ECV) three times (with a maximum detected concentration of 35.2 mg/kg at XMW-9 (10 feet bgs), as shown in Tables C2-4 and C2-11. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (1,600 mg/kg and 16,000 mg/kg, respectively). All concentrations exceeding the BTV were in soil samples collected at XMW-9; concentrations ranged from 28. 5 to 35.2 mg/kg. Samples with concentrations below the screening levels are located to the west but not to the north, east, or south of XMW-9. At this location, the concentration in the deepest samples is well below the BTV.

2.3.9 Zinc

Zinc was detected in 167 of 167 soil samples collected at AOC 1. Detected concentrations of zinc exceeded the interim screening level (58 mg/kg) (BTV) 13 times (with a maximum detected concentration of 132 mg/kg at SSB-6 at 6 feet bgs), as shown in Tables C2-4 and C2-10 and Figures C2-16 and C2-17. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively). With the exception of the surface soil samples from AOC1-BCW4 and AOC1-BCW4, AOC 1 samples with concentrations exceeding the zinc BTV were located south of Interstate 40 and north of SWMU 1.

With the exception of the deepest sample collected at AOC1-T1b (69 to 70 feet bgs), the deepest zinc concentration at all locations is below the BTV.

2.3.10 Benzo(a)pyrene, Benzo(a)pyrene Equivalents, and PAHs

Benzo(a)pyrene was detected in 25 of 111 soil samples collected from AOC 1. Detected concentrations of benzo(a)pyrene exceeded the interim screening level of 38 µg/kg (residential CHHSL) three times (with a maximum detected concentration of 170 µg/kg at AOC1-T4c at 5 to 6 feet bgs). Several other PAHs were detected in soil samples collected from AOC 1; only benzo(a)anthracene and benzo(b)fluoranthene were detected at concentrations above their respective interim screening levels. These constituents were detected above their interim screening levels (residential CHHSLs) once each. At each location, individual constituent concentrations in the deepest samples are below the applicable interim screening levels. To assist with evaluation of PAHs for human health, benzo(a)pyrene equivalents were calculated for each of the soil samples collected at AOC 1, as shown in Table C2-6. Benzo(a)pyrene equivalent values exceeded the interim screening level (38 µg/kg) (residential CHHSL) five times (maximum detected concentration of 290 µg/kg at AOC1-T4c at 5 to 6 feet bgs), as shown in Tables C2-6 and C2-11 and Figures C2-18 and C2-19. Screening level exceedances were limited to five sample locations (AOC1-T1c at 0 to 0.5 foot bgs; AOC1-T4c at 2 to 3, 5 to 6, and 9 to 10 feet bgs; and AOC1-T5c at 5 to 6 feet bgs). At each location, the deepest samples have concentrations below the screening levels, with the exception of sample location AOC1-T4c. The deepest sample at AOC1-T4c (at 9 to 10 foot bgs) had a lower benzo(a)pyrene equivalent concentration than the two samples above this depth.

To assist with evaluation of PAHs for ecological risk, detected concentrations of low molecular weight PAHs and high molecular weight PAHs were summed and compared to the total low molecular weight PAHs and total high molecular weight PAHs ECVs of 10,000 µg/kg and 1,160 µg/kg, respectively. One total high molecular weight PAH sum of detected concentrations exceeded the ECV of 1,160 µg/kg, and none of the totals of detected low molecular weight PAH concentrations exceeded the ECVs. The ECV for total high molecular weight PAHs was exceeded in sample AOC1-T4c at 5 to 6 feet bgs (2,900 µg/kg); the sum of total high molecular weight PAHs was well below the ECV in the deeper sample at this location (9 to 10 feet bgs).

2.3.11 Target Analyte List/Target Compound List Constituents

As described above, aluminum, calcium, iron, magnesium, manganese, potassium, sodium, bis(2-ethylhexyl) phthalate, methyl acetate, Aroclor-1254, and total PCBs were detected in the AOC 1 soil samples analyzed for the complete TAL/TCL suite of compounds. (Note that some of these constituents, including semivolatile organic compounds and PCBs, were also analyzed at varying frequencies in other samples.) Manganese and total PCBs were the only constituents in this group that were detected at a concentration exceeding the interim screening.

Aluminum was detected in 12 of 12 surface soil samples collected from AOC 1. The detected concentrations did not exceed the BTV (16,400 mg/kg). The maximum detected concentration was 14,000 mg/kg at AOC1-BCW6. Remaining detected concentrations of aluminum ranged from 5,300 to 11,000 mg/kg, as shown in Tables C2-5 and C2-11. None of the detected concentrations exceeded residential and commercial RSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in 12 of 12 surface soil samples collected from AOC 1. The detected concentrations did not exceed the interim screening level of 66,500 mg/kg (BTV). The maximum detected concentration was 35,000 mg/kg at AOC1-BCW6. Remaining detected concentrations of calcium ranged from 14,000 to 30,000 mg/kg, as shown in Tables C2-5 and C2-11. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium.

Iron was detected in 31 of 31 soil samples collected from AOC 1. The detected concentrations did not exceed the interim screening value (55,000 mg/kg [residential regional screening level (RSL)]). The maximum detected concentration was 22,600 mg/kg at XMW-9 at 10 feet bgs. Remaining detected concentrations of iron ranged from 3,510 to 22,200 mg/kg, as shown in Tables C2-5 and C2-11. Residential and commercial/industrial CHHSLs and an ECV have not been established for iron.

Magnesium was detected in 12 of 12 surface soil samples collected from AOC 1. Detected concentrations of magnesium were below the interim screening level of 12,100 mg/kg (BTV). The maximum detected concentration was 11,000 mg/kg, at AOC1-BCW6, as shown in Tables C2-5 and C2-11. Remaining detections ranged from 5,300 to 8,100 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium.

Manganese was detected in 31 of 31 samples collected from AOC 1. One detected concentration of magnesium (420 mg/kg in AOC1-BCW6 at 0 to 0.5 foot bgs) slightly exceeded the interim screening level of 402 mg/kg (BTV/ECV), as shown in Tables C2-5 and C2-11. The detected concentration did not exceed the residential and commercial/industrial RSLs (1,800 mg/kg and 23,000 mg/kg, respectively). Only the surface sample at AOC1-BCW6 was analyzed for manganese. Manganese concentrations in the remaining 29 samples were all below the BTV and ranged from 92.1 to 353 mg/kg.

Potassium was detected in 12 of 12 surface soil samples collected from AOC 1. The detected concentrations did not exceed the BTV (4,400 mg/kg). The maximum detected concentration was 4,000 mg/kg at AOC1-BCW6. Remaining detected concentrations of potassium ranged from 1,600 to 3,900 mg/kg, as shown in Tables C2-5 and C2-11. Residential and commercial/industrial CHHSLs and an ECV have not been established for potassium.

Sodium was detected in eight of 12 surface soil samples collected from AOC 1. The maximum detected concentration of sodium was 660 mg/kg at AOC1-BCW6, which is below the interim screening level of 2,070 mg/kg (BTV), as shown in Tables C2-5 and C2-11. Remaining detected concentrations of sodium ranged from non-detect to 340 mg/kg. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for sodium.

Bis(2-ethylhexyl)phthalate was detected in two of 108 soil samples collected at AOC 1, both surface and subsurface soil samples were collected, as shown in Tables C2-7 and C2-11. The maximum detected concentration was 810 µg/kg at AOC4-1 (at 2 to 3 feet bgs), which is below the interim screening level of 2,870 µg/kg (ECV), and well below the residential and commercial/industrial RSLs (35,000 µg/kg and 120,000 µg/kg, respectively).

Methyl acetate was detected in two of 12 soil samples collected at AOC 1; all samples were collected at 2 to 3 feet bgs, as shown in Tables C2-7 and C2-11. The maximum detected concentration was 12 µg/kg at AOC4-1 (at 2 to 3 feet bgs), which is below the interim screening level of 22,000,000 µg/kg (residential RSL). An ECV and residential and commercial CHHSLs have not been defined for methyl acetate.

The PCB Aroclor-1254 was detected in seven of 17 soil samples collected from AOC 1; both surface and shallow soil (2 to 3 feet bgs) samples were collected. The maximum detected concentration of Aroclor-1254 of 900 µg/kg was detected at AOC4-GB11 at 0 feet bgs. Remaining detected concentration of Aroclor-1254 range from 24 to 420 µg/kg. None of the detected concentrations of Aroclor-1254 within AOC 1 exceeded the interim screening level of 220 µg/kg (residential RSL). Detected concentrations in AOC 1 samples ranged from 24 to 91 µg/kg, as shown in Table C2-9. All three AOC 4 gabion samples had Aroclor-1254 concentrations above the interim screening level.

To assist with evaluation of PCBs for ecological risk, detected concentrations of the Aroclors (only Aroclor-1254 at AOC 1) were summed, and the total PCB values were compared to the ECV. Total PCB concentrations in the three AOC 4 gabion samples exceeded the total PCB ECV of 204 µg/kg, as shown in Table C2-9. The maximum calculated value for total PCBs was 900 µg/kg. The remaining calculated total PCB concentrations ranged from 24 to 420 µg/kg. All total PCB concentrations within AOC 1 itself were well below the ECV.

As discussed in Section C.2 of Appendix C, PG&E recommends that PCBs be evaluated further in AOC 1. PG&E also recommends aluminum, calcium, iron, magnesium, manganese, potassium, sodium, methyl acetate, and bis(2-ethylhexyl)phthalate not be considered COPCs/COPECs for this SWMU, and no further sampling is proposed for these constituents. These constituents have been fully discussed in Section C.2 of Appendix C.

The three gabion sample locations associated with AOC 4 were also analyzed for dioxins and furans. As shown in Table C2-10, none of the individual dioxin and furan concentrations exceeded the applicable interim screening levels (residential CHHSL). To assist with evaluation of dioxins and furans for human health, 2,3,7,8-TCDD TEQs were calculated for each of the soil samples, as shown in Table C2-10. The TEQs for two of the three samples exceeded the interim screening level of 50 ng/kg. The two detected concentrations exceeding the screening levels were 94.5 ng/kg collected at 5 feet bgs from location AOC4-GB11 and 74.5 ng/kg collected from 5 feet bgs at location AOC4-GB10. The remaining detected concentration was 8.9 ng/kg, which is below the screening level.

2.4 Central Tendency Comparison to Background Threshold Values

Ten metals (arsenic, barium, total chromium, hexavalent chromium, copper, lead, manganese, molybdenum, nickel, and zinc) were detected above their respective BTVs in soil samples. A central tendency comparison was performed for nine of these ten metals (arsenic, barium, total chromium, copper, lead, manganese, molybdenum, nickel, and zinc) to compare the AOC 1 soil data set with the corresponding soil background data set. A central tendency comparison for hexavalent chromium was not conducted because there were insufficient detections of hexavalent chromium in the background data set.

The purpose of this comparison is to determine whether a difference exists between the two populations and if additional sampling is required for a given metal (see Table C2-12 and

Figure 3-1 in the Data Gaps Evaluation Report). No statistical difference between the two populations was noted for any of the nine metals evaluated (arsenic, barium, total chromium, copper, lead, manganese, molybdenum, nickel and zinc, as shown in Table C2-12).

2.5 Potential New White Powder Area

A new area of potential white powder material was identified subsequent to the January 2010 rain event. This area is shown in Figure B-5 in Appendix B to the Data Gaps Evaluation Report. While this potential new white powder area has been assigned to AOC 1, it is actually located high on a steep bluff and may represent a natural soil material (no known disposal or use of white powder material occurred in this area).

2.6 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review indicates than decision error has been held to an acceptable level. Sufficient data of acceptable quality have been attained by the collection of historical/Part A soil samples in areas most likely to have been impacted by the waste water discharges to Bat Cave Wash, potential overflows or discharges from the former percolation bed in SWMU 1, stormwater runoff and incidental spills from the western side of the compressor station, stormwater runoff from Interstate 40 (from culverts discharging to Bat Cave Wash), military activities on the mesas in the vicinity of Bat Cave Wash (i.e., surface runoff from surrounding areas), and runoff from AOC 14. Further sampling is required to more closely define the extent of some areas with metals concentrations above the interim screening levels.

Potential impacts from discharges from the Debris Ravine (AOC 4), runoff from the former "Workman's Roadhouse" and service station (near the mouth of Bat Cave Wash), and the potential new white powder area on the bluff above AOC 1 have either not been characterized or have been only partially characterized. Further investigation is also required in the vicinity of AOC1-BCW6 located at the lower end of Bat Cave Wash in the tamarisk area where soil is transitioning to sediment. In addition, DOI has requested (December 15, 2010 email) that PG&E further evaluate and fully characterize the lower end of Bat Cave Wash, specifically in the tamarisk thicket area located near the mouth. This area is a historical and current depositional area of fine-grained materials being transported down the wash during rain events and may have received historical releases from the Topock Compressor Station. The evaluation of the tamarisk area near the mouth of Bat Cave Wash is discussed in Section 7.0 of this sub-appendix.

Based on the review of the data for AOC 1 and the Part A DQO, four data gaps were identified to resolve Decision 1 – Nature and Extent, and limited additional sampling is proposed in Phase 2 to fill the following data gaps:

- Data Gap #1 – Lateral and vertical extent of contamination in the bottom of Bat Cave Wash (within the portion of AOC 1 between the northern boundary of SWMU 1 and Interstate 40).
- Data Gap #2 – Extent of constituents associated with the discharge from the Debris Ravine, including PCBs and dioxins and furans.

- Data Gap #3 – Chemical concentrations of soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.
- Data Gap #4– Characteristics of the potential white powder material on the eastern slope of Bat Cave Wash.
- Data Gap #5 – Assess potential impoundment area near railroad bridge culvert and IM-3 road crossing.

The proposed Phase 2 soil sample locations to fill the identified data gaps are presented in Section 6.0.

3.0 Decision 2 – Data Sufficiency to Estimate Representative Exposure Point Concentrations

For Decision 2, AOC 1 data were combined with SWMU 1 data to determine whether SWMU 1/AOC 1 data are sufficient to conduct human health and ecological risk assessments. The principal consideration for Decision 2 was whether there were sufficient data to estimate a representative exposure point concentration (EPC) for the combined SWMU 1/AOC 1 area. Data reviewed were all available Category 1 data (including historical data) at SWMU 1/AOC 1. The samples designated as "white powder" were included in the data reviewed as a conservative measure assuming that exposure to white powder areas would not differ significantly from exposure to surrounding soil areas. Category 1 soil sampling results and results from locations SS-1 and AOC1-BCW-6, in an area of soil transitioning to sediment, were included in the data set for the Decision 2 evaluation.

Tables C2-3 and C2-14 summarize the results of the evaluation to determine whether data are sufficient to estimate representative EPCs. Table C2-13 documents the review of all combined AOC 1/SWMU 1 soil data. Table C2-14 presents the review of only those data from locations north of the Burlington Northern Santa Fe railroad corridor on Bureau of Reclamation land managed by the Bureau of Land Management. These data were reviewed separately to evaluate whether there are sufficient data to estimate representative EPCs for a hypothetical residential exposure scenario. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value.

Table C2-15 summarizes the results of the evaluation to determine if sediment data are sufficient to estimate representative ecological EPCs. Samples considered in this evaluation were those from the preliminary AOC 1 sediment exposure area at the mouth of Bat Cave Wash. The sediment exposure area defined for this evaluation extends from the east margin of the Tamarisk thicket near the mouth of Bat Cave Wash to the easternmost end of the wash. Samples from both the west and east side of National Trails Highway at the mouth of Bat Cave Wash were included.

In general, existing data are adequate to support soil and sediment EPC development for detected chemicals that exceeded one or more comparison values in one or both media (12 metals, three Contract Laboratory Program inorganics, and PAHs), as described below. In addition, data are adequate to support human health risk assessment EPC development for arsenic in the area north of the railroad corridor. Arsenic was the only compound that exceeded at least one human health risk-based comparison value in the area north of the railroad corridor, as shown in Table C2-14. Phase 2 data will be added to the existing data set to calculate the final EPC (i.e., after Decision 1 is satisfied).

3.1 Metals

Sufficient soil data (numbers of samples and detections) are available to calculate EPCs for arsenic, barium, total chromium, hexavalent chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, and zinc using the ProUCL software; these data are presented in Tables C2-13 and C2-14. For selenium, additional soil data collection is not expected to significantly change the results of the risk assessment because the compound is very infrequently detected (i.e., additional non-detects would be expected).

Sufficient sediment data are available to calculate EPCs for chromium using the ProUCL software, as shown in Table C2-15. For arsenic, additional data collection is not expected to significantly change the results of the risk assessment because the maximum detected concentration (13 mg/kg) is comparable to soil background (11 mg/kg), a conservative estimate of the sediment background value. Therefore, additional data collection would be anticipated to yield similar results. Similarly, for hexavalent chromium, additional data collection may not significantly change the results of the risk assessment because the compound is very infrequently detected in sediment. However, as noted in Section 2.0 of this sub-appendix, historical reporting limits for hexavalent chromium were elevated relative to the soil BTV, and no TEC is available for this compound. Therefore, the potential effect of additional sampling on the EPC is uncertain. To reduce this uncertainty and to provide further data to resolve Decision 1, an additional sediment sampling location is proposed and is discussed in Section 5.0.

3.2 Inorganics

Sufficient data (numbers of samples and detections) are available to calculate EPCs for calcium, magnesium, and potassium using ProUCL, although additional data are not available for deeper locations associated with the scouring scenarios. No additional data collection appears warranted because it is reasonable to assume that the nature and extent of these inorganics in the shallow exposure intervals (0 to 0.5 or 0 to 3 feet bgs) are representative of the deeper depths. In addition, maximum concentrations of calcium, magnesium, and potassium detected in the standard exposure intervals (0 to 0.5, 0 to 3, 0 to 6, and 0 to 10 feet bgs) are comparable to background (all detections were below the BTV, as shown in Tables C2-5 and C2-11).

3.3 Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene toxicity equivalents and high molecular weights PAHs using ProUCL.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

A conservative, three-tiered approach was used in the evaluation to assess the potential impact to groundwater from source areas in the vadose zone. A full description of the three-tiered approach is provided in Section 5.0 of the Data Gaps Evaluation Report. For this analysis, AOC 1 was separated into a northern and a southern portion as shown in Figure C-1 in Appendix C. The potential threat to groundwater analysis in this sub-appendix focuses on the northern portion. A similar analysis for the southern portion is combined with the SWMU 1 analysis presented in Appendix C1.

The following preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, are needed to resolve Decision 3. Additional evaluation will be performed as appropriate, as data are collected to resolve Decision 1. Data collected to satisfy Decision 1 – Nature and Extent evaluation will provide the final representative data set that will be used to assess the threat to groundwater. No current or potential threat to groundwater was identified for the northern portion of AOC 1.

The results of the tiered analysis presented in Table C2-16 show that seven metals had soil concentrations exceeding their BTVs. Of those seven metals, only hexavalent chromium and molybdenum had concentrations above the calculated soil screening levels, as shown in Table C2-17. Based on the initial screening model, the potential for hexavalent chromium and molybdenum to leach to groundwater was ruled out. Consequently, none of the metals detected in soil in AOC 1 north presents a threat to current or future groundwater, and no further sampling is required to address Decision 3 for AOC 1.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Gaps Evaluation Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study (CMS/FS). The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fence line include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite).
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil washing technologies).
- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies).
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- If present, volumes of white powder and debris.

The following is a summary of data for AOC 1 that are currently available to support CMS/FS. Data gaps identified for Decision 4 will be filled using samples being collected to fill data gaps identified for other decisions. Data will not be collected to solely fill Decision 4 data gaps.

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. The lateral and vertical extent of the COPCs and COPECs is discussed in Section 2.3 above. Data results for selected constituents are shown in Figures C2-1, C2-2, and C2-4 through C2-10, and data gaps associated with lateral and vertical delineation are discussed in Section 6.0 of this sub-appendix.

5.2 Waste Characterization Parameters

Only partial waste characterization data are available to characterize the soil and other materials to be potentially removed for remedial action and disposed in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations (TTLCs). The maximum concentrations of these metals for each of the units were compared to the TTLCs, as shown in Table C2-18. The maximum detected concentrations were also compared to the soluble threshold limit concentrations (STLCs). Concentrations of barium exceeded 10 times the STLC once, and total chromium exceeded 10 times the STLC 13 times, respectively, as shown in Table C2-18. In addition, total chromium also exceeded 20 times the toxicity characteristic leaching procedure (TCLP) in six samples, as indicated in Table C2-18. Because these metals have the potential to exceed STLC or TCLP thresholds, additional leachability testing for waste characterization purposes may be required if soil excavation and offsite disposal is chosen as a remedy. For the purposes of supporting the CMS/FS, the lack of STLC or TCLP analysis is not considered a data gap, for the existing total concentrations are sufficient for the purposes of evaluating various remedial alternatives. Additional data regarding potential COPC/COPEC leachability include SPLP analysis for total and hexavalent chromium, as shown in Table C2-2. SPLP analysis was conducted only for soil samples (no white powder or debris samples were tested using SPLP).

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 soil investigation was limited to grain size analysis only. Specific soil physical properties data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 in the Data Gaps Report. Additional soil physical parameter data are needed to support the CMS/FS.

5.4 Surface and Subsurface Features

While there is extensive information regarding surface and subsurface features at AOC 1, additional information may be required once areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are known for AOC 1. However, subsurface utilities, including gas transmission pipelines and any culverts or other features, may have to be more precisely defined to evaluate the feasibility and cost of certain remedial alternatives and to prepare construction specifications.

6.0 Summary of Data Gaps, Proposed Phase 2 Soil Sample Locations to Fill Identified Gaps, and Access Restrictions

Based on the Part A DQOs, five data gaps were identified for two of the four decisions and are summarized below by decisions:

- **Decision 1 – Nature and Extent**. The following data gaps were identified to resolve this decision:
  - Data Gap #1 – Lateral and vertical extent of contamination in the bottom of Bat Cave Wash (within the portion of AOC 1 between the northern boundary of SWMU 1 and Interstate 40).
  - Data Gap #2 – Extent of constituents associated with the discharge from the Debris Ravine (AOC 4), including PCBs and dioxins and furans.
  - Data Gap #3 – Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk thicket area near the mouth of Bat Cave Wash.
  - Data Gap #4 – Characteristics of the potential white powder material on the eastern slope of Bat Cave Wash.
  - Data Gap #5 – Assess potential impoundment area near railroad bridge culvert and IM-3 road crossing.
- **Decision 2 (Data Sufficient to Estimate Representative Exposure Point Concentrations)**. No data gap was identified for this decision.
- **Decision 3 (Potential Threat to Groundwater from Residual Soil Concentrations)**. No data gap was identified to resolve this decision.
- **Decision 4 (Data Sufficient to Estimate Soil Properties and Contaminant Distribution in Support of the CMS/FS).** The following data gap was identified to resolve this decision**:**
  - Data gap #6 – Soil physical parameters to support the CMS/FS. Three samples each from boring locations AOC1-BCW7, AOC1-BCW13, AOC1-BCW25, AOC1-T5d, and AOC1-T6d are proposed to be analyzed for soil physical parameters.

Table C2-19 summarizes the proposed Phase 2 sample locations, depths, description/ rationale for each proposed location, and analytes. Proposed Phase 2 sample locations are also shown in Figures C2-20 and C2-21.

6.1 Access Restrictions

The following access restrictions apply and may impact soil sampling in AOC 1:

- Proposed Phase 2 sample locations AOC1-1 through AOC1-4 are located on a plateau approximately 10 feet in elevation from the bottom of Bat Cave Wash. Possible road improvement and/or minor grading may be necessary to access these samples.

- Proposed Phase 2 sample location AOC1-6d is located in Bat Cave Wash between two culverts (Interstate 40 and Burlington North and Santa Fe (BNSF) railroad tracks). To access this location a drill rig will need to pass through the railroad culvert; a BNSF railroad permit is required for this activity.
- A significant storm event occurred in early January 2010, which deposited a large amount of material (i.e., large and small cobbles) in the southern reaches of Bat Cave Wash near the confluence of AOC 4 – Debris Ravine. This material will need to be cleared prior to collection of the proposed Phase 2 sample locations near the mouth of AOC 4 – Debris Ravine (AOC4-BCW1 through AOC4-BCW6).

7.0 Tamarisk Area Evaluation

The thick vegetation, widening of the channel near the end of Bat Cave Wash, and blockage of flow by National Trails Highway greatly reduces the energy of flow during runoff events, resulting in deposition of entrained soil within the vegetated area at the lower end of Bat Cave Wash. This area is heavily vegetated, predominately with salt cedar (also known as tamarisk), which is an invasive, exotic plant species (CH2M HILL, 2007). This heavily vegetated portion of Bat Cave Wash is a long-term depositional area that existed before the compressor station was built. Depositional history and patterns within this area are not known with certainty. As requested by DOI in the December 15, 2010 email, PG&E is proposing grid-based sampling near the mouth of Bat Cave Wash in the tamarisk area to assess the potential for historical deposition of potentially contaminated fine-grained materials that may have been transported down Bat Cave Wash during rain events.

Twenty-three borings are proposed to be advanced in an approximate 100-foot grid pattern across the tamarisk area near the mouth of Bat Cave Wash, as shown in Figure C2-21. Due to the thick vegetation in this area, a path will need to be cut through the vegetation to allow passage of necessary drilling equipment. The path will be up to 25 feet wide to accommodate a track-mounted spider rig (or equivalent) and necessary support vehicles (pickup truck or all-terrain vehicles). The approximate location of the paths are show on Figure C2-21; however, the exact path may change based on field conditions (i.e., boulders, large pieces of debris, sink holes, and low areas filled with water) and to save larger trees and species of interest (i.e., palo verde and mesquite). Therefore, the area of potential impact includes the entire vegetated area at the lower end of Bat Cave Wash, as shown on Figure C2-21. Every effort will be made to remove as little vegetation as possible. The amount of vegetation removal will be approximately 2 acres.

[1] Interim screening level is equal to the to the lower value between the TEC and PEC. If neither is available, then the soil background value, if available, is used.

[2] CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California". May.

[3] MacDonald et al. (2000)

[4] This location is in an area where soil is transitioning into sediment.

Results greater than or equal to the interim screening level are circled; however, if the interim screening level is equal to the background value, only results greater than the interim screening level are circled.

*	Reporting limits greater than or equal to the interim screening level.
NE	not established
mg/kg	milligrams per kilogram
ft bgs	feet below ground surface
N	primary sample
FD	field duplicate
---	not analyzed
ND	not detected at the listed reporting limit
J	concentration or reporting limit estimated by laboratory or data validation

TABLE C2-4

Soil Sample Results: Metals

AOC 1 - Area Around Former Percolation Bed

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

TABLE C2-6

Sample Results: Polycyclic Aromatic Hydrocarbons
AOC 1 - Area Around Former Percolation Bed
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

AOC 1 - Area Around Former Percolation Bed
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] For SVOCs and VOCs, interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used. For TPHs, interim screening level is the Regional Water Quality Control Board environmental screening level.

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted.

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

mg/kg	miligrams per kilogram
µg/kg	micrograms per kilogram

Decision 2 Data Gaps Summary - AOC1 and SWMU1
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth	Adequate EPC?		Maximum Detected Value	> HHCV or Background as Applicable? [1]	> ECV or Background as Applicable? [1]	Proposed Sample ID	Notes
	Y or N	Det/# results		Y or N	Y or N [2]		
Contract Laboratory Program Inorganics							
Calcium				**66500 mg/kg (bckg)**	**66500 mg/kg (bckg)**		
0-0.5 ft bgs	Y	30 of 30	280000 mg/kg	Y	Y	None	Compound may exceed HHCV and ECV (both background). Existing data adequate for EPC. Under the scouring scenarios, very limited data are available. However, additional data collection to support the scouring scenarios does not appear warranted given that the concentrations are comparable to background (Attachment 1, Section 3.3). In addition, it is reasonable to assume that the nature and extent of the calcium detected in the 0 to 3.0 ft interval is representative of concentrations at deeper depths.
0-3 ft bgs	Y	30 of 30	280000 mg/kg	Y	Y		
0-6 ft bgs	Y	31 of 31	280000 mg/kg	Y	Y		
0-10 ft bgs	Y	31 of 31	280000 mg/kg	Y	NA		
Scouring Scenario 1: 2-3 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Scouring Scenario 1: 2-6 ft bgs	N	1 of 1	255000 mg/kg	Y	Y		
Scouring Scenario 1: 2-10 ft bgs	N	1 of 1	255000 mg/kg	Y	Y		
Scouring Scenario 1: 2-12 ft bgs	N	1 of 1	255000 mg/kg	Y	NA		
Scouring Scenario 2: 5-6 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Scouring Scenario 2: 5-10 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Scouring Scenario 2: 5-15 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Magnesium				**12100 mg/kg (bckg)**	**12100 mg/kg (bckg)**		
0-0.5 ft bgs	Y	30 of 30	14300 mg/kg	Y	Y	None	Compound may exceed HHCV and ECV (both background). Existing data adequate for EPC. Under the scouring scenarios, very limited data are available. However, additional data collection to support the scouring scenarios does not appear warranted given that the maximum concentration is slightly greater than background. In addition, it is reasonable to assume that the nature and extent of the magnesium detected in the 0 to 3.0 ft interval is representative of concentrations at deeper depths.
0-3 ft bgs	Y	30 of 30	14300 mg/kg	Y	Y		
0-6 ft bgs	Y	31 of 31	14700 mg/kg	Y	Y		
0-10 ft bgs	Y	31 of 31	14700 mg/kg	Y	NA		
Scouring Scenario 1: 2-3 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Scouring Scenario 1: 2-6 ft bgs	N	1 of 1	14700 mg/kg	Y	Y

Scouring Scenario 2: 5-15 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Potassium				**4400 mg/kg (bckg)**	**4400 mg/kg (bckg)**		
0-0.5 ft bgs	Y	30 of 30	4900 mg/kg	Y	Y	None	Compound may exceed HHCV and ECV (both background). Existing data adequate for EPC. Under the scouring scenarios, very limited data are available. However, additional data collection to support the scouring scenarios does not appear warranted given that the maximum concentration is slightly greater than background. In addition, it is reasonable to assume that the nature and extent of the potassium detected in the 0 to 3.0 ft interval is representative of concentrations at deeper depths.
0-3 ft bgs	Y	30 of 30	4900 mg/kg	Y	Y		
0-6 ft bgs	Y	31 of 31	4900 mg/kg	Y	Y		
0-10 ft bgs	Y	31 of 31	4900 mg/kg	Y	NA		
Scouring Scenario 1: 2-3 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Scouring Scenario 1: 2-6 ft bgs	N	1 of 1	1520 mg/kg	N	N		
Scouring Scenario 1: 2-10 ft bgs	N	1 of 1	1520 mg/kg	N	N		
Scouring Scenario 1: 2-12 ft bgs	N	1 of 1	1520 mg/kg	N	NA		
Scouring Scenario 2: 5-6 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Scouring Scenario 2: 5-10 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		
Scouring Scenario 2: 5-15 ft bgs	NA	0 of 0	NA mg/kg	NA	NA		

TABLE C2-13

Decision 2 Data Gaps Summary - AOC1 and SWMU1

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

	Adequate EPC?		Maximum Detected Value	> HHCV or Background as Applicable? [1]	> ECV or Background as Applicable? [1]	Proposed Sample ID	
Compound/Depth	Y or N	Det/# results		Y or N	Y or N [2]		Notes
Polycyclic Aromatic Hydrocarbons							
PAHs (BaP TEQ)				**38 µg/kg**	**NA**		
0-0.5 ft bgs	Y	23 of 54	40 µg/kg	Y	NA	None	Compound exceeds HHCV. Existing data adequate for EPC.
0-3 ft bgs	Y	37 of 108	80 µg/kg	Y	NA		
0-6 ft bgs	Y	42 of 160	290 µg/kg	Y	NA		
0-10 ft bgs	Y	45 of 215	290 µg/kg	Y	NA		
Scouring Scenario 1: 2-3 ft bgs	Y	14 of 54	80 µg/kg	Y	NA		
Scouring Scenario 1: 2-6 ft bgs	Y	19 of 106	290 µg/kg	Y	NA		
Scouring Scenario 1: 2-10 ft bgs	Y	22 of 161	290 µg/kg	Y	NA		
Scouring Scenario 1: 2-12 ft bgs	Y	22 of 166	290 µg/kg	Y	NA		
Scouring Scenario 2: 5-6 ft bgs	Y	5 of 51	290 µg/kg	Y	NA		
Scouring Scenario 2: 5-10 ft bgs	Y	8 of 106	290 µg/kg	Y	NA		
Scouring Scenario 2: 5-15 ft bgs	Y	8 of 118	290 µg/kg	Y	NA		
HMW PAHs				**NA**	**1160 µg/kg**		
0-0.5 ft bgs	Y	23 of 54	900 µg/kg	NA	N	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	37 of 108	900 µg/kg	NA	N		
0-6 ft bgs	Y	42 of 160	2900 µg/kg	NA	Y		
Scouring Scenario 1: 2-3 ft bgs	Y	14 of 54	540 µg/kg	NA	N		
Scouring Scenario 1: 2-6 ft bgs	Y	19 of 106	2900 µg/kg	NA	Y		
Scouring Scenario 1: 2-10 ft bgs	Y	22 of 161	2900 µg/kg	NA	Y		
Scouring Scenario 2: 5-6 ft bgs	Y	5 of 51	2900 µg/kg	NA	Y		
Scouring Scenario 2: 5-10 ft bgs	Y	8 of 106	2900 µg/kg	NA	Y		
Scouring Scenario 2: 5-15 ft bgs	Y	8 of 118	2900 µg/kg	NA	Y		

Footnotes:

[1] The higher value of either the HHCV/ECV or background was selected as the screening criteria and are included in these columns for the respective compound in **BOLDED BLUE FONT**. Values based on background are indicated with "(bckg)" next to the value.

[2] AOC1/SWMU1 soil data was evaluated for sufficiency to support the ecological risk assessment including sampling locations in areas of soil transitioning to sediment. These locations are BCW-6 and SS-1.

Acronyms and Abbreviations:

AOC - area of concern
BaP TEQ - benzo(a)pyrene toxic equivalents
ECV - ecological comparison values
EPC - exposure point concentration
ft bgs - feet below ground surface
HHCV - human health comparison values
HMW PAH - high molecular weight polycyclic aromatic hydrocarbons
mg/kg - milligrams per kilogram
µg/kg - micrograms per kilogram
N - no
NA - not applicable
Y - yes

NA - not applicable
Y - yes

TABLE C2-15
Decision 2 Data Gaps Summary - AOC1 Sediment Samples
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth[1]	Adequate EPC? [2]		Maximum Detected Value	> TEC or Soil Background[1]	Proposed Sample ID	Notes
	Y or N	Det/# results		Y or N		
Metals						
Arsenic				**9.79 mg/kg (TEC)**		
0-0.5 ft bgs	N	4 of 5	13 mg/kg	Y	None	Compound exceeds TEC and is less than PEC (33 mg/kg). Existing data not adequate to calculate UCL using ProUCL. Maximum is within two time the TEC and may be naturally occurring at this concentration. Additional sampling is expected to yield comparable concentrations and not significantly change the EPC.
0-2 ft bgs	N	4 of 5	13 mg/kg	Y		
0-3 ft bgs	N	5 of 6	13 mg/kg	Y		
Chromium-Total				**43.4 mg/kg (TEC)**		
0-0.5 ft bgs	N	11 of 11	71 mg/kg	Y	None	Compound exceeds TEC and is less than PEC (111 mg/kg). Existing data adequate to calculate UCL using ProUCL.
0-2 ft bgs	Y	11 of 11	71 mg/kg	Y		
0-3 ft bgs	Y	12 of 12	71 mg/kg	Y		
Chromium-Hexavalent				**0.83 mg/kg (soil background)**		
0-0.5 ft bgs	N	1 of 11	2.63 mg/kg	Y	None	Compound exceeds soil background used as a conservative estimate of sediment background. Existing data are not adequate to calculate UCL using ProUCL; however, collecting additional samples is likely to yield additional non-detected values. Additional data collected to satisfy Decision 1 will be included in the EPC calculations as appropriate. Data for the surface interval include historical sediment samples collected from 0 to 2 feet below sediment surface.
0-2 ft bgs	N	1 of 11	2.63 mg/kg	Y		
0-3 ft bgs	N	1 of 12	2.63 mg/kg	Y		

Footnotes:

[1] Compounds included are those that exceed the TEC. If a TEC was unavailable, soil background was applied as a conservative estimate of sediment background values. The 0 to 0.5 ft exposure interval includes samples collected from 0 to 2 ft below sediment surface.

[2] Samples considered in this evaluation were those from the preliminary AOC-1 sediment exposure area at the mouth of Bat Cave Wash. Samples included were those in sediment or soil transitioning to sediment within the exposure area: AOC1-BCW6-122, AOC1-BCW6-123, SED-10, SED-11, SED-12, SED-5, SED-6, SED-7, SED-8, SED-9, SS-1-0.5, SS-1-1.5. Samples from upriver and downriver (i.e., DrSed-1, DrSed-2, DrSed-3, SED-1, SED-2, SED-3, SED-4, SED-27, SED-28, and SED-29) were not included.

c. The TEC or soil background value is included in this column for the respective compound in **BOLDED BLUE FONT**.

Acronyms and Abbreviations:
AOC - area of concern
EPC - exposure point concentration
ft bgs - feet below ground surface
mg/kg - milligrams per kilogram
N - no
NA - not applicable
PEC - probable effects concentration
TEC - threshold effects concentration
UCL - upper confidence limit
Y - yes

TABLE C2-16
Results of Tiered Analysis at AOC 1 – North
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California

Metal	**Step 1 Do COPCs/COPECs Exceed Background?**	**Step 2 Do COPCs/COPECs Exceed SSL?**	**Step 3 Does Screening Model Eliminate Potential for Leaching to Groundwater?**
Arsenic	√		
Chromium	√		
Chromium, Hexavalent	√	√	Yes
Copper	√		
Lead	√		
Molybdenum	√	√	Yes
Zinc	√		

✓ = Constituents concentration exceeds background and/or SSL.
SSL = soil screening level.

TABLE C2-17

Sample Results Compared to the Calculated Soil Screening Levels
AOC1-North
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] Soil Screening Level (SSL) calculation was provided in the technical memorandum entitled "Calculation of Soil Screening Levels for Protection of Groundwater at the PGE Topock Compressor Station", CH2MHill 2008.

[2] CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

Results greater than or equal to the SSL and greater than or equal to the background value are circled.

mg/kg	milligrams per kilogram
ft bgs	feet below ground surface
N	primary sample
FD	field duplicate
---	not analyzed
ND	not detected at the listed reporting limit
J	concentration or reporting limit estimated by laboratory or data validation

TABLE C2-18

Constituent Concentrations in Soil Compared to Total Threshold Limit Concentration (TTLC), Soluble Threshold Limit Concentration (STLC), and Toxic Characteristic Leaching Procedure (TCLP)
AOC 1 - Area Around Former Percolation Bed
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Topock Compressor Station, Needles, California

		Maximum Detected Value (mg/kg)	TTLC in mg/kg[1]		STLC in mg/L[1]			TCLP in mg/L[1]		
Parameter	**Frequency of detection**		**# of Exceedences**	**TTLC**	**# of Exceedences of STLC x 10**	**STLC x 10**	**STLC**	**# of Exceedences of TCLP x 20**	**TCLP x 20**	**TCLP**
Antimony	0 / 111 (0%)	ND (5.8)	0	500	0	150	15	0	NE	NE

Thallium	0 / 111 (0%)	ND (5.8)	0	700	0	70	7	0	NE	NE
Vanadium	130 / 130 (100%)	44.5	0	2400	0	240	24	0	NE	NE
Zinc	167 / 167 (100%)	132	0	5000	0	2500	250	0	NE	NE

Notes:

[1] Code of Regulations, Title 22, Chapter 11, Article 3

mg/kg	miligrams per kilogram
mg/L	milligrams per liter
ND	not detected in any of the samples
NE	not established
‡	maximum reporting limit greater than or equal to the STLC x 10.

TABLE C2-19
Proposed Phase 2 Sampling Locations at AOC 1
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Proposed Collection Method[b]
AOC1-BCW7	0. 2, 5, 9, 14, and 20	To resolve Data Gaps #5 and #6 - Assess potential impoundment area at IM-3 road crossing and support CMS/FS	Hexavalent chromium, PCBs[a]; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – 3 samples from boring	Rotosonic
AOC1-BCW8	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW9	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW10	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW11	0, 2, 5, and 9	To resolve Data Gap #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW12	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW13	0, 2, 5, and 9	To resolve Data Gaps #3, and #6 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash support CMS/FS.	Hexavalent chromium, PCBs[a]; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – 3 samples from boring	Rotosonic
AOC1-BCW14	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW15	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW16	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW17	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic

		tamarisk area near the mouth of Bat Cave Wash.		
AOC1-BCW18	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW19	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW20	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW21	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW22	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW23	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW24	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW25	0, 2, 5, and 9	To resolve Data Gaps #3, and #6 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash support CMS/FS.	Hexavalent chromium, PCBs[a]; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – 3 samples from boring	Rotosonic
AOC1-BCW26	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic
AOC1-BCW27	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic or backhoe
AOC1-BCW28	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic or backhoe

TABLE C2-19
Proposed Phase 2 Sampling Locations at AOC 1
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Proposed Collection Method[b]
		tamarisk area near the mouth of Bat Cave Wash.		
AOC1-BCW29	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic or backhoe
AOC1-BCW30	0, 2, 5, and 9	To resolve Data Gaps #3 - Chemical concentrations soil and sediment in the vicinity of AOC1-BCW6 and evaluation of tamarisk area near the mouth of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PCBs[a]	Rotosonic or backhoe
AOC1-1 (contingent)	0, 2, 5, 9, 14, 20, and 30	To resolve Data Gap #1 - Define lateral extent in bottom of Bat Cave Wash. Contingent upon results of AOC1-2 and AOC1-3.	Hexavalent chromium, Title 22 metals, PAHs, pH, PCBs[a]	Rotosonic
AOC1-2	0, 2, 5, 9, 14, 20, and 30	To resolve Data Gap #1 - Define lateral extent in bottom of Bat Cave Wash.	Hexavalent chromium, molybdenum, total chromium, PCBs[a]	Rotosonic
AOC1-3	0, 2, 5, 9, 14, 20, 30, 40, 50, 60, 70, and 80	To resolve Data Gap #1 - Define lateral extent in bottom of Bat Cave Wash.	Hexavalent chromium, Title 22 metals, PAHs, pH, PCBs[a]	Rotosonic
AOC1-4 (contingent)	0, 2, 5, 9, 14, 20, and 30	To resolve Data Gap #1 - Define lateral extent in bottom of Bat Cave Wash. Contingent upon results of AOC1-2 and AOC1-3.	Hexavalent chromium, Title 22 metals, PAHs, pH, PCBs[a]	Rotosonic
AOC1-T1e	0, 2, 5, 9, and 14	To resolve Data Gap #1 - Define lateral extent at AOC1-T1c.	Hexavalent chromium, Title 22 metals, PAHs, pH, PCBs[a]	Rotosonic
AOC1-T1f	0, 2, 5, 9, and 14	To resolve Data Gap #1 - Define lateral extent at AOC1-T1c.	Hexavalent chromium, Title 22 metals, PAHs, pH, PCBs[a]	Rotosonic
AOC1-T2f	0, 2	To resolve Data Gap #4 - Evaluate potential white powder.	Title 22 metals, hexavalent chromium, pH, PCBs[a]	Hand tools/ Repelling
AOC1-T5d	0, 2, 5, 9, 14, and 20	To resolve Data Gaps #1 and #6- Define lateral extent near sample transect AOC1-T5 and support CMS/FS.	Hexavalent chromium, Title 22 metals, PAHs, PCBs[a] ; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – 3 samples from boring	Rotosonic
AOC1-T6d	0, 2, 5, 9, 14, and 20	To resolve Data Gaps #5 and #6 – Assess potential impoundment area near railroad bridge culvert and support CMS/FS.	Hexavalent chromium, Title 22 metals, PAHs, PCBs[a] ; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – 3 samples from boring	Rotosonic

TABLE C2-19
Proposed Phase 2 Sampling Locations at AOC 1
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report, PG&E Topock Compressor Station, Needles, California

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Proposed Collection Method[b]
AOC4-BCW1	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs, dioxins/furans	Rotosonic
AOC4-BCW2	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs, dioxins/furans	Rotosonic
AOC4-BCW3	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs, dioxins/furans	Rotosonic
AOC4-BCW4	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs, dioxins/furans	Rotosonic
AOC4-BCW5	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs, dioxins/furans, asbestos (surface soil sample only)	Rotosonic
AOC4-BCW6	0, 2, 5, and 9	To resolve Data Gap #2 - Extent of constituents associated with the discharge from the Debris Ravine (AOC 4).	Title 22 metals, hexavalent chromium , PCBs, dioxins/furans	Rotosonic

Notes:

[a] PCB analysis only on soil samples collected at 0 and 2 feet bgs.

[b] Proposed collection methods listed on this table are based on experience and knowledge of the site; actual collection method will be chosen in the field based on field conditions and site access restrictions.

TPH	total petroleum hydrocarbons
VOC	volatile organic compound

APPENDIX C3

Area of Concern 9 Data Gaps Evaluation Results

1.0 Introduction and Background

This sub-appendix presents the results of the data gaps evaluation and Part A Phase 2 Sampling Program for Area of Concern (AOC) 9 – Southeast Fence Line at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the data gaps evaluation is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report.

1.1 Background

AOC 9 is located in the southeast portion of Topock Compressor Station east of the facility fence line and just south of the visitor parking lot, as shown in Figure C3-1. It is located entirely on PG&E-owned property. The original extent of AOC 9 consisted of a small area of discolored soil that had been uncovered due to erosion. A broken stormwater discharge pipe was located in the same area of the stained soil, and information from former employees indicated that the pipe trench leading to the storm drain may have received runoff from leaks originating near the Auxiliary Building. Approximate location of the storm drain is shown on Figure C3-2.

On April 6, 2000, approximately 1.5 cubic yards of the stained soil were excavated and shipped offsite for disposal. The approximate location and size of the excavation is shown in Figure C3-2. After the majority of the stained soil was removed, a new stormwater drainage pipe was installed, and the area was backfilled with clean soil to prevent erosion of the slope. Sampling was conducted after the majority of the stained soil had been removed (PG&E, 2000). Due to the extremely steep slope at AOC 9, removal of additional soil was not feasible at the time. The excavated area was covered with 1 to 2 feet of clean fill (PG&E, 2000).

The approximate location of the storm drain and the April 2000 excavation shown on Figure C3-2 are based on historical employee interviews, site walk observations (i.e., depression in excavation area where backfill had settled), and the April 2000 excavation letter report (PG&E, 2000). However, recent employee interviews have revealed a possible alternate location for this storm drain located further south of the original location. This alternate location of the storm drain is shown on Figure C3-2.

The AOC 9 boundary was extended to include additional sampling locations in response to California Environmental Protection Agency, Department of Toxic Substances Control comments on the *RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan, Part A, PG&E Topock Compressor Station, Needles, California,* referred to as the Soil Part A Work Plan (CH2M HILL, 2006). The extension was approximately 100 feet north to south and 50 feet east to west, centered on the alignment of the storm drain.

A graphical conceptual site model has been developed for AOC 9 based on the above site history and background, as shown in Figure C3-2. Table C3-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 9. (All tables and figures appear at the end of this sub-appendix.) A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the Soil Part A Data Quality Objective [DQO] Technical Memorandum, presented as Appendix A to the Data Gaps Evaluation Report.

The primary source of contamination at AOC 9 is historical liquid discharge from a broken storm drain to shallow soil. While the actual depth of the pipe break is not known with certainty, based on similar site facilities and the limitations due to the steep slope at this location, it is expected to have been between 1 to 3 feet below ground surface (bgs). The quantity of liquid released from the broken storm drain is expected to be relatively small since—with the exception of storm events—the drain would have only captured small incidental leaks or spills from various systems at the Topock Compressor Station. The area could also have received surface runoff from the compressor station. Dark soil—what appears to be stained soil—is present along the west side of AOC 9 in a May 19, 1955 aerial photograph. This area is shown in Figure C3-2.

The primary source media at AOC 9 are surface and shallow soils. Liquids released to these areas could have infiltrated to deeper soils and/or flowed downhill in surface or shallow subsurface runoff. These flows would have entered the East Ravine and are addressed as part of AOC 10. Due to the steep angle of the slope at AOC 9, infiltration is likely to be a lesser pathway than surface runoff. Chemicals of potential concern (COPCs) in residual contamination in the area of the former broken stormwater discharge pipe could have migrated to deeper soils. Due to the relatively small quantity of liquid released, the angle of the slope, and shallow depth of the release of cooling water, leaching to groundwater from this area is unlikely; however, this pathway is assessed as part of DQO Decision 3. If present, organic constituents in surface soils would be expected to have been degraded by heat and light.

For AOC 9, a potential secondary release pathway is windblown dust contamination, which could have occurred as a result of dust being transported from the AOC. Windblown contamination, if any, would be limited to surface soils.

Because potential sources of COPCs to this unit are runoff from the compressor station and discharge of chromium-containing cooling water from the facility via a broken stormwater discharge pipe, Part A Phase 1 and historical soil were collected throughout AOC 9, including at the top of the slope near the compressor station, near the bottom of the slope, as confirmation samples following the excavation, and near the broken storm drain pipe and excavation.

1.2 AOC 9 Data

Nine historical soil samples (0 to 0.5 foot bgs) were collected from nine locations (#4 through #12) in AOC 9, as shown in Figure C3-1. These historical samples may have been collected along the alternate location of the storm drain shown on Figure C3-2. Historical soil samples were analyzed for five constituents: total chromium, hexavalent chromium, copper, nickel, and zinc.

During the 2008 Part A Phase 1 soil investigation, 30 soil samples (from 0 to 0.5, 2 to 3, and 5 to 6 feet bgs) were collected from 14 sample locations (AOC9-1 through AOC9-14), as shown in Figure C3-1. Part A Phase 1 soil samples collected in AOC 9 were generally analyzed for Title 22 metals, hexavalent chromium, volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), polycyclic aromatic hydrocarbons (PAHs), total petroleum hydrocarbons (TPH), pH, asbestos, pesticides, and polychlorinated biphenyls (PCBs). Ten percent of the Phase 1 soil samples collected in AOC 9 (three soil samples) were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL). Surface soil samples were not analyzed for VOCs. In addition, synthetic precipitation leaching procedure extraction was conducted on surface soil samples (collected from 0 to 0.5 foot bgs) at sample locations AOC9-7 and AOC9-8. The leachate from the synthetic precipitation leaching procedure extractions was analyzed for total and hexavalent chromium. The leachate results from the synthetic precipitation leaching procedure extractions are presented in Table C3-2. Soil results were validated, and the data quality evaluation is included in Appendix D to the Data Gaps Evaluation Report.

A small area of surficial white powder material was observed in AOC 9 in the immediate vicinity of AOC9-14. A sample of this white powder material was collected at 0.5 foot bgs at sample location AOC9-14. A soil sample was also collected at 2 to 3 feet bgs, beneath the white powder. The white powder sample was analyzed for Title 22 metals, hexavalent chromium, SVOCs, PAHs, asbestos, and pH, and the soil sample was analyzed for Title 22 metals, hexavalent chromium, PAHs, asbestos, and pH.

All historical and Part A Phase 1 data considered Category 1 were used as inputs to the four DQO decisions for AOC 9.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of COPCs and chemicals of potential ecological concern (COPECs) at AOC 9. Laboratory analytical results for historical and Phase 1 soil samples and the white powder sample at AOC 9 are presented in Tables C3-3 through C3-9. Table C3-10 presents a statistical summary of soil analytical results for COPCs and COPECs that were either detected above the laboratory reporting limits or not detected but where the reporting limits for one or more samples was greater than the interim screening value. The white powder sample results are not included in the statistical summary of soil data. The soil data are discussed first, followed by the data for the white powder sample.

2.1 Summary of AOC 9 Soil Data

Antimony, beryllium, cadmium, selenium, silver, cyanide, TPH-gasoline, VOCs, and SVOCs were not detected in soil samples collected in AOC 9. Table C3-10 lists the 44 detected constituents, including four calculated quantities (benzo(a)pyrene equivalents, total low molecular weight PAHs, total high molecular weight PAHs, and total PCBs). Ten of these constituents (aluminum, calcium, iron, magnesium, manganese, potassium, sodium, Aroclor-1254, total PCBs, and 4,4-dichlorodiphenyldichloroethylene [4,4-DDE]) were detected in the TAL/TCL samples.

Thirty-two of the constituents detected at AOC 9 (arsenic, barium, cobalt, vanadium, aluminum, calcium, iron, magnesium, manganese, potassium, sodium, Aroclor-1254, 1-methylnaphthalene, 2-methylnaphthalene, acenaphthene, anthracene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, pyrene, total PCBs, total low molecular weight PAHs, total high molecular weight PAHs, TPH-diesel, and TPH-motor-oil) were detected at concentrations below their respective interim screening levels. Twelve constituents (total chromium, hexavalent chromium, copper, lead, mercury, molybdenum, nickel, thallium, zinc, benzo(a)pyrene, benzo(a)pyrene equivalents, and 4,4-DDE) were detected one or more times at concentrations exceeding the interim screening levels.

Eight constituents (total chromium, hexavalent chromium, copper, lead, mercury, zinc, benzo(a)pyrene, and benzo(a)pyrene equivalents) were detected four or more times at concentrations exceeding the interim screening level; the distribution of these constituents are shown in Figures C3-1 and C3-3 to C3-8.

One sample associated with AOC 10 (AOC 10a-1) is located within approximately 30 feet of the AOC 9 boundary and slightly down/cross-slope. This sample was collected in a stained area below a stormwater pipe outfall. To provide further context for the evaluation of potential data gaps, the data for this sample are also shown in Figures C3-1 and C3-3 to C3-8. Two proposed AOC 10 Phase 2 sample locations (AOC10a-2 and AOC10a-3) associated with sample location AOC10a-1 are reflected in the AOC 9 data gaps evaluation since these proposed AOC 10 Phase 2 sample locations are downslope of AOC 9.

2.2 Nature and Extent Evaluation for Soil

The following subsection discusses the nature and extent of detected COPCs and COPECs detected above interim screening levels at AOC 9. As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Section 2.5 of this sub-appendix summarizes the constituents that may require further evaluation, and Section 6.0 of this sub-appendix provides the recommended follow-up sampling for the Part A Phase 2 soil investigation needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

2.2.1 Total Chromium

Total chromium was detected in 38 of 38 soil samples collected at AOC 9. Detected concentrations of total chromium exceeded the interim screening level (39.8 milligrams per kilogram [mg/kg]) (background threshold value [BTV]/ecological comparison value [ECV]) eight times (maximum detected concentration of 398 mg/kg at #10), as shown in Tables C3-3 and C3-10 and Figure C3-1. Only one of the detected concentrations of total chromium (old sample location #10 collected at 0.5 foot bgs) exceeded the United States Environmental Protection Agency 2008 regional screening level (RSL) for residential use (280 mg/kg) but was well below the commercial/industrial regional screening level (1,400 mg/kg). The lateral extent of concentrations exceeding the interim screening level is generally limited to the western AOC 9 boundary, with the exception of two locations (#10 and AOC9-7). Location #10 is located in the north central portion of AOC 9, and AOC9-7 is located outside the AOC boundary and downslope from the AOC.

2.2.2 Hexavalent Chromium

Hexavalent chromium was detected in 22 of 38 soil samples collected at AOC 9. Detected concentrations of hexavalent chromium exceeded the interim screening level (0.83 mg/kg) (BTV) 16 times (maximum detected concentration of 114 mg/kg at #10), as shown in Tables C3-3 and C3-10 and Figure C3-2. Only two of the detected concentrations of hexavalent chromium exceeded the residential California Environmental Protection Agency, Department of Toxic Substances Control residential California human health screening level (CHHSL) of 17 mg/kg and commercial/industrial CHHSL of 37 mg/kg; no detected concentrations exceeded the ECV (139.6 mg/kg). The lateral extent of samples with concentrations exceeding the interim screening level is limited to the northern portion of AOC 9 and areas downslope of this AOC. At many locations, the deepest samples have concentrations exceeding the interim screening level; however, in most cases, only shallow samples (maximum depth of 6 feet bgs) were collected during the Part A Phase 1 and previous investigations.

2.2.3 Copper

Copper was detected in 38 of 38 soil samples collected at AOC 9. Detected concentrations of copper exceeded the interim screening level (16.8 mg/kg) (BTV) 10 times (maximum detected concentration of 50.4 mg/kg at #9), as shown in Tables C3-3 and C3-10 and Figure C3-3. Four samples exceeded the ECV (20.6 mg/kg). The maximum sample result of 50.4 mg/kg at #9 exceeded two times the ECV. None of the detected concentrations exceeded residential or commercial/industrial CHHSLs (3,000 mg/kg and 38,000 mg/kg, respectively). This location is located near the northwest portion of the AOC near the compressor station fence line and the historical broken stormwater discharge pipe. Samples with concentrations below the interim screening level surround this location laterally and vertically. Remaining detected concentrations exceeding the interim screening level ranged from 17 to 35.6 mg/kg.

2.2.4 Lead

Lead was detected in 29 of 29 soil samples collected at AOC 9. Detected concentrations of lead exceeded the interim screening level (8.39 mg/kg) (BTV/ECV) 19 times (maximum detected concentration of 59 mg/kg at AOC9-8), as shown in Tables C3-3 and C3-10 and Figure C3-4. None of the detected concentrations exceeded the residential or commercial/industrial CHHSLs (80 mg/kg and 320 mg/kg, respectively). Lead concentrations exceeded the interim screening level across most of AOC 9. At many locations, the deepest samples, collected at 2 feet bgs, have concentrations exceeding the interim screening level.

2.2.5 Mercury

Mercury was detected in four of 29 samples collected at AOC 9. Detected concentrations of mercury exceeded the interim screening level (0.0125 mg/kg) (ECV) four times (maximum detected concentration of 0.27 mg/kg at AOC9-5), as shown in Tables C3-3 and C3-10 and Figure C3-5. None of the detected concentrations exceeded the residential and commercial/ industrial CHHSLs (18 mg/kg and 180 mg/kg, respectively). The ECV of 0.0125 mg/kg is below the capability of the instrumentation to detect mercury. As a result, the 25 non-detected sample results had reporting limits that exceeded the ECV. These reporting limits ranged from 0.099 to 0.1 mg/kg. The four sample locations with detectable concentrations of mercury are located in the central portion of AOC 9. Samples with concentrations below the detection limits are located to the north and south of these locations but not the east and west. At two of the four locations, only the deeper samples, collected at 2 feet bgs, have detectable concentrations exceeding the interim screening level; mercury concentrations in the shallow samples were below the detection limit.

2.2.6 Molybdenum

Molybdenum was detected in two of 29 soil samples collected from AOC 9, both from boring AOC9-8. One detected concentration of 4.5 mg/kg exceeded the interim screening level of 1.37 mg/kg (BTV) and the ECV (2.25 mg/kg), as shown in Tables C3-3 and C3-10. Neither detected concentration exceeded residential and commercial/industrial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). AOC9-8 is located in the northwestern portion of the AOC near the compressor station fence line and the historical broken stormwater discharge pipe. Samples with concentrations below the interim screening level are located to the north, east, and south of this location. Samples were not collected west of this sample location (closer to the compressor station fence line). The deepest sample at AOC9-8 has a molybdenum concentration below the interim screening level.

2.2.7 Nickel

Nickel was detected in 38 of 38 soil samples collected from AOC 9. As shown in Tables C3-3 and C3-10, one detected concentration of 29 mg/kg at AOC 9-12 slightly exceeded the interim screening level (27.3 mg/kg) (BTV/ECV) but did not exceed the residential and commercial/industrial CHHSLs (1,600 mg/kg and 16,000 mg/kg, respectively). This location is located in the southwestern portion of the AOC near the compressor station fence line. Samples with concentrations below the interim screening level are located to the north and east of this location. Samples were not collected to the west (on the compressor station) or to the south of this location. The exceedance was detected in the deepest soil sample collected at this location.

2.2.8 Thallium

Thallium was detected in one of 29 soil samples collected from AOC 9. As shown in Tables C3-3 and C3-10, the detected concentration of thallium (4.1 mg/kg at AOC9-8) exceeded the interim screening level (2.32 mg/kg) (ECV) but did not exceed the residential and commercial/industrial CHHSLs (5 mg/kg and 63 mg/kg, respectively). This location is located in the northwestern portion of the AOC near the compressor station fence line and the historical broken stormwater discharge pipe. Samples with concentrations below the interim screening level are located to the north, east, and south of this location but were not collected to the west closer to the compressor station fence line. At location AOC9-8, the deepest sample has a nickel concentration below the interim screening level.

2.2.9 Zinc

Zinc was detected in 38 of 38 soil samples collected at AOC 9. Detected concentrations of zinc exceeded the interim screening level (58 mg/kg) (BTV/ECV) 18 times (maximum detected concentration of 1,000 mg/kg at AOC9-8), as shown in Tables C3-3 and C3-10 and Figure C3-6. None of the detected concentrations exceeded residential and commercial/ industrial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively). The lateral extent of samples with concentrations exceeding interim screening level is limited to the central portion of AOC 9 and areas downslope of this AOC. Samples with concentrations below the interim screening level are located to the north and south of these locations but not to the west or to the east. At many locations, the deepest samples have concentrations exceeding the interim screening level; however, in most cases, only shallow samples (maximum depth of 6 feet bgs) were collected during the Part A Phase 1 and previous investigation.

2.2.10 Benzo(a)pyrene, Benzo(a)pyrene Equivalents, and PAHs

Benzo(a)pyrene was detected in 24 of 29 soil samples collected from AOC 9. Detected concentrations of benzo(a)pyrene exceeded the interim screening level (38 micrograms per kilograms [µg/kg]) (residential CHHSL) six times. Several other PAHs were detected in soil samples collected from AOC 9 but had concentrations below respective interim screening levels. To assist with evaluation of PAHs for human health, benzo(a)pyrene equivalents were calculated for each of the soil samples collected at AOC 9, as shown in Table C3-5. Benzo(a)pyrene equivalents values exceeded the interim screening level of 38 µg/kg (residential CHHSL) seven times (maximum calculated concentration of 110 µg/kg at AOC 9-5 and AOC 9-6), as shown in Tables C3-5 and C3-10 and Figure C3-7. The lateral extent of samples with concentrations exceeding interim screening level is limited to the eastern, southern, and western portions of AOC 9. Samples with concentrations below the interim screening level are located to the north but not to the east, south, or west. At two locations (AOC9-5 and AOC9-10), the deepest samples (collected at 3 feet bgs) have concentrations exceeding interim screening level.

To assist with evaluation of PAHs for ecological risk, detected concentrations of low molecular weight PAHs and high molecular weight PAHs were summed and compared to the PAH low molecular weight and PAH high molecular weight ECVs (10,000 µg/kg and 1,160 µg/kg, respectively). None of the sums of detected concentrations exceeded the PAH low molecular weight and PAH high molecular weight ECVs.

2.2.11 Target Analyte List/Target Compound List Constituents

Aluminum, calcium, magnesium, potassium, sodium, Aroclor-1254, and 4,4-DDE were detected in the AOC 9 surface soil samples analyzed for the complete TAL/TCL suite of compounds. These constituents are discussed below.

Aluminum was detected in three of three surface soil samples collected from AOC 9. The maximum detected concentration of aluminum was 13,000 mg/kg at AOC9-12, which is below the interim screening level (16,400 mg/kg) (BTV), as shown in Tables C3-4 and C3-10. Remaining detected concentrations of aluminum are 6,900 and 10,000 mg/kg. None of the detected concentrations exceeded residential and commercial CHHSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in three of three surface soil samples collected from AOC 9. The maximum detected concentration of calcium was 38,000 mg/kg at AOC9-12, which is below the interim screening level (66,500 mg/kg) (background value), as shown in Tables C3-4 and C3-10. Remaining detected concentrations of calcium are both 26,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium.

Iron was detected in three of three surface soil samples collected from AOC 9. The maximum detected concentration of iron was 22,000 mg/kg at AOC9-12, which is below the interim screening level of 55,000 mg/kg (residential RSL), as shown in Tables C3-4 and C3-10. Remaining detected concentrations of iron are 12,000 and 17,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for iron.

Magnesium was detected in three of three surface soil samples collected from AOC 9. The maximum detected concentration of magnesium was 9,600 mg/kg at AOC9-12, which is below the interim screening level (12,100 mg/kg) (background value), as shown in Tables C3-4 and C3-10. Remaining detected concentrations of magnesium are 5,700 and 7,400 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium.

Manganese was detected in three of three surface soil samples collected from AOC 9. The maximum detected concentration of manganese was 310 mg/kg at AOC9-12, which is below the interim screening level (402 mg/kg) (BTV/ECV), as shown in Tables C3-4 and C3-10. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (1,800 mg/kg and 23,000 mg/kg, respectively).

Potassium was detected in three of three surface soil samples collected from AOC 9. The maximum detected concentration of potassium was 2,500 mg/kg at AOC9-12, which is below the interim screening level of 4,400 mg/kg (BTV), as shown in Tables C3-4 and C3-10. Remaining detected concentrations of potassium are 1,500 and 2,300 mg/kg. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for potassium.

Sodium was detected in three of three surface soil samples collected from AOC 9. The maximum detected concentration of sodium was 810 mg/kg at AOC9-5, which is below the interim screening level of 2,070 mg/kg (BTV), as shown in Tables C3-4 and C3-10. Remaining detected concentrations of sodium are 450 and 620 mg/kg. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for sodium.

Aroclor-1254 was detected in three of five soil samples collected from AOC 9; both surface and subsurface soil (2 to 3 feet bgs) samples were collected. The maximum detected concentration of Aroclor-1254 was 160 µg/kg at AOC9-5 at 2 to 3 feet bgs, which is below the interim screening level of 220 µg/kg (residential RSL). Remaining detected concentrations of Aroclor 1254 are 44 and 160 µg/kg. To assist with evaluation of PCBs for ecological risk, detected concentrations of the Aroclors detected (only Aroclor-1254 was detected at AOC 9) were summed and the total PCB values were compared to the ECV. The maximum calculated value for total PCBs was 160 µg/kg, which is below the total PCB ECV of 204 µg/kg, as shown in Table C3-8. The remaining calculated total PCB concentrations are 44 and 160 µg/kg (both surface and shallow soil samples at AOC9-5 contained 160 µg/kg total PCBs).

4,4-DDE (3.2 µg/kg at AOC9-11), the daughter product of pesticide 4,4-dichlorodipheynyl-trichloroethane (4,4-DDT), was the only pesticide detected, which was above the interim screening level (2.1 µg/kg, ECV), as shown in Tables C3-7 and C3-10. The detected concentration did not exceed the residential or commercial/industrial CHHSLs (1,600 µg/kg and 6,300 µg/kg, respectively).

The only possible historical source of 4,4-DDT and its daughter products in the area would have been pest (insect) control. As such, any presence of 4,4-DDT and its daughter products would represent a nonpoint source and should be evaluated as such. 4,4-DDE was detected very infrequently in two other AOCs (AOC 11 and AOC 14) in addition to AOC 9. Sitewide, 4,4-DDE was only detected three times above its interim screening value (out of 72 total samples analyzed for this compound).

As discussed in Section C.2 of the main text of this appendix, PG&E recommends that 4,4-DDE not be considered COPC/COPEC for this AOC, and no further sampling is recommended for this constituents. Pesticides and other TAL/TCL constituents have been fully discussed in Section C.2.

2.3 White Powder Sample

As previously mentioned, a sample of white powder material (location AOC9-14 at 0 to 0.5 foot bgs) was collected and sent to the laboratory for analysis. White powder material was encountered only in this one location and only in the surface sample. In addition, a soil sample was collected beneath the white powder at 2 to 3 feet bgs and sent to the laboratory for analysis. The following compounds were detected in the white powder material sample: arsenic, barium, total chromium, hexavalent chromium, copper, lead, nickel, vanadium, zinc, and TPH-motor-oil. Of those compounds detected, arsenic (12 mg/kg), hexavalent chromium (1.7 mg/kg), copper (24 mg/kg), lead (34 mg/kg), and zinc (81 mg/kg) were detected above their respective interim screening levels.

The following compounds were detected in the soil sample collected at 2 to 3 feet bgs, beneath the white powder material: arsenic, barium, total chromium, cobalt, copper, lead, nickel, vanadium, zinc, several PAHs, TPH-diesel, and TPH-motor-oil. Of those compounds detected, only copper (17 mg/kg), lead (13 mg/kg), and zinc (61 mg/kg) were detected above their respective interim screening levels.

The lateral and vertical extents of the white powder material at AOC 9 have been defined. The nature and extent discussion presented above incorporates all of the constituents detected at this location that exceeded the lowest interim screening value, with the exception of arsenic. This was the only location where the arsenic concentration exceeded the interim screening value, and the lateral and vertical extent of arsenic at AOC 9 has been defined.

The white powder sample and the underlying soil sample were also analyzed for asbestos. Bulk samples analyzed by polarized light microscopy indicated that asbestos fibers were present in both samples. To confirm the presence of asbestos fibers, the white powder sample was also analyzed by California Air Resource Board Method 435 and transmission electron microscopy. California Air Resource Board Method 435 did indicate that very low levels of asbestos were present in the soil sample (detected concentration of less than 0.1 percent, where the detection limit was less than 0.1 percent); however, the transmission electron microscopy analysis indicated that asbestos was not detected above the detection limit. Based on these results, a very small percentage of asbestos fibers (less than 0.1 percent) are present in the white powder and soil samples.

2.4 Central Tendency Comparison to Background Threshold Values

Seven metals (total chromium, hexavalent chromium, copper, lead, molybdenum, nickel, and zinc) were detected above their respective Topock site-specific BTVs in soil samples collected from AOC 9. A central tendency comparison was performed for five of these seven metals (total chromium, copper, lead, nickel, and zinc) to compare the AOC 9 soil data set for these metals with the corresponding Topock soil background data set to determine whether a difference exists between the two populations and if additional sampling is required for a given metal (see Table C3-11 at the end of this sub-appendix and Figure 3-1 in the Data Gaps Evaluation Report).

Metals in either the AOC 9 data set or background data set that were detected infrequently (less than five detects) or had a limited number of results (less than eight) were not tested. There were insufficient detections of molybdenum at AOC 9 to conduct the test, and there were insufficient detections of hexavalent chromium in the background data set to allow for a central tendency comparison.

No statistical difference between the two populations was noted for nickel, as shown in Table C3-11. Results from the Gehan test indicated that site concentrations for total chromium, copper, lead, and zinc may exceed background. The lateral and vertical extents of copper have been adequately defined, and additional sampling is proposed for total chromium, lead, and zinc.

2.5 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review indicates than decision error has been held to an acceptable level. Although a recent employee interview presented a possible alternate location for the storm drain, sufficient data of acceptable quality have been attained through collection of historical/Part A soil samples in areas most likely to have been impacted by incidental leaks and stormwater from the facility via a broken stormwater discharge pipe (e.g., downslope of the approximate location of the broken stormwater pipe and in the former stained soil removal area). Detections of PAHs, lead, pesticides, and PCBs in soils outside of the expected area impacted by the broken discharge pipe may be related to the compressor station runoff or other factors. Evaluation of potential impacts to soil from compressor station runoff or other factors is currently planned to be addressed in the forthcoming Part B perimeter sampling program.

Review of the nature and extent discussions above indicates that the lateral extent of samples with concentrations exceeding the interim screening level is confined primarily to the area near the eastern downslope portion of AOC 9 and along the bottom of the ravine in AOC 10, vertical extent in and downslope of the former stained soil removal area, and vertical extent in the central portion of AOC 9 near the top of the slope close to the fence line. Within these areas, the lateral and/or vertical extents of hexavalent chromium, lead, mercury, PAHs, total chromium, and zinc have not been defined.

Based on the DQO, the following data gaps were identified to resolve Decision 1:

- Data Gap #1 - Vertical extent of contamination in and downslope of the former stained soil removal area.
- Data Gap #2 - Vertical extent of contamination outside of the former stained soil removal area near the top of the AOC 9 slope.
- Data Gap #3 - Lateral and vertical extents of contamination near the eastern (downslope portion of AOC 9) and along the bottom of the ravine.

The proposed Phase 2 soil sample locations to fill the identified data gaps are presented in Section 6.0.

3.0 Decision 2 – Data Sufficient to Estimate Representative Exposure Point Concentrations

For Decision 2, data were evaluated to determine if the AOC 9 data are sufficient to conduct human health and ecological risk assessments based on the criteria described in Section 4.0 of the Data Gaps Evaluation Report. The principal consideration for Decision 2 was whether there were sufficient data to estimate a representative exposure point concentration (EPC). All available data (including historical data) at AOC 9 were reviewed. The sample designated as “white powder” (AOC9-14 at 0 to 0.5 foot bgs) was included in the data reviewed as a conservative measure, assuming that exposure to material described as “white powder” would not differ significantly from exposure to surrounding soil. Data from AOC 10a-1 were also included in the evaluation to support the ecological risk assessment because this sample location is within approximately 30 feet of the AOC 9 boundary and slightly down/cross-slope. The data for AOC 10a-1 are provided in Appendix C4.

Table C3-10 summarizes the results of the evaluation to determine if data are sufficient to estimate a representative EPC. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value. In general, existing data are adequate to support EPC development for detected chemicals that exceeded one or more comparison values (10 metals, PAHs, and total DDT [i.e., DDT-R]), as described below. Phase 2 data will be added to the existing data set to calculate the final EPC (i.e., after Decision 1 is satisfied).

3.1 Metals

Sufficient data (numbers of samples and detections) are available to calculate EPCs for arsenic, total chromium, hexavalent chromium, copper, lead, nickel, and zinc using ProUCL. For the remaining metals (mercury, molybdenum, and thallium), additional data collection is not expected to significantly change the results of the risk assessment for one or both of the following reasons:

- The compound is very infrequently detected (mercury, molybdenum, and thallium) and additional nondetects would be expected.
- The maximum detected concentration is within two times the lowest risk-based comparison value (thallium).

3.2 Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene toxicity equivalents and high molecular weight PAHs using ProUCL.

3.3 Pesticides

4,4-DDE was detected in one of three samples at a concentration near the ECV and the detection limit, as shown in Table C3-12. The data are insufficient to allow calculation of an EPC using ProUCL, and the maximum would be selected as the EPC with the existing data set. The total concentration of DDT and metabolites (DDT-R) (3.2 µg/kg) is less than two times the ECV. Collection of additional data is not expected to yield sufficient detections to strongly influence the EPC. Therefore, no additional data collection is recommended to support EPC development.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

The following preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, is needed to resolve Decision 3. Additional evaluations will be performed as appropriate as data are collected to resolve Decision 1. Data collected to satisfy Decision 1 - Nature and Extent Evaluation - will provide the final representative data set that will be used to assess the threat to groundwater.

Table C3-13 presents the results of the tiered screening analysis for AOC 9. Ten metals had concentrations in excess of their respective background threshold value. Of those 10, hexavalent chromium, molybdenum, and thallium had one or more concentrations exceeding the calculated soil screening levels, as shown in Table C3-14. Numerical modeling was conducted to evaluate the potential of these three metals to leach into groundwater. Based on initial model screening simulations, the potential for hexavalent chromium and thallium to leach to groundwater could not be ruled out. These two constituents are discussed further below.

4.1 Thallium

At AOC 9, only one out of 29 samples had a detectable concentration of thallium (4.1 mg/kg). This single detection prompted the additional analysis. The simulated leaching concentration of thallium was likely due to the following factors:

- Nondetects in the initial concentration profile were input as one-half of the detection limit, resulting in a non-zero concentration and mass throughout the simulated vadose zone.
- Thallium has a very low Kd (dissociation constant) of 3.2 milliliters per gram.
- The background upper tolerance limit for thallium in groundwater is very low at 0.908 micrograms per liter.

Additional data are not needed for thallium; however, further refinement of the vadose zone model is proposed.

4.2 Hexavalent Chromium

The simulated leaching concentrations of hexavalent chromium were likely due to the following factors:

- The initial screening approach assigned the maximum concentration found at each depth interval across the entire interval, even though many other samples with far lower concentrations were observed at each level.
- The presence of hexavalent chromium at the deepest sampling interval at several locations required assignment of that concentration from that depth down to the water table.

Additional data are needed to better define the vertical extent of hexavalent chromium at AOC 9 and to assess if a current threat to groundwater exists. The screening model will be also refined with the new vertical data to more closely simulate vadose zone soil conditions.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Gaps Evaluation Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study (CMS/FS). The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fence line include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite), as discussed in Table 6-1 in the Data Gaps Evaluation Report.
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil washing technologies).

- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies), as discussed in Table 6-1 in the Data Gaps Evaluation Report.
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- If present, volumes of white powder and debris.

The following is a summary of data for AOC 9 that are currently available to support CMS/FS.

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. The lateral and vertical extent of the COPCs and COPECs is discussed in Section 2.2, data results for selected constituents are shown in Figure C3-1 and Figures C3-3 through C3-8, and data gaps associated with lateral and vertical delineation are discussed in Section 6.0.

5.2 Waste Characterization Parameters

Only partial waste characterization data are available to characterize the soil and other materials to be potentially removed for remedial action and disposed in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations. The maximum concentrations of these metals were compared to the California Title 22 total threshold limit and none of the metals in AOC 9 exceeded the total threshold limit, as shown in Table C3-15. The maximum detected concentrations were also compared to the soluble threshold limit concentrations, and none of the metals concentrations in AOC 9 exceeded 10 times the soluble threshold limit concentrations, as shown in Table C3-15. Additional data regarding potential COPC/COPEC leachability include synthetic precipitation leaching procedure (SPLP) analysis for total and hexavalent chromium, as shown in Table C3-2. SPLP analysis was conducted only for soil samples (no white powder or debris samples were tested using SPLP).

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 investigation was limited to grain size analysis only. Specific soil physical property data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 of the Data Gaps Evaluation Report.

5.4 Surface and Subsurface Features

While there is extensive information regarding surface and subsurface features at AOC 9, additional information may be required once areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are known for AOC 9. However, subsurface utilities, including gas transmission pipelines and any culverts or other features, may have to be more precisely defined to evaluate the feasibility and cost of certain remedial alternatives and to prepare construction specifications.

5.5 Volumes of White Powder and Debris

Only a small patch of white powder was observed and sampled at AOC 9, as discussed in Section 2.3 of this sub-appendix. No debris was observed at AOC 9.

Additional soil physical parameter data are needed to support the corrective measures study/feasibility study.

6.0 Summary of Data Gaps and Proposed Phase 2 Soil Sample Locations to Fill Identified Gaps

Based on the Part A DQO, data gaps were identified for three of the four decisions and are summarized below by decision:

- **Decision 1 (Nature and Extent)** – the following data gaps were identified to resolve this decision:
    - Data Gap #1 – Vertical extent of contamination in and downslope of the previous stained soil removal area.
    - Data Gap #2 – Vertical extent of contamination outside of the previous stained soil removal area near the top of the AOC 9 slope.
    - Data Gap #3 – Lateral and vertical extents of contamination near the western (downslope portion of AOC 9) and along the bottom of the ravine.
- **Decision 2 (Data Sufficient to Estimate Representative Exposure Point Concentrations)** – no data gap was identified for this decision.
- **Decision 3 (Potential Threat to Groundwater from Residual Soil Concentrations)** – the following data gap was identified to resolve this decision:
    - Data Gap #4 – Vertical extent of contamination information to support refinement of the vadose leaching zone model.
- **Decision 4 (Data Sufficient to Support the CMS/FS)** – the following data gap was identified to resolve this decision:
    - Data Gap #5 – Soil physical property parameters to support the corrective measures study/feasibility study.

Table C3-16 summarizes the proposed Phase 2 sample locations, depths, description/ rationale for each location (i.e., which data gaps they would address), and analytes. Proposed Phase 2 sample locations are also shown on Figure C3-9.

6.1 Access Restrictions

AOC 9 is located on a steep slope just outside the compressor station fence line. Most of the proposed Phase 2 sample locations are located on the steep slope or in drainage areas along the pipeline access road located at the toe of the slope beneath the AOC. Due to the unstable nature of the slope and lack of level ground, sample collection methods are limited to hand tools and/or backhoe.

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

Decision 2 Data Gaps Summary AOC 9 - *Southeast Fence Line*
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth	Adequate EPC?		Maximum Detected Value [1]	> HHCV or Background as Applicable? [2]	> ECV or Background as Applicable? [1, 2]	Proposed Sample ID	Notes
	Y or N	Det/# results [1]		Y or N [3]	Y or N		
Metals							
Arsenic				**11 mg/kg (bckg)**	**11.4 mg/kg**		
0-0.5 ft bgs	Y	15 of 15	12 mg/kg	Y	Y	None	Compound exceeds HHCV and ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	29 of 29	12 mg/kg	Y	Y		
0-6 ft bgs	Y	31 of 31	12 mg/kg	Y	Y		
0-10 ft bgs	Y	31 of 31	12 mg/kg	Y	NA		
Chromium-Total				**280 mg/kg**	**39.8 mg/kg (bckg)**		
0-0.5 ft bgs	Y	15 of 15	230 mg/kg	N	Y	None	Compound exceeds HHCV and ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	398 mg/kg	Y	Y		
0-6 ft bgs	Y	40 of 40	398 mg/kg	Y	Y		
0-10 ft bgs	Y	40 of 40	398 mg/kg	Y	NA		
Chromium - Hexavalent				**17 mg/kg**	**139.6 mg/kg**		
0-0.5 ft bgs	Y	10 of 15	48.6 mg/kg	Y	N	None	Compound exceeds HHCV. Existing data adequate for EPC.
0-3 ft bgs	Y	22 of 38	114 mg/kg	Y	N		
0-6 ft bgs	Y	24 of 40	114 mg/kg	Y	N		
0-10 ft bgs	Y	24 of 40	114 mg/kg	Y	NA		
Copper				**3000 mg/kg**	**20.6 mg/kg**		
0-0.5 ft bgs	Y	15 of 15	270 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	270 mg/kg	N	Y		
0-6 ft bgs	Y	40 of 40	270 mg/kg	N	Y		
0-10 ft bgs	Y	40 of 40	270 mg/kg	N	NA		
Lead				**80 mg/kg**	**8.39 mg/kg (bckg)**		
0-0.5 ft bgs	Y	15 of 15	200 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	29 of 29	200 mg/kg	N	Y		
0-6 ft bgs	Y	31 of 31	200 mg/kg	N	Y		
0-10 ft bgs	Y	31 of 31	200 mg/kg	N	NA		
Mercury				**18 mg/kg**	**0.0125 mg/kg**		
0-0.5 ft bgs	N	3 of 15	0.64 mg/kg	N	Y	None	Compound exceeds ECV and no background value has been established. Detection limits are elevated relative to the ECV. Data not adequate (for the 0-0.5 ft bgs exposure interval) to calculate EPC using ProUCL. However, additional data collection is likely to yield additional non-detected values. The EPC has been defined within the limits of the analytical instrumentation.
0-3 ft bgs	Y	5 of 29	0.64 mg/kg	N	Y		
0-6 ft bgs	Y	5 of 31	0.64 mg/kg	N	Y		
0-10 ft bgs	Y	5 of 31	0.64 mg/kg	N	NA		

TABLE C3-12

Decision 2 Data Gaps Summary AOC 9 - Southeast Fence Line

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth	Adequate EPC?		Maximum Detected Value [1]	> HHCV or Background as Applicable? [2]	> ECV or Background as Applicable? [1, 2]	Proposed Sample ID	Notes
	Y or N	Det/# results [1]		Y or N [3]	Y or N		
Molybdenum				**380 mg/kg**	**2.25 mg/kg**		
0-0.5 ft bgs	N	2 of 15	19 mg/kg	N	Y	None	Compound exceeds ECV. Although there are insufficient detections to allow calculation of a 95% UCL on the mean, additional data collection is not expected to yield sufficient detections to strongly influence the EPC because additional sampling would likely result in additional non-detect values.
0-3 ft bgs	N	3 of 29	19 mg/kg	N	Y		
0-6 ft bgs	N	3 of 31	19 mg/kg	N	Y		
0-10 ft bgs	N	3 of 31	19 mg/kg	N	NA		
Nickel				**1600 mg/kg**	**27.3 mg/kg (bckg)**		
0-0.5 ft bgs	Y	15 of 15	28 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	29 mg/kg	N	Y		
0-6 ft bgs	Y	40 of 40	29 mg/kg	N	Y		
0-10 ft bgs	Y	40 of 40	29 mg/kg	N	NA		
Thallium				**5 mg/kg**	**2.32 mg/kg**		
0-0.5 ft bgs	NA	0 of 15	NA mg/kg	N	N	None	Compound exceeds ECV. Although there are insufficient detections to allow calculation of a 95% UCL on the mean, additional data collection is not expected to yield sufficient detections to strongly influence the EPC because additional sampling would likely result in additional non-detect values and because the maximum detected value is within two times the lowest comparison value.
0-3 ft bgs	N	1 of 29	4.1 mg/kg	N	Y		
0-6 ft bgs	N	1 of 31	4.1 mg/kg	N	Y		
0-10 ft bgs	N	1 of 31	4.1 mg/kg	N	NA		
Zinc				**23000 mg/kg**	**58 mg/kg (bckg)**		
0-0.5 ft bgs	Y	15 of 15	1000 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	1000 mg/kg	N	Y		
0-6 ft bgs	Y	40 of 40	1000 mg/kg	N	Y		
0-10 ft bgs	Y	40 of 40	1000 mg/kg	N	NA		
Polynuclear Aromatic Hydrocarbons							
PAHs (BaP TEQ)				**38 µg/kg**	NA		
0-0.5 ft bgs	Y	14 of 15	1400 µg/kg	Y	NA	None	Compound exceeds HHCV. Existing data adequate for EPC.
0-3 ft bgs	Y	25 of 29	1400 µg/kg	Y	NA		
0-6 ft bgs	Y	27 of 31	1400 µg/kg	Y	NA

HMW PAHs				**NA**	**1160 µg/kg**		
0-0.5 ft bgs	Y	14 of 15	9500 µg/kg	NA	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	25 of 29	9500 µg/kg	NA	Y		
0-6 ft bgs	Y	27 of 31	9500 µg/kg	NA	Y		

TABLE C3-12
Decision 2 Data Gaps Summary AOC 9 - Southeast Fence Line
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth	Adequate EPC? Y or N	Adequate EPC? Det/# results [1]	Maximum Detected Value [1]	> HHCV or Background as Applicable? [2] Y or N [3]	> ECV or Background as Applicable? [1, 2] Y or N	Proposed Sample ID	Notes
Pesticides							
DDT-R				**1600 µg/kg**	**2.1 µg/kg**		
0-0.5 ft bgs	N	1 of 4	3.2 µg/kg	N	Y	None	Compound exceeds ECV and existing data not adequate to calculate 95% UCL. DDE was detected in 1 of 4 samples (including AOC10a-1); DDT and DDD were not detected. The magnitude of the detection is low relative to the ECV and the detection limit (2 µg/kg). Additional sampling is not expected to significantly change the results (NDs are likely and the EPC would still be the maximum detected value).
0-3 ft bgs	N	1 of 4	3.2 µg/kg	N	Y		
0-6 ft bgs	N	1 of 4	3.2 µg/kg	N	Y		
0-10 ft bgs	N	1 of 4	3.2 µg/kg	N	NA		

Footnotes:

[1] AOC 9 was evaluated for adequacy to support EPC calculations including location AOC10a-1 due to its close proximity to AOC 9 and topography. Number of detects and total sample counts as well as maximum detected value incorporate sample AOC10a-1. Total number of samples exceeding ECVs, or background as applicable, includes location AOC10a-1. A summary of results for AOC10a-1 is provided in Appendix C, Attachment 4.

[2] The higher value of either the HHCV/ECV or background was selected as the screening criteria and are included in these columns for the respective compound in **BOLDED BLUE FONT**. Values based on background are indicated with "(bckg)" next to the value.

[3] AOC9 was evaluated for data sufficiency to support the human health risk assessment excluding AOC10a-1.

Acronyms and Abbreviations:
AOC - area of concern
BaP TEQ - benzo(a)pyrene toxic equivalents
ECV - ecological comparison values
EPC - exposure point concentration
ft bgs - feet below ground surface
HHCV - human health comparison values
HMW PAH - high molecular weight polycyclic aromatic hydrocarbons
mg/kg - milligrams per kilogram
µg/kg - micrograms per kilogram
N - no
NA - not applicable
Y - yes

APPENDIX C4

Area of Concern 10 Data Gaps Evaluation Results

1.0 Introduction and Background

This sub-appendix presents the results of the Data Gaps Evaluation and Part A Phase 2 Sampling Program for Area of Concern (AOC) 10 – East Ravine at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the data gaps evaluation is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report.

1.1 Background

AOC 10 – East Ravine is a small ravine located on the southeast side of the compressor station. The ravine runs eastward toward the Colorado River. Portions of the East Ravine are on PG&E property outside the facility fence line, and other portions of the ravine are located on property owned by Havasu National Wildlife Refuge.

The East Ravine is approximately 1,600 feet long and is bisected by three constructed berms (one constructed berm and two dirt roads, also constructed berms). The constructed berm was built circa early 1950s, the Southern California Gas Pipeline road was built in the 1950s, and the lower dirt road was built in 1916 and is associated with the old Route 66. The lower dirt road is the only berm that contains a culvert. Due to the berms, surface flow from most of the length of this ravine (west of the lower dirt road that forms the eastern boundary of AOC 10d) does not typically reach the Colorado River. The drainage for this ravine includes runoff from the compressor station access road (a curb was installed along the access road in 2006), runoff from the mountains to the south, and runoff from the compressor station itself.

During a site visit in May 2006, a storm drain was noted leading from the southeastern portion of the compressor station and discharging into the East Ravine. A small area, approximately 3 feet by 3 feet, of stained soil (possibly old hydrocarbon staining) was noted at the discharge of the storm drain. This is shown in Figure C4-1 as Subarea 10a. While discharge from the steam-cleaning area has always been directed to the oily water treatment system, this storm drain may have captured some runoff from the steam-cleaning area before the steam-cleaning area was fully bermed (CH2M HILL, 2006).

Three additional subareas (Subareas 10b, 10c, and 10d) where water and soil collect (either within lower-lying areas along the ravine course or behind berms) have been identified within the East Ravine and are shown in Figure C4-1. Subarea 10b, a natural drainage depression in the upper portion of the ravine, is located in a flat area of the ravine. These three subareas are downstream from Subarea 10a.

In 2008, during a site walk, California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) observed a layer of white powder material in the floor of the wash in three locations between Subareas 10c and 10d and collected samples from this area (sample locations DTSC-AOC10d-1 through DTSC-AOC10d-3). The material was approximately 1 inch wide, 15 inches long, and 0.25 inch thick and was similar in appearance to the white material in Bat Cave Wash and at the Railroad Debris site. Samples collected from the powder indicate it contains elevated concentrations of calcium, chromium, copper, magnesium, sodium, and zinc.

In 2009, in response to DTSC's request in the conditional approval of the Soil Part A Work Plan (CH2M HILL, 2006), PG&E mapped white powder and debris in the East Ravine (results are described in Section 2.5 of this sub-appendix). Furthermore, after a January 2010 storm event, three additional white powder areas were discovered on the northern face of the East Ravine. Per DTSC's request, these three white powder areas are included in this data summary.

A graphical conceptual site model has been developed for AOC 10 based on the above site history and background and is shown in Figure C4-2. Table C4-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 10. Yellow arrows shown in Figure C4-2 represent flow within the East Ravine, and blue arrows represent surface water flow into East Ravine. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in Appendix A of the Data Gaps Evaluation Report.

For AOC 10, the primary potential sources of contamination are (1) runoff from the compressor station, the access road to the compressor station, and AOC 9; (2) discharge from stormwater drain pipes; (3) surface debris disposed of on the slopes of the ravine; and (4) incidental overflows of chromium-containing wastewater via the former trench drain at the top of the station access road. Potential releases would primarily have been in liquid form and would have affected surface soil. Releases from debris, whether consisting of solid particles or dissolved constituents, would also have affected surface soil.

Surface soil is the primary source medium. From surface soil, contaminants could have migrated to shallow and deeper soils; shallow soils may act as a secondary source medium to subsurface soil and subsurface soil may act as a secondary source medium to groundwater. Periodic rainfall events and runoffs to the East Ravine would have pooled in the drainage depressions identified as Subareas 10b, 10c, and 10d. In these subareas, contaminants could potentially be driven deeper and could potentially reach groundwater. If released, volatile organic compounds (VOCs) in surface soils would be expected to have been degraded by heat and light and are likely no longer present.

A secondary source may also include contaminated windblown dust. For AOC 10, windblown dust contamination, either from AOC 9 or other areas of the East Ravine, could have been deposited in the ravine or on shallow portions of the banks of the ravine. Windblown contamination, if any, is expected to be limited to surface soils.

Due to the berms within East Ravine, surface flow to the Colorado River is not considered a significant potential migration pathway. At least one berm was constructed prior to the development of the station, and another was constructed around the time the station was built. Although a culvert exists in the lower dirt road berm, chemicals of potential concern

(COPCs) concentrations east of this road are low, and there are no reports of flow through the culvert. Hexavalent chromium was not detected, and total chromium was below background in the soil sample immediately east of the lower dirt road berm.

In January 2011, additional historical aerial photographs of the compressor station were located and provided to DTSC. One photo (date unknown) indicated potential runoff of fluids from the station into East Ravine (see Figure C4-3). Figure C4-2 shows an overlay of this photo onto the site figure. Runoff can be seen originating from a point upslope of subarea 10A and flowing into East Ravine, and water appears to be impounded in subarea 10C. DTSC directed PG&E in a March 21, 2011 email to be sure that samples are included at appropriate locations along the line of apparent run ff. Soil sample locations have been added and presented in Section 6.0 of this sub-appendix.

1.1.1 AOC 10 Data

Fourteen historical soil samples (0 to 2 feet below ground surface [bgs]) were collected from nine locations (PS-21, PS-22, Bank 1, L-2-2, L-2-3, L-3-2, and L-1 through L3) in AOC 10, as shown in Figure C4-1. Historical soil samples were analyzed for five constituents: total chromium, hexavalent chromium, copper, nickel, and zinc. One historical sample collected at 1 foot bgs at location L-3 was also analyzed for calcium, iron, magnesium, and sodium.

During the 2008 Soil Part A Phase 1 soil investigation, 82 soil samples (generally collected at sample depths of 0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet bgs) were collected from 26 sample locations (AOC10-1 through AOC10-8, AOC10a-1, AOC10b-1 through AOC10b-4, AOC10c-1 through AOC10c-5, AOC10d-1 through AOC10d-4, AOC10-XRF-01 through AOC10-XRF-03, and AOC10-XRF-10), as shown in Figure C4-1. Soil Part A Phase 1 soil samples collected in AOC 10 were analyzed for Title 22 metals, hexavalent chromium, VOCs, semivolatile organic compounds, polycyclic aromatic hydrocarbons (PAHs), total petroleum hydrocarbons (TPH), general chemistry parameters, pesticides, and polychlorinated biphenyls (PCBs). Surface soil samples were not analyzed for VOCs.

Ten percent of the Phase 1 soil samples collected in AOC 10 (nine soil samples) were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL). In addition, synthetic precipitation leaching procedure (SPLP) extraction was performed on the surface soil sample (collected from 0 to 0.5 foot bgs) at sample location AOC10b-3 and soil samples collected at 2 to 3 feet bgs at sample locations AOC10c-1, AOC10c-5, and AOC10d-4. The leachate from the SPLP extractions was analyzed for total and hexavalent chromium. The leachate results from the SPLP extractions are presented in Table C4-2. The soil results were validated and the data quality evaluation is included in Appendix D to the Data Gaps Evaluation Report.

In addition, nine soil samples were collected during the installation of two monitoring wells (MW-57BR and MW-58BR_S) associated with the 2009 East Ravine Groundwater Investigation (2009 ERGI). Soil samples were collected at 3-4, 8-9, and 18-19 feet bgs at location MW-57BR and at 1.5-2, 19-20, 29-30, 39-40, 49-50, and 59-60 feet bgs at location MW-58BR_S and were analyzed for Title 22 metals, hexavalent chromium, VOCs, semivolatile organic compounds, PAHs, TPH, and pH. The soil results for samples collected during the 2009 ERGI were validated, and the data quality evaluation is included in Appendix A of the Final Corrective Measures Study/Feasibility Study (CMS/FS) (see

Appendix E of the *Summary of Findings Associated with the East Ravine Groundwater Investigation, PG&E Topock Compressor Station, Needles, California)* (CH2M HILL, 2009).

The DTSC also collected three soil samples of white powder at locations DTSC-AOC10d-1, DTSC-AOC10d-2, and DTSC-AOC10d-3. The samples were analyzed at two different analytical laboratories, as directed by DTSC and PG&E. The samples were analyzed for Title 22 metals, hexavalent chromium, general minerals, and pH and are included in the data tables for this unit.

All historical data, validated Phase 1 data, and the 2009 ERGI data that are considered Category 1 were used as inputs to the four data quality objective (DQO) decisions for AOC 10.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of COPCs and chemicals of potential ecological concern (COPECs) at AOC 10. Laboratory analytical results for historical, Phase 1, and 2009 ERGI soil samples at AOC 10 are presented in Tables C4-3 through C4-8. Table C4-9 presents a statistical summary of soil analytical results for COPCs and COPECs that were either (1) detected above the laboratory reporting limits or (2) not detected but where the reporting limits for one more samples was greater than the interim screening value. Data for soil samples are presented first, followed by data for the white powder samples collected by DTSC.

2.1 Summary of AOC 10 Soil Data

Antimony, beryllium, cadmium, selenium, silver, cyanide, VOCs, TPH-gasoline, pesticides, and most species of PCBs were not detected in soil samples collected at AOC 10. Table C4-9 lists the 39 constituents detected, including four calculated quantities: benzo(a)pyrene equivalents, total low molecular weight PAHs, total high molecular weight PAHs, and total PCBs. Nine of these constituents (aluminum, calcium, iron, magnesium, manganese, potassium, sodium, Aroclor 1254, and total PCBs) were detected in the TAL/TCL samples.

Fifteen of these constituents (vanadium, iron, potassium, sodium, Aroclor-1254, total PCBs, anthracene, benzo(g,h,i)perylene, chrysene, fluoranthene, phenanthrene, pyrene, low molecular weight PAHs, TPH-diesel, and TPH-motor-oil) were detected at concentrations below their respective interim screening levels. Twenty-four constituents, including two calculated quantities, were detected one or more times at concentrations exceeding the interim screening levels. These constituents included 16 metals (aluminum, arsenic, barium, calcium, total chromium, hexavalent chromium, cobalt, copper, lead, magnesium, manganese, mercury, molybdenum, nickel, thallium, and zinc), six PAHs (benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenz (a,h) anthracene, and indeno (1,2,3-cd)pyrene), and the two calculated quantities (benzo(a)pyrene equivalents and high molecular weight PAHs).

Eleven constituents (arsenic, total chromium, hexavalent chromium, copper, lead, molybdenum, thallium, zinc, benzo(a)pyrene, benzo(a)pyrene equivalents, and high molecular weight PAHs) were detected at concentrations exceeding their respective interim screening levels four or more times. The distributions of total chromium, hexavalent chromium, copper, lead, molybdenum, and zinc are shown in Figure C4-1 and Figures C4-4 to C4-8. The distributions of benzo(a)pyrene equivalents and high molecular weight PAHs are shown in Figures C4-9 and C4-10. Benzo(a)pyrene is not shown separately, as it is encompassed in the benzo(a)pyrene equivalents values. No figures are provided for arsenic and thallium. The four arsenic detections exceeding the arsenic interim screening level (background threshold value [BTV]) are all very close to the BTV (maximum detected concentration of 13 milligrams per kilogram [mg/kg], compared to the BTV of 11 mg/kg). All four detections of thallium exceeding the thallium interim screening level (ECV) were found in one location, in the samples from MW-58BR_S.

Four sample locations associated with AOC 9 (AOC9-4, AOC9-7, #11, and #12) are located within AOC 10 or immediately upslope of AOC 10. To provide further context for the evaluation of potential data gaps, the data for these samples are also shown in Figure C4-1 and Figures C4-4 to C4-10. The nature and extent discussion for the four AOC 9 sample locations are presented in Appendix C3. Two proposed AOC 9 Phase 2 sample locations (AOC9-15 and AOC9-16) located near AOC 10a have been included in the AOC 10 data gaps evaluation because these proposed AOC 9 Phase 2 sample locations are upslope of AOC 10a.

2.2 Nature and Extent Evaluation

The following subsection discusses the nature and extent of COPCs and COPECs detected above interim screening levels at AOC 10. As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Section 2.5 of this sub-appendix summarizes the constituents that may require further evaluation, and Section 6.0 of this sub-appendix provides the proposed follow-up sampling for the Part A Phase 2 soil investigation. The proposed Phase 2 sample locations are needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

2.2.1 Arsenic

Arsenic was detected in 84 of 87 soil samples collected at AOC 10. Detected concentrations of arsenic slightly exceeded the interim screening level (11 mg/kg) (BTV) four times (maximum detected concentration of 13 mg/kg at MW-58BR), as shown in Table C4-9. Four of the detected concentrations of arsenic also exceeded the ECV (11.4 mg/kg). The detected concentrations of arsenic slightly exceeding the screening levels ranged from 12 to 13 mg/kg and were collected from two sample locations (MW-58BR at 19 to 20, 29 to 30, and 39 to 40 feet bgs and AOC10-5 at 5 to 6 feet bgs). At MW-58BR deeper samples (at 49 to 50 feet bgs, and 59 to 60 feet bgs) have concentrations below the interim screening level. At AOC10-5, the deepest sample (collected at 6 feet bgs) has a concentration (12 mg/kg) that slightly exceeds the interim screening level.

2.2.2 Barium

Barium was detected in 87 of 87 soil samples collected from AOC 10. Detected concentrations of barium exceeded the interim screening level (410 mg/kg) (BTV/ECV) twice in AOC10-5 (500 mg/kg at 0 to 0.5 foot bgs and 1,300 mg/kg at 5 to 6 feet bgs), as shown in Tables C4-3 and C4-9. None of the detected concentrations exceeded residential and commercial/industrial California human health screening levels (CHHSLs) (5,200 mg/kg and 63,000 mg/kg, respectively). This sample location is located north of the small access road near Subarea 10d in the bottom of the ravine. Samples with concentrations below the screening levels are located to the north and west of this location but not the east the ravine walls. The deepest sample at AOC10-5 (5 to 6 feet bgs), had a concentration exceeding the screening levels.

2.2.3 Total Chromium

Total chromium was detected in 105 of 105 soil samples collected at AOC 10. Detected concentrations of total chromium exceeded the interim screening level (39.8 mg/kg) (BTV/ECV) 41 times (with a maximum detected concentration of 4,000 mg/kg at MW-58BR in the surface sample), as shown in Tables C4-3 and C4-9 and in Figure C4-1. Nine detected concentrations of total chromium exceeded the United States Environmental Protection Agency regional screening level (RSL) for residential use (280 mg/kg), and five detected concentration of total chromium exceeded the RSL for commercial/industrial use (1,400 mg/kg). Total chromium was detected at concentrations below the screening levels in borings MW-57BR, AOC10-5, AOC10-6, AOC10-7, and AOC10-8, which are located in the lower reaches of AOC 10. The lateral extent of samples with concentrations exceeding the screening levels is confined primarily to the ravine bottom, in Subarea 10c, the eastern portion of Subarea 10b, and the southern portion of Subarea 10d. At many locations, the deepest samples have concentrations exceeding the interim screening level; however, in most cases, only shallow samples were collected during the Part A Phase 1 and previous investigations. The deepest sample was collected at 59 to 60 feet bgs at MW-58BR, which had a detected concentration of total chromium (27 mg/kg) below the interim screening level.

2.2.4 Hexavalent Chromium

Hexavalent chromium was detected in 53 of 105 soil samples collected at AOC 10. Detected concentrations of hexavalent chromium exceeded the interim screening level (0.83 mg/kg) (background value) 36 times (with a maximum detected concentration of 150 mg/kg at MW-58BR at 1.5 to 2 feet bgs), as shown in Tables C4-3 and C4-9 and in Figure C4-4. Five of the detected concentrations of hexavalent chromium exceeded the residential CHHSL (17 mg/kg), three exceeded the commercial/industrial CHHSL (37 mg/kg), and one exceeded the ECV (139.6 mg/kg). Hexavalent chromium was detected at concentrations below the screening levels in borings MW-57BR, AOC10-5, AOC10-6, AOC10-7, and AOC10-8, which are located in the lower reaches of AOC 10. The lateral extent of samples with concentrations exceeding the screening levels is confined primarily to the ravine bottom in the portion of East Ravine upstream of the small access road near Subarea 10d. At many locations, the deepest samples have concentrations exceeding the interim screening level; however, in most cases, only shallow samples were collected during the Part A Phase 1 and previous investigations. The deepest sample was collected at 59 to 60 feet bgs at MW-58BR, in which hexavalent chromium was not detected above laboratory reporting limits.

2.2.5 Cobalt

Cobalt was detected in 87 of 87 soil samples collected from AOC 10. In one sample from MW-58BR_S, the detected concentrations of cobalt (13 mg/kg) slightly exceeded the interim screening level (12.7 mg/kg) (background value) and the ECV (13 mg/kg), as shown in Tables C4-3 and C4-9. None of the detected concentrations exceeded residential and commercial/industrial RSLs (23 mg/kg and 300 mg/kg, respectively). This sample location is a monitoring well that was installed behind the berm in Subarea 10c. The detected concentration that slightly exceeds the screening levels was detected in the deepest sample collected at this location (59 to 60 feet bgs).

2.2.6 Copper

Copper was detected in 101 of 101 soil samples collected at AOC 10. Detected concentrations of copper exceeded the interim screening level (16.8 mg/kg) (BTV) 42 times (with a maximum detected concentration of 300 mg/kg at MW-58BR at 1.5 to 2 feet bgs), as shown in Tables C4-3 and C4-9 and in Figure C4-5. Thirty-three detected concentrations of copper exceeded the ECV (20.6 mg/kg). None of the detected concentrations exceeded the residential or commercial/industrial CHHSLs (3,000 mg/kg, and 38,000 mg/kg, respectively). Copper was detected at concentrations below the screening levels in borings MW-57BR, AOC10-5, AOC10-6, AOC10-7, and AOC10-8, which are located in the lower reaches of AOC 10. The lateral extent of samples with concentrations exceeding the screening levels is confined primarily to the ravine bottom. At many locations, the deepest samples have concentrations exceeding the interim screening level; however, in most cases, only shallow samples were collected during the Part A Phase 1 and previous investigations. The deepest sample was collected at 59 to 60 feet bgs at MW-58BR, which had a detected concentration of copper (58 mg/kg) exceeding the interim screening level.

2.2.7 Lead

Lead was detected in 86 of 87 soil samples collected at AOC 10. Detected concentrations of lead exceeded the interim screening level (8.39 mg/kg) (BTV/ECV) 32 times (with a maximum detected concentration of 200 mg/kg at AOC10a-1), as shown In Tables C4-3 and C4-9 and in Figure C4-6. Only two of the detected concentrations (at AOC10a-1 at 0 to 0.5 feet bgs and MW-58BR at 1.5 to 2 feet bgs) exceeded the residential CHHSL (80 mg/kg). None of the detected concentrations exceeded the commercial/industrial CHHSL (320 mg/kg). Lead was detected at concentrations exceeding the interim screening level in most sample locations in AOC 10. With two exceptions (AOC10c-4 and AOC10d-4), the lead exceedances were limited to the upper three feet. The distribution of lead exceedances is not consistent with the site-specific conceptual site model for AOC 10 (i.e., flow in the bottom of the ravine and accumulation of liquids and fine-grained materials behind the berms), suggesting other potential sources. Much of the lead present at AOC 10 is most likely from other anthropogenic sources (i.e., proximity to former Route 66 and the use of lead in gasoline until 1970s), which would cause a more widespread distribution of lead, as discussed in Appendix C, Section C.3.

2.2.8 Mercury

Mercury was detected in two of 87 soil samples collected from AOC 10. Detected concentrations of mercury exceeded the interim screening level (0.0125 mg/kg) (ECV) twice (at AOC10a-1 [0.64 mg/kg at 0 to 0.5 foot bgs] and MW-58BR_S [0.33 mg/kg at 1.5 to 2 feet bgs]), as shown in Tables C4-3 and C4-9. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (18 mg/kg and 180 mg/kg, respectively). The ECV (0.0125 mg/kg) is below the capability of the instrumentation to detect mercury. As a result, the 85 non-detected sample results had reporting limits that exceeded the ECV. The mercury reporting limits ranged from 0.0198 to 0.1 mg/kg. The two samples with detectable concentrations of mercury are located in different subareas of AOC 10 (Subarea 10a and Subarea 10c). Samples with concentrations below the detection level surround location MW-58BR_S, and deeper samples collected at this location had concentrations below the detection level. Only one sample (AOC10a-1) was collected in Subarea 10A; however, four samples collected at AOC 9 contained detectable concentrations of mercury.

2.2.9 Molybdenum

Molybdenum was detected in 15 of 87 soil samples collected from AOC 10. Detected concentrations of molybdenum exceeded the interim screening level (1.37 mg/kg) (BTV) eight times (with a maximum detected concentration of 19 mg/kg at AOC10a-1), as shown in Tables C4-3 and C4-9 and in Figure C4-7. Four detected concentrations exceeded the ECV (2.25 mg/kg). None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). The lateral extent of samples with concentrations exceeding the interim screening level is confined primarily to the ravine bottom in Subareas 10b and 10c (i.e., upstream of the upper most berm), with the exception of the exceedance at location MW-57BR located on the small access road near Subarea 10d. Samples with concentrations below the screening levels are located near and in Subarea 10d. At most locations, the deepest samples have concentrations below the interim screening level, with the exception of locations AOC10a-1 (where only a surface soil could be collected) and MW-57BR (molybdenum was detected at 3 mg/kg at 18 to 19 feet bgs, the deepest depth sampled). Samples from MW-57BR collected at 3 to 4 feet and 8 to 9 feet bgs were below the interim screening level.

2.2.10 Nickel

Nickel was detected in 101 of 101 soil samples collected from AOC 10. As shown in Tables C4-3 and C4-9, one detected concentration (28 mg/kg at AOC10a-1) slightly exceeded the interim screening level (27.3 mg/kg) (BTV/ECV). None of the detected concentrations exceeded the residential and commercial/industrial CHHSLs (1,600 mg/kg and 16,000 mg/kg, respectively).

2.2.11 Thallium

Thallium was detected in four of 87 soil samples collected from AOC 10. Detected concentrations of thallium exceeded the interim screening level (2.32 mg/kg) (ECV) four times; all four exceedances were found in samples from MW-58BR_S in samples collected at 1.5 to 2, 19 to 20, 29 to 30, and 39 to 40 feet bgs, with a maximum detected concentration of 6.1 mg/kg at 1.5 to 2 feet bgs), as shown in Tables C4-3 and C4-9. Only one of the detected concentrations exceeded the residential CHHSL (5 mg/kg), and none exceeded the commercial/industrial CHHSL (63 mg/kg) at location MW-58BR_S, as shown in Table C4-3. Samples with concentrations below the interim screening level surround this location. The deeper samples at this location (at 49 to 50 feet bgs, and 59 to 60 feet bgs) have concentrations below the interim screening level.

2.2.12 Zinc

Zinc was detected in 101 of 101 soil samples collected at AOC 10. Detected concentrations of zinc exceeded the interim screening level (58 mg/kg) (BTV/ECV) 46 times (with a maximum detected concentration of 1,000 mg/kg at AOC10a-1), as shown in Tables C4-3 and C4-9 and in Figure C4-8. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively). The lateral extent of samples with concentrations exceeding the screening levels is confined primarily to the ravine bottom, with exceedances of the interim screening level in all four subareas. Zinc was detected at concentrations below the screening levels in borings AOC10-6 and AOC10-7. At many locations, the deepest samples have concentrations exceeding the interim screening level; however, in most cases, only shallow samples were collected during the Part A Phase 1 and previous investigations. The deepest sample collect was collected at 59 to 60 feet bgs at MW-58BR, which had a detected concentration of zinc (41 mg/kg) below the interim screening level.

2.2.13 Polycyclic Aromatic Hydrocarbons

Benzo(a)pyrene was detected in 34 of 86 soil samples collected from AOC 10. Detected concentrations of benzo(a)pyrene exceeded the interim screening level (38 micrograms per kilogram [µg/kg]) (residential CHHSL) 13 times and the commercial/industrial CHHSL (130 µg/kg) four times. Several other PAHs were detected in soil samples collected from AOC 10; only benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were detected at concentrations above their respective interim screening levels. To assist with evaluation of PAHs for human health, benzo(a)pyrene equivalents were calculated for each of the soil samples collected at AOC 10, as shown in Table C4-5. Benzo(a)pyrene equivalents values exceeded the interim screening level of 38 µg/kg (residential CHHSL) 15 times (maximum calculated concentration of 1,400 µg/kg at AOC10a-1), as shown in Tables C4-5 and C4-9 and in Figure C4-9, and exceeded the commercial/industrial CHHSL (130 µg/kg) five times. PAHs were detected at concentrations exceeding the screening levels in Subareas 10a, 10c, 10d and into the area downstream of a small access road near Subarea 10d. At all locations, PAH exceedances were limited to the upper three feet. With two exceptions (AOC10a-1 and AOC10-6), the deepest samples have concentrations below the interim screening level; only shallow samples could be collected at AOC10a-1 and AOC10-6.

To assist with evaluation of PAHs for ecological risk, detected concentrations of low molecular weight PAHs and high molecular weight PAHs were summed and compared to the PAH low molecular weight and PAH high molecular weight ECVs (10,000 µg/kg and 1,160 µg/kg, respectively). Five PAH high molecular weight sums of detected concentrations exceeded the ECV of 1,160 µg/kg; as shown in Tables C4-5 and C4-9 and Figure C4-10. PAH high molecular weight sums exceeding the interim screening level are collocated with the highest benzo(a)pyrene equivalents detections. As discussed above, none of the sums of detected concentrations exceeded the PAH low molecular weight ECVs.

2.2.14 Target Analyte List/Target Compound List Constituents

As described above, aluminum, calcium, iron, magnesium, manganese, potassium, sodium, and Aroclor 1254 were detected in the AOC 10 soil samples analyzed for the complete TAL/TCL suite of compounds. These constituents are discussed below.

Aluminum was detected in nine of nine surface soil samples collected from AOC 10. Detected concentrations of aluminum exceeded the interim screening level (16,400 mg/kg) (BTV) once at a concentration of 18,000 mg/kg at AOC10-5, as shown in Tables C4-4 and C4-9. Remaining detected concentrations of aluminum ranged from 4,100 to 11,000 mg/kg. None of the detected concentrations exceeded residential and commercial CHHSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in 10 of 10 surface soil samples collected from AOC 10. Detected concentrations of calcium exceeded the interim screening level (66,500 mg/kg) (background value) once at a concentration of 139,000 mg/kg at L-3, as shown in Tables C4-4 and C4-9. Remaining detected concentrations of calcium ranged from 18,000 to 44,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium.

Iron was detected in 10 of 10 surface soil samples collected from AOC 10. The maximum detected concentration of iron was 32,000 mg/kg at AOC10-a1, which is below the interim screening level of 55,000 mg/kg (residential RSL), as shown in Tables C4-4 and C4-9. Remaining detected concentrations of iron ranged from 540 to 28,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for iron.

Magnesium was detected in 10 of 10 surface soil samples collected from AOC 10. Detected concentrations of magnesium exceeded the interim screening level (12,100 mg/kg) (background value) once at a concentration of 12,800 at L-3, as shown in Tables C4-4 and C4-9. Remaining detected concentrations of magnesium ranged from 3,900 to 12,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium.

Manganese was detected in nine of nine surface soil samples collected from AOC 10. Detected concentrations of manganese exceeded the interim screening level (402 mg/kg) (BTV) twice (AOC10-5 [1,300 mg/kg] and AOC10-8 [470 mg/kg]), as shown in Tables C4-4 and C4-9. None of the detected concentrations exceeded residential and commercial/industrial CHHSLs (1,800 mg/kg and 23,000 mg/kg, respectively). These manganese exceedances are probably not related to compressor station release sources as the lateral extent of samples with concentrations for the majority of the COPCs/COPECs exceeding the screening levels is confined primarily to the ravine bottom in the portion of East Ravine upstream of the small access road near Subarea 10d, whereas these two locations are on the western ravine slope northwest of Subarea 10d and north of the berm on the north side of Subarea 10d.

Potassium was detected in nine of nine surface soil samples collected from AOC 10. The maximum detected concentration of potassium was 4,100 mg/kg at AOC10-5, which is below the interim screening level of 4,400 mg/kg (BTV), as shown in Tables C4-4 and C4-9. Remaining detected concentrations of potassium ranged from 990 to 2,300 mg/kg.

Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for potassium.

Sodium was detected in 10 of 10 surface soil samples collected from AOC 10. The maximum detected concentration of sodium was 1,280 mg/kg at L-3, which is below the interim screening level of 2,070 mg/kg (BTV), as shown in Tables C4-4 and C4-9. Remaining detected concentrations of sodium ranged from 160 to 540 mg/kg. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for sodium.

Aroclor 1254 was detected in seven of 13 soil samples collected from AOC 10; both surface (0 to 0.5 feet bgs) and subsurface soil (2 to 3 feet bgs) samples were collected. The maximum detected concentration of Aroclor 1254 was 71 µg/kg at AOC10a-1, which is well below the interim screening level of 220 µg/kg (residential RSL). Remaining detections of Aroclor 1254 ranged from 19 to 68 µg/kg. To assist with evaluation of PCBs for ecological risk, detected concentrations of the Aroclors (only Aroclor 1254 at AOC 10) were summed, and the total PCB values were compared to the ECV. The maximum calculated value for total PCBs was 71 µg/kg, which is well below the total PCB ECV of 204 µg/kg, as shown in Table C4-8. The remaining calculated total PCB concentrations ranged from 19 to 68 µg/kg.

As discussed in Section C.2 in Appendix C, PG&E recommends that aluminum, calcium, iron, magnesium, manganese, potassium, sodium, and Aroclor 1254 not be considered COPCs/COPECs for this SWMU, and no further sampling for these constituents is proposed. These constituents have been fully discussed in Section C.2.

2.3 White Powder Sample Results (Collected by DTSC)

The three soil samples of white powder collected by DTSC at locations DTSC-AOC10d-1, DTSC-AOC10d-2, and DTSC-AOC10d-3 were analyzed for inorganic constituents only (for Title 22 metals, hexavalent chromium, general minerals and pH). As shown in Tables C4-3 and C4-4, 13 metals were detected in these samples (arsenic, barium, calcium, total chromium, hexavalent chromium, copper, iron, lead, magnesium, potassium, sodium, vanadium, and zinc). Arsenic, iron, potassium, and vanadium did not exceed their respective BTVs. Barium and sodium were detected above their respective BTVs once each, and calcium was detected above its BTV twice. Total chromium, hexavalent chromium, copper, lead, magnesium, and zinc were detected above their respective BTVs in all three samples. Hexavalent chromium also exceeded the residential CHHSL in one sample, and copper exceeded the ECV in all three samples. The remaining metals were not detected above any other comparison values.

2.4 Central Tendency Comparison to Background Threshold Values

Fourteen metals (aluminum, arsenic, barium, calcium, total chromium, hexavalent chromium, cobalt, copper, lead, magnesium, manganese, molybdenum, nickel, and zinc) were detected above their respective background values in the soil data set. A central tendency comparison was performed for 13 of these 14 metals (aluminum, arsenic, barium, calcium, total chromium, cobalt, copper, lead, magnesium, manganese, molybdenum, nickel, and zinc) to compare the AOC 10 soil data set for these metals with the corresponding Topock soil background data set to determine whether a difference exists between the two populations and whether additional sampling may be required for a given metal, as shown in Table C4-10 of this sub-appendix and in Figure 3-1 in the Data Gaps Evaluation Report).

Metals in either the AOC 10 data set or background data set that were detected infrequently (less than five detects) or had a limited number of results (less than eight) were not tested. There were insufficient detections of hexavalent chromium in the background data set to allow for a central tendency comparison.

No statistical difference between the two populations was noted for aluminum, barium, calcium, cobalt, magnesium, manganese, molybdenum, and nickel, as shown in Table C4-10. However, results from the Gehan test show that site concentrations for arsenic, total chromium, copper, lead, and zinc may exceed background. The lateral and vertical extents of arsenic have been adequately defined, as discussed above; therefore, no additional sampling is proposed for arsenic. Additional sampling is proposed for total chromium, copper, lead, and zinc.

2.5 White Powder and Debris Mapping

As part of the conditional approval of the Soil Part A Work Plan (CH2M HILL, 2006), DTSC requested that the white powder and metal debris observed in AOC 10 be mapped to assist in planning for Phase 2. PG&E conducted a site walk at AOC 10 in May 2009 to map the white powder and debris areas. White powder was observed in the ravine bottom within Subarea 10d and between Subareas 10c and 10d. Several areas of miscellaneous debris were identified, as shown in Figures C4-1, C4-2, and C4-4 through C4-10. Miscellaneous debris consisted of pieces of metal, cans, tires, concrete rubble, tiles, and bricks. A small dirt pile with small pieces of green-colored wood was observed near the access road adjacent to Subarea 10d. Two areas of discolored, light soil were observed in the debris areas located on the northern ravine wall, as shown in Figure C4-1, C4-2, and C4-4 through C4-10 (these were also classified as potential white powder areas). DTSC noted during a site visit that these areas appear to be unusually weathered. Following recent heavy rainfall, an additional white powder area was discovered on the slope near the station access road slightly west of Subarea 10b; this area is also shown in the figures.

Sampling of the white powder and debris is proposed to determine the nature and extent of contamination in the white powder and debris areas. Additional characterization of debris may be needed to assess if asbestos-containing materials are present.

2.6 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review indicates than decision error has been held to an acceptable level. Sufficient data of acceptable quality have been attained by the collection of historical/Part A soil samples in areas most likely to have been impacted by the runoff from the compressor station, discharge from known stormwater drain pipes, and overflows of chromium-containing wastewater from the facility entering the East Ravine from the former trench drain. Those areas include areas down gradient of AOC 9, along the bottom and most of the length of the ravine, in drainage depression areas (Subareas 10b, 10c, and 10d), and on the northern slope of AOC 10, primarily north of Subarea 10c, although low-level contamination from station runoff may be present along other parts of the northern slope. Some of the newly-identified debris and white powder areas have not been sampled.

Review of the nature and extent discussions above indicates that the lateral extent of samples with concentrations exceeding the screening levels is confined primarily to the ravine bottom behind the berms. Within this portion of East Ravine, the lateral and vertical extents of hexavalent chromium, copper, lead, mercury, molybdenum, PAHs, total chromium, and zinc have not been defined. Soil data also indicate that the entire footprint of Subarea AOC 10c may be contaminated. Additional sampling along the side wall of this AOC will not significantly improve remedial decision; therefore, no additional sampling is recommended and uncertainty would be addressed in the CMS/FS.

Based on review of the data and the Part A DQO, data gaps were identified to resolve Decision 1 – Nature and Extent, and limited additional sampling is proposed in Phase 2 to fill the following data gaps:

1. Data Gap #1 – Lateral and vertical extent of contamination in the western portion of AOC10 (Subarea AOC 10a, downslope from AOC9, and downslope from the outfall of the former trench drain).
2. Data Gap #2 – Nature and extent of contamination associated with runoff from station access road to the low point north of Subarea 10d.
3. Data Gap #3 – Nature and extent of contamination associated with the newly identified white powder areas (on the slope below the station access road) and the newly identified debris areas (on the slopes of AOC10).
4. Data Gap #4 - Nature and extent of contamination associated with runoff from pipe upslope from subarea 10a. (Samples associated with perimeter and storm drain sampling programs will evaluate nature and extent on the slope above East Ravine.)

In addition, the location of potential additional storm drains (beyond those identified and mapped in this report) adjacent to the employee parking lot has been identified as a data gap. To address this data gap, PG&E will perform additional research and field reconnaissance. If new information becomes available, it will be incorporated in the Soil Part A Phase 2 Work Plan.

3.0 Decision 2 – Data Sufficient to Estimate Representative Exposure Point Concentrations

For Decision 2, data were evaluated to determine if the AOC 10 data are sufficient to conduct human health and ecological risk assessments based on the criteria described in Section 4.0 of the Data Gaps Evaluation Report. The principal consideration for Decision 2 was whether there were sufficient data to estimate a representative exposure point concentration (EPC). Data reviewed were all available data at AOC 10 (including historical data, soil data collected during the 2009 ERGI, and white powder samples collected by DTSC). Data from AOC10a-1 were included in the evaluation of AOC 9 (Appendix C3) to support the ecological risk assessment because this sample location is within approximately 30 feet of the AOC 9 boundary, and this is consistent with the ecological risk assessment data set definition for AOC 9/10a in the Human Health and Ecological Risk Assessment Work Plan (ARCADIS, 2008). Therefore, the AOC10a-1 data were only included in the AOC 10 evaluation to support the human health risk assessment.

Table C4-11 summarizes the results of the evaluation to determine whether data are sufficient to estimate a representative EPC. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value. In general, existing data are adequate to support EPC development for detected chemicals that exceeded one or more comparison values (10 metals, four Contract Laboratory Program inorganics, and PAHs), as described below. Phase 2 data will be added to the existing data set to calculate the final EPC (i.e., after Decision 1 is satisfied).

3.1 Metals

Sufficient data (numbers of samples and detections) are available to calculate EPCs for arsenic, barium, total chromium, hexavalent chromium, copper, lead, and zinc using ProUCL. For the remaining metals (mercury, molybdenum, and thallium), additional data collection is not expected to significantly change the results of the risk assessment either because the compound is very infrequently detected (mercury and thallium) (i.e., additional nondetects would be expected) or because the maximum detected concentration (excluding AOC10a-1) is within two times the lowest risk-based comparison value (molybdenum).

3.2 Inorganics

Sufficient data (numbers of samples and detections) are available to calculate EPCs for aluminum, calcium, magnesium, and manganese using ProUCL. No additional data collection appears warranted because it is reasonable to assume that the nature and extent of these inorganics in the shallow exposure intervals (0 to 0.5 or 0 to 3 feet bgs) is representative of the deeper depths. In addition, maximum concentrations of aluminum, magnesium, and calcium detected in the standard exposure intervals (0 to 0.5, 0 to 3, 0 to 6, and 0 to 10 feet bgs) are comparable to background, as discussed in Section 2.3 of this appendix.

3.3 Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene toxicity equivalents and high molecular weight PAHs using ProUCL.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

The following preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, are needed to resolve Decision 3. Additional evaluation will be performed as appropriate, as data are collected to resolve Decision 1. Data collected to satisfy Decision 1 – Nature and Extent evaluation will provide the final representative data set that will be used to assess the threat to groundwater.

As discussed in Section 5.2.2 of the Data Gaps Evaluation Report, AOC 10 historically received discharges of water from annual Topock Compressor Station fire pump tests; therefore, percolation rates may vary within AOC 10. For this analysis, AOC 10 was divided into four separate subareas for this analysis to account for the variable percolation rates, as shown in Figure C-1 in Appendix C.

4.1 Subarea AOC 10a

Table C4-12 presents the results of the tiered analysis for AOC 10a. Seven metals were detected at concentrations above their respective BTVs. Of those seven, hexavalent chromium, molybdenum, and lead exceeded the calculated soil screening levels (SSLs), as shown in Table C4-13. Numerical modeling was conducted to evaluate the potential of these three metals to leach into groundwater. Based on initial model screening simulations, the potential for hexavalent chromium, molybdenum, and lead to leach to groundwater could not be ruled out.

The simulated leaching concentrations of groundwater screening criteria at AOC 10a is likely a result of the lack of samples as a function of depth at AOC 10a. Only one surface sample was collected in this AOC subarea. Initial concentrations were input into the model assuming a constant concentration equal to that from the surficial sample down to the water table across the AOC 10a area.

Additional data are needed to better define the vertical extent of hexavalent chromium, molybdenum, and lead at AOC 10a and to better assess the leaching potential. The model will be refined with the new vertical data to more realistically simulate vadose zone contaminant concentrations.

4.2 Subarea AOC 10b

Table C4-12 presents the results of the tiered analysis for AOC 10b. Six metals were detected at concentrations above their respective BTVs. Of those six, total chromium, hexavalent chromium, and molybdenum exceeded the calculated SSLs, as shown in Table C4-14. Numerical modeling was conducted to evaluate the potential of these three metals to leach into groundwater. Based on initial model screening simulations, the potential for total chromium and molybdenum to leach to groundwater was ruled out.

The simulated leaching concentrations of hexavalent chromium were likely due to the following factors:

- The initial screening approach assigned the maximum concentration found at each depth interval across the entire interval, even though other samples with lower concentrations were observed at each level.
- The presence of hexavalent chromium at the deepest sampling interval at one location required assignment of that concentration from that depth down to the water table for the entire area.

Additional data are needed to better define the vertical extent of hexavalent chromium. The model will be refined with the new vertical data and will be discretized spatially to more realistically simulate vadose zone contaminant concentrations.

4.3 Subarea AOC 10c

Table C4-12 presents the results of the tiered analysis for AOC 10c. Seven metals were detected at concentrations exceeding the BTVs. However, the cobalt BTV was exceeded at only one location, and the concentration was only very slightly above the BTV. At sample location MW58BR_S at 59 to 60 feet bgs, the detected concentration of cobalt was 13 mg/kg, compared to the BTV of 12.7 mg/kg. Cobalt was not detected above the BTV in any sample from the 0 to 10 foot bgs interval, and all concentrations of cobalt in MW58BR_S above the 59 to 60 foot bgs interval were below the BTV. Furthermore, the central tendency comparison indicated that the population of cobalt detections is consistent with the background population. Consequently, although cobalt was detected at 13 mg/kg in one sample, cobalt was not evaluated for Decision 3. Of the six remaining metals with detections exceeding the BTV, total chromium, hexavalent chromium, and molybdenum exceeded the calculated SSLs, as shown in Table C4-15. Numerical modeling was conducted to evaluate the potential of these three metals to leach into groundwater. Based on initial model screening simulations, the potential for total chromium and molybdenum to leach to groundwater was ruled out.

The simulated leaching concentrations of hexavalent chromium were likely due to the following factors:

- The initial screening approach assigned the maximum concentration found at each depth interval across the entire interval, even though other samples with lower concentrations were observed at each level.
- The presence of hexavalent chromium at the deepest sampling interval at one location required assignment of that concentration from that depth down to the water table for the entire area.

Additional data are needed to better define the vertical extent of hexavalent chromium. The model will be also refined with the new vertical data and will be discretized spatially to more realistically simulate vadose zone contaminant concentrations.

4.4 Subarea AOC 10d

Table C4-12 presents the results of the tiered analysis for AOC 10d. Eight metals were detected at concentrations above the BTVs. Of those eight, only hexavalent chromium, barium, and molybdenum exceeded the calculated SSLs, as shown in Table C4-16. Subsequent numerical modeling was conducted to evaluate the potential of these three metals to leach into groundwater. Based on initial model screening simulations, the potential for barium and molybdenum to leach to groundwater was ruled out.

The simulated leaching concentrations of hexavalent chromium were likely due to the following factor:

- The initial screening approach assigned the maximum concentration found at each depth interval across the entire interval, even though other samples with lower concentrations were observed at each level.

Additional data are not needed in area AOC 10d to refine the model. The model will be refined by discretizing the area spatially to more realistically simulate vadose zone contaminant concentrations.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Gaps Evaluation Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the CMS/FS. The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fence line include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite), as discussed in Table 6-1 in Data Gaps Evaluation Report.
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil washing technologies).
- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies), as discussed in Table 6-1 in Data Gaps Evaluation Report.
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- If present, volumes of white powder and debris.

The following is a summary of data for AOC 10 that are currently available to support CMS/FS.

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. The lateral and vertical extent of the COPCs and COPECs is discussed in Section 2.2 above. Data results for selected constituents are shown in Figure C4-1 and Figures C4-4 through C4-10, and data gaps associated with lateral and vertical delineation are discussed in Section 6.0.

5.2 Waste Characterization Parameters

Only partial waste characterization data are available to characterize the soil and other materials to be potentially removed for remedial action and disposed in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations (TTLC). The maximum concentrations of these metals for each of the units were compared to the

TTLCs, and total chromium exceeded the TTLCs three times, as shown in Table C4-17. The maximum detected concentrations were also compared to the soluble threshold limit concentrations (STLCs), and concentrations of five metals in AOC 9 (barium, total chromium, hexavalent chromium, copper, and lead) exceeded 10 times STLC one or more times, as shown in Table C4-17. In addition, total chromium and lead also exceeded 20 times TCLP as indicated in Table C4-17. Because these metals have the potential to exceed STLC or TCLP thresholds, additional leachability testing for waste characterization purposes may be required if soil excavation and offsite disposal is chosen as a remedy. For the purposes of supporting the CMS/FS, the lack of STLC or TCLP analysis is not considered a data gap, for the existing total concentrations are sufficient for the purposes of evaluating various remedial alternatives. Additional data regarding potential COPC/COPEC leachability include SPLP analysis for total and hexavalent chromium, as shown in Table C4-2. SPLP analysis was conducted only for soil samples (no white powder or debris samples were tested using SPLP).

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 soil investigation was limited to grain size analysis only. Specific soil physical properties data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 in the Data Gaps Report.

5.4 Surface and Subsurface Features

While there is extensive information regarding surface and subsurface features at AOC 10, additional information may be required once areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are known for AOC 10. However, subsurface utilities, including gas transmission pipelines and any culverts or other features, may have to be more precisely defined to evaluate the feasibility and cost of certain remedial alternatives and to prepare construction specifications.

5.5 Volumes of White Powder and Debris

Preliminary mapping has been conducted to identify the extent and type of debris present in AOC 10; findings of this mapping are presented in Section 3.0 and in Appendix B of this Data Summary Report. Additional soil physical parameter data are needed to support the CMS/FS.

6.0 Summary of Data Gaps and Proposed Phase 2 Soil Sample Locations to Fill the Identified Gaps

Based on the Part A DQO, data gaps were identified for three of the four decisions and are summarized below by decisions:

- **Decision 1 (Nature and Extent)** – the following data gaps were identified to resolve this decision:

  - Data gap #1 – Lateral and vertical extent of contamination in the western portion of AOC10 (Subarea AOC 10a, downslope from AOC9, and downslope from the outfall of the former trench drain).
  - Data gap #2 – Nature and extent of contamination associated with runoff from station access road to the low point north of Subarea 10d.
  - Data gap #3 – Nature and extent of contamination associated with the newly identified white powder areas (on the slope below the station access road) and the newly identified debris areas (on the slopes of AOC10).
  - Data Gap #4 - Nature and extent of contamination associated with runoff from discharge pipe upslope from subarea 10a. (Samples associated with perimeter and storm drain sampling programs will evaluate nature and extent on the slope above East Ravine.)
- **Decision 2 (Data Sufficient to Estimate Representative Exposure Point Concentrations)** – no data gap was identified for this decision.
- **Decision 3 (Potential Threat to Groundwater from Residual Soil Concentrations)** – the following data gap was identified to resolve this decision:
  - Data gap #4 – Vertical extent of contamination information to support refinement of the vadose leaching zone model.
- **Decision 4 (Data Sufficient to Estimate Soil Properties and Contaminant Distribution in Support of the CMS/FS) –** the following data gap was identified to resolve this decision**:**
  - Data gap #5 – Additional soil physical parameter information to support the CMS/FS.

In an effort to reduce intrusive sampling, a portable X-ray fluorescence (XRF) analyzer will be used to assist with identifying possible sample locations in debris areas on the slope of AOC 10 (Data Gap #4). Up to 20 XRF samples will be collected in the debris area. Corrected XRF results will be compared to applicable screening levels on Data Gaps Evaluation Report Table 3-1 on a point-by-point basis. (For field screening purposes, XRF concentration readings will be adjusted using least squares regression equation calculated from the RCRA facility investigation/remedial investigation samples analyzed in the lab and by the XRF.) If the applicable screening levels are not exceeded, no further sampling will occur at that location. However, if applicable screening levels are exceeded, soil samples will be collected at 0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet below ground surface at that location and will be submitted to the laboratory for analysis for hexavalent chromium, PAHs, Title 22 metals, and asbestos.

Table C4-18 shows the proposed sample location IDs, sample depths, rationale for each location, and analytes. Proposed Phase 2 sample locations are shown in Figure C4-11. The proposed Phase 2 sample locations are needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

6.1 Access Restrictions

AOC 10 is a ravine with steep sloped side walls. Majority of proposed Phase 2 sample locations are located on the slopes of the ravines, limiting access by sampling equipment. A few of the proposed Phase 2 sample locations are within the ravine bottom near the toe of the slope.

Sample Results: Metals

AOC 10 - East Ravine

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report

Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

TABLE C4-11

Decision 2 Data Gaps Summary AOC 10 - East Ravine

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,
Pacific Gas and Electric CompanyTopock Compressor Station, Needles, California

	Adequate EPC?		Maximum Detected Value	**> HHCV or Background as Applicable?** [1]	**> ECV or Background as Applicable?** [1]		
Compound/Depth	Y or N	Det/# results		**Y or N**	**Y or N** [2]	**Proposed Sample ID**	**Notes**
Mercury				**18 mg/kg**	**0.0125 mg/kg**		
0-0.5 ft bgs	N	1 of 22	0.64 mg/kg	N	N	None	Compound exceeds ECV and no background value has been established. Detection limits are elevated relative to the ECV. Additional data collection is likely to yield additional non-detected values. The EPC has been defined within the limits of the analytical instrumentation.
0-3 ft bgs	N	2 of 43	0.64 mg/kg	N	Y		
0-6 ft bgs	N	2 of 63	0.64 mg/kg	N	Y		
0-10 ft bgs	N	2 of 81	0.64 mg/kg	N	NA		
Scouring Scenario 1: 2-3 ft bgs	NA	0 of 20	NA mg/kg	N	N		
Scouring Scenario 1: 2-6 ft bgs	NA	0 of 40	NA mg/kg	N	N		
Scouring Scenario 1: 2-10 ft bgs	NA	0 of 58	NA mg/kg	N	N		
Scouring Scenario 1: 2-12 ft bgs	NA	0 of 58	NA mg/kg	N	NA		
Scouring Scenario 2: 5-6 ft bgs	NA	0 of 19	NA mg/kg	N	N		
Scouring Scenario 2: 5-10 ft bgs	NA	0 of 37	NA mg/kg	N	N		
Scouring Scenario 2: 5-15 ft bgs	NA	0 of 37	NA mg/kg	N	N		
Molybdenum				**380 mg/kg**	**2.25 mg/kg**		
0-0.5 ft bgs	N	3 of 22	19 mg/kg	N	N	None	Compound exceeds ECV but maximum shown (19 mg/kg) is from AOC10a-1 located adjacent to AOC9 and included in AOC9 for the ecological risk assessment (ERA). The maximum from the ERA dataset for the 0 to 0.5 feet bgs exposure interval is 1.5 mg/kg which is less than the ECV. Therefore, no additional molybdenum data are required for the 0 to 0.5 ft exposure interval. The remaining exposure intervals (0 to 3, 0 to 6, and 0 to 10 feet bgs) and intervals under Scouring Scenario 1 have sufficient data to support EPC calculation using ProUCL. The maximum detected concentrations from deep intervals under scouring scenario 2 do not exceed the comparison values and therefore no additional data are needed.
0-3 ft bgs	Y	10 of 43	19 mg/kg	N	Y		
0-6 ft bgs	Y	12 of 63	19 mg/kg	N	Y		
0-10 ft bgs	Y	14 of 81	19 mg/kg	N	NA		
Scouring Scenario 1: 2-3 ft bgs	Y	6 of 20	2.9 mg/kg	N	Y		
Scouring Scenario 1: 2-6 ft bgs	Y	8 of 40	2.9 mg/kg	N	Y		
Scouring Scenario 1: 2-10 ft bgs	Y	10 of 58	2.9 mg/kg	N	Y		
Scouring Scenario 1: 2-12 ft bgs	Y	10 of 58	2.9 mg/kg	N	NA		
Scouring Scenario 2: 5-6 ft bgs	N	2 of 19	1.9 mg/kg	N	N		
Scouring Scenario 2: 5-10 ft bgs	N	4 of 37	1.9 mg/kg	N	N		
Scouring Scenario 2: 5-15 ft bgs	N	4 of 37	1.9 mg/kg	N	N

TABLE C4-11

Decision 2 Data Gaps Summary AOC 10 - East Ravine

Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,
Pacific Gas and Electric CompanyTopock Compressor Station, Needles, California

	Adequate EPC?		Maximum Detected Value	**> HHCV or Background as Applicable?** [1]	**> ECV or Background as Applicable?** [1]	**Proposed Sample ID**	
Compound/Depth	Y or N	Det/# results		**Y or N**	**Y or N** [2]		**Notes**
Calcium				**66500 mg/kg (bckg)**	**66500 mg/kg (bckg)**		
0-0.5 ft bgs	Y	9 of 9	44000 mg/kg	N	N	None	Compound may exceed HHCV and ECV (both background). Existing data adequate for EPC. Under the scouring scenarios, no data are available. However, additional data collection to support the scouring scenarios does not appear warranted given that the concentrations are comparable to background (Section 3.3). In addition, it is reasonable to assume that the nature and extent of the calcium detected in the 0 to 3.0 ft interval is representative of concentrations at deeper depths.
0-3 ft bgs	Y	10 of 10	139000 mg/kg	Y	Y		
0-6 ft bgs	Y	10 of 10	139000 mg/kg	Y	Y		
0-10 ft bgs	Y	10 of 10	139000 mg/kg	Y	NA		
Scouring Scenario 1: 2-3 ft bgs	NA	0 of 0	NA mg/kg	NA	NA

Scouring Scenario 2: 5-10 ft bgs	Y	5 of 37	240 µg/kg	NA	N		
Scouring Scenario 2: 5-15 ft bgs	Y	5 of 37	240 µg/kg	NA	N		

Footnotes:

[1] The higher value of either the HHCV/ECV or background was selected as the screening criteria and are included in these columns for the respective compound in **BOLDED BLUE FONT**. Values based on background are indicated with "(bckg)" next to the value.

[2] AOC10 was evaluated for data sufficiency to support the ecological risk assessment excluding AOC10a-1. This sample was included in AOC 9 evaluation for adequacy to support EPC calculations for the ecological risk assessment due to its close proximity to AOC 9 and topography.

Acronyms and Abbreviations:

AOC - area of concern
BaP TEQ - benzo(a)pyrene toxic equivalents
ECV - ecological comparison values
EPC - exposure point concentration
ft bgs - feet below ground surface
HHCV - human health comparison values
HMW PAH - high molecular weight polycyclic aromatic hydrocarbons
mg/kg - milligrams per kilogram
µg/kg - micrograms per kilogram
N - no
NA - not applicable
Y - yes

TABLE C4-18
Proposed Phase 2 Soil Sampling Locations at AOC10 – East Ravine
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
PG&E Topock Compressor Station, Needles, California

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Anticipated Collection Methods[a]
AOC9-15	0, 2, 5 and 9	To resolve Data Gap #1 - Define lateral extent associated with western portion of AOC 10 and down slope of AOC9	Hexavalent chromium, Title 22 metals, PAHs, PCBs, pesticides	Backhoe
AOC9-16	0, 2, 5 and 9	To resolve Data Gaps #1 and 5 - Define lateral extent associated with western portion of AOC 10 and down slope of AOC9 and support CMS/FS	Hexavalent chromium, Title 22 metals, PAHs, PCBs, pesticides; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Backhoe
AOC10-9	0, 2, 5, and 9	To resolve data gap #2 – Assess nature and extent associated with runoff from station access road to the low point north of Subarea 10d	Hexavalent chromium, Title 22 metals, PAHs	Backhoe
AOC10-10	0, 2, 5, and 9	To resolve data gap #1- Assess lateral extent associated with PS-21 and nature and extent of potential impact from soil down slope from the outfall	Hexavalent chromium, Title 22 metals	Rotosonic
AOC10-11	0, 2, 5, and 9	To resolve data gaps #1, 3, and 5 - Assess potential impacts from debris on south slope and support CMS/FS, and the lateral extent between Subareas 10b and 10c	Hexavalent chromium, Title 22 metals, PAHs; pH, TPH, SVOCs, dioxins and furans (if burn material present), PCBs soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution))	Rotosonic
AOC10-12	0, 2, 5, and 9	To resolve data gap #3 -Assess potential impacts from debris on south slope (may not be technically feasible to get to proposed depth)	Hexavalent chromium, Title 22 metals, PAHs	Rotosonic
AOC10-13	White powder only	To resolve data gap #3 - Assess white powder material on north slope	Hexavalent chromium, PAHs, pH, Title 22 metals	Hand tools
AOC10-14	White powder only and discolored soil	To resolve data gap #3 - Assess white powder material on north slope	Hexavalent chromium, PAHs, pH, Title 22 metals	Rotosonic

TABLE C4-18
Proposed Phase 2 Soil Sampling Locations at AOC10 – East Ravine
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
PG&E Topock Compressor Station, Needles, California

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Anticipated Collection Methods[a]
AOC10-15	0, 2, 5, and 9	To resolve data gap #3 – Assess potential impact from debris (dirt pile with green-colored wood*)*	Hexavalent chromium, Title 22 metals, PAHs, pH, TPH, SVOCs, dioxins and furans (if burn material present), PCBs	Backhoe
AOC10-16	0, 2, 5, and 9	To resolve data gap #3 - Assess potential impacts from debris on south slope (may not be technically feasible to get to proposed depth)	Hexavalent chromium, PAHs, pH, Title 22 metals	Hand tools
AOC10-17	White powder and discolored soil only	To resolve data gap #3 -Assess white powder material and discolored soil on north slope	Hexavalent chromium, PAHs, pH, Title 22 metals	Hand tools
AOC10a-2	0, 2, 5, and 9	To resolve data gaps # 1 and #4 - Assess vertical and lateral extent and collect data to assess current threat to groundwater.	Hexavalent chromium, Title 22 metals, PAHs	Backhoe
AOC10a-3	0, 2, 5, and 9	To resolve data gap #1 -Assess lateral extent (down slope of AOC9 and Subarea 10a)	Hexavalent chromium, Title 22 metals, PAHs	Backhoe
AOC10d-9	0, 2, 5, and 9	To resolve data gap #2 -Assess lateral extent associated with AOC 10d-3 and L-3	Hexavalent chromium, Title 22 metals, PAHs	Backhoe

Notes:

ACM = asbestos-containing material.

[a] Anticipated collection methods listed on this table are best guess based on experience and knowledge of the site; actual collection method will be chosen in the field based on field conditions and site access restrictions.

APPENDIX C5

Area of Concern 11 Data Gaps Evaluation Results

1.0 Introduction and Background

This sub-appendix presents the results of the Data Gaps Evaluation and Part A Phase 2 Sampling Program for Area of Concern (AOC) 11 – Topographic Low Areas at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station in Needles, California. The process for the data gaps evaluation is outlined in Sections 2.0 through 6.0 of the Data Gaps Evaluation Report.

1.1 Background

The five topographic low areas that comprise AOC 11 are depicted in Figure C5-1. Low areas AOC 11a, AOC 11b, AOC 11c, and AOC 11d are located on Havasu National Wildlife Refuge property, and 11e is located on PG&E property.

At least three compressor station storm drain outlets may discharge to AOC 11. Two of these storm drains are known to be active; it is not known whether there are any other active storm drains that may discharge into this area. There is an inactive storm drain south of the compressor station office building area that may have discharged into AOC 11. Stormwater runoff from the northeastern portion of the station and from the area containing the Transwestern Meter Station may also have flowed to AOC 11. In addition, stormwater runoff from Interstate 40 (I-40) discharges to AOC 11. A former employee reported that he observed a release from Cooling Tower B that entered the ravine containing AOC 11 (the Northeast Ravine).

Low areas AOC 11c and AOC 11e are associated with the remnants of two small former check berms identified in the Northeast Ravine. Small amounts of fine-grained soils appear to be present behind the remnant of the upper check berm, and a larger volume of fine-grained soil is present behind the lower check dam, which has greater integrity. These check berms may have been constructed to prevent stormwater damage to a gas pipeline and a former access road to the compressor station.

The original plant access road ran through the area now identified as AOC 11a. A stormwater pipe that captures runoff from I-40 and National Trails Highway discharges into AOC 11 north of AOC 11a immediately south of the I-40 overcrossing. Stormwater runoff from I-40 could have resulted in the release of total petroleum hydrocarbons (TPH), polycyclic aromatic hydrocarbons (PAHs), lead, and wear metals (including barium, chromium, copper, nickel, and zinc) into AOC 11, and specifically AOC 11a, that are not due to PG&E's operations at the Topock Compressor Station. Substantial flow from the I-40 stormwater pipe has been observed. After storm events, water pools in area AOC 11a and does not readily percolate.

1.2 Potential Burn Area and Debris Mapping and Newly Identified White Powder and Topographic Low Areas

As discussed in Section 1.2 of the Data Gaps Evaluation Report and in Appendix B to the Data Gaps Evaluation Report, as a result of employee interviews conducted in late 2009/ early 2010 and subsequent additional site reconnaissance, two new topographic low areas, a potential burn area, and a small new white powder area were identified in the vicinity of AOC 11. These new areas are described below.

1.2.1 Topographic Low Areas

Two new topographic low areas that may receive runoff from the compressor station were identified. New Investigation Area 1, shown in Figure C5-1, consists of the drainage area beginning near the current decontamination pad and Transwestern Meter Station and extending downslope to the low area across from AOC 11b. It captures a portion of runoff originating from the compressor station that flows down the station access road. A reported burn area is located within the proposed boundary of New Investigation Area 1 (see Section 2.5.2 of this sub-appendix). Another topographic low area is located between the station access road and the Colorado River west of the Route 66 sign. This area may have also received runoff from the station access road. It is designated New Investigation Area 2.

In addition, miscellaneous debris (concrete and other materials) was noted in areas to the west of the station access road (near the Transwestern Meter Station area). As requested by California Environmental Protection Agency, Department of Toxic Substances Control (AOC/SWMU Specific Comment #5 in the August 10, 2007 Part A Work Plan comment letter), this area will be investigated in conjunction with AOC 11 as part of New Investigation Area 1. Neither of the new investigation areas has been sampled.

1.2.2 Potential Burn Area

According to former employee interviews, fire training exercises were conducted near the location of the current decontamination pad and Transwestern Meter Station. Materials that were burned during fire training exercises consisted primarily of scrap wood. Fire drills were reportedly later expanded to include extinguishing diesel fires in a 55-gallon drum. This area is located in the potential drainage area for one of the newly identified topographic low areas and was therefore incorporated into the boundaries of the new topographic low area (New Investigation Area 1, shown in Figure C5-1).

1.2.3 White Powder Area

A new white powder area was identified upslope of AOC 11e following the January 2010 rain event. This area is located on the steep slope below the northeastern portion of the compressor station and may represent native materials. This area is not accessible by equipment.

1.3 Conceptual Site Model

A graphical conceptual site model has been developed for AOC 11 based on the above site history, background, and newly identified areas, as shown in Figure C5-2. Table C5-1 presents primary sources, primary source media, potential release mechanisms, secondary source media, and potential secondary release mechanisms for AOC 11. A detailed discussion of the migration pathways, exposure media, exposure routes, and human and ecological receptors is included in the Soil Part A Data Quality Objective (DQO) Tech Memo, which is included as Appendix A to the Data Gaps Evaluation Report.

The primary source of contamination to AOC 11 is runoff from the compressor station, the access road to the compressor station, potential railroad debris below the station access road (asphalt, a metal sign, ceramic plates, glass resistors, and concrete were observed during 2008 field activities), the Transwestern Meter Station area, and I-40. Stormwater runoff from the compressor station could have entered the stormwater drains that discharge to AOC 11. Sheet flow surface runoff from the station could also have entered this unit from areas where the edge of the compressor station lacked curbs. Stormwater runoff from the Transwestern Meter Station area and the station access road could also have entered this AOC, including the two new potential investigation areas. Stormwater runoff from I-40 could have resulted in the release of TPH, PAHs, lead, and wear metals (including barium, chromium, copper, nickel, and zinc) into AOC 11, especially AOC 11a, that are not due to PG&E's operations at the Topock Compressor Station. Runoff from the various potential source areas would have discharged to surface soil and collected in low areas within the AOC.

The primary source medium therefore is surface soil. From surface soil, contaminants could have migrated to shallow and deeper soils. Shallow soils may act as a secondary source medium to subsurface soil, and subsurface soil may act as a secondary source medium to groundwater. After storm events, water pools in AOC 11a (the largest topographic low area) and does not readily infiltrate. Historically, water may have also pooled behind the two check berms in AOC 11c and AOC 11e; these structures have been breached and no longer retain water; however, accumulated fine-grained soils are present behind the berm at AOC 11c. Laterally, chemicals of potential concern/chemicals of ecological concern (COPCs/COPECs) in soil would generally be expected to be limited to the area along the topographic drainages. All of the low points within this unit are terminal low points, and there would not have been any flow out of AOC 11. At these low points, contaminants could potentially be driven deeper and potentially could reach groundwater. If released, volatile organic compounds (VOCs) in surface soils would be expected to have been degraded by heat and light and are likely no longer present.

Within the newly identified burn and runoff areas, COPCs/COPECs may be present in surface soil at the burn area and along the runoff pathways. Surface soil would therefore be the primary source medium for these new areas. Contamination may have migrated vertically downward to affect shallow soil at the burn area and shallow and potentially subsurface soil along the runoff pathways. Laterally, COPCs/COPECs in soil would generally be expected to be limited to the immediate vicinity of the burn area and linearly along the topographic drainages (including depressions where runoff might accumulate) from the burn area and compressor station.

Another potential source of contamination to AOC 11 may also include contaminated windblown dust. Contaminated surface soil (either within AOC 11 or from the adjacent compressor station) may have been eroded by wind and deposited at the ground surface within AOC 11.

Part A Phase 1 and historical soil samples were collected at or near the exit drain point of the stormwater drains, bottom of the ravine, in drainage depression areas, and on the western slope near the compressor station.

1.3.1 AOC 11 Data

Historical sampling has not occurred at AOC 11. During Phase 1, 74 soil samples (generally collected at 0 to 0.5, 2 to 3, 5 to 6, and 9 to 10 feet below ground surface [bgs]) were collected from 19 sample locations (AOC11a-1 through AOC11a-5, AOC11b-1, AOC11b-2, AOC11c-1, AOC11c-2, AOC11d-1, AOC11e-1, AOC11e-2, AOC11a-SS-1 through AOC11a-SS-3, AOC11c-SS-1, AOC11c-SS-2, AOC11e-SS1, and AOC11e-SS-2), as shown in Figure C5-3. Part A Phase 1 soil samples collected in AOC 11 were generally analyzed for Title 22 metals, hexavalent chromium, VOCs, semivolatile organic compounds, PAHs, TPH, pH, polychlorinated biphenyls (PCBs), and pesticides. Surface soil samples were not analyzed for VOCs. Ten percent of the Phase 1 soil samples collected in AOC 11 (seven soil samples) were analyzed for the full inorganic and organic suites per the CERCLA Target Analyte List and Target Compound List (TAL/TCL). In addition, synthetic precipitation leaching procedure (SPLP) extraction was performed on a soil sample collected at 2 to 3 feet bgs at sample location AOC11e-2 and a soil sample collected at 9 to 10 feet bgs at sample location AOC11c-1. The leachate from the SPLP extractions was analyzed for total and hexavalent chromium; results are presented in Table C5-2. The soil results were validated, and the data quality evaluation is included as Appendix D to the Data Gaps Evaluation Report.

All validated Part A Phase 1 data are Category 1. Category 1 historical soil data and validated Part A Phase 1 data were used as inputs to the four DQO decisions for AOC 11.

2.0 Decision 1 – Nature and Extent

This section describes the nature and extent of residual soil concentrations of COPCs and COPECs at AOC 11. Laboratory analytical results for Phase 1 soil samples at AOC 11 are presented in Tables C5-3 through C5-8. Table C5-9 presents a statistical summary of soil analytical results for COPCs and COPECs that were either detected above the laboratory reporting limits or not detected but where the reporting limits for one or more samples was greater than the interim screening value.

2.1 Summary of AOC 11 Soil Data

Antimony, beryllium, cadmium, mercury, silver, thallium, cyanide, TPH-gasoline, and most species of PCBs were not detected in soil samples collected at AOC 11. Table C5-9 lists the 45 constituents detected at AOC 11, including four calculated quantities: benzo(a)pyrene equivalents, total low molecular weight PAHs, total high molecular weight PAHs, and total PCBs. Fourteen of these constituents (aluminum, calcium, iron, magnesium, manganese, potassium, sodium, Aroclor-1254, Aroclor-1260, total PCBs, 4,4-dichlorodiphenyldichloroethylene [4,4-DDE], alpha-chlordane, dieldrin, and gamma-chlordane) were detected in the samples analyzed for the full TAL/TCL suite of compounds.

Twenty-three of the constituents detected at AOC 11 (cobalt, nickel, vanadium, calcium, iron, magnesium, sodium, methyl acetate, anthracene, benzo(g,h,i)perylene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, pyrene, low molecular weight PAHs, Aroclor-1254, alpha-chlordane, gamma-chlordane, TPH-diesel, and TPH-motor-oil) were detected at concentrations below their respective interim screening levels. Twenty-two constituents, including three calculated quantities, were detected one or more times at concentrations exceeding their respective interim screening levels. These constituents included 12 metals (aluminum, arsenic, barium, total chromium, hexavalent chromium, copper, lead, manganese, molybdenum, potassium, selenium, and zinc), four PAHs (benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and benzo(k)fluoranthene), one PCB isomer (Aroclor-1260), two pesticides (4,4-DDE and dieldrin), and three calculated quantities (benzo(a)pyrene equivalents, total high molecular weight PAHs, and total PCBs).

Nine constituents (barium, total chromium, hexavalent chromium, copper, lead, molybdenum, zinc, benzo(a)pyrene, and benzo(a)pyrene equivalents) were each detected four or more times at concentrations exceeding their respective interim screening levels; the distributions of these constituents are shown in C5-3 to C5-10.

2.2 Nature and Extent Evaluation

The following subsection discusses the nature and extent of COPCs and COPECs detected above their respective screening levels at AOC 11. As discussed in Section 3.2 of the Data Gaps Evaluation Report, multiple factors were considered to assess whether the nature and extent of a specific constituent has been adequately delineated. Section 2.4 of this sub-appendix summarizes the constituents that may require further evaluation and Section 5.0 of this sub-appendix provides the recommended follow-up sampling for the Part A Phase 2 soil investigation.

2.2.1 Arsenic

Arsenic was detected in 74 of 74 soil samples collected from AOC 11. Only one detected concentrations of arsenic (13 milligrams per kilogram [mg/kg]) collected at AOC 11b-2 at 2 to 3 feet bgs slightly exceeded the interim screening level of 11 mg/kg (background threshold value [BTV]); this same sample also exceeded the ecological comparison value (ECV) of 11.4 mg/kg, as shown in Tables C5-3 and C5-9. This sample was collected in AOC 11b. Sample concentrations in the other samples collected in AOC 11b (AOC11b-1) had concentrations below the interim screening level. The deepest samples in AOC 11b (collected at 9 to 10 feet bgs) have arsenic concentrations below the interim screening level.

2.2.2 Barium

Barium was detected in 74 of 74 soil samples collected at AOC 11. Detected concentrations of barium exceeded the interim screening level (410 mg/kg, BTV) four times (maximum detected concentration of 1,300 mg/kg at AOC11a-2 at 5 to 6 feet bgs), as shown in Tables C5-3 and C5-9 and Figure C5-3. None of the detected concentrations exceeded residential or commercial/industrial California Department of Toxic Substances Control California human health screening levels (CHHSLs) (5,200 mg/kg and 63,000 mg/kg, respectively). The lateral extent of samples with concentrations exceeding the interim screening level is limited to the eastern portion of AOC 11a. Samples with concentrations below the screening levels are located upslope of AOC 11a. At these locations, the deepest samples (collected at 9 to 10 feet bgs) have concentrations exceeding the interim screening level.

2.2.3 Total Chromium

Total chromium was detected in 74 of 74 soil samples collected at AOC 11. Detected concentrations of total chromium exceeded the interim screening level (39.8 mg/kg) (BTV) 14 times (maximum detected concentration of 130 mg/kg at AOC11c-1 at 9 to 10 feet bgs), as shown in Tables C5-3 and C5-9 and Figure C5-4. None of the detected concentrations of total chromium exceeded the United States Environmental Protection Agency residential regional screening level (RSLs) for residential use (280 mg/kg) or the RSL for commercial/industrial use (1,400 mg/kg). The lateral extent of samples with concentrations exceeding the interim screening level is limited the upper reaches of AOC 11 at and between AOC 11e and AOC 11c, with the exception of one sample (AOC11a-3) collected in AOC 11a. Samples with concentrations below the interim screening level are located downslope of AOC 11e and AOC 11c, but no samples have been collected upslope of these areas. Samples with concentrations below the interim screening level surround location AOC11a-2. At three locations in AOC 11c and one location in AOC 11e, the deepest samples (collected at 9 to 10 feet bgs) have concentrations exceeding the interim screening level.

2.2.4 Hexavalent Chromium

Hexavalent chromium was detected in 31 of 74 soil samples collected at AOC 11. Detected concentrations of hexavalent chromium exceeded the interim screening level (0.83 mg/kg) (BTV) 18 times (maximum detected concentration of 7.78 mg/kg), as shown in Tables C5-3 and C5-9 and Figure C5-5. None of the detected concentrations of hexavalent chromium exceeded the residential or commercial CHHSLs (17 mg/kg and 37 mg/kg, respectively) or the ECV (139.6 mg/kg). The lateral extent of samples with concentrations exceeding the interim screening level is limited to the upper reaches of AOC 11, including all of AOC 11e and AOC 11c and the eastern portion of AOC 11a. Samples with concentrations below the interim screening level are located in the western portion of AOC 11a, which is downstream of Subareas 11e and 11c, but no samples have been collected upslope of these areas. At five locations (one in AOC 11a, three in AOC 11c, and one in AOC 11e), the deepest samples (collected at 9 to 10 feet bgs) have concentrations exceeding the interim screening level.

2.2.5 Copper

Copper was detected in 74 of 74 soil samples collected at AOC 11. Detected concentrations of copper exceeded the interim screening level (16.8 mg/kg) (BTV) 16 times (maximum detected concentration of 41 mg/kg at AOC11e-1), as shown in Tables C5-3 and C5-9 and Figure C5-6. Five detected concentrations exceeded the ECV (20.6 mg/kg), and no detected concentrations of copper exceeded the residential or commercial/industrial CHHSLs (3,000 mg/kg, and 38,000 mg/kg, respectively). The lateral extent of concentrations exceeding the interim screening level is limited to the upper reaches of AOC 11, including AOC 11c, AOC 11d, and AOC 11e and a small area near the western portion of AOC 11a. Copper was not detected at concentrations exceeding the screening levels in AOC 11b. Samples with concentrations below the interim screening level are located downslope of AOC 11c, AOC 11d, and AOC 11e, but no samples have been collected upslope of these areas. In four locations in AOC 11c and AOC 11e (two locations in each area), the deepest samples (collected at 9 to 10 feet bgs) have concentrations exceeding the interim screening level.

The small area near the western portion of AOC 11a with copper concentrations above the BTV (locations AOC11a-2, AOC11a-4, AOC 11a-5, and AOC11a-SS-3) is surrounded by samples with concentrations below the interim screening level, and the deepest soil samples at these locations have concentrations below the interim screening level.

2.2.6 Lead

Lead was detected in 74 of 74 soil samples collected at AOC 11. Detected concentrations of lead exceeded the interim screening level (8.39 mg/kg) (BTV/ECV) 36 times (maximum detected concentration of 45 mg/kg at AOC11b-2 at 0 to 0.5 feet bgs), as shown in Tables C5-3 and C5-9 and Figure C5-7. None of the detected concentrations exceeded the residential or commercial/industrial CHHSLs (80 mg/kg and 320 mg/kg, respectively). Lead was detected at concentrations exceeding the interim screening level across most of AOC 11, with the exception of the area north of AOC 11a, where no concentrations were detected above the interim screening level. At seven locations, the deepest (collected at 9 to 10 feet bgs) samples have concentrations exceeding the interim screening level.

2.2.7 Molybdenum

Molybdenum was detected in 17 of 74 soil samples collected from AOC 11. Detected concentrations of molybdenum exceeded the interim screening level (1.37 mg/kg) (BTV) 10 times (maximum detected concentration of 2.9 mg/kg at AOC11c-SS-1 at 5 to 6 feet bgs), as shown in Tables C5-3 and C5-9 and Figure C5-8. Eight detected concentrations exceeded the ECV (2.25 mg/kg), and no detected concentrations of molybdenum exceeded the residential and commercial/industrial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). Concentrations exceeding the interim screening level are limited to AOC 11a, AOC 11c, and AOC 11e. Samples with concentrations below the interim screening level surround the locations in AOC 11a and AOC 11e. At AOC 11c, samples with concentrations below the interim screening level are located up- and downslope of this area; however, within AOC 11c, all sample locations have concentrations exceeding the interim screening levels. At each location, with the exception of location AOC11a-5, the deepest samples (collected at 9 to 10 feet bgs) have concentrations below the interim screening level.

2.2.8 Selenium

Selenium was detected in two of 74 soil samples collected from AOC 11. The two detected concentrations of selenium at AOC11a-1 (1.6 mg/kg at 5 to 6 feet bgs) and AOC11a-5 (3.2 mg/kg at 5 to 6 feet bgs) exceeded the interim screening level (1.47 mg/kg) (BTV/ECV) in both samples, as shown in Tables C5-3 and C5-9. Neither of the detected concentrations exceeded the residential and commercial/industrial CHHSLs (380 mg/kg and 4,800 mg/kg, respectively). These locations are both in AOC 11a. Samples with concentrations below the interim screening level surround these locations. At both locations, the deepest samples (collected at 9 to 10 feet bgs) have concentrations below the interim screening level.

2.2.9 Zinc

Zinc was detected in 74 of 74 soil samples collected at AOC 11. Detected concentrations of zinc exceeded the interim screening level (58 mg/kg) (BTV/ECV) 30 times (with a maximum detected concentration of 290 mg/kg at AOC11c-SS-1 at 9 to 10 feet bgs), as shown in Tables C5-3 and C5-9 and Figure C5-9. None of the detected concentrations exceeded the residential and commercial/industrial CHHSLs (23,000 mg/kg and 100,000 mg/kg, respectively). Zinc was detected at concentrations exceeding the interim screening level across most of AOC 11, with the exception of the areas north of AOC 11a and west of AOC 11e. At six locations, the deepest samples (collected at 9 to 10 feet bgs) have concentrations exceeding the interim screening level.

2.2.10 Polycyclic Aromatic Hydrocarbons

Benzo(a)pyrene was detected in 32 of 74 soil samples collected from AOC 11. Detected concentrations of benzo(a)pyrene exceeded the interim screening level of 38 micrograms per kilograms (µg/kg) (residential CHHSL) 12 times. Several other PAHs were detected in soil samples collected from AOC 11; only benzo(a)anthracene, benzo(b)fluoranthene, and benzo(k)fluoranthene were detected at concentrations above their respective interim screening levels. To assist with evaluation of PAHs for human health, benzo(a)pyrene equivalents were calculated for each of the soil samples collected at AOC 11, as shown in Tables C5-5 and C5-9. Benzo(a)pyrene equivalent values exceeded the interim screening level of 38 µg/kg (residential CHHSL) 17 times (maximum calculated concentration of 510 µg/kg at AOC11e-2 at 0 to 0.5 feet bgs), as shown in Tables C5-5 and C5-9 and Figure C5-10. The lateral extent of concentrations exceeding the interim screening level is limited to the upper and lower reaches of AOC 11, including AOC 11c, AOC 11d, AOC 11e, and AOC 11b. Samples within and surrounding AOC 11a have concentrations below the screening levels. At all locations, except AOC11b-1, the deepest samples (collected at 9 to 10 feet bgs) have concentrations below the interim screening levels.

To assist with evaluation of PAHs for ecological risk, detected concentrations of low molecular weight PAHs and high molecular weight PAHs were summed and compared to the PAH low molecular weight and PAH high molecular weight ECVs (10,000 µg/kg and 1,160 µg/kg, respectively). Three PAH high molecular weight sums of detected concentrations exceeded the ECV (1,160 µg/kg); the maximum sum concentration was 4,900 µg/kg in a surface soil sample collected at location AOC11e-2. None of the sums of detected concentrations exceeded the PAH low molecular weight ECVs.

2.2.11 Target Analyte List/Target Compound List Constituents

Aluminum, calcium, iron, magnesium, manganese, potassium, sodium, Aroclor-1254, Aroclor-1260, 4,4-DDE, dieldrin, alpha-chlordane, and gamma-chlordane were detected in the AOC 11 soil samples analyzed for the complete TAL/TCL suite of compounds. These constituents are discussed below.

Aluminum was detected in seven of seven surface soil samples collected from AOC 11. Detected concentrations of aluminum exceeded the interim screening level (16,400 mg/kg) (BTV) twice (AOC11a-2 [20,000 mg/kg at 0 to 0.5 foot bgs] and AOC11d-1 [19,000 mg/kg at 0 to 0.5 foot bgs]), as shown in Tables C5-4 and C5-9. Remaining concentrations of aluminum ranged from 7,900 to 15,000 mg/kg. None of the detected concentrations exceeded the residential or commercial/industrial RSLs (77,000 mg/kg and 990,000 mg/kg, respectively). An ECV has not been established for aluminum.

Calcium was detected in seven of seven surface soil samples collected from AOC 11. The maximum detected concentration of calcium was 45,000 mg/kg at AOC11a-2, which is below the interim screening level (66,500 mg/kg) (BTV), as shown in Tables C5-4 and C5-9. Remaining detected concentrations of calcium range from 23,000 to 43,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for calcium.

Iron was detected in seven of seven surface soil samples collected from AOC 11. The maximum detected concentration of iron was 26,000 mg/kg at AOC11b-1, which is below the interim screening level of 55,000 mg/kg (residential RSL), as shown in Tables C5-4 and C5-9. Remaining detected concentrations of iron range from 12,000 to 25,000 mg/kg. A BTV and an ECV have not been established for iron.

Magnesium was detected in seven of seven surface soil samples collected from AOC 11. The maximum detected concentration of magnesium was 12,000 mg/kg at AOC11a-2 and AOC11d-1, which is below the interim screening level (12,100 mg/kg) (BTV), as shown in Tables C5-4 and C5-9. Remaining detected concentrations of magnesium range from 6,400 to 11,000 mg/kg. Residential and commercial/industrial CHHSLs and an ECV have not been established for magnesium.

Manganese was detected in seven of seven surface soil samples collected from AOC 11. One detected concentrations of manganese (440 mg/kg at AOC11b-1 at 0 to 0.5 foot bgs) slightly exceeded the interim screening level (402 mg/kg) (BTV/ECV), as shown in Tables C5-4 and C5-9. Remaining detected concentrations of manganese range from 220 to 390 mg/kg. None of the detected concentrations exceeded the residential or commercial/industrial RSLs (1,800 mg/kg and 23,000 mg/kg, respectively).

Potassium was detected in seven of seven surface soil samples collected from AOC 11. Detected concentrations of potassium exceeded the interim screening level (4,400 mg/kg) (BTV) twice (AOC11a-2 [5,000 mg/kg at 0 to 0.5 foot bgs] and AOC11d-1 [5,300 mg/kg at 0 to 0.5 foot bgs]), as shown in Tables C5-4 and C5-9. Remaining concentrations of potassium range from 2,200 to 3,400 mg/kg. Residential and commercial CHHSLs and an ECV have not been established for potassium.

Sodium was detected in six of seven surface soil samples collected from AOC 11. The maximum detected concentration of sodium was 710 mg/kg at AOC11a-2, which is below the interim screening level of 2,070 mg/kg (BTV), as shown in Tables C5-4 and C5-9. Remaining detected concentrations of sodium range from 180 to 580 mg/kg. Residential and commercial/industrial CHHSLs, RSLs, and an ECV have not been established for sodium.

The PCB Aroclor-1254 was detected in nine of 20 soil samples collected from AOC 11; both surface and subsurface soil (up to 10 feet bgs) samples were collected. The maximum detected concentration of Aroclor-1254 of 190 µg/kg was detected at AOC11c-2 at 2 to 3 feet bgs and AOC11e-2 at 0 to 0.5 foot bgs. Remaining detected concentrations of Aroclor-1254 range from 18 to 76 µg/kg. None of the detected concentrations of Aroclor-1254 exceeded the interim screening level of 220 µg/kg (residential RSL), as shown in Tables C5-8 and 5-9.

The PCB Aroclor-1260 was detected in one of 20 soil samples collected from AOC 11. The detected concentrations of Aroclor-1260 (240 µg/kg at AOC11e-2 at 0 to 0.5 foot bgs) exceeded the interim screening level (220 µg/kg) (residential RSL), as shown in Tables C5-8 and C5-9. The detected concentration did not exceed the commercial/industrial RSL (740 µg/kg). To assist with evaluation of PCBs for ecological risk, total PCB values were calculated at AOC 11. The sample containing Aroclor-1260 also exceeded the total PCB screening value (ECV) of 204 µg/kg. Remaining total PCB concentrations range from 26.5 to 199 µg/kg. The location with the exceedance is in the upper reaches of AOC 11 in AOC 11e. No samples were collected immediately downslope of this area. At this location, the deepest sample (collected at 9 to 10 feet bgs) had a concentration below the screening level.

4,4-DDE was detected in one of seven surface soil samples collected from AOC 11. The detected concentration of 4,4-DDE (6.1 µg/kg at AOC11d-1) exceeded the interim screening level (2.1 µg/kg) (ECV), as shown in Tables C5-7 and C5-9. The detected concentration did not exceed the residential or commercial/industrial CHHSLs (1,600 µg/kg and 6,300 µg/kg, respectively). No samples were collected immediately downslope of this area.

Dieldrin was detected in one of seven surface soil samples collected from AOC 11. The detected concentration of dieldrin (6.7 µg/kg at AOC11d-1) exceeded the interim screening level (5 µg/kg) (ECV), as shown in Tables C5-7 and C5-9. The detected concentration did not exceed the residential or commercial/industrial CHHSLs (35 µg/kg and 130 µg/kg, respectively). No samples were collected immediately downslope of this area.

Alpha– and gamma-chlordane were detected in one of seven surface soil samples collected from AOC 11. The detected concentrations of alpha- and gamma-chlordane (12J µg/kg and 13J µg/kg, respectively; at location AOC11d-1) were below the interim screening level (430 µg/kg) (residential CHHSL), as shown in Tables C5-7 and C5-9. The detected concentration did not exceed the ECV (470 µg/kg). Sub-area 11d is a small internally draining drainage depression, with no exit for storm water to flow.

As discussed in Section C.2 of Appendix C, PG&E recommends that PCBs be evaluated further in AOC 11. PG&E also recommends that aluminum, calcium, iron, magnesium, manganese, potassium, sodium, 4,4-DDE, dieldrin, alpha-chlordane, and gamma-chlordane not be considered COPCs/COPECs for this AOC. These constituents have been fully discussed in Section C.2.

2.3 Central Tendency Comparison to Background Threshold Values

Twelve metals, (aluminum, arsenic, barium, total chromium, hexavalent chromium, copper, lead, magnesium, molybdenum, selenium, potassium, and zinc) were detected above their respective Topock BTVs in soil collected from AOC 11. A central tendency comparison was performed for seven of these 12 metals (arsenic, barium, total chromium, copper, lead, molybdenum, and zinc) to compare the AOC 11 soil data set for these metals with the corresponding Topock soil background data set to determine whether a difference exists between the two populations and whether additional sampling may be required for a given metal, as discussed in Table C5-10 of this sub-appendix and in Figure 3-1 of the Data Gaps Evaluation Report.

Metals in either the AOC 11 data set or background data set that were detected infrequently (less than five detects) or had a limited number of results (less than eight) were not tested. There were insufficient detections of aluminum, magnesium, selenium, and potassium at AOC 11 to conduct the test, and there were insufficient detections of hexavalent chromium in the background data set to allow for a central tendency comparison.

No statistical difference between the two populations was noted for barium or molybdenum, as shown in Table C5-10. However, results from the Gehan test suggest that site concentrations for arsenic, total chromium, copper, lead, and zinc may exceed background. Additional sampling is proposed for total chromium, copper, lead, and zinc. Arsenic was detected above the BTV of 11 mg/kg only once at a concentration of 13 mg/kg in a soil sample collected at 2 to 3 feet bgs at sample location AOC11b-2. After careful review of AOC 11 site data and background data set for arsenic, the statistical difference between the two populations is not considered significant enough to warrant additional sampling for arsenic at AOC 11.

2.4 Nature and Extent Conclusions

Based on the site history, background, and conceptual site model, qualitative review indicates that decision error has been held to an acceptable level. Sufficient data of acceptable quality have been attained through collection of historical/Part A soil samples in areas most likely to have been impacted by runoff from the compressor station, the access road to the compressor station, potential railroad debris below the station access road, the Transwestern Meter Station area, and I-40. Stormwater runoff from the compressor station could have entered the stormwater drains that discharge to AOC 11. These areas include the topographic drainage areas (AOC 11a), where water pools after storm events, and areas behind two check berms (AOC 11c and AOC 11e), where historically water may have pooled. The newly identified topographic low areas, burn area, and white powder areas have not been sampled.

Within the topographic low areas in AOC 11, the lateral and/or vertical extents of barium (vertical extent only), hexavalent chromium, copper, lead, molybdenum, PAHs, PCBs, total chromium, and zinc have not been defined.

Based on the DQOs, the following data gaps were identified to resolve Decision 1:

- Data Gap #1 – Lateral and vertical extent of contamination within AOC 11c.
- Data Gap #2 - Lateral extent of contamination upslope of AOC 11c and AOC 11e.
- Data Gap #3 – Lateral and vertical extent of contamination within AOC 11e.
- Data Gap #4 - Nature and extent of contamination associated with New Investigation Areas 1 and 2, the newly identified burn area (near the location of the current decontamination pad and Transwestern Meter Station), and the white powder area (upslope of AOC 11e).

The proposed Phase 2 soil sample locations to fill the identified data gaps are presented in Section 6.0 of this sub-appendix.

3.0 Decision 2 – Data Sufficient to Calculate Exposure Point Concentrations

For Decision 2, data were evaluated to determine whether the AOC 11 data are sufficient to conduct human health and ecological risk assessments based on the criteria described in Section 4.0 of the Data Gaps Evaluation Report. The principal consideration for Decision 2 was whether there were sufficient data to estimate a representative exposure point concentration (EPC). Data reviewed were Part A Phase 1 data at AOC 11; no historical sampling was conducted at this AOC.

Table C5-11 summarizes the results of the evaluation to determine whether data are sufficient to estimate a representative EPC. Data were reviewed for all chemicals that were detected in at least one sample and exceeded at least one comparison value. In general, existing data are adequate to support EPC development for detected chemicals that exceeded one or more comparison values (eight metals, three Contract Laboratory Program inorganics, PAHs, PCBs, and two pesticides), as described below.

3.1 Metals

Sufficient data (numbers of samples and detections) are available to calculate EPCs for arsenic, barium, total chromium, copper, lead, and zinc using ProUCL. For the remaining metals (molybdenum and selenium), additional data collection is not expected to significantly change the results of the risk assessment because the magnitude of the maximum detected concentrations are low relative to the ECVs (i.e., within approximately two times the ECV). Molybdenum concentrations at AOC 11 are also comparable to background. For selenium, additional data collection would also likely result in additional non-detected values and, consequently, would not influence the EPC. Therefore, no additional data collection is recommended for metals to provide data for EPC calculations.

3.2 Inorganics

Sufficient data (numbers of samples and detections) are available to calculate EPCs for all detected inorganics that exceeded one or more comparison values (aluminum, manganese, and potassium) using ProUCL.

3.3 Polycyclic Aromatic Hydrocarbons

Sufficient data (numbers of samples and detections) are available to calculate EPCs for benzo(a)pyrene equivalents and high molecular weight PAHs using ProUCL.

3.4 Pesticides

4,4-DDE and dieldrin were detected in a single sample, as shown in Table C5-7. The data are insufficient to allow calculation of EPCs using ProUCL. The total concentration of dichlorodiphenyl trichloroethane (DDT) and metabolites (DDT-R) is approximately three times the ECV. Dieldrin was detected at less than two times the ECV. Collection of additional data is not expected to yield sufficient detections to strongly influence the EPC for either DDT-R or dieldrin. The EPC would likely remain the maximum detected concentration; therefore, no additional data collection is recommended to support EPC development.

4.0 Decision 3 – Potential Threat to Groundwater from Residual Soil Concentrations

A conservative, three-tiered approach will be used in the evaluation to assess the potential impact to groundwater from source areas in the vadose zone. A full description of the three-tiered approach is provided in Section 5.0 of the Data Gaps Evaluation Report. The analysis of AOC 11 was divided into five separate analyses based on the AOC 11 areas shown in Figure C-1 in Appendix C.

The following preliminary analysis was performed with the existing data set to assess the potential threat to groundwater and to assess if additional data, above and beyond that necessary for Decision 1, are needed to resolve Decision 3. Additional evaluation will be performed, as appropriate, as data are collected to resolve Decision 1. Data collected to satisfy Decision 1 – Nature and Extent evaluation will provide the final representative data set that will be used to assess the threat to groundwater.

4.1 AOC 11a

Table C5-12 presents the results of the tiered analysis for AOC 11a. Eight metals were detected at concentrations above the BTVs. Of those eight metals, hexavalent chromium and molybdenum exceeded the calculated soil screening levels (SSLs), as shown in Table C5-13. Numerical modeling was conducted to evaluate the potential of these two metals to leach into groundwater. Based on the initial screening model, the potential for molybdenum to leach to groundwater was ruled out. Based on the screening model, the potential for hexavalent chromium to leach to groundwater could not be ruled out.

The simulated leaching concentrations of hexavalent chromium were likely due to the following factors:

- The initial screening approach assigned the maximum concentration found at each depth interval across the entire interval, even though other samples with lower concentrations were observed at each level.
- The presence of hexavalent chromium at the deepest sampling interval at one location required assignment of that concentration from that depth down to the water table for the entire area.

Additional data are needed to better define the vertical extent of hexavalent chromium to better assess the leaching potential. The model will be refined with the new vertical data and will be discretized spatially to more realistically simulate vadose zone contaminant concentrations.

4.2 AOC 11b

Table C5-12 presents the results of the tiered analysis for AOC 11b. Three metals (arsenic, lead, and zinc) were detected at concentrations above the BTVs. None of these metals exceeded the calculated SSL, as shown in Table C5-14. Therefore, numerical modeling was not required for AOC 11b, and a current or potential threat to groundwater from this area was ruled out.

4.3 AOC 11c

Table C5-12 presents the results of the tiered analysis for AOC 11c. Six metals were detected at concentrations above the BTVs. Of those six, only hexavalent chromium and molybdenum exceeded the calculated SSLs, as shown in Table C5-15. Numerical modeling was conducted to evaluate the potential of these two metals to leach into groundwater. Based on the initial screening model, the potential for molybdenum to leach to groundwater was ruled out. Based on the screening model, the potential for hexavalent chromium to leach to groundwater could not be ruled out.

The simulated leaching concentration of hexavalent chromium at AOC 11c is likely due to the presence of hexavalent chromium at the deepest sampling interval at one location, which required assignment of that concentration from that depth down to the water table for the entire area.

Additional data are needed to better define the vertical extent of hexavalent chromium to better assess the leaching potential. The model will be refined with the new vertical data and will be discretized spatially to more realistically simulate vadose zone contaminant concentrations.

4.4 AOC 11d

Table C5-12 presents the results of the tiered analysis for AOC 11d. Four metals were detected at concentrations above the BTVs. None of the metals exceeded the calculated SSLs, as shown in Table C5-16. Therefore, numerical modeling was not required for AOC 11d, and a current or potential threat to groundwater from this area was ruled out.

4.5 AOC 11e

Table C5-12 presents the results of the tiered analysis for AOC 11e. Six metals were detected at concentrations above the BTVs. Of those six, only hexavalent chromium and molybdenum exceeded the calculated SSLs, as shown in Table C5-17. Numerical modeling was conducted to evaluate the potential of these two metals to leach into groundwater. Based on the initial screening model, the potential for molybdenum to leach to groundwater was ruled out. Based on the screening model, the potential for hexavalent chromium to leach to groundwater could not be ruled out.

The simulated leaching concentration of hexavalent chromium at AOC 11e is likely due to the presence of hexavalent chromium at the deepest sampling interval at one location, which required assignment of that concentration from that depth down to the water table for the entire area.

Additional data are needed to better define the vertical extent of hexavalent chromium to better assess the leaching potential. The model will be refined with the new vertical data and will be discretized spatially to more realistically simulate vadose zone contaminant concentrations.

5.0 Decision 4 – Data Sufficiency to Support the Corrective Measures Study/Feasibility Study

As discussed in Section 6.0 of the Data Gaps Evaluation Report, various types of data will be needed to support the evaluation of technologies/remedial actions for the corrective measures study/feasibility study (CMS/FS). The types of data needed vary somewhat depending on the specific technology to be evaluated. The categories of data required for technologies that may be applicable to the areas outside the fence line include:

- Extent of COPCs and COPECs above action levels (required for all technologies).
- Waste characterization parameters (required if soil may be disposed of offsite).
- Constituent leachability (required to assess the need for fixation of leachable compounds and/or the feasibility of certain soil washing technologies).
- Soil physical properties (required for all technologies; however, the properties required vary among the different technologies).
- Surface and subsurface features (required to determine whether there are physical impediments to implementing specific technologies and/or remediating specific areas).
- If present, volumes of white powder and debris.

The following is a summary of data for AOC 11 that are currently available to support CMS/FS. Data gaps identified for Decision 4 will be filled using samples being collected to fill data gaps identified for other decisions. Data will not be collected to solely fill Decision 4 data gaps.

5.1 Extent of COPCs and COPECs

A summary of the nature and extent of detected COPCs/COPECs is presented in Section 2.0 Decision 1 – Nature and Extent. Data results for selected constituents are shown in Figures C5-3 through C5-9, and data gaps associated with lateral and vertical delineation are discussed in Section 6.0 of this sub-appendix.

5.2 Waste Characterization Parameters

Only partial waste characterization data are available to characterize the soil and other materials to be potentially removed for remedial action and disposed in an offsite permitted facility. While none of the soils or other materials is considered ignitable, corrosive, or reactive, data are lacking to complete the evaluation of the toxicity characteristic. Total chemical concentrations are available to characterize the soil, certain debris, and white powder material relative to California Title 22 total threshold limit concentrations (TTLCs). The maximum concentrations of these metals for each of the units were compared to the TTLCs, and none of the metals exceeded the TTLC, as shown in Table C5-18. The maximum detected concentrations were also compared to the soluble threshold limit concentrations (STLCs), and concentrations of barium and total chromium in AOC 11 exceeded 10 times the STLC one or more times, as shown in Table C5-18. In addition, total chromium also exceeded 20 times the toxicity characteristic leaching procedure (TCLP), as indicated in

Table C5-18. Because these metals have the potential to exceed STLC or TCLP thresholds, additional leachability testing for waste characterization purposes may be required if soil excavation and offsite disposal is chosen as a remedy. For the purposes of supporting the CMS/FS, the lack of STLC or TCLP analysis is not considered a data gap, for the existing total concentrations are sufficient for the purposes of evaluating various remedial alternatives. Additional data regarding potential COPC/COPEC leachability include SPLP analysis for total and hexavalent chromium, as shown in Table C5-2. SPLP analysis was conducted only for soil samples (no white powder or debris samples were tested using SPLP).

5.3 Soil Physical Properties

Soil physical property data collected during the Part A Phase 1 soil investigation was limited to grain size analysis only. Specific soil physical properties data (i.e., porosity, grain size, density, organic carbon content) are required to support the CMS/FS, as described in Table 6-1 in the Data Gaps Report. Additional soil physical parameter data are needed to support the CMS/FS.

5.4 Surface and Subsurface Features

While there is extensive information regarding surface and subsurface features at AOC 11, additional information may be required once areas requiring remediation have been defined. Nearby roads and road structures, vegetation, and the location of bedrock are known for AOC 11. However, subsurface utilities, including gas transmission pipelines and any culverts or other features, may have to be more precisely defined to evaluate the feasibility and cost of certain remedial alternatives and to prepare construction specifications.

5.5 Volumes of White Powder and Debris

Mapping may be required to assess the extent of debris in New Investigation Areas 1 and 2, as well as the extent of the white powder on the upper slope of AOC 11 near AOC 11 e.

6.0 Summary of Data Gaps and Proposed Phase 2 Soil Sample Locations to Fill Identified Gaps

Based on the Part A DQOs, data gaps were identified for three of the four decisions and are summarized below by decisions:

- **Decision 1 (Nature and Extent)**. The following data gaps were identified to resolve this decision:
  - Data Gap #1 – Lateral and vertical extent of contamination within AOC 11c.
  - Data Gap #2 – Lateral extent of contamination upslope of AOC 11c and AOC 11e.
  - Data Gap #3 – Lateral and vertical extent of contamination within AOC 11e.
  - Data Gap #4 – Nature and extent of contamination associated with New Investigation Areas 1 and 2, the newly identified burn area (near the location of the

current decontamination pad and Transwestern Meter Station), and the white powder area (upslope of AOC 11e).

- **Decision 2 (Data Sufficient to Estimate Representative Exposure Point Concentrations)**. No data gap was identified for this decision.
- **Decision 3 (Potential Threat to Groundwater from Residual Soil Concentrations)**. The following data gap was identified to resolve this decision:
  - Data gap #5 – Vertical extent of hexavalent chromium contamination in AOC 11a, AOC 11C, and AOC 11e to support refinement of the vadose leaching zone model.
- **Decision 4 (Data Sufficient to Estimate Soil Properties and Contaminant Distribution in Support of the CMS/FS).** The following data gap was identified to resolve this decision**:**
  - Data gap #6 – Additional soil physical parameter information to support the CMS/FS.
  - Data gap #7 – Volume and extent of debris in New Investigation Areas 1 and 2, and volume and extent of white powder material on the upper slope of AOC 11, if applicable.

Table C5-19 shows the proposed sample location IDs, sample depths, rationale for each location, and analytes, and proposed locations are shown in Figure C5-11. The proposed Phase 2 sample locations are needed to fill quantitative data gaps, meet agency requirements, and further progress toward decision-making for soil remediation.

6.1 Access Restrictions

The following access restrictions apply and may impact soil sampling in AOC 11:

- Several underground natural gas transmission lines cross AOC 11. Portions of these lines are buried fewer than 6 inches below the ground surface and are above the ground surface in some of the lower-lying areas of this AOC. Sampling cannot occur within 10 feet of these lines and crossing these lines with heavy equipment is restricted.
- Remnants of two former check berms are located in the Northeast Ravine. The check berm associated with area AOC 11c was breached during the 2008 Part A Phase 1 sampling event to allow drilling equipment to access the upper areas of the AOC. Only minor grading occurred at the other former check berm, which is associated with area AOC 11e. Several proposed Phase 2 sample locations are proposed in the upper areas of the AOC. Additional modification of these check berms may be necessary to access these Phase 2 sample locations.

TABLE C5-3
Sample Results: Metals
AOC 11 - Topographic Low Area
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

[1] Interim screening level is background value. If background value is not available then the lesser of the DTSC residential CHHSL or the ecological comparison value is used. If CHHSL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

[1] For VOCs, interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used. For TPHs, interim screening level is the Regional Water Quality Control Board environmental screening level.

[1] Interim screening level is DTSC residential CHHSL. If CHHSL is not available, the USEPA residential regional screening level is used. If an ecological comparison value has been calculated, then the lowest between the ecological comparison value or the CHHSL/regional screening level is used.

TABLE C5-9

Constitiuent Concentrations in Soil Compared to Screening Values
AOC 11 - Topographic Low Area
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

---

Notes:

[1] CH2M HILL. 2009. "Final Soil Background Technical Memorandum at Pacific Gas and Electric Company Topock Compressor Station, Needles, California." May.

[2] ARCADIS. 2008. "Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil." May 28. ARCADIS. 2009. "Topock Compression Station - Final Technical Memorandum 4: Ecological Comparison Values for Additional Detected Chemicals in Soil" July 1

[3] Residential screening level - residential DTSC CHHSL. If the residential DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[4] Water Board. 2008. "Screening For Environmental Concerns at Sites With Contaminated Soil and Groundwater" (Table K-1). May 27.

[5] Commercial screening level - commercial DTSC CHHSL. If the commercial DTSC CHHSL is not established, the USEPA regional screening level is used. (PCBs are an exception to this rule since their final screening levels are equal to the EPA regional screening levels).

[6] Interim screening level is equal to the appropriate background value, if a background value is not available then the lesser of the soil ecological comparison values and DTSC CHHSL is used, if the DTSC CHHSL is not available, the USEPA regional screening level is used.

[7] Number of exceedences are the number of detections exceeding the background threshold value (BTV).

[8] Number of exceedences are the number of detections that are equal to or exceeds the screening level (ecological comparison value, residential reporting limit, commercial reporting limit or interim screening level) or otherwise noted

* Number of exceedances are calculated using background threshold value because it is greater than the respective screening level.

‡ Maxiumum Reporting Limit greater than or equal to the interim screening level

USEPA regional screening level - USEPA. 2009. "Regional Screening Levels for Chemical Contaminants at Superfund Sites." http://epaprgs.ornl.govchemicals/index.shtml. December.

CHHSL - California EPA, Office of Environmental Health Hazard Assessment. 2005. "Human Exposure Based Screening Numbers Developed to Aid Estimation of Cleanup Costs for Contaminated Soil." November 2004 (January 2005 Revision). January.

TABLE C5-11

Decision 2 Data Gaps Summary AOC 11
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

	Adequate EPC?		Maximum Detected	> HHCV or Background as Applicable? [1]	> ECV or Background as Applicable? [1]	Proposed	
Compound/Depth	Y or N	Det/# results	Value	Y or N	Y or N	Sample ID	Notes
Metals							
Arsenic				**11 mg/kg (bckg)**	**11.4 mg/kg**		
0-0.5 ft bgs	Y	19 of 19	9.5 mg/kg	N	N	None	Compound exceeds HHCV and ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	13 mg/kg	Y	Y		
0-6 ft bgs	Y	56 of 56	13 mg/kg	Y	Y		
0-10 ft bgs	Y	74 of 74	13 mg/kg	Y	NA		
Barium				**5200 mg/kg**	**410 mg/kg (bckg)**		
0-0.5 ft bgs	Y	19 of 19	310 mg/kg	N	N	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	370 mg/kg	N	N		
0-6 ft bgs	Y	56 of 56	1300 mg/kg	N	Y		
0-10 ft bgs	Y	74 of 74	1300 mg/kg	N	NA		
Chromium-Total				**280 mg/kg**	**39.8 mg/kg (bckg)**		
0-0.5 ft bgs	Y	19 of 19	43 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	130 mg/kg	N	Y		
0-6 ft bgs	Y	56 of 56	130 mg/kg	N	Y		
0-10 ft bgs	Y	74 of 74	130 mg/kg	N	NA		
Copper				**3000 mg/kg**	**20.6 mg/kg**		
0-0.5 ft bgs	Y	19 of 19	20 mg/kg	N	N	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	41 mg/kg	N	Y		
0-6 ft bgs	Y	56 of 56	41 mg/kg	N	Y		
0-10 ft bgs	Y	74 of 74	41 mg/kg	N	NA		
Lead				**80 mg/kg**	**8.39 mg/kg (bckg)**		
0-0.5 ft bgs	Y	19 of 19	45 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	38 of 38	45 mg/kg	N	Y		
0-6 ft bgs	Y	56 of 56	45 mg/kg	N	Y		
0-10 ft bgs	Y	74 of 74	45 mg/kg	N	NA		
Molybdenum				**380 mg/kg**	**2.25 mg/kg**		
0-0.5 ft bgs	N	3 of 19	2.7 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC with the exception of the 0-0.5 ft bgs exposure interval. While this is insufficient to calculate an EPC using ProUCL for this exposure interval, the maximum concentration is low (i.e., does not exceed two times the lowest comparison value). Therefore, using the maximum result as the EPC is not expected to significantly impact the results of the risk assessment.
0-3 ft bgs	Y	9 of 38	2.9 mg/kg	N	Y		
0-6 ft bgs	Y	13 of 56	2.9 mg/kg	N	Y		
0-10 ft bgs	Y	17 of 74	2.9 mg/kg	N	NA		

TABLE C5-11

Decision 2 Data Gaps Summary AOC 11
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth	Adequate EPC?		Maximum Detected Value	> HHCV or Background as Applicable? [1]	> ECV or Background as Applicable? [1]	Proposed Sample ID	Notes
	Y or N	Det/# results		Y or N	Y or N		
Selenium				**380 mg/kg**	**1.47 mg/kg (bckg)**		
0-0.5 ft bgs	NA	0 of 19	NA mg/kg	N	N	None	Compound exceeds ECV. Although there are insufficient detections to allow calculation of a 95% UCL on the mean, additional data collection is not expected to yield sufficient detections to strongly influence the EPC because additional sampling would likely result in additional non-detect values.
0-3 ft bgs	NA	0 of 38	NA mg/kg	N	N		
0-6 ft bgs	N	2 of 56	3.2 mg/kg	N	Y		
0-10 ft bgs	N	2 of 74	3.2 mg/kg	N	NA		
Zinc				**23000 mg/kg**	**58 mg/kg (bckg)**		
0-0.5 ft bgs	Y	19 of 19	160 mg/kg	N	Y	None	Compound exceeds ECV. Existing data adequate for EPC.

0-10 ft bgs	Y	7 of 7	20000 mg/kg	N	NA		
Manganese				**1800 mg/kg**	**402 mg/kg (bckg)**		
0-0.5 ft bgs	Y	7 of 7	440 mg/kg	N	Y	None	Compound exceeds ECV and background. Existing data adequate for EPC.
0-3 ft bgs	Y	7 of 7	440 mg/kg	N	Y		
0-6 ft bgs	Y	7 of 7	440 mg/kg	N	Y		
0-10 ft bgs	Y	7 of 7	440 mg/kg	N	NA		
Potassium				**4400 mg/kg (bckg)**	**4400 mg/kg (bckg)**		
0-0.5 ft bgs	Y	7 of 7	5300 mg/kg	Y	Y	None	Compound exceeds HHCV and ECV (both background). Existing data adequate for EPC.
0-3 ft bgs	Y	7 of 7	5300 mg/kg	Y	Y		
0-6 ft bgs	Y	7 of 7	5300 mg/kg	Y	Y		
0-10 ft bgs	Y	7 of 7	5300 mg/kg	Y	NA		
Polynuclear Aromatic Hydrocarbons							
PAHs (BaP TEQ)				**38 µg/kg**	**NA**		
0-0.5 ft bgs	Y	19 of 19	510 µg/kg	Y	NA	None	Compound exceeds HHCV. Existing data adequate for EPC.
0-3 ft bgs	Y	30 of 38	510 µg/kg	Y	NA		
0-6 ft bgs	Y	38 of 56	510 µg/kg	Y	NA		
0-10 ft bgs	Y	42 of 74	510 µg/kg	Y	NA		

TABLE C5-11
Decision 2 Data Gaps Summary AOC 11
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report,
Pacific Gas and Electric Company Topock Compressor Station, Needles, California

Compound/Depth	Adequate EPC? Y or N	Adequate EPC? Det/# results	Maximum Detected Value	> HHCV or Background as Applicable? [1] Y or N	> ECV or Background as Applicable? [1] Y or N	Proposed Sample ID	Notes
HMW PAHs				**NA**	**1160 µg/kg**		
0-0.5 ft bgs	Y	19 of 19	4900 µg/kg	NA	Y	None	Compound exceeds ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	30 of 38	4900 µg/kg	NA	Y		
0-6 ft bgs	Y	38 of 56	4900 µg/kg	NA	Y		
Polychlorinated Biphenyls							
Total PCBs				**220 µg/kg**	**204 µg/kg**		
0-0.5 ft bgs	Y	5 of 9	430 µg/kg	Y	Y	None	Compound exceeds HHCV and ECV. Existing data adequate for EPC.
0-3 ft bgs	Y	7 of 14	430 µg/kg	Y	Y		
0-6 ft bgs	Y	9 of 17	430 µg/kg	Y	Y		
0-10 ft bgs	Y	9 of 20	430 µg/kg	Y	NA		
Pesticides							
DDT-R				**1600 µg/kg**	**2.1 µg/kg**		
0-0.5 ft bgs	N	1 of 7	6.1 µg/kg	N	Y	None	Compound exceeds ECV and existing data not adequate to calculate 95% UCL. DDE was detected in 1 of 7 samples; DDT and DDD were not detected. Additional sampling is not expected to significantly change the results (NDs are likely and the EPC would still be the maximum detected value).
0-3 ft bgs	N	1 of 7	6.1 µg/kg	N	Y		
0-6 ft bgs	N	1 of 7	6.1 µg/kg	N	Y		
0-10 ft bgs	N	1 of 7	6.1 µg/kg	N	NA		
Dieldrin				**35 µg/kg**	**5 µg/kg**		
0-0.5 ft bgs	N	1 of 7	6.7 µg/kg	N	Y	None	Compound exceeds ECV and existing data not adequate to calculate 95% UCL. The magnitude of the detection is low relative to the ECV. Additional sampling is not expected to significantly change the results (NDs are likely and the EPC would still be the maximum detected value).
0-3 ft bgs	N	1 of 7	6.7 µg/kg	N	Y		
0-6 ft bgs	N	1 of 7	6.7 µg/kg	N	Y		
0-10 ft bgs	N	1 of 7	6.7 µg/kg	N	NA		

Footnotes:

[1] The higher value of either the HHCV/ECV or background was selected as the screening criteria and are included in these columns for the respective compound in **BOLDED BLUE FONT**. Values based on background are indicated with "(bckg)" next to the value.

Acronyms and Abbreviations:
AOC - area of concern
BaP TEQ - benzo(a)pyrene toxic equivalents
ECV - ecological comparison values
EPC - exposure point concentration

TABLE C5-19
Proposed Phase 2 Sampling Locations at AOC 11
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
PG&E Topock Compressor Station, Needles, California

Location ID	Depths (ft bgs)	Description/Rationale	Analytes	Proposed Collection Method[a]
AOC11c-3	14, 19, 29, 39, 49, 59, and 69 (to groundwater)	To resolve Data Gaps #1, #5, and #6 - Define vertical extent at previous sample location AOC11c-SS2. Collect data to assess current threat to groundwater and support CMS/FS	Hexavalent chromium, Title 22 metals, PCBs soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Rotosonic
AOC11c-4	0, 2, 5, 9 and 14, 19	To resolve Data Gaps #1 and #5 - Define lateral and vertical extent in AOC11c. Collect data to assess current threat to groundwater.	Hexavalent chromium, Title 22 metals, PAHs, PCBs	Rotosonic
AOC11e-3	0, 2, 5, 9, and 14	To resolve Data Gap #2 - Define lateral and vertical extent upslope of AOC 11e (may not be technically feasible to get to depth)	Hexavalent chromium, Title 22 metals, PAHs, PCBs	Backhoe
AOC11e-4	0, 2, 5, 9, and 14	To resolve Data Gaps #2 and #6- Define lateral and vertical extent upslope of AOC 11e (may not be technically feasible to get to depth)) and support CMS/FS.	Hexavalent chromium, Title 22 metals, PAHs, PCBs; soil physical parameters (Atterberg limits, relative compaction, alkalinity, cation exchange, capacity, and particle size distribution) – three samples from boring	Backhoe
AOC11e-5	14, 19, 29, 39, 49, 59, and 69 (to groundwater)	To resolve Data Gaps #3 and #5 - Define vertical extent in AOC 11e. Refine vadose zone leaching model.	Hexavalent chromium, Title 22 metals, PAHs, PCBs	Backhoe
AOC11e-6	0	To resolve Data Gaps #4 and #7– Assess white powder material in newly identified white powder area	Title 22 metals, hexavalent chromium, general chemistry, pH	Hand tools
AOC11-1	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs	Rotosonic
AOC11-2	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area (burn area)	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs, dioxins and furans	Rotosonic
AOC11-3	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area (burn area)	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs , dioxins and furans	Rotosonic
AOC11-4	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs, dioxins and furans	Backhoe
AOC11-5	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs, dioxins and furans	Backhoe

TABLE C5-19
Proposed Phase 2 Sampling Locations at AOC 11
Soil Investigation Part A Phase 1 Data Gaps Evaluation Report
PG&E Topock Compressor Station, Needles, California

Location ID	**Depths (ft bgs)**	**Description/Rationale**	**Analytes**	**Proposed Collection Method**[a]
AOC11-6	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs	Rotosonic
AOC11-7	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs	Rotosonic drill rig
AOC11-8 (contingent)	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area. Contingent based on results of AOC11-6 and AOC 11-7.	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs	Hand tools
AOC11-9 (contingent)	0, 2, 5, and 9	To resolve Data Gaps #4 and #7–Assess newly identified area. Contingent based on results of AOC11-6 and AOC 11-	Title 22 Metals, hexavalent chromium, pH, TPH, SVOCs, PAHs	Hand tools

Notes:

[a] Proposed collection methods listed on this table are based on experience and knowledge of the site; actual collection method will be chosen in the field based on field conditions and site access restrictions.

SVOC = semivolatile organic compound.

2. mg/kg = milligrams per kilogram
3. ft bgs = feet below ground surface
4. Results greater than Background (8.39 mg/kg) are shown in BLUE.
5. Results greater than or equal to the California Department of Toxic Substances Control Residential California Human Health Screening Level (150 mg/kg) are shown in ORANGE.
6. J = Estimated Result.
7. Ecological Comparison (0.0166 mg/kg) is below background value; therefore, the screening level is set at the background value.
9. Topographic contours shown at at 2 foot intervals.

LEGEND

- 🟡 Proposed Phase 2 Sample Location
- ● Soil Boring
- — Property Boundary
- – – Caltrans ROW
- ⁙ White Powder
- 🟩 AOC 11 Boundary
- 🟧 Potential New Investigation Area
- ▨ Potential Burning Related Location
- — Transwestern Pipeline
- — Mojave Pipeline
- — PG&E Pipeline
- — SoCal Gas Pipeline
- ⋯ Approximate Location of Stormwater Piping Below Ground
- — Approximate Location of Stormwater Piping Above Ground

SSB-7 (08) — Sample Location Installation Date
20 [1] — Sample Beginning Depth (ft bgs) — Soil Concentration (mg/kg)

Notes:
1. ND = Not Detected (Reporting Limit in parentheses)
2. mg/kg = milligrams per kilogram
3. ft bgs = feet below ground surface
4. Results greater than Background (1.37 mg/kg) are shown in BLUE.
5. Results greater than or equal to the Ecological Comparison Value (2.25 mg/kg) are shown in PURPLE.
6. Results greater than or equal to the California Department of Toxic Substances Control Residential California Human Health Screening Level (380 mg/kg) are shown in ORANGE.
7. J = Estimated Result.
8. * = Laboratory reporting limit exceeds screening levels.
9. Topographic contours shown are in 2 foot intervals.
