- Once recovery has reached 80%, or 48 hours have elapsed (whichever comes first), a bailer can be used for sample collection. Collect samples for analyses according to PST. Prepare sample containers and collect gas-sensitive analytes first. The preferred collection order will be volatile organic compounds (VOCs), semi-volatile organic compound (SVOCs), metals (including hexavalent chromium [Cr(VI)] and total chromium [Cr(T)]), then general chemistry (cations, anions, stable isotopes).
- If an insufficient volume of water is available to fill all of the sample containers, first contact laboratory personnel to determine the minimum allowable volumes needed for the required analyses. *(Talk to FTM as the FTM may have already contact lab personnel and may have the instructions for you.)* Then verify the critical analyte list with the PM or the FTM and prioritize the sample collection to obtain the critical analytes for the main contaminants of concern first. Continue collecting samples until all samples have been collected, or the groundwater supply is exhausted. Unfiltered samples are to be filled by transferring water directly from the bailer to the sample container.
- For filtered samples, attach a 0.45 micron in-line filter to the bailer and allow approximately 200 mls of sample to pass through the filter before beginning sample collection in accordance with SOP-A6 *Field filtration*. If gravity flow is insufficient to filter the sample, use a pressurized bailer and filter for sample filtration.
- When sample collection is complete, record sample information, final WL, and purge volume data in MIST and on the field sampling log.
- If well was equipped with a transducer, replace the transducer in exactly the same configuration in which it was found and according to SOP-C1, *Solinst Pressure Transducers*.

- Close and secure well protection lid.
- Follow applicable SOPs, the O&M Manual and Procedures Manual for sample handing and management, equipment decontamination, and IDW management (O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

SOP-A2

Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells Modified Well-Volume Method Standard Operating Procedures for PG&E Topock Program

---

This standard operating procedure (SOP) addresses the procedures and equipment to be used for purging and sampling all groundwater monitoring wells at the Topock site with 1-inch casing diameters. This SOP will be used for sampling groundwater monitoring wells using dedicated tubing and a peristaltic pump or a mini-bladder pump. A well-volume based purging and sampling method will be used for such wells.

REQUIRED DOCUMENTS:

- Event-specific planned sample table (PST).
- Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
- Operation and Maintenance Manual (O&M Manual), and Quality Assurance Project Plan (QAPP) (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan), as required during the O&M phase.
- Topock Program Health and Safety Plan (HSP)
- Applicable SOPs may include:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A10, *Decontamination of Water Sampling Equipment*
  - SOP-A11, *Total Depth Measurements*
  - SOP-A12, *Field Water Quality Measurements for Grab Samples*
  - SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
  - SOP-A14, *Pore Water Sampling*
  - SOP-A16, *Access Routes*

  - SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
  - SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
  - SOP-A23, *Sample Handling and Custody*
  - SOP-C1, *Solinst Pressure Transducers*
- Well construction logs/specifications
- Mobile Integrated Sample Tracking (MIST) handheld database
- Previous sampling logs or tabular historic field data
- Current site access map
- Blank sampling logs, maps, sample labels, chains of custody (COC's), and the designated groundwater sampling field notebook

REQUIRED EQUIPMENT:

- 2 or more YSI-556 water quality (WQ) instruments with flow through cells, or equivalent.
- Hach 2100P turbidimeter or equivalent.
- 200 foot Water level indicator (WLI).
- Trimble Rugged Reader hand held instrument for MIST data collection.
- 30 gallon purge water tank.
- Decontamination spray bottles
- Utility vehicles (UTVs) as necessary.
- 12 volt peristaltic pump or mini-bladder pump.
- 12 volt power source.

PREPARATION & SETUP:

- Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, O&M Manual, HSP, and groundwater sampling supplies and equipment check list. (NOTE: the PST should also be reviewed for required "non-analytical event activities" such as water level measurements or other data collection to be performed in association with the groundwater sampling event).
- Acquire the existing field logbook for groundwater sampling and initiate entries.
- Inspect all equipment and verify that the field WQ meters have been calibrated prior to use according to the manufacturer's instructions and SOP-A9, *Calibration of Field Instruments*.

- Inventory sample bottles, build sample sets for the required analytes at each sample location, ensure a sufficient supply of lab de-ionized water for equipment blanks, and confirm the lab courier schedule.
- Field-check sampling equipment and supplies: WLI, WQ meters, flow-through cell, peristaltic pump or mini-bladder pump, power supply, pump discharge/sampling tubing, N-dex gloves, de-ionized water sprayers, 5 gallon buckets, paper towels, 0.45 micron in-line filters, etc.
- Field-check and setup sampling equipment: WLI, WQ meters, flow-through cell, pump and power supply, pump discharge/sampling tubing, etc. Install dedicated tubing and connect to peristaltic pump. Connect peristaltic pump or mini-bladder pump to 12 volt power supply.

FIELD PROCEDURES:

- **Prior to opening any monitor well, remove all pens, lighters, calculators, or any other loose items from vest pockets, or from any other location where they could fall into the well.**
- Upon arrival at the monitoring well, at least 2 members of the sampling team must confirm the well ID. Wells should be clearly marked on the well monument. If the well cannot be positively identified by the marking, measure total depth of the well and compare to the well installation details to confirm the correct location.
- Place spill containment according to SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling.*
- Open the protective casing lid and, ***prior to moving it***, note the exact configuration of the transducer installation if present. Measure static water level (WL) according to SOP-A7, *Water Level Measurements,* moving the transducer if necessary, and record WL value in MIST on the sampling log.
- If the well is equipped with a transducer, remove the transducer from the well according to SOP-C1, *Solinst Pressure Transducers*.
- Collect daily equipment blanks and duplicate samples as required by the PST and instructed by the field team leader.

PURGING AND SAMPLING PROCEDURES:

- Prepare the groundwater sampling log. Use the static water level determined above and the total depth provided on the field data sheet and in the PST to calculate the volume of one casing of standing water in the well. Calculate 3 casing volumes for the minimum required purge amount, and record on purge log.
- Prior to purging, evaluate previous purge rates, amount of drawdown, and purge volume from previous sampling records and historical data tables (Appendix B of *Monitoring Plan for Groundwater and Surface Water Monitoring Program*). If the well has not been previously sampled, estimate the expected purge parameters using previous sampling information from nearby wells.

- Install the dedicated tubing if available, or use new tubing as necessary. Connect the tubing to the peristaltic pump or mini-bladder pump, check that all fittings are tight, and start purging the well. Check for leaks. Measure WL and calculate the purge rate immediately and adjust if necessary. Purge rate will be measured by using the fill-time of a graduated container. The well specific purge rate and pump setting should be available on the previous purge form.
- Allow the flow through cell to fill and field parameters to stabilize, then start recording field indicator parameters on the sampling sheet and in MIST.
- Continue purging, measuring WL and field indicator parameters periodically (time, pH, conductivity, turbidity, dissolved oxygen, temperature, salinity, TDS, ORP, appearance, and any odors present). Time the readings such that there are a minimum of 5 sets of data collected over the course of the full purge.
- If significant drawdown is observed, or turbidity increases dramatically, decrease the purge rate and measure/record new purge rate. Significant drawdown is considered to be 5 percent of the total height of the water column or to the top of screen. Record time for all measurements collected. Note and provide qualifying remarks if parameter readings are anomalous or unstable due to instrument problems.
- During the purge, compare the field parameters to historical purge data. If the parameters are significantly different (greater than 50% difference for SC, pH, and/or ORP) confirm the ID of the well. If the well ID is confirmed by 2 crew members, and the readings continue to be significantly different than prior readings, set up a second WQ instrument in series to confirm readings. If the anomalous readings are confirmed by the second instrument, contact the field coordinator to resolve the issue. If the second WQ instrument produces readings that are comparable to historic values, note an instrument change and use the second instrument's readings.
- Continue purging until ***3-casing volumes*** have been removed ***and*** field parameters stabilize. Indicator parameters are considered stabilized when 3 consecutive readings made several minutes apart fall within the following EPA stabilization criteria:

-	pH	+/- 0.1 pH units
-	Specific conductance	+/- 3%
-	ORP	+/- 10 millivolts
-	Turbidity	10 NTU units or less unless other parameters have stabilized during an extended purge and turbidity is trending flat if still over 10 NTU units. The target turbidity goal (but not a hard criterion) is 5 to 10 NTUs.
-	Dissolved oxygen	+/- 0.3 mg/L
-	Temperature	+/- 2^{o} Celsius

- When the requirements above have been satisfied and the purge cycle is complete, disconnect the flow through cell and prepare to collect samples directly from the pump discharge tubing for analyses according to event-specific PST. For all samples, decrease the discharge rate as necessary to reduce water turbulence at the pump discharge point.

Prepare sample containers and collect gas-sensitive analytes first. The preferred collection order will be volatile organic compounds (VOCs), semi-volatile organic compound (SVOCs), metals (including hexavalent chromium [Cr(VI)] and total chromium [Cr(T)]; see SOP-A6), then general chemistry (cations, anions, stable isotopes).

- For filtered samples, attach a 0.45 micron in-line filter to the pump discharge and allow approx. 500 mls of sample to pass through the filter before beginning sample collection in accordance with SOP A6, *Field filtration*.
- When sample collection is complete, record sample information, final WL, and purge volume data in MIST and on the field sampling log.
- If previously installed, remove the pump from the well, detach the dedicated tubing and carefully drain any residual water to the purge water tank. Fold both ends of the purge tubing and secure with wire ties as a further deterrent to leakage. Store the dedicated tubing in a sealed, labeled trash bag. Decontaminate the pump according to SOP-A10, *Decontamination of Water Sampling Equipment.*
- If well was equipped with a transducer, replace the transducer in exactly the same configuration in which it was found and according to SOP-C1, *Solinst Pressure Transducers*.
- Close and secure well protection lid.
- Follow applicable SOPs in the Procedures Manual and O&M Manual for sample handling and management, equipment decontamination, and investigation-derived waste (IDW) management (O&M Manual, Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

LOW VOLUME AND POOR RECOVERY WELLS:

Some groundwater monitoring wells under the GMP may exhibit slow or poor recovery upon purging. These groundwater monitoring wells may not recover sufficiently during purging and run completely dry without an opportunity to collect the required series of groundwater stabilization parameters, or run dry prior to sampling. The following procedures should be followed for collection representative groundwater samples from wells that go dry during purging activities in preparation for groundwater sampling.

PREPARATION & SETUP:

Follow steps above.

PURGING AND SAMPLING PROCEDURES FOR LOW RECOVERY WELLS:

- Prepare the groundwater sampling log. Use the static water level determined above and the total depth provided on the field data sheet and in the PST to calculate the volume of one casing of standing water in the well.
- Calculate 3 casing volumes for the minimum required purge amount, and record on purge log.

- Evaluate previous purge rates, amount of drawdown, stability of field parameters, and total purge volume prior to sample collection from previous sampling records and historical data tables (Appendix B of *Monitoring Plan for Groundwater and Surface Water Monitoring Program*). If the well has not been previously sampled, estimate the expected purge rate using previous sampling information from nearby wells.
- Connect the dedicated purge tubing if available, or use new tubing if necessary. Install the pump within the well screen or to the previously determined depth and start the purge. Monitor drawdown, and calculate/set the purge rate.
- Continue purging, measuring WL and field indicator parameters periodically (time, pH, conductivity, turbidity, dissolved oxygen, temperature, salinity, TDS, ORP, and any odors present). Space the readings such that there are a minimum of 5 sets of data collected over the course of the available purge volume.
- During the purge, compare the field parameters to previous purge data. If the parameters are significantly different (greater than 50% difference for SC, pH, and/or ORP) confirm the ID of the well. If the well ID is confirmed by 2 crew members, and the readings continue to be significantly different than prior readings, set up a second WQ instrument in series to confirm readings. If the anomalous readings are confirmed by the second instrument, contact the field coordinator to resolve the issue. If the second WQ instrument produces readings that are comparable to historic values, note an instrument change and use the second instrument's readings.
- Continue purging until ***3-casing volumes*** have been removed ***and*** field parameters stabilize, or until the well purges dry. If 3 casing volumes are removed, sample as described above. If the well runs dry, continue as instructed below.
- If previously installed, remove the pump from the well and decontaminate according to SOP-A10, *Decontamination of Water Sampling Equipment.* The pump may also be left in place to facilitate subsequent purging and sampling.
- Record the final water level, time, the volume of water discharged and the elapsed time for the dewatering of the well.
- Allow the well to recharge to 80 percent of the original height of the water column. Ideally, this should be within 24 hours of the monitoring well being purged dry. The recovery period to achieve 80 percent of the height of the water column could take longer than 24 hours in some instances (MW-48).
- Once recovery has reached 80%, or 48 hours have elapsed (whichever comes first), a bailer can be used for sample collection. Collect samples for analyses according to PST. Prepare sample containers and collect gas-sensitive analytes first. The preferred collection order will be volatile organic compounds (VOCs), semi-volatile organic compound (SVOCs), metals (including hexavalent chromium [Cr(VI)] and total chromium [Cr(T)]), then general chemistry (cations, anions, stable isotopes).
- If an insufficient volume of water is available to fill all of the sample containers, first contact laboratory personnel to determine the minimum allowable volumes needed for the required analyses, then verify the critical analyte list with the PM or the FTM and prioritize the sample collection to obtain the critical analytes for the main contaminants

of concern first. Continue collecting samples until all samples have been collected, or the groundwater supply is exhausted. Unfiltered samples are to be filled by transferring water directly from the bailer to the sample container.

- For filtered samples, attach a 0.45 micron in-line filter to the bailer and allow approx. 200 mls of sample to pass through the filter before beginning sample collection in accordance with SOP-A6, *Field filtration*. If gravity flow is insufficient to filter the sample, use a pressurized bailer and filter for sample filtration.
- When sample collection is complete, record sample information, final WL, and purge volume data in MIST and on the field sampling log.
- If well was equipped with a transducer, replace the transducer in exactly the same configuration in which it was found and according to SOP-C1, *Solinst Pressure Transducers*.
- Close and secure well protection lid.
- Follow applicable SOPs, the Procedures Manual, and the O&M Manual for sample handing and management, equipment decontamination, and IDW management (O&M Manual, Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

SOP-A3

Purging and Sampling of Active and Inactive Water Supply Wells Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for purging and sampling active and inactive water supply wells in the vicinity of the Topock site. This procedure also applies to the collection of water quality samples from long-screen extraction, injection, and test wells. Active and inactive water supply wells with functional dedicated pumps and a sampling port will be sampled directly from the sampling port. Inactive supply wells without functional pumps will be sampled using a temporary submersible pump following the well-volume sampling procedure.

REQUIRED DOCUMENTS:

- Event-specific planned sample table (PST).
- Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
- Operation and Maintenance Manual (O&M Manual), and Quality Assurance Project Plan (QAPP) and Addendum to the QAPP (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan), as required during the O&M phase.
- Topock Program Health and Safety Plan (HSP)
- Applicable SOPs may include:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A10, *Decontamination of Water Sampling Equipment*
  - SOP-A11, *Total Depth Measurements*
  - SOP-A12, *Field Water Quality Measurements for Grab Samples*
  - SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
  - SOP-A14, *Pore Water Sampling*
  - SOP-A16, *Access Routes*

  - SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
  - SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
  - SOP-A23, *Sample Handling and Custody*
  - SOP-C1, *Solinst Pressure Transducers*
- Well construction logs/specifications
- Mobile Integrated Sample Tracking (MIST) handheld database
- Previous sampling logs or tabular historic field data
- Current site access map
- Blank sampling logs, maps, sample labels, chains of custody (COCs), and the designated groundwater sampling field notebook

REQUIRED EQUIPMENT:

- 2 or more YSI-556 water quality (WQ) instruments with flow through cells, or equivalent.
- Hach 2100P turbidimeter or equivalent.
- 200 foot Water level indicator (WLI).
- Trimble Rugged Reader hand held instrument for MIST data collection.
- 200 gallon capacity purge tanks (2).
- Utility vehicles (UTV's) as necessary.
- Back-up 2 inch pump and controller.
- Honda 2000 watt generator or alternate power source.

PREPARATION AND SETUP:

- Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, O&M Manual, QAPP and the Addendum to the QAPP, HSP, and groundwater sampling supplies and equipment check list.
- Acquire the existing field logbook for surface water sampling and initiate entries.
- Inspect all equipment and verify that the field WQ meters have been calibrated prior to use according to the manufacturer's instructions and SOP-A9, *Calibration of Field Instruments*.
- Inventory sample bottles, build sample sets for the required analytes at each sample location, ensure a sufficient supply of lab de-ionized water for equipment blanks, and confirm the lab courier schedule.
- Field-check sampling equipment and supplies: WLI, WQ meters, flow-through cell, pump controller, power supply, pump discharge/sampling tubing, N-dex gloves, D.I water sprayers, paper towels, etc.

PURGING AND SAMPLING PROCEDURES FOR *ACTIVE* WATER SUPPLY WELLS:

- **Prior to opening any well, remove all pens, lighters, calculators, or any other loose items from vest pockets, or from any other location where they could fall into the well.**
- Upon arrival at the well, at least 2 members of the sampling team must confirm the well ID. If the well cannot be clearly identified by the marking, measure total depth of the well and compare to the well installation details to confirm the correct location.
- Access the well and, ***prior to moving it***, note the exact configuration of the transducer installation if present. If the well has been inactive for more than 24 hours, a water level measurement can be taken. Measure static water level (WL) according to SOP-A7, *Water Level Measurements,* moving the transducer if necessary, and record WL value in MIST on the sampling log.
- If the well is equipped with a transducer and transducer removal is required for sampling, follow SOP-C1, *Solinst Pressure Transducers*.
- If it is known that 3-casing volumes have been purged from the well in the last 24-hour period, purging will not be necessary prior to sampling. Connect one end of a new or dedicated piece of LDPE tubing to the pump discharge port and connect the other to the inlet of the flow through cell. If it is not possible to connect the flow-through cell, a clean 5-gallon bucket may be used by filling the bucket with purge water and inserting the instrument probes directly into the bucket. If a bucket is used, turbulence in the bucket should be minimized to the extent possible.
- Carefully open the valve at the sampling port until the desired flow rate is achieved, then allow the flow through cell to fill and the parameters to stabilize before collecting a single set of water quality parameters. Record in MIST and on the field data sheet. Note and provide qualifying remarks if parameter readings are anomalous or unstable due to instrument problems. Purge water should be contained in a portable purge water storage tank. If approved by well owner and the governing regulatory agencies, water may be discharged directly to the ground, as directed by the Field Team Manager (FTM).
- Observations on sample appearance and clarity during purging and at sampling are required! For standardization, use a clear glass jar to collect and record observations of discharge water appearance during purging. Also note characteristics such as any odors associated with the discharge water.
- Compare the field parameters to historical purge data. If the parameters are significantly different (greater than 50% difference for SC, pH, and/or ORP) confirm the ID of the well. If the well ID is confirmed by 2 crew members, and the readings continue to be significantly different than prior readings, set up a second WQ instrument in series to confirm readings. If the anomalous readings are confirmed by the second instrument, contact the field coordinator to resolve the issue. If the second WQ instrument produces readings that are comparable to historic values, note an instrument change and use the second instrument's readings.
- Disconnect the flow through cell and collect samples for analyses according to the PST. Sample containers are to be filled by transferring water directly from the pump discharge or sampling spigot to the appropriate sample container.

- For filtered samples, attach a 0.45 micron in-line filter to the pump discharge and allow approx. 500 mls of sample to pass through the filter before beginning sample collection in accordance with SOP-A6, *Field filtration*.
- When sample collection is complete, record sample information, final WL, and purge volume data on field log. If the pump is equipped with a flow meter, record the flow rate as well.
- If well was equipped with a transducer, replace transducer according to SOP-C1, *Solinst Pressure Transducers*.
- Close and secure well including access gates or fences.
- Follow applicable SOPs, the Procedures Manual, and the O&M Manual for sample handing and management, equipment decontamination, and investigation-derived waste (IDW) management (O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

PURGING AND SAMPLING PROCEDURES FOR *INACTIVE* WATER SUPPLY WELLS:

Inactive water wells may include: (1) wells with functioning dedicated pumps, (2) wells without dedicated pumps, and (3) wells with non-functioning dedicated pumps. A well-pump subcontractor may be required to install temporary pumps for purging wells without pumps and non-functioning dedicated pumps.

- **Prior to opening any monitor well, remove all pens, lighters, calculators, or any other loose items from vest pockets, or from any other location where they could fall into the well.**
- Upon arrival at the well, at least 2 members of the sampling team must confirm the well ID. Wells will be clearly marked on the well monument. If the well cannot be clearly identified by the marking, measure total depth of the well and compare to the well installation details to confirm the correct location.
- Access the well and, ***prior to moving it***, note the exact configuration of the transducer installation if present. If the well has been inactive for more than 24 hours, a water level measurement can be taken. Measure static WL according to SOP-A7, *Water Level Measurements,* moving the transducer if necessary, and record WL value in MIST on the sampling log.
- If the well is equipped with a transducer and transducer removal is required for sampling, follow SOP-C1, *Solinst Pressure Transducers*.
- If the well has had well volumes purged in the last 24 hours, then it is an active well and purging before *sampling may be limited to volume sufficient f*or field parameter measurement.
- If it is determined that 3-casing volumes ***have not*** been purged in the last 24-hours, calculate 3-casing volumes using measured WL depth, casing diameter, and total well depth information. If it is not possible to measure the depth to water or total depth of the well, use well records or prior knowledge to calculate 3-casing volumes.
- Start purging using the functional dedicated equipment, if available. Check for any leaks, monitor drawdown, and calculate/set the purge rate.

- If dedicated equipment is not present or nonfunctional, a portable pump installed by subcontractor may be used for purging and sampling. Install a decontaminated pump at the same intake/sampling depth used in prior events and record intake depth. If the well has not been previously sampled, install the pump with the intake in the middle of the screened interval ,or the midpoint of the saturated interval if the water level is lower than the top of the screen, or at the depth proscribed by the Project Manager or FTM.
- Purge water should be contained in a portable purge water storage tank. If approved by well owner and the governing regulatory agencies, water may be discharged directly to the ground, (at present this is only the case at PM-03 and PM-04 supply wells), as directed by the Field Team Manager.
- Continue purging, measuring WL and field indicator parameters periodically (time, pH, conductivity, turbidity, dissolved oxygen, temperature, salinity, TDS, ORP, and any odors present). Time the readings such that there are a minimum of 5 sets of data collected over the course of the full purge.
- Decrease the purge rate and measure/record new purge rate if significant drawdown is observed or turbidity increases dramatically. Significant drawdown is considered to be 5 percent of the total height of the water column or to the top of screen. Record time for all measurements collected. Note and provide qualifying remarks if parameter readings are anomalous or unstable due to instrument problems.
- During the purge, compare the field parameters to previous purge data. If the parameters are significantly different (greater than 50% difference for SC, pH, and/or ORP) confirm the ID of the well. If the well ID is confirmed by 2 crew members, and the readings continue to be significantly different than prior readings, set up a second WQ instrument in series to confirm readings. If the anomalous readings are confirmed by the second instrument, contact the field coordinator to resolve the issue. If the second WQ instrument produces readings that are comparable to historic values, note an instrument change and use the second instrument's readings.
- Continue purging until ***3-casing volumes*** have been removed ***and*** field parameters stabilize. Indicator parameters are considered stabilized when 3 consecutive readings made several minutes apart fall within the following EPA stabilization criteria:

- pH	+/- 0.1 pH units
- Specific conductance	+/- 3%
- ORP	+/- 10 millivolts
- Turbidity	10% NTU units or less unless other parameters have stabilized during an extended purge and turbidity is trending flat if still over 10 NTU units.
- Dissolved oxygen	+/- 0.3 mg/L
- Temperature	+/- 2^{o} Celsius

- When the requirements above have been satisfied and the purge cycle is complete, disconnect the flow through cell and prepare to collect samples directly from the pump discharge tubing for analyses according to event-specific PST. For all samples, decrease the discharge rate as necessary to reduce water turbulence at the pump discharge point.

Prepare sample containers and collect gas-sensitive analytes first. The preferred collection order will be volatile organic compounds (VOCs), semi-volatile organic compound (SVOCs), metals (including hexavalent chromium [Cr(VI)] and total chromium [Cr(T)]; see SOP-A6), then general chemistry (cations, anions, stable isotopes).

- For filtered samples, attach a 0.45 micron in-line filter to the pump discharge and allow approx. 500 mls of sample to pass through the filter before beginning sample collection in accordance with SOP-A6, *Field filtration*.
- When sample collection is complete, record sample information, final WL, and purge volume data in MIST and on the field sampling log.
- If previously installed, remove the pump from the well and decontaminate according to SOP-A10, *Decontamination of Water Sampling Equipment.*
- If well was equipped with a transducer, replace the transducer in exactly the same configuration in which it was found and according to SOP-C1, *Solinst Pressure Transducers*.
- Close and secure well, including fences and gates.
- Follow applicable SOPs, the Procedures Manual, and O&M Manual for sample handing and management, equipment decontamination, and IDW management (O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

SOP-A4

Depth-Specific River Water Sampling
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for river channel and shoreline surface water sampling at the Topock site. This SOP should be used for depth-specific river channel surface water sampling and single depth shoreline sampling stations on the Colorado River.

REQUIRED DOCUMENTS

1) Event-specific planned sample table (PST) or Mobile Integrated Sample Tracking (MIST) handheld database, Plan Versus Actual Report, Delegation of Authority, and Contingency Plan.
2) Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
3) Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
4) Operation and Maintenance Manual (O&M Manual), and Quality Assurance Project Plan (QAPP) (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan), as required during the O&M phase.
5) Topock Program Health and Safety Plan (HSP).
6) Blank sampling logs, MIST database and field notebook. Purge and sampling information will be recorded on hard copy purge form and MIST handheld database.
7) Applicable SOPs may include:
   - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
   - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
   - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
   - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
   - SOP-A6, *Field Filtration*
   - SOP-A7, *Water Level Measurements*
   - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
   - SOP-A9, *Calibration of Field Instruments*
   - SOP-A10, *Decontamination of Water Sampling Equipment*
   - SOP-A11, *Total Depth Measurements*
   - SOP-A12, *Field Water Quality Measurements for Grab Samples*

- SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
- SOP-A14, *Pore Water Sampling*
- SOP-A16, *Access Routes*
- SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
- SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
- SOP-A23, *Sample Handling and Custody*

• SOP-C1, *Solinst Pressure Transducers*

PREPARATION & SETUP

1) Review event-specific Sampling and Analysis Plan or event-specific field instructions, previous sampling logs, Field Procedures Manual, previous lessons learned, and HSP. (NOTE: the PST should also be reviewed for required "non-analytical event activities" in association with the river sampling event).
2) Initiate field logbook for sampling activity.
3) Inspect all equipment and calibrate field water quality (WQ) meters according to SOP-A9, *Calibration of Field Instruments*.
4) Inventory sample bottles and labels, required analyses, and confirm the lab courier schedule.
5) Field-check and set up sampling equipment: WQ meters, health and safety apparatuses (life vest, rescue rope, life preserver), water depth meter or depth-finder, peristaltic pump, filters, sufficient tygon and silicone tubing, polypropylene rope, sampling equipment, etc.
6) Prepare an ambient blank sample at the beginning of each day. Fill a 250 mL sample container with deionized water. This bottle is to remain open near the sampler for the duration of the day's sampling activities. At the end of the day close the sample container. Send the blank samples to the analytical lab for Cr(VI) analysis (by method 218.6), be sure to write "**hold**" on the COC. The blanks will only to be analyzed if there are anomalous results from the river samples.

IN-CHANNEL SAMPLING PROCEDURES

1) Prepare river water sampling log (use attached form).
2) The sampling team will travel to each river sampling station in a motorized boat. A safety inspection of the boat will be performed by the field crew prior to boarding (check for fire extinguisher, etc.). Samples will be collected from selected stations on the river approximately one-third the river width from the California shoreline.
3) Collect an equipment blank sample prior to sampling by running deionized water through a new/dedicated segment of tubing.

4) An industry standard (Trimble or similar) resource grade handheld DGPS unit (GeoXT or similar) will be used with real-time correction (wide area augmentation system) to locate the river channel sampling stations within a 1 meter radius (68% of the time, commonly referred to 1 sigma accuracy). At each location, two anchors should be positioned upstream at least 10 feet from each other (Attachment A). Record the GPS coordinates on the sampling log. In the event a sampling station is too shallow to safely approach by boat, the next closest location with adequate depth will be sampled and a remark noted on the sampling log with the new GPS coordinates.

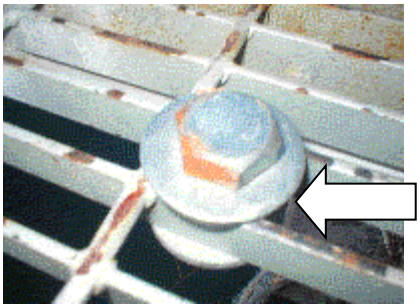
5) Record the depth of the river at each sampling station using the depth-finder or a weighted tape. If a weighted tape is used, read the tape at the river water surface when the weight touches the river floor. Record river depth on the sample log.

6) Samples will be collected from two depths at each river channel sampling station: 1 foot from the bottom of the river, and 1 foot from the water surface.

7) Samples are to be collected using a variable-speed peristaltic pump with ¼-inch tygon tubing attached to a weighted polypropylene rope (Attachment A) and a segment of silicone tubing for use in the peristaltic pump. Alternatively, a weighted pole can be used in place of the polypropylene rope. Dedicated tubing will be used for each sample depth at each sample station. Once the sampling depths have been calculated for each station, pre-cut two pieces of tygon tubing and attach them to the rope so that their intakes are at the proper sampling depths. Lower the weighted rope and tubing until the weight touches the river bottom and the tubing intakes are at the correct depths. Confirm river depth using the depth-finder or weighted tape. Attach the discharge end of the sample tubing to the flow cell of the water quality meter. Start the peristaltic pump and allow the flow cell to fill and the water to equilibrate for approximately 3 minutes, or until the temperature readings remain stable for 30 seconds (+/- 1 °C). Record the time, pH, conductivity, turbidity, dissolved oxygen, temperature, salinity, TDS, and ORP on the field log. Note and provide qualifying remarks if parameter readings are anomalous or unstable due to an instrument problem. Turn off the peristaltic pump, remove tubing from the flow cell, and restart the pump. Attach a 0.45 micron filter when sampling for Cr(T) by USEPA SW-846 Method 6020A or for Cr(VI) by USEPA Method 218.6. Refer to SOP-A6, *Sample Field Filtration and Preservation for Metals Analyses*. Pump approximately 500 ml through the system and begin filling the applicable sample bottles. Remove the filter prior to filling sample bottles for the other analyses, which do not require filtration. Ensure that the samples do not contact any source of metal. Place the samples on ice immediately after collection. Record all sample information on the field log.

8) Collect remaining samples for analyses according to the PST. Use a new piece of tygon tubing and change out the flexible silicone tubing in the peristaltic pump for each depth, at each location.

9) Follow applicable SOPs, the Procedures Manual, O&M Manual, and QAPP for sample handling and management, equipment decontamination, and investigation-derived waste (IDW) management (O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).



SHORELINE SAMPLING PROCEDURES

1) Prepare surface water sampling log (use attached form dated March 2005).
2) An industry standard (Trimble or similar) resource grade handheld DGPS unit (GeoXT or similar) will be used with real-time correction (wide area augmentation system) when available to locate the surface water sampling locations within a 1 meter radius (68% of the time, commonly referred to 1 sigma accuracy).
3) If sampling at locations RRB (Red Rock Bridge) or I-3 (or any other river station where water levels are required), measure river WL according to SOP-A7, *Water level Measurements*. Record WL value on sampling log.

   RRB: Water level measurement will be taken at the "X" on the bridge.

   I-3: There is a bolt and nut in the metal bridge, water level is recorded to the base of the nut (see photo)

4) Where possible, place water quality meter probes in the Colorado River in a secure place near-shore for approximately 3 minutes, until the temperature reading stabilizes prior to reading field parameters from sample. Proceed with sampling activities while the temperature of the probes is equilibrating.
5) Collect samples for analyses according to event-specific PST.

   RRB: Samples are collected using a disposable bailer and directly filling the sample bottles. An attempt will be made to ensure the water is collected from several inches beneath the surface of the water. If the water is too shallow to use a bailer, than the surface water sampling pole can be used. Make a notation on the sample log that the sample was not collected from the recommended depth.

   I-3: Samples are collected using a disposable bailer and directly filling the sample bottles. An attempt will be made to ensure the water is collected from several inches beneath the surface of the water.

   All other locations:

   If collecting sample from the shore, samples are collected using a surface water sampling pole that is extended as far as possible in a safe manner (ideally 4 feet from the shoreline) and the sample collected approximately 6 inches below the surface, or by wading out and dipping the sampling bottle approximately 6 inches beneath the surface. The Sampling

containers are connected to the sampling pole and filled directly from the river. If it is not possible to connect the sampling bottle directly to the sampling pole, a portable sampling bottle will be used. The portable sampling bottle will be decontaminated between locations in accordance with SOP-A10, *Decontamination of Water Sampling Equipment* and protected from ambient conditions as prescribed therein. Prior to filling the portable sampling bottle it will be rinsed with surface water at the sampling location.

If the shoreline samples are collected from a boat, the boat must be able to pull within 4 feet of the shore at the sample location. Samples are collected using a peristaltic pump by lowering the intake tubing 4-inches below the water surface. New or dedicated tubing must be used at each sampling location.

Samples that are to be filtered as part of the analytical suite will be field filtered at the support vehicle using a portable peristaltic pump to transfer water from the collection vessel through a 0.45 micron filter in accordance with SOP-A6 and discharged into the laboratory supplied sample container. At minimum, the required sample volume and an additional 500 milliliters will be collected to ensure there is sufficient volume for filtration.

6) Record sample information on field log.

7) Fill a clean bucket with Colorado River water collected approximately 6 inches below surface using a bailer or by directly filling the bucket (invert until desired depth) for measurement of water quality field parameters. Where possible (all locations except RRB), flowing water is collected for a one-time temperature stable reading of the following field parameters:

   - pH
   - Specific conductance
   - ORP
   - Turbidity
   - Dissolved oxygen
   - Temperature

8) Measure field parameters by removing the water quality probes from the river and inserting the Horiba probes directly into the bucket. The Hach vial shall be filled from the bucket. Record all parameters on the field sheet. Record time for all measurements collected. Note and provide qualifying remarks if parameter readings are anomalous or unstable due to instrument problem.

9) Follow applicable SOPs, the Procedures Manual, the O&M Manual, and QAPP for sample handing and management, equipment decontamination, and IDW management (O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

SOP-A5

Groundwater Sampling from Sonic Drilling Boreholes
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for purging and collection of grab groundwater samples from boreholes during sonic drilling. When a pump sampling system (Prosonic "Isoflow") is available and feasible, Isoflow sampling is the preferred method. When Isoflow sampling is not available or not feasible then a bailer method will be used for grab groundwater sampling while drilling.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP), Work Plan or event-specific field instructions. Planned borehole depth, proposed well construction/specifications, and field sampling summary table, if available.
2) Applicable project work plan or monitoring plan. Refer to Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
3) Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
4) Operation and Maintenance (O&M) Manual, and the Quality Assurance Project Plan (QAPP) and Addendum to the QAPP (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan), as required during the O&M phase.
5) Topock Program Health and Safety Plan (HSP)
6) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available
7) Blank sampling log and field notebook
8) Applicable SOPs may include:
   - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
   - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
   - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
   - SOP-A4, *Depth-Specific River Water Sampling*
   - SOP-A6, *Field Filtration*
   - SOP-A7, *Water Level Measurements*
   - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
   - SOP-A9, *Calibration of Field Instruments*
   - SOP-A10, *Decontamination of Water Sampling Equipment*
   - SOP-A11, *Total Depth Measurements*

- SOP-A12, *Field Water Quality Measurements for Grab Samples*
- SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
- SOP-A14, *Pore Water Sampling*
- SOP-A16, *Access Routes*
- SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
- SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
- SOP-A23, *Sample Handling and Custody*
- SOP-C1, Solinst Pressure Transducers

PREPARATION & SETUP

1) Review event-specific Work Plan or event-specific field instructions, Procedures Manual, O&M Manual, QAPP and the Addendum to the QAPP, and HSP.
2) Initiate field logbook for sampling activity.
3) Review sampling procedures and equipment, and planned sample depths with drilling contractor and field crew.
4) Inspect all required field equipment and calibrate field water quality (WQ) meters according to SOP-A9, *Calibration of Field Instruments*.
5) Inventory sample bottles, review required analyses, and understand lab courier schedule.
6) Field-check and setup sampling equipment: Decontaminated Isoflow pump or stainless steel bailer, rig hoist, generator, containers for purge water management, water level (WL) meter, WQ meters, flow-through cell, pump control and power supply, pump discharge/sampling tubing, health and safety equipment, etc.

PURGING AND SAMPLING PROCEDURES FOR ISOFLOW SAMPLING FROM BOREHOLE

1) Prepare groundwater sampling log (use field notebook and summarize relevant information on sampling form).
2) Insert the Isoflow into the sonic casing. After the Isoflow is set, retract the sonic casing approximately 10 feet. Record the top and bottom of this open borehole interval and identify the grab groundwater sample as the mid-point of this interval. If possible, a water level measurement can be taken before Isoflow pumping begins. Measure initial static WL according to SOP-A7, *Water Level Measurements*. Record WL value on sampling log. Monitor and record Isoflow pumping rate and WL measurements made while pumping. The length of the open borehole interval will be a field decision based on the frequency of Isoflow sampling and the formation conditions. Shorter open borehole intervals (as short as 5 feet) are appropriate for Isoflow sampling frequency of every 20 feet of drilled depth, or in heterogeneous conditions where it is desired to

sample from a specific conductive zone. Longer open borehole intervals of up to 20 feet are appropriate if the Isoflow sampling frequency is every 50 to 60 feet of drill depth.

3) Measure water quality parameters using a flow-through cell connected directly to the sampling port. If it is not possible to connect the flow-through cell, a clean 5-gallon bucket may be used by filling the bucket with purge water and inserting the instrument probes directly into the bucket. If the bucket is used, turbulence in the bucket should be minimized to the extent possible. Record time for all measurements collected. Note and provide qualifying remarks if parameter readings are anomalous or unstable due to instrument problems. Record the purge rate. Purge water should be contained in a portable water storage tank, as directed by the Field Team Manager.

4) Observations on sample appearance and clarity during purging and at sampling are required. For standardization, use a clear glass jar to collect and record observations of discharge water appearance during purging. Also note characteristics such as any odors associated with the discharge water. Record the following water quality data on the field data sheet: pH, specific conductance, ORP, turbidity, TDS, and dissolved oxygen, and temperature. Indicator parameters are considered stabilized, and thus sampling may commence, when 3 consecutive readings made several minutes apart fall within the following EPA-recommended stabilization criteria:

   - pH +/- 0.1 pH units
   - Specific conductance +/- 3%
   - ORP +/- 10 millivolts
   - Turbidity 10% NTU units or less unless other parameters have stabilized during an extended purge and turbidity is trending flat if still over 10 NTU units.
   - Dissolved oxygen +/- 0.3 mg/L

   However, parameter stabilization is not a requirement for sampling from open boreholes. Typically, TDS is used as a reliable indicator for borehole sampling at the site, given the known increasing concentration with depth across the site.

5) Collect samples for analyses according to event-specific SAP. For all samples, decrease the discharge rate to reduce water turbulence at the pump discharge point. Prepare sample containers and collect gas-sensitive analytes first. The preferred collection order will be volatile organic compounds (VOCs), semi-volatile organic compound (SVOCs), metals (including hexavalent chromium [Cr(VI)] and total chromium [Cr(T)]), then general chemistry (cations, anions, stable isotopes). Sample containers are to be filled by transferring water directly from the pump discharge to the appropriate sample container.

6) Record sample information, final WL, and purge volume data on field log.

7) Oversee the driller's removal and decontamination of the Isoflow sampling pump.

8) Oversee the driller in resuming drilling and soil sampling.

9) Follow applicable SOPs, the Procedures Manual and O&M Manual for sample handing and management, equipment decontamination, and investigation-derived waste (IDW) management (O&M Manual, Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

PURGING AND SAMPLING PROCEDURES FOR BAILER SAMPLING FROM BOREHOLE

1) Prepare groundwater sampling log (use field notebook and summarize relevant information on sampling form).

2) Collect the grab groundwater sample by bailing the open hole interval below the sonic casing after removing a 10 to 20-foot sonic core run.

3) Sound the bottom of the borehole after removing the core barrel. Measure initial static WL according to SOP-A7, *Water Level Measurements*. Record WL value on sampling log.

4) Calculate 1-casing volume using measured WL depth, casing diameter, and total well depth information. Insert the decontaminated stainless steel bailer into the borehole and begin bailing a minimum of one casing volume. Purge water should be contained in a portable water storage tank, as directed by the Field Team Manager.

5) Measure water quality parameters using a clean 5-gallon bucket and inserting the instrument probes directly into the bucket. If the bucket is used, turbulence in the bucket should be minimized to the extent possible. Record time for all measurements collected. Record the following water quality data on the field data sheet: pH, specific conductance, ORP, turbidity, TDS, dissolved oxygen, sample appearance, and odor. Parameter stabilization is not a requirement for sampling from open boreholes. Typically, TDS is used as a reliable indicator for borehole sampling at the site, given the known increasing concentration with depth across the site.

6) Collect samples for analyses according to event-specific SAP. Prepare sample containers and collect gas-sensitive analytes first. The preferred collection order will be volatile organic compounds (VOCs), semi-volatile organic compound (SVOCs), metals (including hexavalent chromium [Cr(VI)] and total chromium [Cr(T)]), then general chemistry (cations, anions, stable isotopes). Sample containers are to be filled by transferring water directly from the bailer to the appropriate sample container. For all samples, handle the bailer with care and decant from the bailer slowly to minimize the potential for aeration and turbulence as containers are filled.

7) Record sample information, final WL, and purge volume data on field log.

8) Follow applicable SOPs, the Procedures Manual and O&M Manual for sample handing and management, equipment decontamination, and IDW management (O&M Manual, Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

SOP-A6

Sample Field Filtration and Preservation for Metals Analyses
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for collecting groundwater / surface water samples for field filtered metals analyses at the Topock site. Refer to SOP-A1, A2, A3, or A4 for specific groundwater and surface water sampling methods.

REQUIRED DOCUMENTS

1) Event-specific planned sample table (PST).
2) Applicable project work plan or monitoring plan. Refer to the PG&E Program Quality Assurance Project Plan, (QAPP) or the Addendum to the PG&E Program Quality Assurance Project Plan for the Topock Groundwater Remedy, as required.
3) Topock Program Health and Safety Plan (HSP).
4) Previous sampling logs or tabular table of historic field data.
5) Blank sampling logs and field notebook.

PREPARATION & SETUP

1) Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, Operation and Maintenance (O&M) Manual, and HSP.
2) Initiate field logbook for sampling activity.
3) Inventory sample containers and labels, required analyses, and lab courier schedule.
4) Field-check and setup sampling equipment: field filters, buffering solution, acid, and sample containers.

FIELD-FILTRATION AND SAMPLE COLLECTION PROCEDURES FOR GROUNDWATER FROM MONITORING AND EXTRACTION WELLS

1) Follow SOPs A1 and A2.

Sample Collection

1) Once parameters are stabilized and a minimum 3-casing volumes have been removed from the well, disconnect the tubing from the flow-through cell and connect the inline 0.45 micron filter. (Note: do not change the pump rate, continue to purge from the well at the same rate as used during the stabilization of the parameters.)
2) Allow 500 milliliters (mL) to flow through the inline filter, prior to sample collection. Fill the sample container by transferring water directly from the filter discharge to the appropriate sample container.

Total Chromium and Metals analyzed by the 6000 / 7000 Series of SW 846 Methods and metals analyzed by EPA Methods of the 200 Series

i. Fill a laboratory provided pre-preserved sample container (250 or 500 mL poly containing (HNO_3). CARE MUST BE TAKEN NOT TO OVERFILL THE CONTAINER.

In the event that no pre-preserved sample containers are available, the sampling team will need to follow the following protocol.

ii. If you are preserving the container in the field, check the pH of the sample with laboratory provided pH paper. If the pH of the sample is greater than 2, add 5 drops of HNO_3. Close the container, shake and check the pH. Continue adding HNO_3 in 5-drop increments until the pH is less than 2.

iii. Record the total amount of HNO_3 added to the sample and the pH on the chain of custody and field form. Seal, label, and place the sample on ice.

Hexavalent Chromium Method SM3500 and EPA 218.6

i. Fill a laboratory provided pre-preserved sample container (250 mL poly containing (NH4)2S O4/NH4OH buffer solution) to the top of the container neck.

ii. Seal, label, and place the sample on ice.

In the event that no pre-preserved sample containers are available, the sampling team will need to follow the following protocol.

i. If you are preserving the container in the field, fill a laboratory provided sample container (250 mL poly) to approximately 235 mL, leaving headspace for the addition of buffer solution.

ii. Add 5 mL of laboratory provided buffer solution using a pipette. Place the lid on the sample container and shake gently. Check the pH using laboratory provided pH strips.

iii. If the pH is less than 9.3, add one drop of 20% NaOH, close container, gently shake, and check the pH. Continue until the pH is between 9.3 and 9.7.

iv. When the pH of the sample is between 9.3 and 9.7, record the total amount of pH buffer and NaOH added to the sample and the pH of the sample on the chain of custody and field form. Seal, label, and place the sample on ice.

3) Discard used pH paper(s) and filter in IDW bin.

4) Record sample information, final WL, and purge volume data on field log.

SOP-A7

Water Level Measurements
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for manually measuring the depth to water at surface water locations, groundwater monitoring wells, and production wells.

REQUIRED DOCUMENTS:

- Event-specific planned sample table (PST).
- Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
- Operation and Maintenance (O&M) Manual, and the Quality Assurance Project Plan (QAPP) and Addendum to the QAPP (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan), as required during the O&M phase.
- Topock Program Health and Safety Plan (HSP)
- Well construction logs/specifications
- Current site access map
- Previous water level data
- Water level data collection sheet and field notebook
- Blank sampling logs, if applicable
- Applicable SOPs may include:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A10, *Decontamination of Water Sampling Equipment*
  - SOP-A11, *Total Depth Measurements*

- SOP-A12, *Field Water Quality Measurements for Grab Samples*
- SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
- SOP-A14, *Pore Water Sampling*
- SOP-A16, *Access Routes*
- SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
- SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
- SOP-A23, *Sample Handling and Custody*
- SOP-C1, *Solinst Pressure Transducers*

PREPARATION & SETUP:

- Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, O&M Manual, and HSP.
- Ensure that the water level indicator (WLI) has been decontaminated (check for label/tag) or decontaminate as needed following SOP-A10, *Decontamination of Water Sampling Equipment*.
- Initiate field logbook for sampling activity.
- Inspect all equipment and calibrate WLIs if multiple meters are being used according to SOP-A9, *Calibration of Field Instruments*.
- If a transducer is present in the well and it is necessary to remove the transducer to allow well access, first note the exact position of the transducer and refer to SOP-C1, *Solinst Pressure Transducers*, before proceeding.

REQUIRED EQUIPMENT/SUPPLIES:

- 200-foot or 400-foot WLI
- A set of spare batteries for the field equipment
- Well access keys, including gate keys if necessary
- De-ionized (DI) water spray bottle
- Nitrile gloves, paper towels, clipboard

MEASUREMENT PROCEDURES:

1. Prepare groundwater sampling log or water level data collection form.
2. Decontaminate the lower 5 feet of the water level probe before using by rinsing thoroughly with DI water according to SOP-A10*, Decontamination of Water Sampling Equipment*.
3. Place WLI probe into well, or measure from surface water monitoring point and lower the probe until the tone sounds. Raise the probe out of the water and gently shake the

line to remove any retained water. Adjust the WLI sensitivity if necessary. (The groundwater onsite is highly conductive and may cause a constant tone from the WLI. This means that the sensitivity is set too high; turn the knob to the left to decrease sensitivity. Conversely, if measuring surface water which typically has very low conductance, and you are having difficulty getting a tone, the sensitivity may be set too low; increase the sensitivity by turning the knob to the right.) Slowly lower the probe once again just until the tone sounds. Note depth to water (DTW) value at the measuring point on the PVC well casing. If there is no mark on the PVC casing, measure DTW at the northern edge of the PVC casing. Repeat the measurement 3 times to confirm DTW, and record to the nearest hundredth of a foot on the sampling log. Record well identification, time, date, DTW, and WLI number.

4. Replace pressure transducer if removed. Ensure that transducer is placed exactly as it was before removal.

5. Compare DTW measurement with previous data and note discrepancies on the sampling form. Repeat the previous steps as necessary if an unexpected discrepancy is noted.

6. Decontaminate any portion of the instrument that came in contact with water by rinsing thoroughly with DI water, or wiping with a DI water moistened paper towel according to SOP-A10, *Decontamination of Water Sampling Equipment*.

7. Close and secure well.

Note: Field water level measurements will be loaded into the PG&E database regularly. Once loaded into the database, manual water levels will be adjusted to groundwater elevations and converted to freshwater equivalent heads following the procedures outlined in SOP-A22, *Procedures for Calculation of Freshwater Equivalent Heads*.

SOP-A8

Field Water Quality Measurements Using a Flow-through Cell Standard Operating Procedures for PG&E Topock Program

---

This Standard Operating Procedure (SOP) provides general guidelines for using the YSI-556® water quality (WQ) meter and flow-through cell, or similar device for field measurements of pH, specific conductance, turbidity, dissolved oxygen, oxidation-reduction potential (ORP), and temperature of groundwater samples. Also addressed are procedures for measuring water sample turbidity using the Hach turbidity meter. All instruments will be calibrated daily in accordance with the manufacturer's instructions and SOP-A9, *Calibration of Field Instruments*.

REQUIRED DOCUMENTS:

- Event-specific planned sample table (PST).
- Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
- Operation and Maintenance (O&M) Manual, and the Quality Assurance Project Plan (QAPP) and Addendum to the QAPP (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan), as required during the O&M phase.
- Topock Program Health and Safety Plan (HSP)
- Applicable SOPs may include:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A10, *Decontamination of Water Sampling Equipment*
  - SOP-A11, *Total Depth Measurements*
  - SOP-A12, *Field Water Quality Measurements for Grab Samples*

- SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
- SOP-A14, *Pore Water Sampling*
- SOP-A16, *Access Routes*
- SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
- SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
- SOP-A23, *Sample Handling and Custody*
- SOP-C1, *Solinst Pressure Transducers*

- Well construction logs/specifications
- Mobile Integrated Sample Tracking (MIST) handheld database
- Previous sampling logs or tabular historic field data
- Current site access map
- Blank sampling logs, maps, sample labels, chains of custody (COC's), and the designated groundwater sampling field notebook

REQUIRED EQUIPMENT:

- YSI-556 WQ meter or equivalent
- YSI-556 flow through cell or equivalent
- Hach 2100P turbidimeter or equivalent
- Trimble Rugged Reader hand held device with the CH2M HILL event specific MIST electronic data collection database loaded
- Spare batteries for each piece of equipment

PREPARATION & SETUP:

- Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
- Acquire the existing field logbook for the specific field activity and initiate entries.
- Inspect all equipment : YSI-556 WQ meter or similar device, flow-through cell, o-rings, and fittings , Hach turbidity meter, distilled water in spray bottle.
- Prior to each day's use, clean the probes and flow-through cell and calibrate the field water quality (WQ) meters according to SOP-A9, *Calibration of Field Instruments* and the manufacturer's instructions. Calibration is performed to compensate for changes in potential within the measuring and reference electrodes, as well as any change of potential between them. The calibration also involves checking the slope of the measuring electrode. Slope defines the ability of the measuring electrode to change its output by 59.16 mV per pH unit at 25°C. Virtually all pH instruments use a slope adjustment to compensate for the inability of the measuring electrode to accurately

produce its output signal. If the slope falls outside the manufacturers' recommended range, the probe is replaced.

YSI-556 WQ Meter (or equivalent):

- Attach the probe body securely to the flow through cell. Attach the pump discharge line to the bottom fitting of the flow through cell, and a second discharge line to the top fitting of the flow through cell. Route the flow through cell discharge line to the purge water storage tank and secure.
- Prior to starting the pump, place the flow through cell into a 5 gallon bucket, ensure that all fittings are properly tightened and that spill containment is in place in accordance with SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling.*
- Start the pump and allow the flow through cell to fill. Check for excessive leakage from the cell. A small amount of leakage is typical and allowable, and will be caught by the 5 gallon bucket. If leakage is excessive, stop the pump, remove the probe body from the flow through cell and inspect the O-ring and threads for damage. Replace if necessary, re-attach to flow through cell, and restart the pump.
- Ensure that there are no air bubbles entering the flow through cell since this will skew the dissolved oxygen and ORP readings.
- Allow instrument readings to stabilize and collect water quality data in MIST and on the field data sheet. Time the readings such that there at least 5 sets of readings collected over the length of the full purge. During operation of the WQ meter, the screen on the handheld portion should be shielded from direct sunlight.
- When sampling is complete, carefully remove the fittings and drain the flow through cell into the bucket. Rinse the instrument probes and flow through cell thoroughly with de-ionized water in accordance with SOP-A10, *Decontamination of Water Sampling Equipment,* catching the rinsate in the bucket.
- Mount the specially cut "dumping lid" on the bucket, and carefully pour the contents into the purge water storage tank.
- Carefully clean and store the WQ instrument in accordance with the manufacturer's recommendations in preparation for the next use.

HACH 2100P TURBIDIMETER:

- Turn the turbidity meter on and select the auto-range mode.
- Inspect the measurement vial for scratches, dirt or staining. Replace or clean as necessary.
- Fill the measurement vial with water and carefully wipe dry.
- If bubbles cling to the side of the vial, gently swirl the sample to sweep them loose.
- Place the measurement vial in the instrument, close the lid and press the measure button.

- Record the value on the sample sheet and in MIST.
- Clean and store the instrument and vial. Fill the vial with DI water for storage, this prevents water spotting.

SOP-A9

Calibration of Field Instruments
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for calibration of field instruments at the Topock site. This SOP will be used for calibration of water level meters, YSI-556 water quality (WQ) meter, In-Situ Troll 9500 WQ meter, and Hach turbidity meter.

Required Documents:

- Event-specific planned sample table (PST).
- Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
- Operation and Maintenance (O&M) Manual, and the Quality Assurance Project Plan (QAPP) and Addendum to the QAPP (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan), as required during the O&M phase.
- Equipment Manufacturers' Manuals
- Previous Calibration Records
- Field Equipment Binder (documents equipment servicing, calibration, etc.)
- Blank Calibration Sheets (see attached)
- Zobells ORP vs. temperature chart (see attached)

YSI-556 WQ Meter Calibration Equipment List:

- pH 4, 7, and 10 buffer solutions
- 1000 micro-mhos/cm conductivity solution
- Zobell's ORP check solution
- Spare batteries
- DI water sprayer
- Rinsate bucket
- Calibration vessels

In-situ Troll 9500 WQ Meter Calibration Equipment List:

- Quick-cal. solution
- DI water sprayer
- Spare batteries
- Rinsate bucket
- Calibration vessels
- Dissolved oxygen bubbler

Hach Turbidity Meter Calibration Equipment List:

- Lab DI water, NTU = <1
- Standard Hach solutions, NTU= 10 and NTU=100
- Spare batteries
- Paper towels or cloth rag

Preparation and Setup:

- Acquire the existing field logbook for the specific sampling activity and initiate entries.
- Always use fresh, unexpired solutions for calibration.
- Calibration should be performed prior to use each day, but, with the exception of dissolved oxygen (DO) on the YSI-556, may also be completed in the afternoon of the day before use.
- DO calibration on the YSI-556 is dependent on the current barometric pressure and should be calibrated immediately before use. The DO measurement from the YSI-556 will be used only as backup.
- The Rugged Dissolved Oxygen (RDO) sensor on the Troll 9500 is very resistant to drift and only requires a 100% saturated water calibration once every 3 months. The 0% oxygen calibration is only required once every 3 months as well. The optical O_2 sensor in the Troll 9500 will be used as the primary DO measurement instrument.
- Review Field Equipment Binder and equipment servicing records to anticipate next service.
- All equipment and solutions are stored in an air-conditioned office onsite to maintain their integrity.
- The YSI-556, and In-Situ Troll 9500 WQ meters and Hach turbidity meter will be used as the principal field instruments for measuring water quality parameters during groundwater and surface water sampling.

Calibration Procedures:

YSI-556 WQ Meter:

- Check expiration date of calibration solutions and discard if expired.
- DO calibration: Remove the protective probe cover and thoroughly rinse probes and probe cover with DI water. Gently shake the probe body to remove excess water. Pour about ¼ to ½ inch of water into the protective probe cover and screw slightly onto the probe body. The idea is that the ambient atmospheric pressure be maintained within the vessel, while retaining the water saturated air necessary for calibration. Turn the YSI-556 instrument on, it will be in "run" mode. Using the navigation buttons on the face of the instrument, hit "escape", then scroll down to "calibrate" and hit the "enter" key to begin calibration. Select DO, 2 mil PE (the probe style), then DO %. Enter the current barometric pressure in millimeters of Hg. Of the two YSI-556's on site, one has an on board barometer and the other doesn't. When calibrating the instrument with no barometer, simply enter the barometric pressure displayed by the other instrument. The

barometric pressure is also available at various web sites and also at airports. Press the "enter" key again to begin the calibration. Wait for 10 to 15 minutes for the DO probe to stabilize. When satisfied that that the reading is stable, press the "enter" key a final time to lock in the calibration. Record the temp., barometric pressure, and DO value on the calibration sheet.

- pH calibration: Thoroughly rinse the probes and calibration cups with DI water and gently shake off the excess liquid. Pour a sufficient volume of pH buffer 4 into a calibration cup and insert the probe body, ensuring that the pH probe is fully immersed, and stir gently. Using the navigation keys as above, "escape" from "run" mode and enter "calibration" mode. You may still be in calibration mode if you've just completed the DO calibration. Scroll down to the "pH" entry and push the "enter" key to begin the pH probe calibration process. Select a "3 point calibration", and enter the first pH buffer value (usually 4.00). Allow several minutes for the probe to stabilize, then press the "enter" key to lock in the calibration. Enter the calibration value on the calibration form. Repeat the above steps for the remaining 2 pH buffers, 7.00 and 10.00, rinsing the probe and calibration cup with DI water between buffers. Dispose of used solutions in the rinsate bucket and thoroughly rinse the calibration vessels with DI water.

- Specific conductance (SC) calibration: Thoroughly rinse the probes and calibration cups with DI water and gently shake off the excess liquid. Pour a sufficient volume of 1000 micro-mhos/cm specific conductivity (SC) solution into a calibration cup and insert the probe body, ensuring that the conductivity probe is fully immersed, and stir gently. The SC probe has sensors located very high in the probe, so near full submergence is required. Using the navigation keys as above, "escape" from "run" mode and enter "calibration" mode. You may still be in calibration mode if you've just completed the DO or pH calibrations. Scroll down to the "conductivity" entry and push the "enter" key to begin the SC probe calibration process. Select "specific conductance" and enter the SC solution value (usually 1.000 milli-mhos/cm) making sure of the correct units. The instrument may measure in **milli**-mhos/cm or micro-mhos/cm, and the calibration standard is commonly referenced in **micro**-mhos/cm (1.000 milli-mhos = 1000 micro-mhos). Allow several minutes for the probe to stabilize, then press the "enter" key to lock in the calibration. Enter the calibration value on the calibration form. Dispose of used solutions in the rinsate bucket and thoroughly rinse the calibration cups with DI water.

- ORP calibration: Thoroughly rinse the probes and calibration cups with DI water and gently shake off the excess liquid. Pour a sufficient volume of Zobells ORP solution into a calibration cup and insert the probe body, ensuring that the pH/ORP probe is fully immersed, and stir gently. Using the navigation keys as above, "escape" from "run" mode and enter "calibration" mode. You may still be in calibration mode if you've just completed the DO, pH or SC calibrations. Scroll down to the "ORP" entry and push the "enter" key to begin the ORP probe calibration process. Consult the Zobells ORP vs. temp. table provided with the ORP solution, and enter the temperature corrected ORP value into the instrument. Allow several minutes for the probe to stabilize, then press the "enter" key to lock in the calibration. Enter the calibration value on the calibration form. Dispose of used solutions in the rinsate bucket and thoroughly rinse the calibration vessels with DI water.

- Proceed with field measurements as needed while noting:
  - probes must be rinsed thoroughly with DI water after each well.
  - probes must always be submersed in liquid (DI water or pH 7 buffer when not in use).
  - absolutely no air bubbles or leaks should be present in the flow-through cell, repair and/or replace as needed.
  - ensure all readings have stabilized prior to recording a measurement.
  - all field parameters must be compared with historic data and documented on the field data sheet.

In-Situ Troll 9500 WQ multisensor probe:

- Check expiration date of calibration solutions and discard if expired.
- Connect the Troll 9500 to a data collection device (Trimble Recon or equivalent) and start the Win-situ 4 or Pocket-situ 4 program. Tap to highlight the "COM-1-19200" on the start-up screen, then tap "Find" at the bottom left of the screen to connect to the Troll 9500.
- While waiting for the device to connect, spray the Troll 9500 multi-sensors thoroughly with DI water and shake gently over the rinsate bucket to remove excess water. Fill the In-Situ calibration vessel to the "fill" line with "Quick Cal" solution and gently screw the calibration vessel onto the probe body.
- After the data collection device "finds" the Troll 9500, tap "parameters" near the top of the screen and wait for the device to change screens, then tap "Quick Cal" at the bottom right of the screen. After the screen changes, ensure that the correct parameters are checked (pH, SC, and ORP, but ***not*** DO), then tap "Next" to access the calibration screen.
- Tap "Run" in the middle left of the screen to start the calibration stabilization process. A tone will sound when the pH, ORP, SC, and temperature stabilize to nominal values. The calibration values can be accepted at this point, but it is better to continue to wait until a second tone sounds to indicate that the calibration values are completely stable.
- Tap the "Accept" button at the bottom of the screen to lock the calibration values. After accepting the calibration you will be asked if you want to view the calibration reports. Tap "yes", review, and document on the field calibration data sheet.

Dissolved oxygen (DO) calibration: (Note: DO calibration is only required once every 3 months) Remove the protective probe cover and thoroughly rinse probes and probe cover with DI water.

- Fill the In-Situ DO calibration bubbler with room temperature potable water and activate the pump to begin oxygenation of the water. Place the multi-sensor into the bubbler and ensure that the Rugged Dissolved Oxygen (RDO) sensor is not in the direct stream of the rising bubbles.
- Connect the Troll 9500 to a data collection device (Trimble Recon or equivalent) and start the Win-situ 4 or Pocket-situ 4 program. Tap to highlight the "COM-1-19200" on the

start-up screen, then tap "Find" at the bottom left of the screen to connect to the Troll 9500.

- After the data collection device "finds" the Troll 9500, tap "parameters" near the top of the screen and wait for the device to change screens, then double tap on "DO" in the parameter list. This will open the DO calibration menu. Tap "Calibrate" to continue.
- You will be asked if you want to edit the barometric pressure, tap "Yes", review and record the barometric pressure on the field calibration sheet. Tap "Next" to continue.
- The next screen will show three choices for calibration: "Calibrate", "Restore defaults then calibrate", and "Restore defaults and don't calibrate". Select option one or option two.
- Tap "Run" to begin the 100% DO saturation calibration routine. A tone will sound when the DO and temperature stabilize to nominal values. The calibration values can be accepted at this point, but it is better to continue to wait until a second tone sounds to indicate that the calibration values are completely stable.
- Tap "Accept" to lock in the 100% DO saturation calibration.
- Tap "Next" to continue. You will then be asked if you want to conduct a 0% DO calibration (Note: This calibration is only required once every 3 months). If you are completing a 100% saturated water calibration only, hit "Next", then "Next" again to complete the single point calibration.
- If you want to complete the 0% calibration as well, immerse the probe in the 0% DO solution (Sodium sulfite (Na2SO3), Catalog No. 0017670) and tap "Next", then "Run". The calibration routine will run as before. When the readings are stable hit "Accept", then review the calibration report and record on the field calibration data sheet. This will complete the DO calibration routine.
- Close the calibration report, tap "Parameters", then "Profiler" to enter run mode.
- If you intend to collect electronic data, name the file and hit "Next" to proceed to the live parameters screen. In this screen you may choose to collect continuous or snapshot data.
- If you do not intend to collect electronic data simply hit "Next" to go to the live parameters screen and record the data by hand as necessary.
- Proceed with field measurements as needed while noting:
  - probes must be rinsed thoroughly with DI water after each well.
  - probes must always be submersed in liquid (DI water when not in use).
  - absolutely no air bubbles or leaks should be present in the flow-through cell, repair and/or replace as needed.
  - ensure all readings have stabilized prior to recording a measurement.
  - all field parameters must be compared with historic data and documented on the field data sheet.

Hach Turbidity Meter:

- Perform a check as per manufacturer's instructions with Hach DI water and standard solutions. Wipe each calibration vial carefully to remove any dust and place into instrument.
- Press the measure button and record the result on the calibration sheet. Record reading, time, and date on calibration sheet for both DI water and standard solution.
- If the readings are within 10%, proceed with turbidity measurements; If not within this range, troubleshoot and repeat as needed.

Water-level Meters:

When using multiple water-level meters at the site it is necessary to calibrate each against the other at least once during the sampling event using the following procedure:

- At a well with shallow depth to water (less than 20 feet), without dedicated tubing, piping, pump, or transducer, lower each water level meter into the well and record the reading to the nearest hundredth of a foot on the calibration sheet along with water-level meter number, time, and date.
- Repeat step #1 at a well with deep depth to water (greater than 70 feet).

Horiba U-22/U-23, ORION, and Hach Turbidity Meter Calibration Sheet Updated: February 2005
Project Site: PG&E Topock

Calibrate each day prior to inititating sampling following SOP-A9.

SOP-A10

Decontamination of Water Sampling Equipment
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for decontamination of sampling equipment at the Topock site.

REQUIRED DOCUMENTS:

- Event-specific planned sample table (PST).
- Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
- Operation and Maintenance (O&M) Manual, and the Quality Assurance Project Plan (QAPP) (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan) as required during the O&M phase.
- Topock Program Health and Safety Plan (HSP)
- Applicable SOPs may include:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A11, *Total Depth Measurements*
  - SOP-A12, *Field Water Quality Measurements for Grab Samples*
  - SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
  - SOP-A14, *Pore Water Sampling*
  - SOP-A16, *Access Routes*
  - SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*

- SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
- SOP-A23, *Sample Handling and Custody*
- SOP-C1, Solinst Pressure Transducers

REQUIRED EQUIPMENT AND SUPPLIES:

- 2 each decontamination vessels
- Potable water source
- Purified water source
- 120 volt power source
- 12 volt power source
- Alconox or Liquinox detergent
- Scrub brushes, nitrile gloves, and spray bottle
- Spill containment
- Pump specific submersible pump controllers

PREPARATION AND SET-UP:

- Acquire the existing field logbook for specific activity and initiate entries.
- Inspect all equipment necessary to carry out decontamination activities.
- Place spill containment in accordance with *SOP-A13 Spill Prevention, Containment, and Control Measures for Monitoring Well Development, Purging, and Sampling.*
- Fill a clean tub, bucket , PVC pipe, or similar vessel about 2/3 full of potable water and add the appropriate amount of Alconox or Liquinox detergent. If a new or clean vessel is not available a trash bag can be used to line the vessel prior to use.
- Fill a second tub, bucket, PVC pipe, or similar vessel about 2/3 full with clean potable water.
- Have purified water ready for final decon rinse use.

FIELD EQUIPMENT DECONTAMINATION PROCEDURES:

- Water-level Indicators: Any portion of a water-level indicator that contacts the groundwater must be decontaminated after use by rinsing with purified water, or wiping thoroughly with a paper towel moistened with purified water.
- Instrument probes: Water quality instrument probes (e.g., pH or specific ion electrodes, etc.) that come into contact with groundwater will be decontaminated by rinsing thoroughly with purified water.

- Submersible pumps - Grundfos Rediflo2: TransientRediflo2 submersible pumps will be decontaminated after each use with the following procedure:

  - If attached, detach the discharge tubing from the pump. Carefully drain any excess water to a bucket or the purge water tank. If dedicated, install the dedicated tubing cap to prevent leakage. Coil and store the dedicated tubing in a sealed and marked trash bag. If the tubing is not dedicated, discard.

  - Immerse the pump completely in an Alconox or Liquinox and potable water solution and run the pump at low to medium speed for one minute. A scrub brush will then be used to clean the outside of the pump body using the detergent solution.

  - Allow the pump to drain back into soapy water vessel, then immerse completely in clear potable water and run the pump at low to medium speed for one minute to rinse it. Ensure that the body of the pump is properly rinsed as well.

  - Allow the pump to drain back into clear water vessel, then rinse the pump body thoroughly by pouring purified or bottled water over the entire pump, ensuring that the purified water runs through the internal pump stages as well. Place the pump in a clean plastic bag and store in a plastic tub with the pump reel.

  - If the pump is not to be used immediately, or is to be stored, tag the pump or plastic tub as "decontaminated" with the date and team members initials.

  - If the decontamination vessels contain less than 2 gal. of volume each be sure to change all decontamination fluids for new solutions ***after each use***.

- Submersible pumps – 12V GeoSub, Typhoon, Mega-Monsoon: Transient DC-powered submersible pumps will be ***decontaminated*** after each use as above ***or*** using the following procedures. Pressurized gas powered bladder pumps will be decontaminated after each use using the following procedures:

  - If attached, detach the discharge tubing from the pump. Carefully drain any excess water to a bucket or the purge water tank. If dedicated, install the dedicated tubing cap to prevent leakage. Coil and store the dedicated tubing in a sealed and marked trash bag. If the tubing is not dedicated, discard.

  - Using the tools provided, disassemble the pump body to expose the pumping mechanism. Immerse all parts in an Alconox or Liquinox and potable water solution and scrub thoroughly with a clean scrub brush. Gently shake the pump parts to remove excess soapy water, taking care not to spill or splash any fluids outside of the decon. vessel. Immerse all pump parts in clean potable water and rinse thoroughly. Gently shake the pump parts to remove excess rinse water, taking care not to spill or splash any fluids outside of the decon. vessel. Carefully pour purified (or bottled) water over and through all pump parts. Gently shake the pump parts to remove excess purified rinse water, taking care not to spill or splash any fluids outside of the decon. vessel. Reassemble the pump and place in a clean plastic bag, then store in a plastic tub with the pump reel.

  - Bladder pumps do not typically include a reel and will be stored in a clean plastic bag only.

  - If the pump is not to be used immediately, or is to be stored, tag the pump or plastic tub as decontaminated with the date and team members initials.
  - If the decontamination vessels contain less than 2 gallons of volume each, be sure to change all decontamination fluids for new solutions ***after each use***.

- Water-level Indicators: Any portion of a water-level indicator that contacts the groundwater must be decontaminated after use by rinsing with purified water, or wiping thoroughly with a paper towel moistened with purified water.
- Instrument probes: Water quality instrument probes (e.g., pH or specific ion electrodes, etc.) that come into contact with groundwater will be decontaminated by rinsing thoroughly with purified water.
- Follow applicable SOPs, the Procedures Manual and O&M Manual for handling of investigation-derived waste (IDW) (O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

SOP-A11

Total Depth Measurements
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for manually measuring the total depth at groundwater monitoring wells and production wells.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP).
2) Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
3) Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
4) Operation and Maintenance (O&M) Manual, and Quality Assurance Project Plan (QAPP; Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan) as required during the O&M phase.
5) Topock Program Health and Safety Plan (HSP)
6) Well construction logs/specifications
7) Previous total depth data
8) Blank sampling logs and field notebook
9) Applicable SOPs may include:
   - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
   - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
   - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
   - SOP-A4, *Depth-Specific River Water Sampling*
   - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
   - SOP-A6, *Field Filtration*
   - SOP-A7, *Water Level Measurements*
   - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
   - SOP-A9, *Calibration of Field Instruments*
   - SOP-A10, *Decontamination of Water Sampling Equipment*
   - SOP-A12, *Field Water Quality Measurements for Grab Samples*
   - SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*

- SOP-A14, *Pore Water Sampling*
- SOP-A16, *Access Routes*
- SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
- SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
- SOP-A23, *Sample Handling and Custody*
- SOP-C1, *Solinst Pressure Transducers*

PREPARATION & SETUP

1) Review event-specific SAP or event-specific field instructions, previous sampling logs, Procedures Manual, O&M Manual, and HSP.

2) Ensure that the measurement probe (weighted tape measure) has been decontaminated (check for label/tag) or decontaminate as needed following SOP-A10 *Decontamination of Water Sampling Equipment.*

3) Ensure the tape measure is not crimped and that it will hang free and clear of any obstructions enabling it to fully extend to the bottom of the well.

4) Initiate field logbook for sampling activity.

5) If a transducer is present in the well and it is necessary to remove transducer to allow well access, refer to SOP-C1, *Solinst Pressure Transducers.*

6) Calibrate wrist-watch to the atomic clock at the Topock Compressor Station.

MEASUREMENT PROCEDURES

1) Prepare Total Depth measurement log (use attached form dated March 2005).

2) Decontaminate the entire length of the measuring tape before using, according to SOP-A10*, Decontamination of Water Sampling Equipment.*

3) Place measurement tape into well and lower until the bottom of the probe touches the bottom of the well. Note total depth (TD) measurement to mark on well casing, if there is no mark on casing measure to the north. Repeat 3 times and record final TD to the nearest hundredth of a foot on the log. Also note the condition of the well bottom (i.e. hard bottom, soft bottom). Record well identification, time, date, TD, and measurement tape identification.

4) Compare TD measurement with previous data and note discrepancies on the sampling form. Repeat step #8 if an unexpected discrepancy is noted.

5) Decontaminate the entirety of the measuring tape, or any portion of the instrument that came in contact with water, following SOP-A10, *Decontamination of Water Sampling Equipment*.

SOP-A12

Field Water Quality Measurements for Grab Samples
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) provides general guidelines for using the YSI-556 water quality (WQ) meter or similar device for field measurements of grab groundwater samples for pH, specific conductance, turbidity, dissolved oxygen, oxidation-reduction potential, and temperature. This SOP specifically covers collection of WQ measurements when a flow-through cell cannot be used (for example, surface water sample collection, active extraction well sampling, screening samples collected during drilling operations, grab samples from a well using a bailer, groundwater sample using a Hydrasleeve sampler, etc.). Instruments will be calibrated daily in accordance with the manufacturer's instructions and SOP-A9, *Calibration of Field Instruments*.

REQUIRED DOCUMENTS:

- Event-specific planned sample table
- Monitoring Plan for Groundwater and Surface Water Monitoring Program (current revision)
- Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase
- Operation and Maintenance (O&M) Manual, and Quality Assurance Project Plan and Addendum to the QAPP (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan) for site-wide groundwater monitoring requirements during the O&M phase
- Topock Program Health and Safety Plan
- Manufacturer's instructions for the YSI-556 WQ meter or equivalent
- Applicable SOPs may include:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A10, *Decontamination of Water Sampling Equipment*
  - SOP-A11, *Total Depth Measurements*
  - SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*

  - SOP-A14, *Pore Water Sampling*
  - SOP-A16, *Access Routes*
  - SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
  - SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
  - SOP-A23, *Sample Handling and Custody*
  - SOP-C1, *Solinst Pressure Transducers*
- Well construction logs/specifications
- Previous sampling logs or tabular historic field data
- Current site access map
- Blank sampling logs
- Groundwater sampling field notebook

REQUIRED EQUIPMENT:

- YSI-556 WQ meter or equivalent
- YSI-556 storage cap or equivalent
- De-ionized water in a spray bottle
- Electronic data collection unit with a Topock-event-specific database
- Bucket and pouring lid

PREPARATION AND SETUP:

- Review event-specific planned sample table or event-specific field instructions, previous sampling logs, the Procedures Manual and O&M Manual, and the Health and Safety Plan.
- Acquire the existing field logbook for the specific field activity, and initiate entries documenting field activities.
- Inspect all equipment: YSI-556 WQ meter or similar device, de-ionized water in spray bottle, and electronic data collection unit.
- Prior to each day's use, calibrate the YSI-556 WQ, and clean the probes and storage cup of the field WQ meters according to SOP-A9, *Calibration of Field Instruments,* and the manufacturer's instructions. Document that instrument calibration has occurred and that parameters are calibrated to within the specifications in SOP-A9 in the field logbook.

MEASUREMENT PROCEDURES:

1. Transfer a small volume of sample water—enough to immerse all probes—into the WQ instrument storage cup or a small container. (The instrument storage cup is preferred as it can be sealed and will reduce risk for small volume water spills.)
2. Submerge the probes of the WQ meter into the water. Move the probe back and forth.
3. Allow instrument readings to stabilize, and collect WQ data in the electronic data collection unit and on the field data sheet. During operation of the WQ meter, the screen on the handheld portion should be shielded from direct sunlight.
4. Note in the field forms that the dissolved oxygen and oxidation-reduction potential results are approximate because a flow-through cell could not be used.

5. Water used for the WQ reading will be emptied into the purged wastewater tank.
6. When sampling is complete, rinse the instrument probes and the storage cup or small container with de-ionized water in accordance with SOP-A10, *Decontamination of Water Sampling Equipment,* catching the rinsate in the bucket.
7. Mount the specially cut "pouring lid" on the bucket, and carefully pour the contents into the purge water storage tank.
8. After sampling is complete, carefully clean and store the WQ instrument in accordance with the manufacturer's recommendations in preparation for the next use.

SOP-A13

Spill Prevention, Containment, and Control Measures for Monitoring Well Development, Purging, and Sampling Standard Operating Procedures for PG&E Topock Program

---

This standard operating procedure (SOP) addresses the procedures and equipment to be used for spill prevention, containment, and control associated with monitor well activities at the Topock site. This SOP applies to containment and control of potential spills from purge and equipment decontamination water generated during the development, purging, and sampling of monitoring wells.

REQUIRED DOCUMENTS:

- Topock Program Health and Safety Plan (HSP)
- Emergency Notification Binder
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase
- Operation and Maintenance Manual (O&M Manual) during the O&M phase
- Applicable SOPs may include:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A10, *Decontamination of Water Sampling Equipment*
  - SOP-A11, *Total Depth Measurements*
  - SOP-A12, *Field Water Quality Measurements for Grab Samples*
  - SOP-A14, *Pore Water Sampling*
  - SOP-A16, *Access Routes*
  - SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*

- SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
- SOP-A23, *Sample Handling and Custody*
- SOP-C1, *Solinst Pressure Transducers*

REQUIRED EQUIPMENT:

- Large (10′ by 11′ by 4″ deep) bermed spill containment pad. This pad is to be placed on the ground beneath the truck or utility task vehicle (UTV)-mounted purge water tank. It will be placed so that the work area at the rear of the vehicle is covered and so that small spills or drips from the purge tank or work area are captured.
- Medium (4′ by 8′ by 4″ deep) bermed spill containment pad. This pad is used at the FLUTe wells, Blatypus wells, and peristaltic wells, or for additional work space at any well.
- Small (4′ by 4′ by 4″ deep) bermed spill containment. This pad fits inside the UTV beds beneath the purge tank when sampling using UTVs (flood plain and special access wells, see SOP-A16).
- Small (2′ by 4′ by 4″ deep) bermed "pizza cut" spill containment pad for placement around well heads.
- Additional spill containment pads as necessary or as directed by the field team leader.
- Purge water tanks as appropriate for the task.
- Extra spring clamps, fittings, paper towels, and tools, etc.
- Small trash bags for temporary storage of dedicated transducers removed from wells.
- Trash pump, for transferring purge and decon. water at IM-3.
- 4 or more 5-gallon buckets and specially cut "pouring lid"
- Hydrophilic sorbent material (absorbent pads, booms, or mats)
- Plastic sheeting
- Shovel and/or other hand tools
- Plastic bags or buckets for storage and disposal of used sorbent material

PREPARATION & SETUP:

- Review this and other applicable SOPs, as well as the Emergency Notification Binder.
- Inspect all required spill containment pads for holes or tears that would compromise their effectiveness. Report such damage to the CH2M HILL Topock site coordinator or field team leader. Repair or replace damaged spill containment pads before use.
- Load spill containment equipment onto appropriate vehicle(s) and secure.

GENERAL SPILL PREVENTION PRACTICES:

- Topock is a "No Spill" site. We have all the necessary spill containment equipment, ***use it!***
- Place all items exposed to purge or decon water on the spill containment pads, not directly on the ground.
- No drops of well or purge water should ever hit the ground. Use 5-gallon buckets and spill containment pads to prevent any water from sampling equipment reaching the ground.
- Double check all fittings and connections for tightness before activating any pump.
- Check all fittings and connections for leaks immediately after starting the pump.
- Place the flow through cell and associated fittings in a 5 gal. bucket. There is often a small amount of leakage from the cell.
- If a spill does occur, immediately stop the pump, or take such action as is necessary to safely mitigate the volume or severity of the spill.
- Report all spills to the CH2M HILL site coordinator or field team leader immediately, no matter how small.
- Only use restroom facilities at the CH2M HILL job trailer or the IM-3 facility.

SPILL RESPONSE ACTIONS:

In the event purge water is spilled outside of containment basins, the field team will take the following actions:

Procedures:

- Stop the pump or take what action is necessary to safely stop or mitigate the volume or severity of the spill.
- Notify the CH2M HILL Site Coordinator or field team leader immediately, no matter how small the spill, and follow their instructions. PG&E and CH2M HILL staff may want to photo document the incident, so do not proceed with any clean-up until cleared to do so.
- The CH2M HILL Site Coordinator will perform the notifications as required in the Emergency Notification Binder and complete the Notification Documentation Form provided in the Binder.
- When cleared to do so, use sorbent material and bermed spill containment to absorb and contain the spilled purge water if possible.
- Transfer any contained purge water into the purge water tank.
- When cleared to do so, manually dig up any saturated soil and place in 5-gallon bucket(s) or other appropriate containers for disposal.

- Dispose of containerized soil, used sorbent material, and gloves in accordance with O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction.

CONTAINMENT SCENARIO 1: SAMPLING OF UTV ACCESS WELLS USING DEDICATED OR TRANSIENT PUMPS:

For monitor well sampling at UTV access wells with dedicated or transient pumps, purge water is pumped to a tank placed on 4′ X 4′spill containment pad in the back of the UTV. The UTV is parked on a 10′ X 11′ spill containment pad adjacent to the monitoring well to be sampled. Purge water is pumped directly to a YSI flow through cell contained in a 5 gal. bucket in the work area, and then into the purge tank through a discharge tube at the appropriate purge rate for that well. The small amount of leakage from the YSI flow cell is contained in a 5-gallon bucket and is manually transferred into the purge water tank using the special "pouring lid" to prevent spills.

Potential Spill Scenarios:

- Overfill of UTV-mounted purge water tank
- Failing to place lid on purge tank before mobilizing to next well
- Spills at time of tubing disconnection from tank or during manual transfer into tank from bucket
- Spills from tubing disconnection or leakage from flow cell
- Spills from tubing disconnection at well head between dedicated and non-dedicated tubing
- Spilled bucket of purge water from flow cell
- During removal of dedicated transducers from wells

Procedures:

- Before mobilization to any well, place appropriately sized tanks on small 4′ X 4′ bermed spill containment pads in UTV beds.
- Evaluate the remaining capacity of the tank prior to initiating well purging to ensure that there is sufficient capacity to hold the amount of purge water anticipated to be generated during purging of the well. Offload if needed following procedures under Containment Scenario 4.
- At the well, deploy the large 10′ X 11′ bermed spill containment pad adjacent to the well. Park the UTVs with purge water tanks on the spill pad and as close to the well head as possible, while still leaving room to work. Deploy a second or third spill containment pad as necessary to ensure adequate coverage. There should be no exposed soil between the work area and the well.
- Place the small 2′ X 4′ "pizza cut" bermed spill containment around well head.

- For a dedicated pump well: Attach the transfer tubing to the existing dedicated pump tubing at the top of the well so that the tubing connection is located ***inside*** the well protective casing and any leakage will be contained within the well head.
- Secure the transfer tubing to the bottom connection of the flow cell using hose clamps. Attach the flow through cell discharge tubing to the top fitting of the flow through cell and place the cell into a 5 gal. bucket to contain any leakage from the cell.
- Route the discharge tubing to the purge tank opening and secure using spring clamps.
- Stuff a large, unused trash bag into the top of the protective casing above the tubing connection so that any leakage or spray will be contained inside the protective casing.
- For a transient pump well: Attach the new or well specific dedicated discharge tubing to a decontaminated transient submersible pump and install into well following *SOP-A1 Purging and Sampling of Groundwater Monitoring Wells.* Transport the pump to the well head in a 5 gal. bucket to contain leakage of any residual water. With no tubing connections at the top of the well, no additional spill containment is necessary at the well head.
- All equipment is to be placed on the 10′ X 11′ bermed spill containment pad prior to the start of purging.
- Double check all tubing connections for tightness before activating the pump.
- Double check that discharge tubing is properly secured with spring clamp at purge water tank.
- Immediately after starting the pump, check all tubing connections for leakage.
- During purging, field staff will monitor the transfer of water into the purge water tank. When the tank reaches 80% full, discontinue purging to that tank. Depending on the situation, either stop the pump and properly dispose of the purge water according to the O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction.
- At the completion of purging, stop the pump and carefully disconnect the discharge tubing from both ports of the flow through cell, working inside the bucket and over containment, and allow the tubing and flow cell to drain inside of the bucket.
- Working over containment, clamp the pump discharge tubing inside a 5 gal. bucket and start the pump at low speed. Collect the sample directly from the pump discharge line, allowing excess flow to pump into the 5 gallon bucket.
- When sampling is complete, stop the pump and carefully disconnect and drain all other tubing while working over spill containment to ensure that any drips of purge water are contained on the pad.
- If a transient pump was installed, double fold the end of the dedicated down-hole tubing and secure with wire-ties to prevent leakage during pump removal. Carefully remove the pump from the well while wiping the water and power lines as they emerge with a paper

towel, and coiling the tubing neatly. As the pump clears the well, place it immediately in a 5 gal. bucket, over containment, to drain.

- Disconnect the dedicated tubing from the pump and double fold the end of the tubing, securing with wire ties to prevent leakage of the residual water still contained in the tubing. Place the tubing in its designated storage bag. At the end of the day, use compressed air from the sampling truck to carefully push the residual water out of the dedicated tubing and into the purge tank.
- Place the specially cut "pouring lid" on any 5 gallon buckets containing purge water and carefully pour contents into the purge water tank.
- If any purge water is present on the containment pad, either wipe up the water using paper towels, or collect it a bucket and dump it to the purge tank. Dispose of the wet paper towels with the rest of the contaminated trash.
- Close purge water tank openings and ensure that the tank is well secured to the UTV.
- Before mobilization, check back of UTVs for any drips that may have occurred and wipe up with a paper towel if needed.
- Pull the UTV off of the spill containment pad, fold the pad, load, and secure.
- Mobilize to the next well to be sampled and repeat the preceding steps.
- When the UTV-mounted purge water tank is 80% full, continue with procedures under Containment Scenario 4 to dump the water at IM-3.

CONTAINMENT SCENARIO 2: SAMPLING UTV ACCESS WELLS USING A PERISTALTIC PUMP:

For monitor well sampling using a peristaltic pump, purge water is placed in a small UTV or truck mounted purge tank, or 5 gallon bucket with lid. The purge tank or bucket is situated adjacent to the monitoring well to be sampled. Purge water is pumped directly to a YSI flow cell in a 5 gal. bucket, then to a 5-gallon bucket with lid, or purge tank for storage. The purge water in the bucket is manually dumped to the purge tank using the specially cut "pouring lid" to prevent spills.

Potential Spill Scenarios:

- Spills at time of hose disconnection from pump mechanism
- Spills during manual transfer into purge tank from bucket
- Spills from leakage from flow cell
- During removal or placement of tubing
- Disrupted bucket of purge water

Procedures:

- Before mobilization to any well, place appropriately sized tank on small 4' X 4' bermed spill containment pad in UTV bed.

- Evaluate the remaining capacity of the tank prior to initiating well purging to ensure that there is sufficient capacity to hold the amount of purge water anticipated to be generated during purging of the well. Offload if needed following procedures under Containment Scenario 4.
- At the well, deploy the large 10′ X 11′ bermed spill containment pad adjacent to the well. Park the UTV with the purge water tank on the spill pad and as close to the well as possible, while still leaving room to work. Deploy a second or third spill containment pad as necessary to ensure adequate coverage. There should be no exposed soil between the work area and the well head.
- Place the small 2′ X 4′ "pizza cut" bermed spill containment around well head. With no tubing connections at the well, there is no need for additional spill containment at the well-head.
- Install the dedicated down-hole tubing. Take care to ensure that any residual water in the tubing is contained on spill pads. In the slant wells (MW-52's, 53's and 56's) the dedicated tubing is stored in the well itself.
- Attach the peristaltic pump-head tubing to both the dedicated down-hole tubing and the pump discharge tubing, and use a wire-tie to secure each. Clamp the pump-head tubing into the peristaltic pump, ensuring that it is not pinched in the clamp (this could wear a hole), and place the pump on the 10′ X 11′ bermed spill containment pad.
- Attach the pump discharge tubing to the bottom connection of the flow cell and secure with a wire-tie. Attach the flow cell discharge tubing to the top fitting of the cell, secure with a wire-tie and place the cell into a 5 gal. bucket to contain any leakage.
- Route the discharge tube to a 5-gallon bucket or purge tank and secure with a spring clamp. Make sure additional empty purge buckets are available.
- All equipment is to be placed on the 10′ X 11′ bermed spill containment pad prior to the start of purging.
- Double check all tubing connections for tightness before activating the pump.
- Double check that discharge tubing is properly secured with spring clamp at purge water tank or bucket.
- Immediately after starting the pump, check all tubing connections for leakage.
- During purging, field staff will monitor the transfer of water into the bucket or purge water tank. If purging to a 5 gallon bucket, briefly shut down the pump and move the discharge line to another 5 gal. bucket when the bucket reaches 50% full, then use the specially cut "pouring lid" to transfer the water from the purge bucket to the purge tank. If purging to the UTV mounted purge tank, discontinue purging to that tank when the tank reaches 80% full. Depending on the situation, either stop the pump and properly dispose of the purge water according to O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction, or briefly stop the pump and switch to a different purge bucket or tank. Such investigation-derived waste (IDW) is typically

disposed of to the process stream at IM-3. Refer to Containment Scenario 4 below for instructions.

- At the completion of purging, stop the pump and carefully disconnect the discharge tubing from the flow through cell, working inside the bucket and over containment, and allow the tubing and flow cell to drain inside of the bucket.
- Working over containment, clamp the pump discharge tubing inside a 5 gal. bucket and start the pump. Collect the sample directly from the pump discharge line, allowing excess flow to pump into the 5 gallon bucket.
- When sampling is complete, stop the pump and carefully disconnect and drain all other tubing while working over spill containment to ensure that any drips of purge water are contained on the pad.
- Remove the dedicated tubing from the well and carefully drain any remaining water into purge tank. Working over containment, coil the tubing and place it into the marked ziplock bag from which it was removed.
- Place the specially cut "pouring lid" on any 5 gallon buckets containing purge water and carefully pour contents into the purge water tank.
- If any purge water is present on the containment pad, either wipe up the water using paper towels, or collect it a bucket and dump it to the purge tank. Dispose of the wet paper towels with the rest of the contaminated trash.
- Close purge water tank openings and ensure that the tank is well secured to the UTV.
- Before mobilization, check back of UTVs for any drips that may have occurred and wipe up with a paper towel if needed.
- Pull the UTV off of the spill containment pad, fold the pad, load, and secure.
- Mobilize to the next well to be sampled and repeat the preceding steps.
- When the UTV-mounted purge water tank is 80% full, continue with procedures under Containment Scenario 4.

CONTAINMENT SCENARIO 3: SAMPLING TRUCK ACCESS MONITOR WELLS:

For monitor well sampling in upland, truck accessed areas of the site, purge water is placed in a 400-gallon truck-mounted tank. Purge water is pumped directly into this tank via a transfer tube at rates up to 10 gpm. Purge water leakage from the YSI flow cell is contained in a 5-gallon bucket and is manually transferred into the purge water tank using the specially cut "pouring lid". For upland wells that are UTV access only, follow procedures under Containment Scenarios 1 or 2, as applicable.

Potential Spill Scenarios:

- Overfill of truck-mounted purge water tank
- Spills at time of hose disconnection from tank or during manual transfer into tank from bucket

- Spills from hose disconnection at well head between dedicated and non-dedicated tubing
- Spills from hose disconnection or leakage from flow cell
- During removal of dedicated transducers in wells
- Disrupted bucket of purge water
- During removal or placement of pump and/or tubing
- Spills or leaks from "splitter" if used at wells with higher velocity purge rates

Procedures:

- Evaluate the remaining capacity of the tank prior to initiating well purging to ensure that there is sufficient capacity to hold the amount of purge water anticipated to be generated during purging of the well. Offload if needed following procedures under Containment Scenario 4.
- At the well, deploy the large 10′ X 11′ bermed spill containment pad adjacent to the well. Park the sampling truck on the spill pad and as close to the well as possible, while still leaving room to work. Deploy a second or third spill containment pad as necessary to ensure adequate coverage. There should be no exposed soil between the work area and the well head.
- Place the small 2′ X 4′ "pizza cut" bermed spill containment around well head.
- For a dedicated pump well: Attach the transfer tubing to the existing dedicated pump tubing at the top of the well using the riser and valve provided.
- If a splitter is used to split the flow between the flow cell and the purge tank at high flow wells, wrap the splitter with a fresh trash bag such that any leakage or spray will be contained inside the well head or on containment. Route the high flow purge line to the purge tank and secure.
- For a transient pump well: Working over containment, attach the well specific dedicated discharge tubing to a decontaminated transient submersible pump and install into well following *SOP-A1 Purging and Sampling of Groundwater Monitoring Wells.* Transport the pump to the well head in a 5 gal. bucket to contain leakage of any residual water. With no tubing connections at the top of the well, no additional spill containment is necessary at the well head.
- Secure the transfer tubing to the bottom connection of the flow cell using hose clamps. Attach the flow through cell discharge tubing to the top fitting of the flow through cell and place the cell into a 5 gal. bucket to contain any leakage from the cell.
- Route the flow cell discharge tubing to the purge tank opening and secure using spring clamps.
- All equipment is to be placed on the 10′ X 11′ bermed spill containment pad prior to the start of purging.
- Double check all tubing connections for tightness before activating the pump.

- Double check that discharge tubing is properly secured with spring clamp at purge water tank.
- Immediately after starting the pump, check all tubing connections for leakage.
- During purging, field staff will monitor the transfer of water into the purge water tank. When the tank reaches 90% full, discontinue purging to that tank. Stop the pump and properly dispose of the purge water according to the O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction. Such IDW is typically disposed of to the process stream at IM-3. Refer to Containment Scenario 4 below for instructions. Resume pumping to the empty tank.
- At the completion of purging, stop the pump and carefully disconnect the discharge tubing from the flow through cell, working inside the bucket and over containment, and allow the tubing and flow cell to drain inside of the bucket.
- Clamp the pump discharge line to the sink at the rear of the sampling truck and start the pump at low speed. Collect the sample over containment directly from the pump discharge line, allowing excess flow to pump into the sink.
- When sampling is complete, stop the pump and carefully disconnect and drain all other tubing while working over spill containment to ensure that any drips of purge water are contained on the pad.
- If a transient pump was installed, double fold the end of the dedicated down-hole tubing and secure with wire-ties to prevent leakage during pump removal. Carefully remove the pump from the well while wiping the water and power lines as they emerge with a paper towel, and coiling the tubing neatly. As the pump clears the well, place it immediately in a 5 gal. bucket, over containment, to drain.
- Disconnect the dedicated tubing from the pump and double fold the end of the tubing, securing with wire ties to prevent leakage of the residual water still contained in the tubing. Place the tubing in its designated storage bag. At the end of the day, use compressed air from the sampling truck to carefully push the residual water out of the dedicated tubing and into the purge tank.
- Place the specially cut “pouring lid” on any 5 gallon buckets containing purge water and carefully pour contents into the purge water tank.
- If any purge water is present on the spill containment pad, either wipe up the water using paper towels, or collect it a bucket and dump it to the purge tank. Dispose of the wet paper towels with the rest of the contaminated trash.
- Ensure that all water is pumped from sink into the truck-mounted tanks. Inspect back of truck and sink and wipe off any purge water drops with paper towel.
- Before mobilization, ensure that all tank openings are secure, and wipe up any drips that may have occurred in the work area.
- Mobilize to the next well to be sampled and repeat the preceding steps.

- When the truck mounted purge water tank is 90% full, continue with procedures under Containment Scenario 4 below.

CONTAINMENT SCENARIO 4: TRANSFER OF PURGE WATER FROM TRUCK MOUNTED TANK OR UTV MOUNTED TANK TO IM-3:

When the truck or UTV mounted purge water tank requires emptying, the following procedures will be used. Purge water is transferred into a 5,500-gallon storage tank at the IM-3 Treatment Plant, at rates up to 20 gpm. The 5,500-gallon tank is located within a permanent containment structure.

Potential Spill Scenarios:

- Overfill of tank at final storage location
- Pump or transfer hose leakage during pumping into tank or at time of hose disconnection.

Procedures:

- See an IM-3 plant operator for assistance in transferring purge water.
- Park the truck or UTV on the bermed spill containment pad at the IM-3 transfer location.
- Follow the instructions of the IM-3 plant operator and use the trash pump to transfer purge water from the purge tank to the receiving tank. The IM-3 plant operator and field staff will be present during the entire transfer to monitor the water level in the receiving tank and to ensure no leakage or spills occur. If the receiving tank approaches being full, discontinue transfer operations.
- At the completion of transfer operations, take care when removing the transfer hose from the truck or UTV mounted purge water tank opening, since some residual water will be present in the hose.
- Secure tank openings on the truck-mounted or UTV-mounted purge water tank.
- Proceed to the next well for sampling.

SOP-A14

Pore Water Sampling
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for pore water sampling at the Topock site. This SOP should be used for pore water sampling stations on the Colorado River.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP).
2) Pore Water and Seepage Study Work Plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Field Procedures Manual).
3) Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
4) Operation and Maintenance (O&M) Manual, and Quality Assurance Project Plan (QAPP) (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan) as required during the O&M phase.
5) Topock Program Health and Safety Plan (HSP).
6) Blank sampling logs and field notebook.
7) Applicable SOPs may include:
   - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
   - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
   - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
   - SOP-A4, *Depth-Specific River Water Sampling*
   - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
   - SOP-A6, *Field Filtration*
   - SOP-A7, *Water Level Measurements*
   - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
   - SOP-A9, *Calibration of Field Instruments*
   - SOP-A10, *Decontamination of Water Sampling Equipment*
   - SOP-A11, *Total Depth Measurements*
   - SOP-A12, *Field Water Quality Measurements for Grab Samples*
   - SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
   - SOP-A16, *Access Routes*

- SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
- SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
- SOP-A23, *Sample Handling and Custody*
- SOP-C1, *Solinst Pressure Transducers*

PREPARATION & SETUP

1) Review event-specific SAP or event-specific field instructions, Work Plan, O&M Manual, and HSP.
2) Initiate field logbook for sampling activity.
3) Inspect all equipment and calibrate field water quality (WQ) meters according to SOP-A9, *Calibration of Field Instruments*.
4) Inventory sample bottles, required analyses, and confirm the lab courier schedule.
5) Field-check and set up sampling equipment: drive point sampler, WQ meters, health and safety apparatuses (life vest, rescue rope, life preserver), water depth meter or depth-finder, weighted tape, peristaltic pump, filters, sufficient tygon and silicone tubing, sampling equipment, etc.
6) Conduct tailgate meeting to discuss health and safety issues and event objectives.

SAMPLING PROCEDURES

1) Prepare pore water sampling log (use attached form).
2) The sampling team will travel to each pore water sampling station in a motorized boat. A safety inspection of the boat will be performed by the field crew prior to boarding (check for fire extinguisher, etc.). Samples will be collected from selected stations along transects across the river.
3) An industry standard (Trimble or similar) resource grade handheld DGPS unit (GeoXT or similar) will be used with real-time correction (wide area augmentation system) to locate the sampling stations within a 1 meter radius (68% of the time, commonly referred to 1 sigma accuracy). At each location, two anchors should be positioned upstream at least 10 feet from each other. Record the GPS coordinates on the sampling log. In the event a sampling station is too shallow to safely approach by boat, the next closest location with adequate depth will be sampled and a remark noted on the sampling log with the new GPS coordinates.
4) Record the depth of the river at each sampling station using the depth-finder or a weighted tape. If a weighted tape is used, read the tape at the river water surface when the weight touches the river floor. Record river depth on the sample log.
5) Samples will be collected at a depth below the river bottom determined from the pilot study.
6) Samples are to be collected using a drive point sampler and variable-speed peristaltic pump with ¾-inch tygon tubing. Dedicated tubing will be used for each sample. Once

the sampling depths have been calculated for each station, pre-cut two pieces of tygon tubing and attach them to the drive point sampler. Lower the sampler and tubing until the tip of the sampler touches the river bottom. Then hand-drive the sampler into the river sediment until desired depth is achieved. Attach the discharge end of the sample tubing to the flow cell of the water quality meter. Start the peristaltic pump and purge 3 sampler volumes. Record the time, pH, conductivity, turbidity, dissolved oxygen, temperature, salinity, TDS, and ORP on the field log. Note and provide qualifying remarks if parameter readings are anomalous or unstable due to an instrument problem. Turn off the peristaltic pump, remove tubing from the flow cell, and restart the pump. Attach a 0.45 micron filter when sampling for Cr(T) by USEPA Method 6010B or for Cr(VI) by USEPA Method 7199. Refer to SOP-A6 in the Field Procedures Manual for filtration procedures. Pump approximately 500 ml through the system and begin filling the applicable sample bottles. Remove the filter prior to filling sample bottles for the other analyses, which do not require filtration. Record all sample information on the field log.

7) Collect remaining samples for analyses according to the event-specific SAP. Use a new piece of tygon tubing and change out the flexible silicone tubing in the peristaltic pump at each location.

8) Follow the Field Procedures Manual and O&M Manual for sample handling and management, equipment decontamination, and investigation-derived waste (IDW) management.

9) Decontaminate the sampling apparatus after each sample is collected. The decontamination will be a triple rinse with 5-gallon buckets containing soapy water, potable water, and deionized (DI) water, respectively. First, the apparatus will be placed in the soapy water and the outside scrubbed. Then pump approximately 3 sampler volumes through the apparatus using the peristaltic pump and dedicated tubing used. Re-circulate the water back into the 5-gallon bucket. Repeat the rinse with the potable and deionized water.

10) Collect an equipment rinse blank after the first decontamination of the day. Collect the sample by attaching the decontaminated sampling apparatus to a length of clean peristaltic tubing. Run deionized water through the sampler and collect a sample to be shipped to the analytic laboratory for hexavalent chromium analysis.

SOP-A16

Access Routes
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures to be used when accessing wells or other sampling stations at the Topock site. This SOP should be used for all travel to collect data on site. All field personnel and subcontractors are required to read this SOP and sign on the Employee Signoff Form. Although no groundwater sampling is currently planned to be conducted at any SWFL habitat wells during SWFL nesting season, the procedures below will be used if such sampling does become necessary.

OVERVIEW:

Figure 1 at the end of this SOP shows the Topock project groundwater and surface water data collection locations. The map also shows the access routes used for sampling and transducer downloads. These lines indicate vehicle access on existing roads, and indicate where utility vehicle (UTV) or foot access is used at locations where pickup truck access is not allowed. Purple lines on the map indicate where either pickup trucks or UTVs are used. Blue lines indicate routes with allowed access by UTV but not by pickup truck. Black dotted lines indicate foot access routes. Where the black dots overlay the blue routes on the floodplain area, the access is on foot or by electric UTV during the southwestern willow flycatcher (SWFL) nesting season (May 1st through September 30th), and by any UTV outside of nesting season. The access routes with specific mitigation measures or access procedures discussed herein are highlighted in green.

There are 3 access procedures that are to be followed depending on when/where fieldwork is to occur:

A = Universal for the site

B = SWFL habitat during SWFL summer nesting season (May 1st through September 30th)

C = Upland close to cultural resources (Year-round)

A site sensitivity orientation is to be provided to all field personnel regarding cultural and biological resources and the spiritual importance of the geographic area and the river to local tribes. The orientation will emphasize that cultural resources are a concern in all areas of the project, and the need to stay within the established, marked access routes as well as work areas, and to prevent enlargement of previously used areas.

A SITES ACCESS PROCEDURES – APPLIES TO ALL SITES:

Personnel must obey the following procedures when accessing all data collection sites (refer to Figure 1):

- Access by vehicles is restricted to established roads or tracks. For off-road access the number of vehicles used should be minimized.
- All vehicles are to observe a 10-mph speed limit on Historic Route 66 (H-66), drive in the center of H-66 to avoid wear on the H-66 shoulders, and not cut corners when exiting H-66 to access well locations.
- All vehicles are to travel slowly off-road (5 mph speed where possible) to give time to observe and avoid wildlife and minimize noise, dust, and vehicle rutting.
- Most off-road access is to be by low-impact utility vehicles (UTV's) which carry sampling or data collection equipment as well as purge water tanks.
- Access beyond the purple lines on the map is by UTV (blue lines). Dotted black lines indicate access by foot or electric UTV. Access follows consistent routes or paths.
- Minimize time near possible wildlife habitat.
- Coordinate with on-site field client representative (FCR) to prevent unauthorized access to site areas.

These minimum procedures are followed for all data collection locations. More rigorous procedures are to be used at locations where potential concerns have been identified.

B SITES ACCESS PROCEDURES:

Field crews are to follow the following mitigation measures for the floodplain wells listed below during the SWFL nesting season, May 1st through September 30th. The universal A sites measures that were outlined above will also apply at these locations. Site B locations include:

- Well clusters MW-27, MW-34, and shoreline location R-27 on the Bureau of Land Management (BLM) managed area
- Well clusters MW-22, MW-43, MW-52, MW-53, and shoreline location R-22 on the Havasu National Wildlife Refuge (HNWR) area

Well sampling, transducer data collection, and any other work activities will not occur during the biennial protocol survey for SWFL's. Upon completion of the surveys, the onsite biologist will approve/disapprove of work activities depending on the survey results. If a SWFL is not detected, then the biologist will permit the activities. If a SWFL is detected, then the biologist will not permit the work activities, and the regulatory agencies will be consulted.

Specialized Field Equipment:

An electric UTV will be utilized while accessing B sites on BLM and HNWR property during the nesting season. The electric UTV will minimize noise and enable the sampling crew to minimize the number of trips needed to transport equipment to a well cluster in SWFL habitat.

Power supply outlets have been installed at PE-1 and a leak detection vault north of MW-39. By using this power supply to power the groundwater pumps instead of a generator, the sampling operation is virtually noiseless when sampling the MW-34 monitor well cluster.

New ½" I.D. LDPE tubing will be used to connect the pumps at the well head to the purge tanks at the staging areas. Spill containment will be placed under any hose connections where multiple hose segments are required to reach more distant wells. The hose will be cleared of all water after sampling is completed. Clearing water from the hose will be accomplished by lifting the hose to shoulder height to drain the water into the purge water storage tank.

New dedicated pumps were installed in late 2005 in MW-27, MW-34, and MW-43 well clusters. Therefore, pumps and decontamination equipment will no longer need to be transported to these wells, decreasing the overall impact associated with sampling at these locations.

Access Procedures for Wells on BLM Property:

Well clusters MW-27, MW-30, MW-34, MW-36, MW-39, MW-42 and MW-45 will be accessed directly by UTV's from the south access, under the railroad tracks. For sampling the MW-34 cluster, an electric UTV will be used to carry equipment and access the wells, and a second UTV with the purge tank will park in the staging area at the PE-1 location. New or dedicated ½" ID LDPE tubing and a power cord will be stretched from the well heads to the purge tank and power source at PE-1. For sampling the MW-27 cluster and R-27 when necessary, the electric UTV will be used to carry equipment and access the wells, and a second UTV with the purge tank will park in the staging area just north of the railroad bridge between MW-42 and MW-27. New or dedicated ½" ID LDPE tubing and a power cord will be stretched from the well heads to the purge tank and generator at the staging area.

Access Procedures for Wells on HNWR Property:

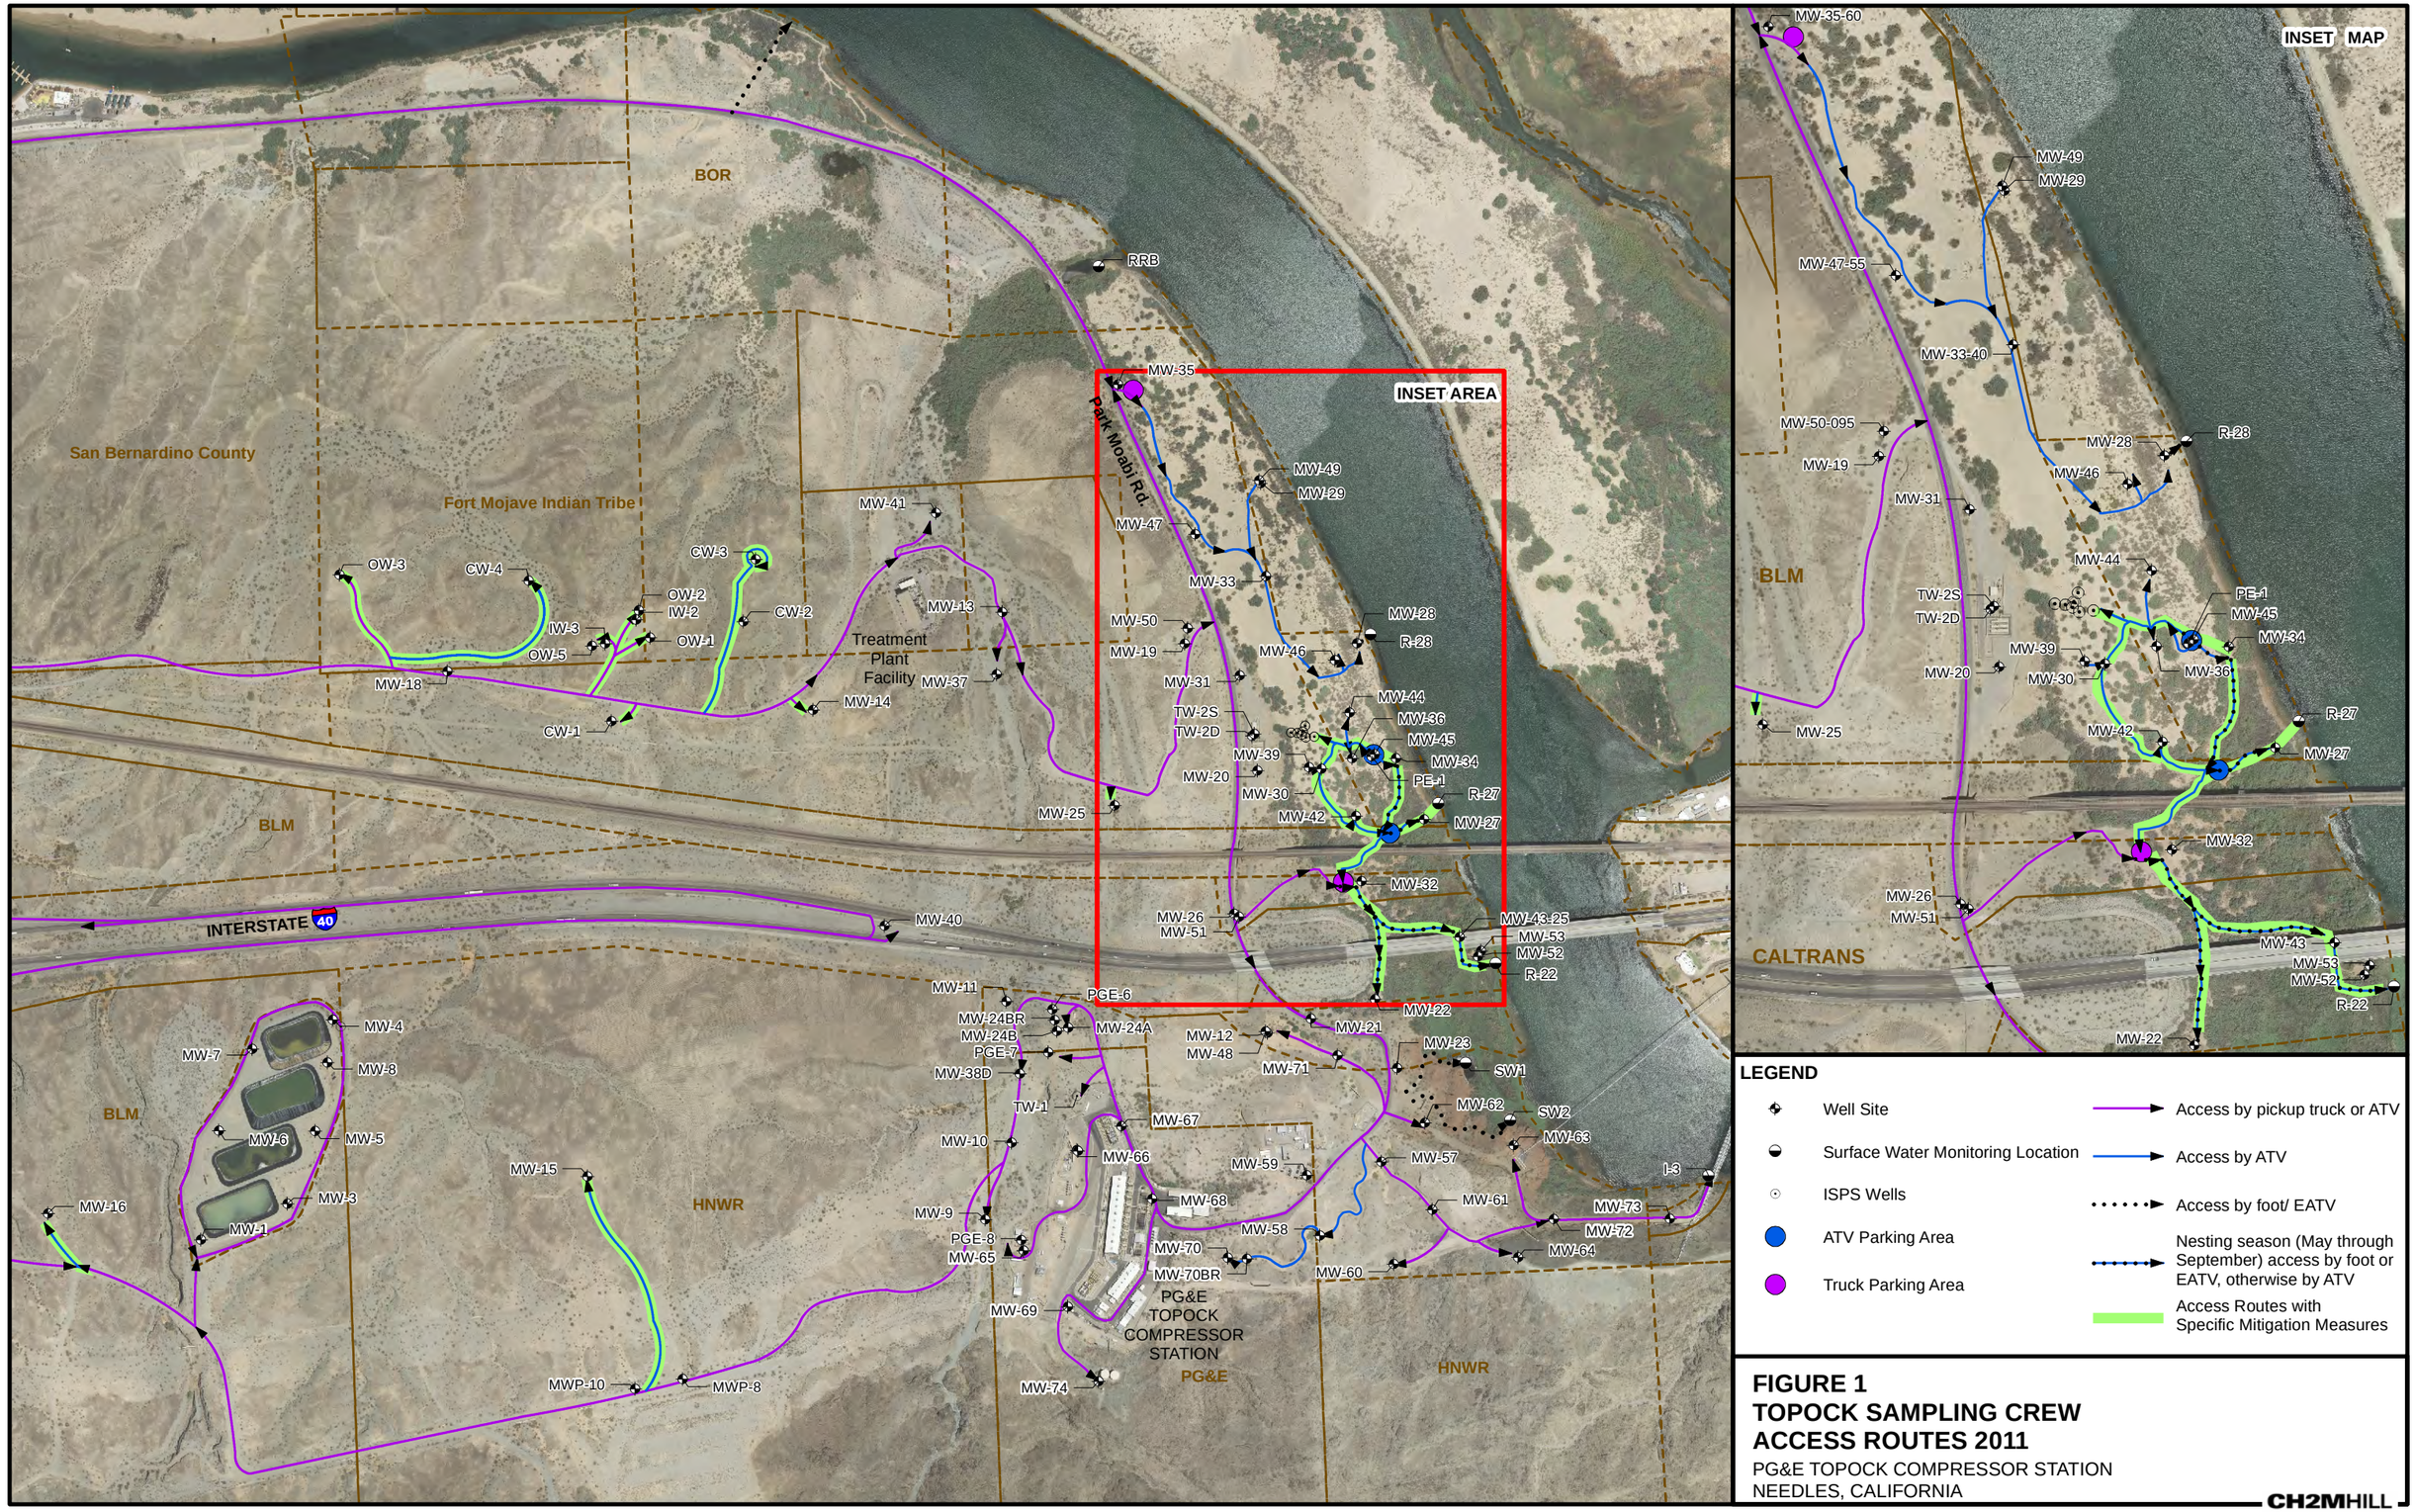
Monitor well clusters MW-22, MW-43, MW-52, and MW-53 and shoreline station R-22 are located on HNWR property, south of the railroad bridge. UTV mounted equipment is to be staged at the cleared and graded area to the west of well cluster MW-32 (Figure 1). All power generation equipment and purge water storage tanks are staged at this location. The electric UTV will be used to carry equipment and access the wells, and a second UTV with the large purge tank will park in the staging area described above. New or dedicated ½" ID LDPE tubing and a power cord will be stretched from the well heads to the purge tank and power source at the staging area. For MW-22 and the MW-52 and MW-53 clusters, a peristaltic pump and battery are used for purging directly to a small tank on the electric UTV.

Sampling Procedures for B Site Wells:

The following list summarizes the modified "nesting season" sampling procedures for the B site monitoring wells with dedicated pumps. These modified procedures will be followed each year during May 1st through September 30th:

- A biologist or authorized individual will pre-survey the planned work area for the presence of nesting listed-bird species, and sampling will proceed if the survey results are negative. BLM and DTSC will be contacted and sampling will not proceed if the pre-survey finds nesting listed-bird species.
- New sampling procedures and biological resource sensitivity will be reviewed at each field event kickoff briefing.
- The UTVs will maintain low speeds and low revolutions per minute to minimize noise. The target speed will be 5 mph on the floodplain, per BLM direction. The UTVs will maintain a reduced speed to the extent possible while avoiding getting lodged or stuck.
- A biologist will accompany the sampling team upon startup of activities and will provide a reconnaissance "sweep" during the sampling event.
- A generator will be operated at the staging areas only when there is no nearby power supply (HNWR).
- Water level measurements are to be taken at the beginning and end of the purge only. No measurements will be taken during the purge.
- Spill prevention, containment, and control measures outlined in SOP-A13 will be implemented.
- At all times, conversation noise and abrupt or unnecessary movements will be avoided, and equipment noise will be minimized. Equipment will be muffled or padded during transport and setup to avoid clanging or other impact noises from bottles and metal components.
- A biologist's report of the sampling activities will be completed within a week of the sampling and submitted to DTSC and BLM.

C SITES ACCESS PROCEDURES:



Field crews are to implement the following mitigation measures for the upland wells listed below to prevent impact from data collection on cultural or biological resources.

- East Mesa wells (IW-2, IW-3, OW-1, OW-2, and OW-5 well clusters)
- West Mesa wells (OW-3 well cluster)
- Compliance wells (CW-1, CW-2, CW-3, and CW-4 well clusters).
- Monitoring wells MW-14, MW-15, MW-16, MW-18, and MW-25.

The goal of these additional precautions is to prevent any excursion onto areas that were not previously disturbed and minimize the impact of field work. Unlike the B sites access procedures that were developed for use on the floodplain only during the summer SWFL nesting season, the precautions for these upland area C sites will be applied on a year-round

basis. The universal A sites measures that were outlined above will also apply at these locations year round.

- Personnel and vehicles are required to stay within the areas that were previously disturbed. The work areas are delineated where possible using straw "wattles", these barriers are not to be crossed with any vehicle.
- For the less frequent quarterly or semiannual access to wells MW-15, MW-16, MW-18, and MW-25, crews must stay on the clearly defined gravel access roads to each well.
- Use lathe stakes to mark boundaries during construction and well installation, rather than orange plastic fencing. These boundary stakes will be maintained, and if needed a similar marker for both access routes and work area boundaries may be substituted in the future. Any replacement should have limited visual impacts, such as straw wattles to prevent travel off existing designated work areas. Specific areas where these boundary markings are maintained include:
  - Access route on and off H-66 and edges of the East Mesa.
  - Access route from H-66 and a turnaround/work area near OW-3 on the West Mesa.
  - Access route from H-66 and a turnaround/work area near CW-4 in the unnamed wash.
  - Access routes past CW-2 and turnaround area at CW-3.
  - Defined access turn-off from H-66 to CW-1 and MW-14.
- Drive one-way on the CW-2 and CW-3 access track and turn vehicles only at the established turnaround at CW-3.
- Drive in only the active channel area of the wash when accessing CW-4. Follow the previous access path, marked where possible with straw wattles.
- Stay on established roads to access MW-15 and MW-16.

LEGEND

- Well Site
- Surface Water Monitoring Location
- ISPS Wells
- ATV Parking Area
- Truck Parking Area
- Access by pickup truck or ATV
- Access by ATV
- Access by foot/ EATV
- Nesting season (May through September) access by foot or EATV, otherwise by ATV

SOP-A17

Groundwater and Surface Water Mobile Integrated Sample Tracking Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and tools to be used for collecting and managing field data as well as managing analytical samples collected in the field associated with the Topock Monitoring Programs. This SOP is a guideline to be used during the collection of surface water and groundwater data. This includes the Groundwater Monitoring Program (GMP), Compliance Monitoring Program (CMP), and River Monitoring Program (RMP) samples.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP).
2) Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual, and Operation and Maintenance (O&M) Manual, as required.
3) Mobile Integrated Sample Tracking (MIST) Operators Manual
4) PG&E Programs Data Management Plan
5) Topock Quality Assurance Program Plan (QAPP)

FIELD DATABASE PREPARATION & SETUP

This section describes the upfront planning a preparation steps necessary to properly set-up a groundwater or surface water sampling event using the Topock Field Database. This SOP provides the how-to information for properly entering information into the field database.

1) Ensure that you have the latest version of the Topock field database. This actually consists of two database files. The "Front end" that is the interface for information entry and management and the "backend" that stores the field data and sampling information.
2) Set up the "Project Name" in the field database using the established Topock Event nomenclature, year-program-event number. For example, if you are preparing the field database for the 144th GMP sampling event, which will occur in 2008, the event title will be 2008-GMP-144.
3) Sample IDs will be entered into the database using the following convention: well ID--event number. For example, well MW-34-100 sampled during event 2008-GMP-144 would be named MW-34-100-144.
4) Analyses will be entered into the field database in accordance with the most recent SAP and any modifying documents or correspondences. Modifying documents may include the most recent Contract Work Assignment, correspondences from the regulatory agencies and client, and additional direction from project managers.

QUALITY CONTROL PROCEDURES PRIOR TO SAMPLING EVENT

The following steps describe the QC procedures prior to the initiation of sampling activities necessary to ensure all the required samples are collected.

1) Prepare a planned sample table (PST) from the database including all locations and analyses for the sampling event to be performed. An example of the PST is included as an attachment to this SOP.

2) The PST is to be reviewed by the project manager (PM) responsible for the upcoming event and the designated QC manager. If the PM and the QC manager concur with the PST, both will sign the form indicating that the samples listed are complete in accordance with all guidance documents.

3) When the PST is reviewed and accepted, prepare the event paperwork from the field database. This includes sample labels, purge forms and blank chains of custody. In addition, a list of bottles can be generated to be used to order sample bottles from the analytical laboratories. Compare the forms against the approved PST for completeness and accuracy.

USING THE MIST HANDHELD UNIT AND FIELD DATABASE

The Topock monitoring program uses the CH2M HILL proprietary Mobile Integrated Sample Tracking (MIST) system for field data acquisition and analytical sample tracking. This SOP provides an outline of steps for using the system. Details for using the MIST system are provided in the MIST operator's manual.

1. Load the appropriate field database onto the computer that is to be used for sample tracking during the field sampling event. Follow the steps in the users manual to properly prepare the database for upload into the handheld unit (Recon).

2. Load the data for the upcoming sampling event(s) onto the MIST handheld computer. Boot the system and check to ensure that the complete sampling set is included.

3. Upon arrival at a monitoring well or other sample location select the correct sample location ID manually or scan the radio frequency identification (RFID) tag if the location is so equipped. The RFID tag is a black disc approximately the size of a quarter that is attached to the well casing. Upon scanning the RFID tag, the well ID and construction information will appear on the Recon screen. **Confirm that you are at the location you intend to sample. If the well cannot be properly identified via RFID tag and or clear marking, the location is to be identified by measuring the total depth of the well.** Wells sampled on a monthly sampling frequency are indicated by a colored band around the top of the well casing.

4. Purge and sample the location in accordance with the appropriate sampling SOP (see SOPs A-1 through A-4 for sampling procedures). Record the well and purge information in the MIST unit as directed by the MIST Operator's Manual. In addition, record all field data on a hardcopy purge form. The hardcopy forms will serve as backup in case the data on the handheld unit is lost.

5. When the necessary purge volume has been purged, use the MIST unit to confirm that the field parameters are stable in accordance with site SOPs. If the parameters are not stable, continue purge. If stabilization is achieved, collect the analytical samples.

6. The MIST handheld unit will provide a table of samples to be collected at the location. The table will also indicated required preservation and filtration. Confirm that the appropriate bottle, preservative and filtration is used for each analyte. Confirm the collection of the bottle for each analyte by entering the sample time and date. Doing so indicates that the sample has been collected and it will be recorded as such in the database.

7. After the completion of each sample location, run the "Sprite Backup" tool on the Recon unit to ensure that no data is lost in the event of power loss or other unforeseen mishap. Backup the Recon before changing battery units as well.

8. At the end of sampling each day, the data in the handheld unit is to be uploaded to the field database as directed by the MIST Operator's Manual. Once the upload is completed, run the automated COC forms from the field database.

POST SAMPLING QUALITY CONTROL

This section describes the quality control steps required at the end of each sampling day. In addition, proper sample packing and shipment are discussed.

1. After the field data has been collected and uploaded into the field database as described above, COCs forms are to be generated from the field database. Compare the COC forms to the sample bottles collected to confirm all samples are properly recorded in the COC forms.

2. Compare the COC forms to the PST to confirm that all samples were collected. Certain quality control samples may be required to be held by the lab and not analyzed unless there is a data discrepancy. Confirm that these samples are labeled "Hold" in the comments column of the COC form. If there are any deviations from the PST that are intentional record the reasons for the change on the appropriate purge form and daily log. **If there are any sampling inconsistencies that cannot be explained, the location that needs additional or other samples will need to be re-sampled. The Sampling coordinator, Project Chemist and Project Manager should be notified as soon as possible, at a minimum on each day of the sampling event, of any inconsistencies that are identified.**

3. The field database has an additional tool to compare planned samples versus samples that were actually collected. Run the Planned vs. Actual (PvA) at the end of each day to confirm that all samples were collected as planned. If there are any deviations from the PST that are intentional record the reasons for the change on the appropriate purge form and daily log. **If there are any sampling inconsistencies that cannot be explained, the location that needs additional or other samples will need to be re-sampled. The Sampling coordinator, Project Chemist and Project Manager should be notified as soon as possible, at a minimum on each day of the sampling event, of any inconsistencies that are identified.**

4. At the end of each day, forward the purge forms and COCs to the sampling task lead via email or fax. The sampling task lead is responsible for additional review of the purge and sampling information for the following:

    - Appropriate purge and sampling techniques were used.
    - The purge was complete.
    - The purge parameters are in-line with historic purge data.
    - The correct samples were collected from each location.

If there are discrepancies in the purge or sample the location may need to be re-sampled.

SOP-A18

Purging and Sampling of Groundwater Monitoring Wells
Minimal Drawdown Method
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for purging and sampling all groundwater monitoring wells approved for the minimal drawdown sampling approach. This SOP will be used for sampling groundwater monitoring wells using an adjustable rate, positive displacement pump.

REQUIRED DOCUMENTS:

- Event-specific planned sample table (PST).
- Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
- Operation and Maintenance (O&M) Manual, and Quality Assurance Project Plan (QAPP) (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan) as required during the O&M phase.
- Topock Program Health and Safety Plan (HSP)
- Applicable SOPs may include:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A10, *Decontamination of Water Sampling Equipment*
  - SOP-A11, *Total Depth Measurements*
  - SOP-A12, *Field Water Quality Measurements for Grab Samples*
  - SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
  - SOP-A14, *Pore Water Sampling*

  - SOP-A16, *Access Routes*
  - SOP-A19, *Sampling of Groundwater Monitoring Wells, Hydrasleeve No Purge Method*
  - SOP-A23, *Sample Handling and Custody*
  - SOP-C1, *Solinst Pressure Transducers*
- Well construction logs/specifications
- Mobile Integrated Sample Tracking (MIST) handheld database
- Previous sampling logs or tabular historic field data tables
- Current site access map
- Blank sampling logs, maps, sample labels, chains of custody (COC's), and the designated groundwater sampling field notebook

REQUIRED EQUIPMENT:

- 2 or more (i.e. one is backup) WQ instruments with flow through cells, or equivalent.
- Hach 2100P turbidimeter or equivalent.
- 200 foot (or longer as needed) water level indicator (WLI).
- Trimble Rugged Reader hand held instrument for MIST data collection.
- Two, 200 gallon capacity purge tanks.
- Utility vehicles (UTVs) as necessary.
- Honda 2000 watt generator or alternate power source.
- Adjustable-rate, positive-displacement pump
- Sample containers, cooler and ice

PREPARATION & SETUP:

- Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, O&M Manual, HSP, and groundwater sampling supplies and equipment check list. (NOTE: the PST should also be reviewed for required "non-analytical event activities" such as water level measurements or other data collection that is planned in association with the groundwater sampling event).
- Acquire the existing field logbook for groundwater sampling and initiate entries.
- Inspect all equipment and verify that the field water quality (WQ) meters have been calibrated prior to use according to the manufacturer's instructions and SOP-A9, *Calibration of Field Instruments*.
- Inventory sample bottles, build sample sets for the required analytes at each sample location, ensure a sufficient supply of lab de-ionized water for equipment blanks, and confirm the lab courier schedule.

- Field-check sampling equipment and supplies: water level indicator (WLI), WQ meters, flow-through cell, pump controller, power supply, pump discharge/sampling tubing, N-dex gloves, deionized water sprayers, 5 gallon buckets, paper towels, 0.45 micron in-line filters, etc.

FIELD PROCEDURES:

- **Prior to opening any monitor well, remove all pens, lighters, calculators, or any other loose items from vest pockets, or from any other location where they could fall into the well.**
- Upon arrival at the monitoring well, at least 2 members of the sampling team must confirm the well ID. Wells should be clearly marked on the well monument. If the well cannot be positively identified by the marking, measure total depth of the well and compare to the well installation details to confirm the correct location. Report worn or unclear well markings to the on-site field coordinator.
- Place spill containment according to SOP-A13 *Spill Prevention, Containment, and Control Measures for Monitoring Well Development, Purging, and Sampling.*
- If using a transient pump, collect an "EB", equipment blank, ***prior to pump installation*** if necessary according to the PST.
- Open the protective casing lid and, ***prior to moving it***, note the exact configuration of the transducer installation if present. Measure static WL according to SOP-A7, *Water level Measurements,* moving the transducer if necessary, and record WL value in MIST and on the sampling log.
- If the well is equipped with a transducer and does not have a dedicated pump installed, remove the transducer from the well according to SOP-C1, *Solinst Pressure Transducers*.
- If the well does not have a dedicated pump installed, but does have dedicated sample tubing, attach the dedicated tubing to the appropriate pump and install decontaminated pump at the same intake/sampling depth as used in prior events. There is a marking on the purge tubing which corresponds with the monitor well top of casing (TOC) to facilitate this requirement. Purge and sample the well as described below.
- If the well does not have a dedicated pump ***or*** tubing, or has not been previously sampled, use new low-density polyethylene tubing and install the pump with the intake at approximately the midpoint of the well screen. Purge and sample the well as described below.
- If the well ***does*** have a dedicated pumping system, connect the discharge tubing and purge and sample the well as described below.
- Collect daily equipment blanks and duplicate samples as required by the PST and instructed by the field team leader.

PURGING AND SAMPLING PROCEDURES:

- Install the pump in the well. Slowly lower the pump (with the attached tubing and safety line) into the well to the desired depth. The pump will be set near the middle of the well

screen, if possible. At a minimum, the pump intake will not be positioned lower than 2 feet from the bottom of the well. The depth to the pump intake will be recorded on the Groundwater Sampling Form. If there is less than 3 feet of available water, the groundwater well will be purged and sampled using a bottom-loading bailer.

- Measure the water level in the well after pump insertion. Leave the water level probe in the well to facilitate continued water level monitoring during purging activities.
- Start purging the well at a low flow rate between 0.2 and 0.5 liters per minute. Measure the purge rate using a container of known volume, and record this information on the Groundwater Sampling Form
- The water level should be monitored during purging, and ideally, the purge rate should equal the well recharge rate so there is limited drawdown in the well. (The water level should stabilize for the specific purge rate). The purge rate may be increased above 0.2 and 0.5 liters per minute as long as a constant water level in the well can be maintained, and the target drawdown of no more than 1 foot is being met. There should be at least 1 foot of water over the pump intake. This assures that there is no risk of the pump suction being broken, or of entrainment of air in the sample. Record adjustments in the purge rate and changes in depth to water on the field data sheet. If the target drawdown is not met, purge rates should be decreased to the minimum capabilities of the pump (0.1 to 0.2 liters per minute). If using a pulse style pump, measure the water level at the end of the pressure cycle when the water level has recovered as much as it will, before again filling the pump during the fill cycle. This method will generate consistent drawdown data.
- During purging, the water quality parameters will be measured periodically (every 3 to 5 minutes) until the parameters have stabilized as shown below. If parameter stabilization has not occurred after 4 hours, purging activities will be considered complete.

- pH	+/- 0.1 pH units
- Specific conductance	+/- 3%
- ORP	+/- 10 millivolts
- Turbidity	10% NTU units or less unless other parameters have stabilized during an extended purge and turbidity is trending flat if still over 10 NTU units. The target turbidity goal (but not a hard criterion) is 5 to 10 NTUs.
- Dissolved oxygen	+/- 0.3 mg/L
- Temperature	+/- 2^{o} Celsius

- When the requirements above have been satisfied and the purge cycle is complete, disconnect the flow through cell and prepare to collect samples directly from the pump discharge tubing for analyses according to event-specific PST. Prepare sample containers and collect gas-sensitive analytes first. The preferred collection order will be volatile organic compounds (VOCs), semi-volatile organic compound (SVOCs), metals (including

hexavalent chromium [Cr(VI)] and total chromium [Cr(T)]; see SOP-A6), then general chemistry (cations, anions, stable isotopes).

- For filtered samples, attach a 0.45 micron in-line filter to the pump discharge and allow approximately 500 mL of sample to pass through the filter before beginning sample collection in accordance with SOP-A6 *Field filtration* and the QAPP.
- When sample collection is complete, record sample information, final WL, and purge volume data in MIST and on the field sampling log.
- If transient pump previously installed, remove the pump from the well, detach the dedicated tubing and carefully drain any residual water to the purge water tank. Fold both ends of the purge tubing and secure with wire ties as a further deterrent to leakage. Store the dedicated tubing in a sealed, labeled trash bag. Decontaminate the pump according to SOP-A10, *Decontamination of Water Sampling Equipment.*
- If well was equipped with a transducer, replace the transducer in exactly the same configuration in which it was found and in accordance with SOP-C1, *Solinst Pressure Transducers*.
- Close and secure well protection lid.
- Follow applicable SOPs, the Procedures Manual, and O&M Manual for sample handing and management, equipment decontamination, and investigation-derived waste (IDW) management (O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

SOP-A19

Sampling of Groundwater Monitoring Wells
HydraSleeve No Purge Method
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures and equipment to be used for sampling all groundwater monitoring wells approved for the HydraSleeve sampling approach.

REQUIRED DOCUMENTS:

- Event-specific planned sample table (PST).
- Applicable project work plan or monitoring plan. Refer to the Topock Program Sampling, Analysis, and Field Procedures Manual (Procedures Manual).
- Construction/Remedial Action Work Plan (C/RAWP) during the construction phase.
- Operation and Maintenance (O&M) Manual, and QAPP (Appendix B of the O&M Manual Volume 2, Sampling and Monitoring Plan) as required during the O&M phase.
- Topock Program Health and Safety Plan (HSP)
- Applicable SOPs:
  - SOP-A1, *Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method*
  - SOP-A2, *Purging and Sampling of 1-inch Diameter Groundwater Monitoring Wells, Modified Well-Volume Method*
  - SOP-A3, *Purging and Sampling of Active and Inactive Water Supply Wells*
  - SOP-A4, *Depth-Specific River Water Sampling*
  - SOP-A5, *Groundwater Sampling from Sonic Drilling Boreholes*
  - SOP-A6, *Field Filtration*
  - SOP-A7, *Water Level Measurements*
  - SOP-A8, *Field Water Quality Measurements Using a Flow-through Cell*
  - SOP-A9, *Calibration of Field Instruments*
  - SOP-A10, *Decontamination of Water Sampling Equipment*
  - SOP-A11, *Total Depth Measurements*
  - SOP-A12, *Field Water Quality Measurements for Grab Samples*
  - SOP-A13, *Spill Prevention, Containment, and Control Measures for Monitoring Well Sampling*
  - SOP-A14, *Pore Water Sampling*
  - SOP-A16, *Access Routes*

  - SOP-A18, *Purging and Sampling of Groundwater Monitoring Wells, Minimal Drawdown Method*
  - SOP-A23, *Sample Handling and Custody*
  - SOP-C1, *Solinst Pressure Transducers*
- Well construction logs/specifications
- Mobile Integrated Sample Tracking (MIST) handheld database
- Previous sampling logs or tabular historic field data tables
- Current site access map
- Blank sampling logs, maps, sample labels, chains of custody (COCs), and the designated groundwater sampling field notebook

REQUIRED EQUIPMENT:

- 2 or more (i.e. one is backup) YSI-556 WQ instruments, or equivalent.
- Hach 2100P turbidimeter or equivalent.
- 200 foot (or longer as needed) water level indicator (WLI).
- Trimble Rugged Reader hand held instrument for MIST data collection.
- HydraSleeve samplers (from supplier)
- Pointed plastic discharge tube (included with sampler)
- Polypropylene strapping (from supplier)
- Stainless steel weights
- Small cable ties
- String reel
- Utility knife
- Scissors (stainless steel)
- Well caps with small eyelet on bottom allowing a string to be tied off
- Sample containers, cooler and ice

PREPARATION & SETUP:

- Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, HSP, and groundwater sampling supplies and equipment check list. (NOTE: the PST should also be reviewed for required "non-analytical event activities" such as water level measurements or other data collection that is planned in association with the groundwater sampling event).
- Acquire the existing field logbook for groundwater sampling and initiate entries.

- Inspect all equipment and verify that the field water quality (WQ) meters have been calibrated prior to use according to the manufacturer's instructions and SOP-A9, *Calibration of Field Instruments*.
- Inventory sample bottles, build sample sets for the required analytes at each sample location, ensure a sufficient supply of lab de-ionized water for equipment blanks, and confirm the lab courier schedule.
- Field-check sampling equipment and supplies: water level indicator (WLI), WQ meters, HydraSleeve supplies, N-dex gloves, D.I water sprayers, 5 gallon buckets, paper towels, 0.45 micron in-line filters, etc.
- Evaluate the required sample volume and well construction to select the appropriate size (2-inch or 4-inch diameter) and number of Hydrasleeve samplers for each well.

FIELD PROCEDURES:

- **Prior to opening any monitor well, remove all pens, lighters, calculators, or any other loose items from vest pockets, or from any other location where they could fall into the well.**
- Upon arrival at the monitoring well, at least 2 members of the sampling team must confirm the well ID. Wells should be clearly marked on the well monument. If the well cannot be positively identified by the marking, measure total depth of the well and compare to the well installation details to confirm the correct location. Report worn or unclear well markings to the on-site field coordinator.
- Place spill containment according to SOP-A13 *Spill Prevention, Containment, and Control Measures for Monitoring Well Development, Purging, and Sampling.*
- Open the protective casing lid and, ***prior to moving it***, note the exact configuration of the transducer installation if present. Measure static WL according to SOP-A7, *Water level Measurements,* moving the transducer if necessary, and record WL value in MIST and on the sampling log.
- If the well is equipped with a transducer and does not have a dedicated pump installed, remove the transducer from the well according to SOP-C1, *Solinst Pressure Transducers*.

PURGING AND SAMPLING PROCEDURES:

HydraSleeve Deployment

1. Remove HydraSleeve sampler from package and pinch the top to create an opening. See Attachment 1 for a representation of an unfilled HydraSleeve sampler.
2. Use a HydraSleeve Spring Clip to fasten the pre-looped string to the top of the HydraSleeve sampler. Fold the two holes at the bottom of the HydraSleeve together and attach a weight using a HydraSleeve Stainless Steel weight clip. Attach the weight clip to the pre-measured string.
3. If using two HydraSleeve samplers, follow steps 1 and 2 above for placing the second sampler below the first on the pre-measured string.

4. Lower the sampler into the well until the pre-marked hanging location is level with the ground surface.
5. Following placement in the well, fasten the end of the string to the locking tab on the well casing, secure with a cable tie and the well lock.
6. Place cap back onto well.
7. Secure monitoring well and area prior to demobilization.

HydraSleeve Sample Recovery

Once a sufficient period of time has elapsed so that re-equilibration of the water within the well with surrounding groundwater conditions has occurred (typically a minimum of 48 hours), the HydraSleeve samplers can be recovered and samples collected for analysis.

For standard HydraSleeve sampler recovery, the following procedures will be performed at each well:

1. Measure the depth to water to the nearest 0.01 foot.
2. Remove all securing cable ties and remove the sampler from the well. The best method is to pull the HydraSleeve sampler upward continuously from its starting point, at a rate of one to two feet per second or faster, until the sampler is full, which is a vertical distance of 36 to 72 inches for a 36-inch long sampler.
3. The condition of the sampler should be recorded in the field sampling sheets, including the presence of any headspace within the sampler.

HydraSleeve Sample Collection

Samples for chemical analysis will be collected from the HydraSleeve samplers immediately following removal from the well. The following sampling procedures will be used at each well:

1. Identification labels for sample bottles will be filled out for each sample.
2. Hang the filled HydraSleeve from the hanger device after removal from the well.
3. Squeeze the full sampler just below its top to expel water resting above the flexible check valve.
4. Push the pointed discharge tube perpendicularly through the outer polyethylene sleeve approximately three to four inches above the bottom of the HydraSleeve.
5. Transfer the sample from both HydraSleeve samplers into a 2.5 liter compositing container. Pinching the sample sleeve just above the discharge tube will control the flow of the sample. The sample sleeve can also be squeezed, forcing fluid up through the discharge tube, similar to squeezing a tube of toothpaste.
    - The preferred collection order will be volatile organic compounds (VOCs), semi-volatile organic compound (SVOCs), metals (including hexavalent chromium [Cr(VI)] and total chromium [Cr(T)]; see SOP-A6), then general chemistry (cations, anions, stable isotopes).

- For filtered samples, transfer the sample out of the compositing container using a peristaltic pump through a 0.45 micron in-line and allow approximately 250 mL of sample to pass through the filter beginning sample collection. The limited volume in the HydraSleeve sampler requires that less sample be run through the filter than is dictated in SOP-A6 *Field filtration* and the QAPP.

6. If sample volume allows, transfer water into a container to obtain field parameter readings with a YSI-556 WQ or equivalent instrument (note in the field forms the results are approximate because a flow-through cell could not be used). Field parameter readings are to be recorded on the groundwater sample form.
7. Excess sampler water will be emptied into the purged waste water tank.
8. Samples will be preserved and managed as detailed in the QAPP. Time of sampling will be recorded in the field logbook, field sample sheets, sample labels, MIST and chains of custody.
9. After the samples have been collected, immediately place the sample bottles in an ice-filled cooler. Before decontamination of field equipment, the well cap will be replaced and locked.
10. If redeployment of a new HydraSleeve sampler is not intended, sampling equipment, except for string, stainless steel weight and rubber stopper, will be discarded as with other PPE trash, and the blank string with weight will be Stored for later use. However, if deployment of a new sampler is required, the new sampler will be reattached to the existing string and stainless steel weight. The sampler can then be deployed in the well for the next sampling event.
11. If well was equipped with a transducer, replace the transducer in exactly the same configuration in which it was found and in accordance with SOP-C1, *Solinst Pressure Transducers*.
12. Prior to leaving the site, field documentation, including the chain-of-custody form, will be completed.
13. Secure monitoring well and area prior to demobilization.
14. Follow applicable SOPs, the Procedures Manual, and O&M Manual for sample handing and management, equipment decontamination, and investigation-derived waste (IDW) management (O&M Manual Volume 1, Section 6 during O&M or Appendix R of the C/RAWP during construction).

SOP-A22

Procedures for Calculation of Freshwater Equivalent Heads Standard Operating Procedures for PG&E Topock Program

This Standard Operating Procedure (SOP) provides instructions for adjusting measured groundwater elevations to freshwater equivalent heads.

INTRODUCTION

Salinity is directly related to water density, which in turn affects the height to which water will rise in a well under static conditions. "Groundwater head" represents the energy state of a groundwater system and groundwater flows from a high energy state to a lower one. Groundwater head takes density, fluid pressure, and elevation into account. When water in a system has the same density, the elevations of water in the wells simply represent the groundwater head distribution. Because there is a range of groundwater salinity at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station (the site), accurate measurements of head require adjustment to a standard density, commonly called a "freshwater equivalent head." Water density also has temperature dependence, with density decreasing with increasing temperature. Salinity and temperature adjustments are currently performed for all water levels in the PG&E database (manual water-level measurements and the pressure transducer measurements).

The most commonly used standard density is that of freshwater. Where densities vary, as they do at Topock, the head in each well is recalculated to the value it would be if freshwater were present. In this way, these freshwater equivalent heads can be compared directly with one another, and groundwater gradients can be mapped. The heads have not been "corrected" (an often-used term), but rather have been converted to an equivalent common standard to provide and accurate comparison.

PARAMETERS MEASURED FOR CALCULATION OF DENSITY

The parameters shown in Table 1 are typically measured in the field or laboratory and may be used to determine the density of the water column, as discussed in the following sections.

TABLE 1
Parameters Used for Calculating Density

Parameter	Units	Typical Range	Description
Specific Conductance	µS/cm @ 25°C	**FW:** 0-1,500 µS/cm **BW:** 1,500-15,000 µS/cm **SW:** 15,000 to 150,000 µS/cm **BR:** >150,000 µS/cm	The conductivity normalized to a temperature of 25°C. The term electrical conductivity is often used interchangeably, although this parameter is not corrected to 25°C.
Salinity	%	**FW:** 0-0.1% **BW:** 0.1-1% **SW:** 1-10% **BR:** >10%	A measure of the dissolved salts in water on a mass-per-mass basis.
Total Dissolved Solids	mg/L	**FW:** 0-1,000 mg/L **BW:** 1,000-10,000 mg/L **SW:** 10,000-100,000 mg/L **BR:** >100,000 mg/L	A measure of the mass of dissolved solids in water on a mass-per-volume basis.

Notes:
°C = degrees Celsius
µS/cm = microSiemens per centimeter
mg/L = milligrams per liter
BR = brine
BW = brackish water
FW = freshwater
SW = saltwater

CALCULATION OF DENSITY

The density of well water must be determined before adjusting hydraulic heads to freshwater equivalent heads. However, the density of water is rarely directly measured; rather, either the salinity or specific conductance (SC) of the water is measured in the field, or the SC or total dissolved solids (TDS) are measured in the laboratory, and a density is calculated from these values.

Salinity and TDS measurements share similar properties, and conversion between the two parameters can be performed using the following formula:

$$Salinity(\%) = \frac{TDS}{10{,}051.1} \quad (1)$$

where:

TDS = the total dissolved solids of the water in milligrams per liter (mg/L).

Salinity and TDS are typically laboratory-based measurements. If salinity or TDS are provided as field measurements, these measurements are likely based upon a linear, non-site-specific conversion from an SC measurement.

Specific conductance (electrical conductivity [EC] at 25°C) is the most commonly available measurement. Specific conductance is a measure of a water's ability to conduct electricity and can be used to estimate the density of the water. The following formula is used to convert SC to TDS:

$$TDS\ (mg/L) = SC \cdot K \quad (2)$$

where:

SC = specific conductance of the water in microsiemens per cm (µS/cm).
K = a dimensionless constant typically ranging from 0.55 to 0.8.

The dimensionless constant K is often assumed to be 0.65 for typical groundwater. This value is used for site calculations at the compressor station. Where sufficient laboratory TDS data exist, a unique conversion factor will be calculated for each well.

DATABASE SETUP

Within the Topock database, manual and transducer water-level data are stored in the tables ***tblWaterLevel*** (Figure 1) and ***tblPT*** (Figure 2), respectively. Salinity and temperature data used to adjust the water levels are also stored for each measurement in these tables. The design of both tables is shown below. The information shown is associated with each water-level measurement in the database.

FIGURE 1
tblWaterLevel Table

tblWaterlevel : Table

Field Name	Data Type	Description
LocID	Text	Location ID (e.g., well, boring, station)
SampleDate	Date/Time	Date of measurement
SampleTime	Date/Time	Time of measurement
EventCode	Text	Monitoring event code
SrcCode	Text	Data source (e.g., CH2M HILL, PG&E, Legacy, etc.)
MeasPtElev	Number	Elevation (ft AMSL) from which depth to water was measured (e.g., top of PVC)
DTW	Number	Depth to water (ft)
RawSalinity	Number	Raw salinity measurement (e.g., salinity, field measured specific conductance, lab TDS, etc.)
RawSalinityDate	Date/Time	Date of salinity measurement, if applicable
CalcCode	Text	Code identifying the type of raw salinity and conversion used to convert to salinity
CalcComment	Text	Comment on salinity conversion
Salinity	Number	Final salinity of water column (%)
Temperature	Number	Temperature of water column (°F)
TemperatureComment	Text	Comment on temperature conversion
RawWElev	Number	Unadjusted groundwater elevation (ft AMSL)
CorrectWElev	Number	Final salinity and temperature adjusted groundwater elevation (ft AMSL)
Comments	Text	General comment
dbdate	Date/Time	db upload date

FIGURE 2
tblPT Table

tblPT : Table

Field Name	Data Type	Description
LocID	Text	Location ID (e.g., well, boring, station)
Date	Date/Time	Date of measurement
Time	Date/Time	Time of measurement
ElapsedTime	Number	Elapsed time since transducer test began (minutes)
Temp	Number	Temperature (°C)
PressHead	Number	Raw pressure head (ft)
Offset_ft	Number	Offset or elevation of transducer above datum (ft)
Salinity	Number	Salinity of water columnn (%)
SalCorr	Number	Salinity correction to be applied (ft)
TempCorr	Number	Temperature correction to be applied (ft)
HydHead	Number	Final salinity and temperature adjusted hydraulic head (ft AMSL)
Comment	Text	Comment regarding measurement
DST	Number	True (-1) if PDT; FALSE (0) if standard PST
Exclude	Number	True (-1) if data point to be excluded; FALSE (0) if valid data

In ***tblWaterLevel,*** the field ***CalcCode*** identifies what value is stored in the ***RawSalinity*** field and how the final salinity value is determined. Possible conversion codes and the corresponding conversions to salinity (in percent [%]) include:

FEC2SAL Field-measured EC[1] (microSiemens per centimeter [µS/cm]) converted to salinity (%) [SAL=EC*0.65/10051.1]

LEC2SAL Laboratory-measured EC[1] (µS/cm) converted to salinity (%) [SAL=EC*0.65/10051.1]

FTDS2SAL Field-measured TDS (milligrams per liter [mg/L]) converted to salinity (%) [SAL=TDS/10051.1]

LTDS2SAL Laboratory-measured TDS (mg/L) converted to salinity (%) [SAL=TDS/10051.1]

LSAL Laboratory-measured salinity (%) [no conversion]

FSAL Field-measured salinity (%) [no conversion]

PSAL Salinity (%) measured during previous event [no conversion]

DETERMINATION OF DENSITY AS A FUNCTION OF TEMPERATURE

The density of water is also dependent upon temperature. Table 2 summarizes the density of freshwater at various temperatures.

TABLE 2
Relationship Between Temperature and Density of Freshwater

Temp. (°C)	Density (g/cm3)	Temp. (°C)	Density (g/cm3)	Temp. (°C)	Density (g/cm3)
1	0.999900	11	0.999605	21	0.997992
2	0.999941	12	0.999498	22	0.997770
3	0.999965	13	0.999377	23	0.997538
4	0.999973	14	0.999244	24	0.997296
5	0.999965	15	0.999099	25	0.997044
6	0.999941	16	0.998943	26	0.996783
7	0.999902	17	0.998774	27	0.996512
8	0.999849	18	0.998595	28	0.996232
9	0.999781	19	0.998405	29	0.995944
10	0.999700	20	0.998203	30	0.995646

Source: *Win-Situ 4 User Manual* (In-Situ, 2003)

The United States Geological Survey paper *Quality Assurance and Analysis of Water Levels in Wells on Pahute Mesa and Vicinity, Nevada Test Site* (WRIR 00-4014), available at http://pubs.usgs.gov/wri/WRIR00-4014/text/contents.htm, summarizes the methodology to correct groundwater elevations for temperature-dependent density.

[1] The term EC, as used here, is actually SC because Topock field meters automatically convert to conductance at 25°C.

SALINITY AND TEMPERATURE ADJUSTMENTS FOR GROUNDWATER ELEVATIONS

Manual and transducer water-level data at Topock have been adjusted for salinity and temperature since January 2003. The salinity- and temperature-adjusted water elevations are stored in the ***CorrectWElev*** field in ***tblWaterLevel*** (manual water-level data) and in the ***HydHead*** field in ***tblPT*** (transducer data). It is assumed that:

- The salinity of the water column in wells is constant throughout the water column.
- The bottom of the well is the measurement point, and the entire water column is adjusted for salinity and temperature by the processes in this SOP.

The salinity adjustment (SalCorr), measured in feet (ft), for each water elevation is calculated as follows:

$$SalCorr\ (ft) = Column \times SAL \times 0.0071 \quad (3)$$

where:

SAL = the salinity of the water column in percent (%).
Column = the height of the water column to be adjusted in feet (ft).

The temperature-dependent density of water within the well is determined using the following empirical equation:

$$Density\ (g/cm^3) = 4.78\text{x}10^{-8}\ T^3 - 8.15\text{x}10^{-6}\ T^2 + 6.16^{-5}\ T + 1.00 \quad (4)$$

where:

T = temperature in degrees Celsius (°C).

The temperature adjustment (TempCorr) for each water elevation is calculated as follows:

$$TempCorr\ (ft) = Column \times [1/Density] - Column \quad (5)$$

For manual water-level data, the temperature- and salinity-adjusted groundwater elevation is calculated as follows:

$$CorrectElev\ (ft\ AMSL) = RawElev + SalCorr + TempCorr \quad (6)$$

where:

RawElev = the groundwater elevation in feet above mean sea level (ft AMSL) with no adjustment for temperature or salinity.

For transducer data, the temperature- and salinity-adjusted groundwater elevation is calculated as follows:

$$HydHead\ (ft\ AMSL) = PressHead + Offset + SalCorr + TempCorr \quad (7)$$

where:

PressHead = the height of the water column above the transducer in ft
Offset = the elevation of the transducer above the datum in ft AMSL.

SOP-A23

Sample Handling and Custody
Standard Operating Procedures for PG&E Topock Program

PURPOSE

The purpose of this standard operating procedure (SOP) is to delineate protocols for sample handling and custody for the PG&E Topock Program environmental monitoring activities associated with the Topock Compressor Station (TCS) in Needles, California. An example chain-of-custody (CoC) form and sample custody seals are provided as part of this procedure (see Attachment 1). Other formats with essentially identical information are acceptable.

SCOPE

This procedure applies to all PG&E personnel, contractors, and subcontractors engaged in collecting environmental samples related to the Topock investigation and remedial activities.

GENERAL

An essential part of the sampling activities of any environmental project is assuring the integrity of the sample from collection through data reporting. This SOP will address all sample custody issues up through sample relinquishment to the courier to deliver samples to the laboratory final destination. Sample labels, CoC forms and custody seals are used to document identification and handling/control (custody) of samples from the time of collection through the completion of chemical analysis. Accountability of the history of a sample must be available to demonstrate that the data are a true representation of the environment. The CoC record is used as evidence to demonstrate that a sample was not tampered with or altered in any way that might bias the analytical accuracy of the laboratory results since the time of its collection. It is extremely important that chain-of-custody records be complete, accurate, and consistent. In some projects, including this one, sample custody records and analytical data may be used in litigation. In all cases of custody, the accuracy and completeness of records is critical for evidentiary use whether as part of the normal data validation procedure or in a litigious project environment. All sampling activities for the Topock environmental program must adhere to the procedures in this SOP in order to ensure complete, accurate, and consistent project data.

DEFINITIONS

1. Custody: A sample is under custody if it is in physical possession or under control so as to prevent tampering or alteration of its characteristics. A sample is considered to be in an individual's custody if it is (1) in the physical possession of the responsible party, (2) in view of the responsible party after being in their possession, or (3) placed by the responsible party in a designated, secure area that is controlled with restricted access.

2. Sample Label: A record attached to samples to ensure legal documentation of traceability. Attachment 1 includes an example of the sample labels that are used.

3. Chain-of-Custody Record: Legal documentation of custody of sample materials and instructions for the analytical laboratory. Attachment 1 includes an example of a CoC form.

RESPONSIBILITIES

Project Manager

The *Project Manager* (PM) shall ensure that staff conducting these procedures are properly trained. Prior to the sampling event, the PM shall review and approve the planned sample table (PST). In addition, sampling staff must consult the PM if any complications arise with following these critical sample handling and custody procedures.

Project Chemist

The *Project Chemist* shall review and approve the PST. In addition the chemist shall be consulted in the event any questions surface concerning sample handling and custody procedures.

Field Team Leader/Sampling Coordinator

The *Field Team Leader/ Sampling Coordinator* (FTL/SC) shall assure that the systems are maintained to create CoC forms from the sample-tracking database. In addition, the FTL/SC is responsible for production of CoC forms and sample labels for the field crews. The FTL/SC shall also take responsibility for or delegate the packing of the sample shipping coolers, ensure that the CoC forms are correct, and ship the samples (or transfer to laboratory sample pickup) as described in this SOP. The FTL/SC shall determine or seek guidance as to which samples are potentially hazardous and the appropriate shipping method, if needed.

Sample Collector

The *Sample Collector* shall ensure that the samples are correctly collected (following the appropriate SOP), labeled, and stored until the FTL/SC takes custody of the samples for shipping to the laboratory. The Sample Collector shall maintain custody of the samples until said time that the FTL/SC takes custody. The Sample Collector shall be responsible for informing the FTL/SC of sampling conditions and recording sampling conditions on the groundwater sampling log. (Note: The FTL/SC, Sample Collector, and Sample Shipper may be the same person.)

Sample Custodian

The *Sample Custodian* is any individual who is responsible for the custody of samples and completion of associated documentation and may include the FTL/SC, Sample Collector, or on large events, a separate Sample Shipper.

PROCEDURE

Sample Custody

Sample custody procedures are designed to ensure that sample integrity is maintained from collection to the final receipt of the analytical report. A critical aspect of sound sample collection and analysis protocols is the maintenance of strict CoC procedures, as described in this SOP. CoC procedures include tracking and documentation during sample collection and shipment.

As noted above, a sample is considered to be in an individual's custody if it is (1) in the physical possession of the responsible party, (2) in view of the responsible party after being in their possession, or (3) placed by the responsible party in a designated, secure area that is controlled with restricted access.

Custody will be documented throughout all sampling activities by the electronic sample-tracking database or on the official CoC record for each day of sampling. The electronic data will be used to generate the official CoC if an electronic sample-tracking database program is used. In either case the official CoC will accompany the samples from the site to the laboratory. The sampling team member who relinquishes the samples to the courier or laboratory personnel is required to sign, date, and note on the CoC the time when relinquishing samples from his or her immediate custody. Once signed by the FTL/SC/Sample Collector and the laboratory courier, a copy of the CoC will be made and kept with the other sampling related paperwork. Any discrepancies in the custody procedure noted and corrected must be communicated to the PM and project chemist immediately to determine possible corrective action(s).

Samples will be shipped to subcontractor laboratories via laboratory courier. In some cases, samples may be hand-delivered to the laboratory; hand delivery will be noted on the CoC form. In the event the laboratory is not within driving distance, an overnight air courier will be used. Bills of lading will be used in addition to other custody documentation during this time and will be retained as part of the permanent sample custody documentation. The subcontractor laboratory is responsible for sample custody once samples are relinquished to their custody and at that point laboratory SOPs for custody must be followed. Final completed CoCs from the field and shipping efforts as well as internal laboratory custody records will be provided with the final laboratory data submission.

Sample Labels

A sample label must be attached to all sample containers prior to collecting the sample. (**Note**: Do not attach new labels to pre-weighed soil volatile organic compound or gasoline range organic vials; use the labels attached by the laboratory. Additional labels may be affixed to the recloseable plastic bag if needed). The label may be generated along with the CoC form using a sample-tracking database (use waterproof labels), or may be hand-generated using a blank sample label purchased or provided by the laboratory with the sample bottles. For certain types of samples (for example, Summa™ soil gas canisters), blank labels are provided by the laboratory when the lab provides sample containers. All sample labels generated will contain the following information in indelible ink:

- Unique Sample ID
- Analyses requested
- Preservative used
- Date and time of sample collection
- Sampler's initials

Once the sample has been collected and the sample labeling is complete, the Sample Collector will place the samples in recloseable plastic bags and place in a cooler on ice. Labeling for other types of containers (such as soil gas and air samples) will follow the same labeling procedure except that the labels are attached to the sample containers (summa canisters, filters or tubes) via a sample tag attached to the container by the laboratory.

Chain-of-Custody Record

CoC forms are legal documents that record the custody of the sample from collection through reporting. If the sampling event is using an electronic sample-tracking database, the CoC will be

generated at the end of the day; if not, CoC form(s) will be filled out for each sample at each sampling location to maintain a record of sample collection, shipment of samples, and receipt of samples by the laboratory.

The FTL/SC or Sample Collector will generate the CoC form. Information entered on the CoC includes:

- Project name and project number or task order
- PG&E/contractor address and contact information
- Name and address of laboratory to receive the samples
- Unique sample ID
- Matrix type
- Analyses requested
- Field quality control (QC) for matrix spike and matrix spike duplicate (MS/MSD) samples, if applicable
- Container type, size and number
- Preservatives used
- Turn-around-time for laboratory analysis
- Comments to Laboratory, if applicable
- Date of collection
- Time of collection (24-hour format)

The FTL/SC or Sample Collector shall verify that the CoC record is complete, accurate in all aspects, and consistent with all other sample documentation (for example, number of samples, sample labels, purge forms, field logs). The FTL/SC or Sample Collector will sign the "Relinquished By" fields on the CoC record, marking the date and time custody is transferred to the laboratory courier or other common carrier service (e.g., FedEx, UPS, U.S. Postal Service, Golden State).

If using a common carrier service, the Sample Shipper will perform the following duties:

- Obtain any required signatures from sampling team.
- Record the carrier service and airbill number on the CoC.
- Sign and enter the date and time relinquished to the common carrier service or courier.

Corrections: If there are any corrections to the CoC form needed, corrections will be made by a single-line strike mark through the incorrect item, and then entering the correct entry adjacent to the strikeout item. Corrections will be initialed and dated by the person making the change. After the form has been inspected and determined to be satisfactorily complete, the Sample Shipper will sign, date, and note the time of transfer and will reference a shipper tracking number on the form (if applicable). If the samples are being shipped by common carrier service, the CoC form will be placed in a recloseable plastic bag and placed inside the cooler after the

sample packer has detached or made an appropriate copy of the form. Field copies of the completed CoC forms are maintained in project files by on site personnel.

Overnight Sample Storage

In some cases, samples cannot be shipped immediately to a laboratory and must be temporarily stored in a secured onsite facility. There are two locations where secured refrigeration is available onsite.

The IM-3 field lab has limited space for samples in its refrigerator and can be used to temporarily store samples associated with the IM-3 operations. The facility is manned 24 hours a day 7 days a week and has restricted access.

The Topock field office trailer has a refrigerator that is dedicated to short-term sample storage, as well as two freezers that can be used for samples that require freezing. The field trailer is locked during non-business hours and the refrigerator is locked when staff are not present.

The samples placed in the refrigerators cannot be in coolers, but should be stored in recloseable plastic bags, grouped by sample location and laboratory. The refrigerators must be maintained at a temperature between 2° and 6°C.

Custody Seals

For normal shipping (samples sent via laboratory courier) no custody seals are required. For shipping via common carrier service, the shipping cooler must have two custody seals: one on the front and one on the side of the cooler, signed, dated, and marked with the time the cooler was sealed (the signed CoC should be in a recloseable plastic bag, taped to the inside of the cooler's lid). In addition, each custody seal will be covered with transparent packing tape.

RECORDS

The FTL is responsible for the distribution of the CoC record:

- Original: Sealed in plastic bag and taped inside the top of the shipping container (if shipped via common carrier service) or handed to the laboratory representative.
- Copies to Project Chemist and PM or Task Manager

SOP-B16

Field-portable X-Ray Fluorescence Soil Sampling Standard Operating Procedures for PG&E Topock Program

---

This SOP describes the analysis of *in-situ* and *ex-situ* soil samples using a field portable X-Ray Fluorescence instrument (XRF). SOP-B2 and SOP-B3 in the *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (Procedures Manual; CH2M HILL, 2005) provide additional guidance for soil characterization and logging.

Required Documents

1) Event-specific planned sample table (PST).
2) Applicable project work plan or monitoring plan. Refer to the Procedures Manual, Operation and Maintenance (O&M) Manual, and QAPP as required.
3) Topock Program Health and Safety Plan (HSP).
4) Field notebook.
5) Database generated chain-of-custody.
6) XRF Functional Check Log

Preparation and Setup

1) Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Coordinate with the Project Chemist for coolers, sample containers, and courier pickup of the samples.
3) Initiate field logbook for sampling activity.
4) Initiate electronic file for X-Ray Fluorescence (XRF) instrument download.
5) Review sampling procedures and planned sample depths with field crew.
6) Field-check and set up equipment for functional checks, sampling, decontamination, spill prevention, and health and safety.

Equipment List

- Niton XRF Meter and stand
- Spare battery chargers
- Field notebook
- Trowel for smoothing soil surfaces
- Reusable plastic bags or stainless steel tray

- Disposable Sample cups with X-ray film and lids
- X-Ray window film (Mylar, Kapton, Spectrolene, polypropylene, or equivalent; 2.5 – 6.0 micrometers (um) thick)
- Disposable scoops, stainless steel spoons or other appropriate mixing tools
- Appropriate quality control (QC)/quality assurance (QA) standards, and blank sand
- Chemwipes
- Decontamination equipment (Alconox® solution (or equivalent) in spray bottle, brushes, buckets, rinse water spray bottle) for mixing tools and trowels
- Protective waterproof gloves (nitrile or latex)

XRF SOIL ANALYSIS DOCUMENTATION

The XRF sample results will be recorded by the associated software in an excel format. The files will be downloaded at the end of each day and emailed to the project chemist for review. Any additional sample logging and sample collection should follow the protocol and procedures found in the *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL,2005). Detailed notes should be recorded in the sampler's field notebook or in a log generated from the field database. Items to be documented on the sampling log include (note: include as much of the following information in the XRF software as possible):

1) Record type of boring or excavation equipment and the total boring or excavation depth.
2) If multiple samples are being collected at one location at a variety of depths, record all sample depths.
3) Record date and time of sample collection in addition to the full sample ID that is listed in the PST.
4) Sampling difficulties shall be noted (i.e. difficult slope or abnormal debris in sample location).
5) Analysis start time and the source count time (i.e. 60 sec, 90 sec, or 120 sec etc.) will be documented on sample collection sheet. Note: analysis and count time are automatically recorded in the XRF software.

Field-portable X-Ray Fluorescence Soil Sampling- COLLECTION OF SAMPLES FOR ANALYSIS

***In-Situ* Sample Preparation**

When the soil moisture is less than 20 percent, the error associated with moisture may be minimal. If areas are encountered where the moisture content is greater than 20 percent (moisture is visible), consult with the project chemist for options available for proceeding with field analysis.

For *in-situ* analysis:

1) Large or non-representative debris must be removed from the selected location. This debris includes rocks, gravel, vegetation and concrete.

2) The location chosen for analysis should be homogenized by mixing in place an area approximately 4" by 4" by 3" deep, using a clean (or decontaminated) stainless steel or disposable spoon. The location should then be smoothed and firmly tamped to provide as flat and smooth an area as possible.

3) A section of x-ray window film should be stretched over the area to be tested to maintain a dust free environment for the nose of the instrument. (Note: use in-situ analysis for metals only samples).

4) To initiate a reading, the nose of the XRF will be positioned against the x-ray film, squeezing the shutter release, and firmly pressing the instrument flat against the surface. Source count times for *in-situ* analysis usually range from one to two minutes, varying among instruments and depending on requirement detection limits.

5) After the *in-situ* field screening is performed, inspect the nose of the instrument for contamination, which may affect future analysis. If necessary, clean it with a soft cloth or tissue.

For confirmation samples, or where samples for organic analysis are to be collected the soil samples should be treated as ex-situ samples, below.

Ex-Situ Sample Preparation

For *ex-situ* analysis:

There are several possible correct methods for the ex-situ analysis of samples. The area that previously would have been homogenized for the in-situ analysis should be scooped out and placed into a clean (or decontaminated) stainless steel or disposable pan (do not use plastic if organic analysis will be performed on any of this homogenized sample), using a stainless steel or disposable spoon or spatula (do not use plastic if organic analysis are associated with the homogenized sample). The sample should then be thoroughly mixed (homogenized) using the same spoon or spatula.

1) The preferred method is to setup the portable field stand in an area where the XRF can be stationed and left in place for the day. Use the Niton software and a laptop computer to setup the method criteria and control the XRF instrument during the soil analysis.

    a) Starting with the previously homogenized sample, use the supplied soil sieves, bowl, and mortar to generate a finely ground well homogenized sample. (Note: This step is not required if the soil sample was passed through a sieve during the homogenization step.)

    b) Transfer the prepared sample into a new sample cup (order replacement supplies from Niton), place the X-ray film over the cup and snap the lid in place. Place the sample cup in the portable field test stand (The XRF points upward, the sample rests

on top of the XRF with the X-ray film directly in contact with the nose of the XRF - cup lid facing down).

c) Using the computer, start the analysis. The source count time should be at least two minutes for chromium. Consult previous analysis to determine if multiple scan frequencies are required (or contact the project chemist).

d) Prepare the next sample while the XRF is analyzing the current sample.

2) An alternative method to using the portable field stand is to identify the sample for XRF analysis and homogenize the sample (as described above).

a) Transfer the sample to a re-sealable plastic bag and firmly molded into a flat smooth surface.

b) Use the Niton software and a laptop computer or the included PDA to setup the method criteria.

c) To start the analysis, position the nose of the XRF against the flat smooth surface of the sample and squeeze the shutter release (or press the start button on the laptop or PDA). Be sure to maintain constant pressure against the sample. If contact is broken, the analysis will need to be restarted. The source count time for *ex-situ* analysis usually range from one to two minutes, depending on the required detection limits (see *c* above for count times).

d) After the ex-situ field screening is performed, inspect the nose of the instrument for contamination, which may affect future analysis. If necessary, clean it with a soft cloth or tissue.

3) Transfer the sample to a labeled glass jar for shipment to the confirmation laboratory (if applicable).

Sample Analysis

In today's modern XRF models:

1) An X-ray source is used for detection. Expose the sample to the X-ray source for a minimum of one minute. Longer exposure times may be needed depending on the media that is being analyzed and the required detection levels. The time needed for analysis will be determined in the field by analyzing standards that have concentrations of the metals of concern near the required detection levels. Better detection limits can usually be obtained by homogenizing the sample, increasing the exposure time, and using two or more scan frequencies (Use a minimum of a two minute exposure for Chromium analysis).

2) When the XRF instrument displays the results they include the analyte, the result, and a percent confidence (displayed as a ± value). The result is displayed as non-detect for analytes that do not meet the percent confidence established in the instrument. The lower the required detection levels, the longer the analysis time required to meet the percent confidence.

3) Download saved data from XRF instrument daily (if data is collected in PDA). Foreword the data files to the project chemist daily.

4) All samples collected for off-site confirmation will also be analyzed using the XRF and treated as *ex-situ* samples.

Using older models:

1) Expose the sample to the energy source for a minimum of one minute. Longer exposure times may be needed depending on the media that is being analyzed as well as the age of the detector (non X-ray detectors). The time needed for analysis will be determined in the field by analyzing standards that have concentrations of the metals of concern near the required detection levels. Better detection limits can usually be obtained by homogenizing the sample, increasing the exposure time. (Use a minimum of a two minute exposure for Chromium)
2) When the XRF instrument indicates the results for the suite of analyzed elements and their concentrations, it includes a standard deviation for the reported concentrations. An analyte concentration is considered **not detected** if the result value is **less than two times the standard deviation**. The lower the required detection levels, the longer the analysis time required to reduce the result's standard deviation.
3) Record the readings (electronically or documented on the sampling log). Review the standard deviations for the elements of interest and determine if a longer analysis time is needed to reduce the standard deviations, thereby allowing the desired accuracy and precision for the concentrations. The standards will be analyzed using increasingly longer times until the required detection level is achieved.
4) Record values in field notebooks.
5) Download saved data from XRF instrument daily.
6) Samples collected for off-site confirmation will also be analyzed using the XRF and will be treated as *ex-situ* samples.

Calibration

Two forms of calibration are important with XRF testing: an energy calibration and a sample matrix calibration.

Energy Calibration

The Niton XLi 702 automatically re-calibrates the energy scale when powered on. The energy scale can also be re-calibrated by pressing "Reset" on the instrument. The energy calibration should be performed every two hours.

Sample Matrix Calibration

Modern XRF instruments, such as the Niton Xli 702, do not require site specific calibrations to account for sample matrix effects. EPA Method 6200 allows both fundamental parameters and Compton normalization as two techniques to eliminate site specific calibrations. Niton uses the Compton normalization method to automatically correct for sample specific matrix effects. The XRF is calibrated internally at the factory on NIST standard reference soil samples. Ensure the annual factory calibration certification is on file. This internal calibration is used for subsequent field work, without need for adjustment or recalibration at other sites.

Quality Assurance and Quality Control (Functional Checks)

Even though no onsite calibration will be performed, the method does require QA/QC Functional check testing protocols. The QA/QC that will be used to document that the XRF is operating properly will have the following steps:

- A startup operations check
- Analysis of a blank sample (clean sand)
- Analysis of standard sample(s)
- Analysis of duplicate samples
- QA/QC procedures will be compliant with manufacture's instructions.

1) At the beginning of each day perform QA/QC functional check procedure or when the instrument is turned on after more than 2 hours of down time or if the operating environment changes, such as a temperature change of more than 20 degrees Fahrenheit.

2) Two types of blanks should be analyzed, an instrument blank and a method blank. An instrument blank sample (silicon dioxide, provided by Niton) will be analyzed at the start and end of each day and once every 20 samples, to confirm proper zero calibration of the XRF. The blank will be analyzed following the procedure for the *ex-situ* sample analysis. A method blank is used to monitor for any field induced contamination. The method blank should follow any preparation procedures performed on the samples, such as mixing or *exsitu* analysis. **A method blank will be analyzed each day**.

3) A set of three to ten QC samples will be collected from the site during the initial field activities. These samples will be well homogenized, and a portion sent to the off-site laboratory for characterization. The remaining sample will be collected in re-sealable bags, labeled and stored with the XRF for use as standards. Three to five of the on-site standards will be analyzed at the start of each day. The results of the standards will be plotted against the original XRF results and a correlation value calculated. A correlation coefficient of 0.90 or greater must be achieved to meet the project objectives. A running log of all on-site standards analyzed will be maintained. One of the standards will be analyzed after every 20 samples. The readout from the XRF **must be within 20 percent RPD of the known QC sample concentration**.

4) The last QA/QC step will be to analyze duplicate samples (two separate aliquots) at a rate of 1 in 10. These duplicate measurements must be within 35 percent of each other for the analysis to continue. If the sample results are not in agreement, then the reason for this discrepancy must be determined.

5) The Niton XL3t 600 displays both concentration and precision for each sample analyte measurement. The precision displayed by the Niton's 95% (2-sigma) confidence intervals; where as the precision calculated in EPA method 6200 is at a 68% (1-sigma) level. The Niton also calculates and displays detection limits for analytes if the concentration is below three standard deviations. This bypasses the need for replicate measurements on low level standards.

Note: VOC, SVOC, and other organic samples can not be collected from the homogenized soil if plastic is used for homogenizing or after XRF analysis, if contacted by plastic.

SOP-C1

Solinst Pressure Transducers
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures, equipment, and documentation needed when using Solinst Levelogger pressure transducers (PTs) at the Topock site.

REQUIRED SOFTWARE:

Solinst Levelogger software – latest version

REQUIRED DOCUMENTATION:

- Solinst User Guide – Levelogger Series – Software Version 4 (November 5, 2013) (User Guide 1) or more recent updates
- Solinst User Guide – Leveloader Gold (October 23, 2013) (User Guide 2) or more recent updates
- Performance Monitoring Program Transducer Download Log (attached)
- Compliance Monitoring Program Transducer Download Log (attached)
- Groundwater Sampling Log (attached)

REQUIRED EQUIPMENT/SUPPLIES:

- One or more Solinst Levelogger PT
- One or more Solinst Leveloader
- One or more Solinst Barologger
- Solinst Optical Connector
- Solinst Direct Read Cable
- Solinst Direct Read Connector
- Solinst PC Interface Cable
- PVC well cap with slot cut in the side for PT or Solinst 2-inch well cap or expanding locking well cap
- Deionized water
- Paper towels
- Personal computer (PC) with internet access
- Camera for documenting PT installations
- Water-level meter
- Assemble a tool kit containing:
  - Replacement PT O-rings
  - Replacement PT locating pins
  - Wire ties (also called zip-ties or cable ties)
  - C-flex tubing

*****Note: Read the user guides for equipment before working with the transducer network at Topock.*****

SOFTWARE SETUP:

1. Install the Levelogger software on the PC as described in the User Guide 1, Section 3.0.
2. Configure the Levelogger program and install drivers as described in User Guide 1, Section 4.0.

TRANSDUCER SETUP:

*****Note: If reprograming a PT that has previously been used at Topock, verify all data have been downloaded from the device before proceeding with transducer setup to prevent unintentional loss of data.*****

***With a PC*:**

1. Open the Levelogger program previously installed on the PC.
2. Connect the PT to the computer using either an optical reader or a PC interface cable.
3. Connect to the PT as directed in User Guide 1, Section 5.0.
4. Download data from the PT as described in the "Downloading Data from a Transducer" section below, this will prevent unintentional loss of any data stored on the PT.
5. Update the PT settings in the "Datalogger" section of the Datalogger Settings Tab in the Levelogger program (shown in User Guide 1, Section 5.0) as follows:
   a) Location: Well name (for example, MW-34-100)
   b) Project ID: PG&E Topock
   c) Ch1: Level
      - Identification: Level
      - Unit: ft
      - Offset (ft): 0
   d) Ch2: Temperature
      - Identification: Temperature
      - Unit: °C
   e) Datalogger Sampling Mode
      - Sampling Type: Linear
      - Sampling Rate: 30 minutes
   f) Datalogger Memory Mode: Continuous
   g) Start/Stop Datalogger:
      - Click the *Start Now* button to load the above settings into the PT, then click the *Stop Now* button when it becomes an available option to stop the logger.
      - Next, set to *Future Start* at the next round half hour after approximate anticipated PT installation time (for example, if PT installation is expected at around 8:00 to 8:15 a.m., set *Future Start* for 8:30:00 a.m.).
      - **Note:** The *Future Start* setting can be added in the field with the instructions below if the approximate installation time is not known.
6. Disconnect the PT and install in monitoring well as described below.
7. Setting the time on the PT: Sync to the Leveloader as described in the "With a Leveloader Gold (Handheld) Device" section below.

With a Leveloader Gold (Handheld) Device:

1. Power on the Leveloader device.
2. Connect the PT to the Leveloader via a direct-read connector (when already installed in the well) or optical connector.
3. On the main Leveloader Screen, select *Connect to Logger*.
4. Download data from the PT as described in the "Downloading Data from a Transducer" section below; this will prevent unintentional loss of any data stored on the PT.
5. Return to the main menu.
6. Scroll down to *Edit Levelogger* and click *OK*.
   a) If the PT is currently logging, a prompt will appear to push both the up and down arrows simultaneously to stop the logging before edits can be made. Edit each category by scrolling to it and clicking *OK* as shown in User Guide 2, Section 8.4. Use the values listed in the "With a PC" section above for each category.
   b) The final step of any edit is to scroll to and highlight *Submit* and press *OK*.
   c) Setting the time on the PT: It is best practice to sync the time whenever an edit is made to the PT.
      - The time will sync by clicking *Edit* with the time entry selected.
      - **Note**: The PT time is set to Pacific Standard Time year-round. This means that the time shown on the Leveloader and the time on the PT will be 1 hour behind the actual time during the daylight saving time period (second Sunday in March through the first Sunday in November).

TRANSDUCER INSTALLATION:

Proper installation of PTs is very important. The PTs measure the height of water above the sensor, or pressure head. Following calibration, the height of water (pressure head) is converted into a groundwater elevation (or hydraulic head, which is pressure head plus the elevation). Improper installations can result in errors in PT readings completely invalidating data. Some goals for PT installation are:

1. Install the PT so that it is possible to remove and reinstall it easily in the same location.
2. Install the PT from a solid mount so that it will not move due to gravity, opening or closing of the well, etc.
3. Install the PT at least 5 feet below the current depth to groundwater, but no more than 15 feet below the current depth to groundwater, unless the monitoring well is located near a pumping well. If the monitoring well is located near a pumping well, install the transducer at least 5 feet below the maximum expected pumping depth to water (DTW); see step 4 below.
4. If a PT is to be installed near a pumping well, request the estimated pumping water-level depth before installation. Install the PT to at least 5 feet below the estimated maximum pumping DTW.

Installation Procedure:

1. The PT will be installed using one of the following methods:
   - A slotted PVC cap and a positive stop on the PT direct-read cable. The PT is either positioned to the side of the PVC cap, where there is room, or on top of the PVC cap.

Positioning instructions should be written on the PVC cap with permanent marker (see Figure 1 below).

  - The positive stop is typically a 1- to 2-inch piece of white c-flex tubing cut along the long axis and secured around the direct read cable with two wire ties.

- A Solinst well cap for 2-inch-diameter wells. The PT and attached direct-read cable are threaded through the large hole on top of the Solinst well cap. The large end of the direct-read cable fits snuggly into the hole on top of the well cap (see Figure 2 below).
- Hanging the PT securely from the bottom of the expandable locking well cap in flush-mount wells (this applies to all flush-mount wells with PT installations). The method of attachment to the expandable locking well cap will depend on the cap itself and should be discussed with the field coordinator prior to installation.
- If necessary, the PT can be hung on other brackets or hangers already installed at the well head (for example, pump brackets).

2. The PT should be attached to a large object prior to bringing it to the well to prevent the PT from being accidentally lost down the well. The most common object is a large, orange plastic disk.
3. The PT should then be lowered down the well and securely positioned at a predetermined depth.
   - The depth of the installation depends on the DTW and the pressure range of the sensor. F30/M10 (30 feet/10 meter) PTs have a pressure range of ~30 feet and should be installed at least 5 feet below the water table but not more than ~25 feet below the water table. A PT with a range of F15/M5 should be installed no more than ~10 feet below the water table.
   - The submersion depth of the PT can be monitored by using the Real Time data view described below.
   - If wells will be used for monitoring pumping tests, water levels could drop significantly (that is, do not install the PT only 5 feet below the water table if expected drawdown is 10 feet).
   - If the direct-read cable used for the installation is longer than needed, secure the extra length neatly inside of the secured/locked well vault with wire ties.
4. Record time-synchronized manual water level and PT pressure readings:
   - Measure DTW below top of casing (BTOC) at the measuring point (see SOP A-7, Water Level Measurements, for detailed instructions). Record this information along with the date and time in the field logbook or the appropriate transducer download log.
   - Record real-time pressure in feet measured by the PT in the field logbook or transducer download log as described below:
     a) Connect the PT direct-read cable to the Leveloader device (or PC using instructions in the "PT Setup" section above) with a direct-read connector.
        - The direct-read connector has a tendency to become loose at the connection to the Leveloader; verify full connection prior to connecting to the PT.
     b) Select *Connect to Logger* and click *OK*.
     c) If the PT does not connect or shows a data corrupt error, see "Transducer Troubleshooting" section below.

d) When PT is connected, select *Real Time – View Only* and click *OK*.

e) Record the real-time value for pressure measured in feet.

Figure 1 – Installation of PT with PVC Cap and Positive Stop

Figure 2 – Installation of PT with Solinst Well Cap

TEMPORARY PT REMOVAL/REINSTALLATION DURING WELL SAMPLING:

1. Open well protection lid and inspect PT installation. Note the PT installation setup to ensure the PT will be reinstalled in exactly the same place. Take a photograph before PT removal to document PT position.
2. Before removing the PT, measure DTW BTOC according to SOP-A7, Water Level Measurements. Record the exact time to the nearest minute and the DTW BTOC in the transducer section of the groundwater sampling log.
3. Remove the PT, coil the cable, and store in a manner to prevent contamination of the cable and probe. Record the time of removal on the sampling field sheet.
   - A clean, plastic garbage bag or leaf bag can be used to store the PT. Alternately, the PT can be stored in the bag used to contain the well-specific pump tubing.
   - If the PT becomes dirty or contaminated, rinse with purified water or wipe thoroughly with a purified water moistened paper towel to decontaminate per SOP A-10, Decontamination of Water Sampling Equipment.
4. When groundwater sampling is completed, reinstall the PT, restoring the correct setup of the PT mounting hardware as documented in the setup photograph. Record the time of reinstallation on the sampling log.
5. Measure the DTW BTOC at least 5 minutes after reinstalling the PT according to SOP-A7, Water Level Measurements. Record the time and DTW BTOC on the sampling log.

DOWNLOADING DATA FROM A TRANSDUCER:

Data downloads should be conducted at least monthly to provide data for analysis and evaluation and to ensure the PT is working properly.

- Data should be screened in the field to ensure that data extend to the download date (that is, is still recording) and that the data make sense (that is, the sensor has not "maxed out" its pressure range and data are garbled, which can happen when a PT fails).
- Battery life should be checked to ensure the PT will continue to operate well into the future.

Downloading the Data from the Transducer with a Leveloader Gold Device:

This procedure will be used when downloading data from a PT.

1. Open well protection lid and inspect PT installation. Note the PT installation setup to ensure the PT will remain in exactly the same place. Take a photograph to document PT position.
2. Measure the DTW BTOC according to SOP-A7, Water Level Measurements. Record the exact time to the nearest minute and the DTW BTOC on the appropriate transducer download log.
3. Connect the direct-read cable to the Leveloader device with a direct-read connector.
   - You can also connect directly to the PT with an optical connector.
4. Select *Connect to Logger* and click *OK*.
   - If the PT does not connect or shows a "data corrupt" error, see "Transducer Troubleshooting" section below.
5. Select *Real Time – View Only* and click *OK*.
6. Record the real-time value for pressure/depth on the appropriate transducer download log.
7. Click the *Menu* button to return to the main menu.

8. Select *Data from Logger* and click *OK*.
9. Record the Levelogger serial number (shown as, e.g., #1013653 or similar at the top of the screen) and battery remaining percentage (shown on the top of the screen) on the appropriate transducer download log.
10. Click the *Save Log* button to begin the download.
11. When download is complete, click the *Menu* button to return to the main menu.
12. Select *View Stored Data* and click *OK*.
    - Scroll as necessary to the last log collected and check the serial number to ensure that the log was properly recorded to the Leveloader.
13. Click the *Menu* button to return to the main menu, then click *Return* to disconnect from the Levelogger.
14. Disconnect the Leveloader from the PT direct read cable. Replace all PT hanging mounting hardware as it was before the download, referring to the photograph taken previously if needed.
15. Record the File Number on the appropriate transducer download log in the format: Unit Number-File Number (for example, 4-25).

Saving the Data from the Leveloader to PC:

1. Connect the Leveloader device to a PC with a USB or RS-232 connection cable.
2. Connect the Leveloader as directed in User Guide 2, Section 9.0.
3. Select the files to save to the PC and download as shown in User Guide 2, Section 9.0.
    - Note: when downloading from a Leveloader, all logs are automatically selected.
    - It is helpful to save all files from a download event in an event-specific folder.
4. Confirm that a separate file for each well downloaded on the field log has been transferred to the PC folder.

Downloading Data from a Transducer with a PC:

This procedure will be used when downloading data from a PT in the office.

1. Open the Levelogger software.
2. Connect the PT to the computer using either an optical reader or a PC interface cable.
3. Connect to the Levelogger as directed in User Guide 1, Section 5.0.
4. Download data from the PT according to User Guide 1, Section 7.1.2.
    - Select to download *All Data*.
5. Save to a file on your PC according to User Guide 1, Section 7.1.3.
    - It is helpful to save all files from a download event in an event-specific folder.

Packaging and Sending Data for Incorporation in the Topock Transducer Database:

1. Scan the transducer download log to a PDF file and save it to your computer in the same folder as the downloaded data files.
2. Download the data from the onsite Barologger using instructions for downloading data from a PT above. Save these data in the same folder as the other downloaded data files.

- The Barologger data must be collected after all other field data have been collected.

3. Create a .zip file of the folder (right click >*Send to*> *Compressed (zipped) folder*).
4. Send the .zip file via email to the current database manager and transducer data lead(s).
   - The Field Coordinator or Project Manager can supply these contacts if needed.

TRANSDUCER TROUBLESHOOTING:

Occasionally, a PT will fail to connect to the Leveloader device in the field or show a data corrupt error message. Follow these steps to troubleshoot the problem:

1. Remove the PT from the well.
2. Disconnect the PT from the direct read cable.
3. Clean the optical "eyes" on the top of the PT.
   - Work over the tool tray or another container because the small locating pin on the cable sometimes falls out and can be lost. If the pin is lost or broken, replacements are available in the tool kit.
4. If the small "O" rings around the optical eyes look flattened out, replace them with spares from the tool kit.
5. Test for a proper connection before re-installing.
6. If the PT continues to fail to connect, clean the eyes again.
7. If the PT fails to connect after a second cleaning, attach the optical connector and attempt to connect.
8. If the PT connects with the optical connector then a defective direct-read PT cable is indicated; replace the cable.
   - Mark the direct-read PT cable with the well number and date as "bad" and discard the cable as appropriate.
9. If the PT still fails to connect, the PT has failed and will need to be replaced.
10. Mark the PT with the well number and date as "bad" and take the failed PT back to the field office and attempt to connect to the PT with the optical reader to a PC (this works sometimes to get the data). Inform the Field Coordinator and Project Manager if equipment has failed.

POINTS OF CONTACT FOR QUESTIONS CONCERNING THESE PROCEDURES:

SOP-C2

Pressure Transducer Upload to Topock Database
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) details field instructions for uploading pressure transducer (PT) data collected using Solinst Levelogger PTs to the Pacific Gas and Electric Company (PG&E) Topock site database.

DATA TRANSFER, COMPENSATION, AND UPLOADING:

Data files are transferred from the field in a Solinst proprietary format (.lev or .xle) or in a comma-delimited (.csv) file. The .xle files must be opened using the Solinst Levelogger software version 4.0 or newer versions—older versions of the Solinst Levelogger software will not recognize the .xle formats. Lev files are compatible with all available versions. A Barologger file (.lev format) will also be included to barometrically compensate the transducer data files. The .lev and .xle files are compensated using the Solinst software and the .csv files are compensated in the Topock Transducer_loading database.

.lev and .xle Files:

1. Open the Solinst Levelogger program and import the Barologger file by clicking the *Open* icon on the *Data Control* tab and double-clicking on the Barologger data file which, for example, is named as follows:

   1024290_BAROLOGGER_5MIN_2014_04_01_.lev

   where:

   – The transducer serial number is 1024290.
   – The pressure head levels in feet were collected at 5-minute intervals.
   – The last measurement was taken on April 1, 2014.

2. Import the .xle or .lev transducer data file by clicking the *Open* icon on the *Data Control* tab and double-clicking on the data file. The transducer data files are named, for example, as follows:

   2005344_MW-36-50.xle

   where:

   – The transducer serial number is 2005344.
   – The well name MW-36-50.

   Note: The header information (listing information including the location name and PT settings) will appear on the left of the imported file. The serial number and location should match what is in the filename.

3. Go to the *Data Compensation* tab and click through the following three steps:

   a. Select the Levelogger file(s) to compensate by marking the checkbox next to the file name.

b. Make sure "Barometric Compensation" has a checkmark.

c. Select the Barologger file by highlighting the filename.

4. Click *Finish* to compensate. The compensated transducer file will be saved in the same folder as the transducer data files with "Compensated" at the end of the original filename, as in the following example:

   2005344_MW-36-50Compensated.xle

   Note: Compensation cannot be completed if the transducer data file's date and time is not within 3 hours of the Barologger file's date and time. Some files may need to compensated with multiple Barologger files or, if the transducer data were downloaded after the Barologger data, the measurements taken after the Barologger's last date/time field should not be uploaded into the database.

5. A dialog box will open when compensation is complete. Click *Finish and Open*.

6. Export the compensated transducer data file as a .csv file by clicking the export button on the *Data Control* tab and selecting data; save the files in the same directory using the same name as the compensated files:

   2005344_MW-36-50Compensated.csv

7. Repeat process for next transducer file.

   Note: Multiple transducer data files can be compensated at the same time by repeating the importing step before going to the data compensation step; however, the compensated files will not automatically open. The compensated files will have to be imported into the Solinst Levelogger software and then exported into a .csv file one at a time.

8. Once all of the transducer data files have been converted to .csv files, the files can be viewed from File Explorer, which will sort the files in alpha-numeric order. The files should then be imported into the database in this order to ensure all files are imported and to assist in making sure there are no duplicates, misnaming, missed files, etc.

9. Open the first file in a text editor or Microsoft Excel. The first dozen or so lines are header lines that should be noted. The header lines identify the transducer serial number and location (should be the well or *LocID*) Double check the same *LocID* exists in the file name.

10. Select all the numeric data (excluding header lines) and copy to the clipboard.

11. Open the Topock Transducer_loading frontend database. The Transducer Control Form *(frmTransducerCalibrationSummary)* should automatically open. Click *View Temp Table for LEV files* (should be empty), select the entire row, and paste the data.

12. Enter the following information onto the Transducer Control Form:

    - Select the *LocID* for the transducer from dropdown menu.
    - Enter the filename of the .csv file to be imported.
    - Enter your name or initials.

    Note: This information, as well as the date of loading and last date-time of the .csv file, will be stored in the *LoadingInfo* field. If questions or problems arise following upload, it

is the *LoadingInfo* field that can be used to purge bad data or apply corrections if, for example, the data are inadvertently uploaded with the wrong *LocID*.

13. Enter any comments or descriptions regarding the upload (optional).
14. With the data in *tblPT_Temp* and the fields filled out in the *Data Upload* section, press the *Upload Lev Transducer Data*. This will transfer the data from the temporary table to the table tblPT while appending *LocID* and *LoadingInfo*.
15. As the upload process continues, a prompt to confirm the appending of records to *tblPT* will appear. Select *Yes* unless a mistake has been made (this may be the only chance to stop the upload). If some of the records already exist in *tblPT* (that is, were uploaded during a previous upload session), a second prompt box stating that some records will not be uploaded due to primary key violations (the database will not let records with duplicate LocID, Date & Time be uploaded to tblPT). If it makes sense that records are duplicates, proceed with the upload to append only new data to the database.
16. Repeat process for next well Levelogger file.

.csv Files:

When .csv files are to be loaded into the database barometric compensation is performed within the database rather than using the Solinst Levelogger program. The procedures below describe this process.

1. Open the Solinst Levelogger program, Import the Barologger file by clicking the *Open* icon on the *Data Control* tab and double clicking on the Barologger data file which is named as follows:

   1024290_BAROLOGGER_5MIN_2014_04_01_.lev

   where:
   - The serial number is 1024290.
   - The levels were collected in 5-minute intervals.
   - The last measurement was taken on April 1, 2014.
2. Export the Barologger file as a .csv file by clicking the export button on the *Data Control* tab and selecting data; save the file in the same directory using the same name as the Barologger file:

   1024290_BAROLOGGER_5MIN_2014_04_01_.csv
3. Open the Barologger .csv file in a text editor or in Microsoft Excel. Select all the numeric data (excluding header lines) and copy to the clipboard.
4. Open the Topock Transducer_loading frontend database. The Transducer Control Form *(frmTransducerCalibrationSummary)* should automatically open. Open table *ttblPT_Barologger*, select a new row, and paste the data.
5. If some of the records already exist in *ttblPT_Barologger* (that is, were uploaded during a previous upload session), a prompt box will appear stating that some records will not be uploaded due to primary key violations (the database will not let records with duplicate *Date* & *Time* be uploaded to *ttblPT_Barologger*). If it makes sense that records are duplicates, proceed with the upload appending only new data records by pressing *OK*. A

second prompt box will open asking if you want to suppress further error messages, click *Yes*.

6. Open the transducer .csv file in a text editor or Microsoft Excel. Select all the numeric data (excluding header lines) and copy to the clipboard.
7. Empty the table *ttblPT_Transducer_YSI* by running the query *qryManualCompensation01_YSI,* open table *ttblPT_Transducer_YSI,* select the entire row, and paste the data.
8. Compensate the transducer file and append the compensated data to the *tblPT_Temp* table by running the query *qryManualCompensation02_append_YSI*. A prompt to confirm the appending of records will appear. Select *Yes*. A second prompt will confirm the appending and have the number of rows appended. This number should match the number of records in *ttblPT_Transducer_YSI.* If the numbers do not match, check that the time is in 5-minute intervals and that the date time records in the Barologger table extend as far as the transducer records.
9. Adjust for daylight savings as appropriate by running the query *qupdLevTime*.
10. Enter the following information onto the Transducer Control Form:
    - Select the *LocID* for the transducer from the drop-down menu.
    - Enter the filename of the .csv file to be imported.
    - Enter your name or initials.

    Note: This information, as well as the date of loading and last date-time of the .csv file, will be stored in the *LoadingInfo* field. If questions or problems arise following upload, it is the *LoadingInfo* field that can be used to purge bad data or apply corrections if, for example, the data are inadvertently uploaded with the wrong *LocID***.**

    - Enter any comments or descriptions regarding the upload (optional).
11. With the data in *tblPT_Temp* and the fields filled out in the *Data Upload* section, press the *Upload Lev Transducer Data*. This will transfer the data from the temporary table to the table *tblPT* while appending *LocID* and *LoadingInfo*.
12. As the upload process continues, a prompt to confirm the appending of records to *tblPT* will appear. Select *Yes* unless a mistake has been made (this may be the only chance to stop the upload). If some of the records already exist in *tblPT* (that is, were uploaded during a previous upload session), a second prompt box stating that some records will not be uploaded due to primary key violations (the database will not let records with duplicate LocID, Date & Time be uploaded to tblPT). If it makes sense that records are duplicates, proceed with the upload to append only new data to the database.
13. Repeat process for next well .csv file.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Hexavalent Chromium Analysis by Hach Method 1560
Number: SOP-L01_Rev4
Revision Date: 10/13/2015

Scope

Standard Operating Procedure (SOP) for the analysis of hexavalent chromium (Cr^{+6}).

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach DR 4000V spectrophotometer or equivalent.
- Vacuum filter apparatus: 47 mm magnetic filter funnels, 1,000 mL Erlenmeyer flask, and vacuum pump. Use a 0.45 µm, 47 mm diameter filter membrane.
- 0.45 µm filter disc fitted to a disposable 50 mL syringe (syringe filter).
- pH meter.
- Reaction vessel and cap or means of sealing the reaction vessel (Hach sample cell, 50 mL beaker, vial capable of holding 30 mL and parafilm if the vessel doesn't have a cap).
- 1 packet of ChromaVer® 3 Reagent per sample.
- 2.5 mg/L hexavalent chromium (Cr^{+6}) (working) standard.

Procedure

1. Collect the sample(s) following the appropriate SOP (see list below). Samples should be analyzed as soon as possible (within 24 hours). **Note: all samples must be filtered**.
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
    - SOP-A4 – Depth-Specific Surface Water Sampling
    - SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
    - SOP-A14 – Pore Water Sampling
    - SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method

- SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
- Remedy-SOP-01 – Process Water Sampling

2. Filtering can be performed using an inline filter at the time of sampling (see SOP–A6, Sample Field Filtration and Preservation for Metals Analyses) or in the laboratory by vacuum filter:

   - Set up the vacuum filter apparatus.
   - Filter ~100 mL of sample.

3. Measure the pH of the raw sample (**Record the results in the Cr^{+6} bench log book**).

4. Verify the spectrophotometer is set for **Hexavalent Chromium (Cr^{+6})** (Hach DR/4000V program **1560)** and verify all reagents are for 25 mL sample size (or adjust accordingly).

5. Transfer 25 mL of filtered sample into a reaction vessel (sample cell, beaker, etc.)

6. Add one packet of ChromaVer® 3 Reagent to the sample.

7. Invert sample 4–5 times or swirl the sample until powdered reagent is dissolved.

8. Start timer (8 mins.).

9. Run a blank: Use a 25 mL aliquot of filtered sample to "zero" the spectrophotometer.

   - Transfer 25 mL of raw filtered sample into the pour-thru-cell funnel.
   - Allow the meter to stabilize and press the Zero button.

10. After 8 minute timer, pour the sample with the reagent added into a syringe filter to remove the excess reagent powder. Transfer the sample into the pour-thru-cell funnel (sample port of the Hach DR/4000V).

11. Record the instrument reading in the Cr^{+6} bench log book.

12. If the result is out of range for the spectrophotometer, reanalyze the sample using a dilution.

    Note: if a dilution is required, the spectrophotometer should be zeroed using sample from the same dilution.

    Common dilutions:

    - 1:2 dilution: 25 mL of sample are diluted with 25 mL of deionized (DI) water; multiply the instrument reading (result) by 2 for the adjusted value.

      Example: instrument reading is 0.304
      x 2
      = .608 mg/L (final result)

- 1:5 dilution: 10 mL of sample are diluted with 40 mL of DI water; multiply the instrument reading (result) by 5 for the adjusted value.

  Example: instrument reading is 0.304
  x 5
  = 1.52 mg/L (final result)

- 1:10 dilution: 10 mL of sample are diluted with 90 mL of DI water; multiply the instrument reading (result) by 10 for the adjusted value.
- 1:20 dilution: 5 mL of sample are diluted with 95 mL of DI water; multiply the instrument reading (result) by 20 for the adjusted value.

Quality Control (QC)

- With the first analysis of hexavalent chromium each shift, **analyze a CCV** (Continuing Calibration Verification) standard as a **Quality Control** check:
  - Carefully measure 24 mL of DI water into a reaction vessel (sample cell, beaker, etc.).
  - Add 1 mL of 2.5 mg/L hexavalent chromium (Cr^{+6}) standard.
  - Add the hexavalent chromium reagent pillow at the same time as your samples. (ChromaVer® 3 Reagent).
  - Invert the CCV sample 4–5 times, or swirl the sample, until powdered reagent is dissolved.
  - Use the same 8 minute timer for CCV and field samples. **Note:** The blank for the CCV should be DI water.
  - **Record the CCV results in the Cr^{+6} bench log book.** If the instrument reading is not between 0.075 mg/L and 0.125 mg/L, re-prepare the standard and reanalyze.
- Periodic **Matrix Spikes (MSs)** should be analyzed. Any time a sample result appears anomalous, consider analyzing an MS of that sample.
  - Determine what dilution if any is required for the matrix spike (note: you will be adding 0.1 mg/L to the sample concentration [the instrument reading]).
  - Carefully measure 24 mL of filtered sample (diluted if required) into a reaction vessel (sample cell, beaker, etc.)
  - Add 1 mL of 2.5 mg/L hexavalent chromium (Cr^{+6}) standard to the 24 mL of filtered sample (this solution is called the MS)**.**
  - Add ChromaVer® 3 Reagent to the MS.
  - Invert sample 4 – 5 times – or swirl the sample; until powdered reagent is dissolved.
  - Start timer (8 min)
  - Use a 25 mL aliquot of filtered sample to Zero the Spectrometer. (Blank)
    - Transfer 25 mL of raw filtered sample into the pour-thru-cell funnel.
    - Allow the meter to stabilize and press the Zero button.

- After 8 minute timer, pour the sample into a syringe filter to remove the excess reagent powder. Transfer the sample into the pour-thru-cell funnel (sample port of the Hach DR/4000V).
- Record the instrument reading in the Cr^{+6} bench log book.
- Check the recovery of the MS:

  Example: Matrix Spike (0.117 mg/L) - Sample (0.006 mg/L) = 0.111 mg/L

  Concentration of Spike Standard = 0.100 mg/L

  % recovery is = 0.111/0.100 = 111%

  MS % recovery must be between 75 – 125% or you will need to reanalyze.

- If the CCV or MS are still not between 0.075 mg/L and 0.125 mg/L after reanalyses, call the Project Chemist (Shawn Duffy) at 530-229-3303.

Known Interferences

- Iron may interfere at levels above 1 mg/L.
- Highly buffered samples or extreme sample pH may exceed the buffering capacity of the reagents.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Ferrous Iron Analysis by Hach Method 8146
Number: SOP-L02_Rev03
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for analysis of ferrous iron (Fe^{+2}). The practical range of the method is 0.02 mg/L to 3 mg/L.

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach DR 4000V spectrophotometer or equivalent.
- pH meter.
- Reaction vessel and cap or means of sealing the reaction vessel (Hach sample cell, 50 mL beaker, vial capable of holding 30 mL and parafilm if the vessel doesn't have a cap).
- 1 packet of Ferrous Iron Reagent per sample.
- 0.45 µm filter disc fitted to a disposable 50 mL syringe (syringe filter).

Procedure

1. Collect the sample(s) following the appropriate SOP (see list below). Ferrous iron samples should be analyzed as soon as possible (within 6 hours).
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
    - SOP-A4 – Depth-Specific Surface Water Sampling
    - SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
    - SOP-A14 – Pore Water Sampling
    - SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
    - SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
    - Remedy-SOP-01 – Process Water Sampling

2. Measure the pH of the raw sample. (Record the results in the Fe+2 bench log book.)
3. Verify the spectrophotometer is set for Ferrous Iron (Hach DR/4000V, program 2150) and verify all reagents are for 25 mL sample size (or adjust accordingly).
4. Transfer 25 mL of the sample into a reaction vessel (sample cell, beaker, etc.).
5. Add one packet of Ferrous Iron Reagent.
6. Invert sample 4–5 times or swirl the sample until powdered reagent is dissolved.
7. Start timer (3 mins.).
8. Run a blank: Use a syringe filter to filter 25 mL of the raw sample and use to "zero" the spectrophotometer.
   - Transfer 25 mL of raw filtered sample into the pour-thru-cell funnel.
   - Allow the meter to stabilize and press the Zero button.
9. After 3 minute timer, use a syringe filter to filter the sample with the reagent added and transfer the sample into the pour-thru-cell funnel (the sample port of the Hach DR/4000V).
10. Record the instrument reading in the Fe+2 bench log book.
11. If the result is out of range for the spectrophotometer, reanalyze the sample using a dilution.

    Note: if a dilution is required, the spectrophotometer should be zeroed using sample from the same dilution.

    If it's determined in step 11 that a dilution is required, select one of the common dilutions listed below and re-analyze (step 4 thru step 11) using the selected dilution (remember to multiply the instrument reading by the dilution factor as listed below).

    - 1:2 dilution: 25 mL of sample are diluted with 25 mL of deionized (DI) water; multiply the instrument reading (result) by 2 for the adjusted value.

      Example: instrument reading is 0.304
      x 2
      = .608 mg/L (final result)

    - 1:5 dilution: 10 mL of sample are diluted with 40 mL of DI water; multiply the instrument reading (result) by 5 for the adjusted value.

      Example: instrument reading is 0.304
      x 5
      = 1.52 mg/L (final result)

    - 1:10 dilution: 10 mL of sample are diluted with 90 mL of DI water; multiply the instrument reading (result) by 10 for the adjusted value.
    - 1:20 dilution: 5 mL of sample are diluted with 95 mL of DI water; multiply the instrument reading (result) by 20 for the adjusted value.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Total Chromium Analysis by Hach Method 8024
Number: SOP-L03_Rev02
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for analysis of total chromium (Cr^{+3}).

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach DR 4000V spectrophotometer or equivalent.
- Vacuum filter apparatus: 47 mm magnetic filter funnels, 1,000 mL Erlenmeyer flask, and vacuum pump. Use a 0.45 µm, 47 mm diameter filter membrane.
- 0.45 µm filter disc fitted to a disposable 50 mL syringe (syringe filter).
- pH meter.
- Hach sample cell or vial capable of holding 30 mL.
- 1 packet of ChromaVer® 3 Reagent per sample.
- 1 packet of Chromium 1 Reagent per sample.
- 1 packet of Chromium 2 Reagent per sample.
- 1 packet of Acid Reagent per sample.
- 2.5 mg/L Chromium, Total (Cr^{+3}) (working) standard.
- Hot plate and water bath or heating block.
- Ice bath (baking pan with water and ice - approximately 1" deep)

Procedure

1. Collect the sample(s) following the appropriate SOP (see list below). The samples should be analyzed within 24 hours if possible. Note: all samples must be filtered.
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells

- SOP-A4 – Depth-Specific Surface Water Sampling
- SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
- SOP-A14 – Pore Water Sampling
- SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
- SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
- Remedy-SOP-01 – Process Water Sampling

2. Filtering can be performed using an inline filter at the time of sampling (see SOP–A6, Sample Field Filtration and Preservation for Metals Analyses) or in the laboratory by vacuum filter:
   - Set up the vacuum filter apparatus.
   - Filter ~100 mL of sample.
3. Turn on the hot plate and set to 390°F.
   - Make sure the water bath is ~ ½ inch below the top.
4. Measure the pH of the raw sample. (**Record the results in the Cr^{+3} bench log book.**)
5. Verify the spectrophotometer is set for **Chromium, Total (Cr^{+3})** (Hach DR/4000V program **1580)** and verify all reagents are for 25 mL sample size (or adjust accordingly).
6. Transfer 25 mL of filtered sample into a sample cell or vial.
7. Add Chromium 1 Reagent to each of the sample cells/vials.
8. Invert samples 4–5 times or swirl the sample until powdered reagent is dissolved.
9. Place the samples into the sample rack in the hot water bath (water should be boiling) and start the 5-minute "Heat" timer.
10. After 5 minutes, remove the sample cells/vials and cool to room temperature in an ice bath.
11. Add Chromium 2 Reagent to each of the sample cells/vials.
12. Invert samples 4–5 times or swirl the sample until powdered reagent is dissolved.
13. Add Acid Reagent to each of the sample cells.
14. Invert samples 4–5 times or swirl the sample until powdered reagent is dissolved.
15. Add ChromaVer® 3 Reagent to each of the sample cells/vials; invert samples 4–5 times or swirl the sample until powdered reagent is dissolved.
16. Start the 5-min. "wait" timer.
17. Run a blank: Use a 25 mL aliquot of filtered sample to "zero" the spectrophotometer:
    - Transfer 25 mL of raw filtered sample into the pour-thru-cell funnel.
    - Allow the meter to stabilize and press the Zero button.

18. After 5 minute "wait" timer, pour the sample with the reagent added into a syringe filter to remove the excess reagent powder. Transfer the sample into the pour-thru-cell funnel (sample port of the Hach DR/4000V).
19. Record the instrument reading in the Cr^{+3} bench log book.
20. If the result is out of range for the spectrophotometer, reanalyze the sample using a dilution.

    Note: if a dilution is required, the Spectrometer should be zeroed using sample from the same dilution.

    Common dilutions:

    - 1:2 dilution: 25 mL of sample are diluted with 25 mL of deionized (DI) water; multiply the instrument reading (result) by 2 for the adjusted value.

      Example: instrument reading is 0.304
      x 2
      = .608 mg/L (final result)

    - 1:5 dilution: 10 mL of sample are diluted with 40 mL of DI water; multiply the instrument reading (result) by 5 for the adjusted value.

      Example: instrument reading is 0.304
      x 5
      = 1.52 mg/L (final result)

    - 1:10 dilution: 10 mL of sample are diluted with 90 mL of DI water; multiply the instrument reading (result) by 10 for the adjusted value.
    - 1:20 dilution: 5 mL of sample are diluted with 95 mL of DI water; multiply the instrument reading (result) by 20 for the adjusted value.

Quality Control (QC)

- With the first analysis of Chromium, Total each shift, **analyze a CCV** (Continuing Calibration Verification) standard as a **Quality Control** check:
  - Carefully measure 24 mL of DI water into a reaction vessel (sample cell).
  - Add 1 mL of 2.5 mg/L Chromium, Total (Cr^{+3}) standard.
  - Add the Chromium 1 Reagent at the same time as your samples.
  - Follow the remaining procedures as listed above for the samples (hot water bath, cool with ice, add additional reagents, filter, and analyze). **Note:** The Blank for the CCV should be DI water.
  - **Record the CCV results in the Cr^{+3} bench log book.** If the instrument reading is not between 0.075 mg/L and 0.125 mg/L, re-prepare the standard and reanalyze.
- Periodic **Matrix Spikes (MSs)** should be analyzed. Any time a sample result appears anomalous, consider analyzing a matrix spike of that sample.
  - Determine what dilution, if any, is required for the matrix spike (note: you will be adding 0.1 mg/L to the sample concentration [the instrument reading]).

- Carefully measure 24 mL of filtered sample (diluted if required) into a reaction vessel (sample cell/vial).
- Add 1 mL of 2.5 mg/L Chromium, Total (Cr^{+3}) standard to the 24 mL of filtered sample (this solution is called the MS).
- Add the Chromium 1 Reagent at the same time as your samples.
- Follow the remaining procedures as listed above for the samples (hot water bath, cool with ice, add additional reagents, filter and analyze).
- Run a blank: Use a 25 mL aliquot of filtered sample to zero the spectrophotometer:
  - Transfer 25 mL of raw filtered sample into the pour-thru-cell funnel.
  - Allow the meter to stabilize and press the Zero button.
- After the 5-minute "wait" timer, pour the sample into a syringe filter to remove the excess reagent powder. Transfer the sample into the pour-thru-cell funnel (sample port of the Hach DR/4000V).
- Record the instrument reading in the **Cr^{+3}** bench log book.
- Check the recovery of the MS.

  Example: Matrix Spike (0.117 mg/L) - Sample (0.006 mg/L) = 0.111 mg/L

  Concentration of Spike Standard is = 0.100 mg/L

  % recovery is = 0.111/0.100 = 111%

  MS % recovery must be between 75 – 125% or you will need to reanalyze.
- If the CCV or MS are still not between 0.075 mg/L and 0.125 mg/L after reanalyses, call the Project Chemist (Shawn Duffy) at 530-229-3303.

Known Interferences

- High concentrations of organic material may inhibit complete oxidation of trivalent chromium.
- Highly buffered samples or extreme sample pH may exceed the buffering capacity of the reagents.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Conductivity Analysis by Hach Method 8160
Number: SOP-L04_Rev01
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for analysis of conductivity. The practical range of the method is 0.01 µS/cm to 200 mS/cm (0.01 to 200,000 µS/cm).

Conductivity is the measure of the ability of a solution to conduct an electric current and is dependent on temperature. The conductivity can then be multiplied by an empirically derived factor to calculate the approximate amount of total dissolved solids (TDS) in the sample.

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach sensION 378 Multiparameter Meter or equivalent
- Hach Quick Reference Guide booklet for the sensION156 and sensION378 Multiparameter Meters (54650-23)
- Conductivity Standards – 1000 µS/cm (Hach 14400-42) (Ensure that the conductivity standard solution is not expired.)
- Deionized (DI) water
- 100 mL beakers
- Calibration sheet
- Kimwipes
- Magnetic stir plate and magnetic stir bar.

Procedure

1. Collect the sample(s) following the appropriate SOP (see list below). Samples should be analyzed as soon as possible (within 24 hours).
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
    - SOP-A4 – Depth-Specific Surface Water Sampling

- SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
- SOP-A14 – Pore Water Sampling
- SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
- SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
- Remedy-SOP-01 – Process Water Sampling

2. Verify the meter is in COND mode.
3. Rinse the conductivity probe with DI water and shake it to remove excess water. (Check to make sure there are no bubbles in probe cell.) The meter should read below 10 µS/cm.
4. Confirm the calibration by checking the conductivity of the 1000 µS/cm standard at the beginning of each shift. (If a sample's conductivity is expected or measured between 10,000 µS/cm and 20,000 µS/cm, use a standard between 10,000 to 18,000 µS/cm to also verify the calibration. Likewise, if a sample's conductivity is, or expected to be, greater than 20,000 µS/cm, use a standard between 20,000 and 45,000 µS/cm to verify the calibration. Follow the steps below substituting the higher concentration standards.)
   a. Pour ~50 mL of 1000 µS/cm standard in a 100 mL beaker.
   b. Add a clean stir rod to the standard.
   c. Start the stir plate at a moderate rate (fast enough to stir the sample, but not fast enough to cause a vortex to form).
   d. Allow the meter to stabilize.
   e. After the reading stabilizes, record value on the calibration sheet.
5. If not within 10% of the true value (e.g., 900 to 1,100 µS/cm for the 1,000 µS/cm standard), recalibrate the meter following the steps on page 5 of the Hach **Quick Reference Guide** booklet for the **sensION156** and **sensION378** Multiparameter Meters (54650-23).

   Be sure to clean the probe cell first. If DI water does not clean the cell, try cleaning the cell as follows: Wash with warm water and laboratory soap and rinse with copious amounts of DI water before use. Alternatively a 3% HCl acid solution may be used. Solvents such as acetone or ethanol should only be used as a last resort, and the cell should not be immersed for longer than 5 minutes. Always completely rinse with DI water. Re-calibrate after these cleanings.
6. If the standard results are within 10% of the true value (e.g., 900 to 1,100 µS/cm for the 1,000 µS/cm standard), continue with analysis for each of the samples. (Ensure the temperature of the sample is between 20°C and 25°C.)
7. Pour a fresh portion (~ 50-mL) of the sample into a clean 100 mL beaker.
8. Add a clean stir rod to the sample.

9. Start the stir plate at a moderate rate (fast enough to stir the sample, but not fast enough to cause a vortex to form).
10. Place probe in sample.
11. Allow the meter to stabilize.
12. Record the conductivity result on the Conductivity bench sheet and include the units. (Note: The meter automatically changes the units from µS/cm to mS/cm above 1,999 µS/cm.) The result is automatically corrected to the reference temperature of 20°C.
13. Rinse the probe and cell with DI water after each sample.

Calculations

- To convert from mS/cm to µS/cm multiply the result by 1000.
- TDS, mg/L (ppm) ≅ Conductivity (µS/cm) * 0.63.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Spike Preparation
Number: SOP-L08_Rev01
Revision Date: 06/05/2014

Scope

Standard operating procedure (SOP) for preparing "working concentration" spike solutions for the analysis of reagent spikes (Continuing Calibration Verifications or CCVs) and sample matrix spikes (MSs).

Equipment and Supplies

- Safety glasses
- Latex gloves
- 100 mL or 1000 mL volumetric flask with cap
- 1 mL or 5 mL pipette
- Deionized (DI) water
- Glass standards bottle or 1 liter poly bottle and labels
- Chemical standard:

    a. Hexavalent Chromium: 50 mg/L hexavalent chromium standard; also see SOP-L01, Hexavalent Chromium Analysis by Hach Method 1560

    b. Total Chromium: 50 mg/L total chromium standard; also see SOP-L03, Total Chromium Analysis by Hach Method 8024

    c. Manganese: 25 mg/L manganese standard; also see SOP-L18, Manganese Analysis by Hach Method 8149

    d. Nitrate: 100 mg/L nitrate standard; also see SOP-L13, Nitrate Analysis by Hach Method 8171

    e. Sulfate: 1000 mg/L sulfate standard and 1 packet of SulfaVer® 4 Reagent; also see SOP-L14, Sulfate Analysis by Hach Method 8051

    f. Total Organic Carbon (TOC): 1000 mg/L TOC standard (potassium hydrogen phthalate [KHP]); also see SOP-L16, Total Organic Carbon Analysis by Hach Method 10129

Procedures

a. Hexavalent Chromium

1. Add ~50 mL of DI water to a 100 mL volumetric flask.
2. Add 5 mL of a 50 mg/L hexavalent chromium standard using a 1 mL pipette.
3. Bring the volume of the flask to 100 mL using DI water.

4. Cap, and mix thoroughly.
5. The resultant concentration of the standard is 2.5 mg/L. This standard solution can be used to prepare an MS and/or a CCV standard as outlined in SOP-L01, Hexavalent Chromium Analysis by Hach Method 1560.
6. Transfer the 2.5 mg/L working standard to a glass standards bottle and label.
7. Verify the concentration by following the CCV procedure as detailed in SOP-L01, Hexavalent Chromium Analysis by Hach Method 1560.

b. Total Chromium

1. Add ~50 mL of DI water to a 100 mL volumetric flask.
2. Add 5 mL of a 50 mg/L total chromium standard using a 1 mL pipette.
3. Bring the volume of the flask to 100 mL using DI water.
4. Cap, and mix thoroughly.
5. The resultant concentration of the standard is 2.5 mg/L. This standard solution can be used to prepare an MS and/or a CCV standard as outlined in SOP-L03, Total Chromium Analysis by Hach Method 8024.
6. Transfer the 2.5 mg/L working standard to a glass standards bottle and label.
7. Verify the concentration by following the CCV procedure as detailed in SOP-L03, Total Chromium Analysis by Hach Method 8024.

c. Manganese

1. Add ~25 mL of DI water to a 50 mL volumetric flask.
2. Add 2 mL of a 25 mg/L manganese standard using a 1 mL pipette.
3. Bring the volume of the flask to 50 mL using DI water.
4. Cap, and mix thoroughly.
5. The resultant concentration of the standard is 1 mg/L. This standard solution can be used to prepare an MS and/or a CCV standard as outlined in SOP-L18, Manganese Analysis by Hach Method 8149.
6. Transfer the 1 mg/L working standard to a glass standards bottle and label.
7. Verify the concentration by following the CCV procedure as detailed in SOP-L18, Manganese Analysis by Hach Method 8149.

d. Nitrate

1. Add ~50 mL of DI water to a 100 mL volumetric flask.
2. Add 25 mL of a 100 mg/L nitrate standard using a 5 mL pipette.
3. Bring the volume of the flask to 100 mL using DI water.

4. Cap, and mix thoroughly.
5. The resultant concentration of the standard is 25 mg/L. This standard solution can be used to prepare an MS and/or a CCV standard as outlined in SOP-L13, Nitrate Analysis by Hach Method 8171.
6. Transfer the 25 mg/L working standard to a glass standards bottle and label.
7. Verify the concentration by following the CCV procedure as detailed in SOP-L13, Nitrate Analysis by Hach Method 8171.

e. Sulfate

1. Add ~500 mL of DI water to a 1000 mL volumetric flask.
2. Add 70 mL of a 1000 mg/L sulfate standard using graduated cylinder.
3. Bring the volume of the flask to 1000 mL using DI water.
4. Cap, and mix thoroughly.
5. The resultant concentration of the standard is 70 mg/L. This working standard can be used at this concentration for a CCV standard as outlined in SOP-L14, Sulfate Analysis by Hach Method 8051.
6. Transfer the 70 mg/L working standard to a 1 liter poly bottle and label.
7. Verify the concentration by following the CCV procedure as detailed in SOP-L14, Sulfate Analysis by Hach Method 8051.

f. TOC

1. Add ~500 mL of DI water to a 1000 mL volumetric flask.
2. Add 10 mL of a 1000 mg/L TOC standard (KHP) using a 5 mL pipette.
3. Bring the volume of the flask to 1000 mL using DI water.
4. Cap, and mix thoroughly.
5. Transfer the 10 mg/L working standard to a glass standards bottle and label.
6. The resultant concentration of the standard is 10 mg/L. This standard solution can be used to prepare an MS and/or a CCV standard as outlined in SOP-L16, TOC Analysis.
7. Transfer the 10 mg/L working standard to a 1 liter poly bottle and label.
8. Verify the concentration by following the CCV procedure as detailed in SOP-L16, TOC Analysis by Hach Method 10129.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: pH Measurement
Number: SOP-L09_Rev02
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for pH measurement.

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach sensION 378 Multiparameter Meter or equivalent

  Note: Store the pH electrode in the pH 4 or 7 buffer solution when it's not in use, or use the manufacturer's storage solution. Replace the storage solution every week.
- Hach Quick Reference Guide for sensION156 and sensION378 Multiparameter Meters (54650-23).
- pH buffer solutions for pH 4, 7 and 10. (Make sure the buffer solutions are not expired.)
- 100 mL beakers
- De-ionized (DI) water (squirt bottle)
- Calibration beakers. (Calibration beakers are provided by the instrument manufacturer and have sealable lids that allow the calibrations standards to be reused. Do not pour the calibration standards back into the original bottles. Replace the working buffer solution at least twice a week or if re-calibrating the meter is required.)
- Calibration sheet
- Kimwipes
- Magnetic stir plate and magnetic stir bar.

Procedure

1. Collect the sample(s) following the appropriate SOP (see list below). Samples should be analyzed as soon as possible (within 24 hours).
   - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
   - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method

- SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
- SOP-A4 – Depth-Specific Surface Water Sampling
- SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
- SOP-A14 – Pore Water Sampling
- SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
- SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
- Remedy-SOP-01 – Process Water Sampling

Notes prior to beginning calibration:

- The pH meter must be calibrated at the beginning of each day and any time the pH reading does not make sense.
- Make sure the electrode is rinsed well between samples.
- Make sure the buffers and samples are at a constant temperature before beginning the calibration or analysis procedure (pH is affected by temperature).

2. To start the calibration pour fresh portions (~ 50-mL) of the pH 4, 7 and 10 buffers into the calibration beakers (buffers should be replaced at least twice per week). Rinse each calibration beaker 3 times with small portions of buffer before filling the beaker with the portion to be analyzed.
3. Add a clean stir rod to each standard.
4. Start the stir plate at a moderate rate (fast enough to stir the sample, but not fast enough to cause a vortex to form).
5. Turn the pH meter on.
6. Make sure the meter is in pH mode.
7. Rinse the electrode with DI water.
8. Follow the calibration procedures on page 3 in the Hach **Quick Reference Guide** for **sensION156** and **sensION378** Multiparameter Meters (54650-23).
    - Be careful not to hit the electrode end against the sides of the beaker.
9. If the pH probe does not recognize the pH 4 buffer within 2 – 3 minutes, re-rinse the electrode with DI water, dry with a Kimwipe and try again. If you've cleaned the probe three times and the pH meter still doesn't recognize the pH 4 buffer, call the Project Chemist (Shawn Duffy) at 530-229-3303.
10. Rinse the electrode with DI water between each buffer solution.
11. After calibrating with the pH 4, 7 and 10 buffers, record the Slope value on the calibration sheet and press Enter to accept and return to the reading mode.

12. Rinse the electrode with DI water.
13. To analyze samples, pour a fresh portion (~ 50-mL) of the sample into a clean 100 mL beaker.
14. Add a clean stir bar.
15. Start the stir plate at a moderate rate (fast enough to stir the sample, but not fast enough to cause a vortex to form).
16. Place the pH meter electrode in the sample.
17. Allow the meter to stabilize, record the pH in the appropriate bench log book.
18. If the meter does not stabilize during a pH measurement a new calibration may be needed. Rinse the electrode with DI water and re-start the calibration.

Standard Operating Procedure
PG&E Topock Program

Title: Hach Model 2100P Turbidimeter Calibration and Analysis
Number: SOP-L10 Rev02
Revision Date: 10/13/2015

Scope

Standard Operating Procedure (SOP) for the analysis of turbidity. This SOP covers the calibration and operating procedures for the Hach Model 2100P turbidimeter.

Precautions/Hazards

- Operators should not attempt the full calibration task until they have been properly trained.
- Hazards include exposure to Formazin and silicone oil (please refer to material safety data sheets [MSDSs] for all chemicals).

Equipment and Supplies List

- Safety glasses
- Latex gloves
- Kimwipes
- Oiling cloths
- Hach Model 2100P portable turbidimeter
- Model 2100P Turbidimeter Instrument and Procedure Manual (Cat. No. 46500-88)
- Carrying case
- Four AA alkaline batteries
- Sample cells with caps
- Check and calibration log
- Turbidimeter kit
- Reagents:
  - Formazin Primary Standards: Hach Part # 26594-05, StablCal® Standards, <0.1, 20, 100, 800 NTU ampoules
  - Gelex Secondary Standards: Hach Part # 24641-05
  - Silicone oil: Hach Part # 1269-36

Daily Gelex Check Procedure

1. Turn on turbidimeter and select automatic range mode. You should see "AUTO RNG" on display.
2. Thoroughly clean the outside of all three Gelex vials with Kimwipes, apply one drop of silicone oil to each vial, and wipe with oiling cloth.
    - Dirty, scratched, or damaged cells can cause inaccurate readings. Handle cells only by the top to minimize dirt, scratches and fingerprints in the light path.
    - The silicone oil is used to eliminate the effects of fine scratches in the glass cell. If the vial has any large visible scratches, notify the supervisor so a replacement Gelex set can be ordered.
    - Avoid excess coating of oil. Oil is not needed if the sample cells are properly maintained.
3. Beginning with Gelex standard 0-10 NTU, place Gelex cell into compartment so that the diamond aligns with orientation mark on the turbidimeter. Close the lid.
4. When taking a reading, place the instrument on a level, stationary surface. It should not be held in the hand during measurement.
5. Press the Read button.
6. If 9.99 or 99.9 are flashing on display, press 'Range' button to change range of meter.
7. Record the displayed value in the check and calibration log.
8. Repeat steps 2 through 5 for remaining Gelex standards.

If any of the Gelex standards are +/- 5% from assigned value, the turbidimeter must be calibrated.

Turbidimeter Calibration Procedure

For expediency you will be referred to the instrument manual (Section 3.6, pages 35-54) to perform these procedures.

1. Prepare Formazin standards, located in the turbidimeter kit (small blue tool box located in cabinet under counter below mixer), according to procedure on page 37, **Section 3.6.1.3** of **Model 2100P Turbidimeter Instrument and Procedure Manual**.
2. Cap the sample cells to prevent spillage of Formazin into the instrument.
3. Begin calibration procedure on page 42, **Section 3.6.3** of **Model 2100P Turbidimeter Instrument and Procedure Manual**.
4. After the turbidimeter has accepted the calibration, assign new values to all Gelex standards using the Daily Gelex Check Procedure above.

Sample Analysis Procedure

1. Transfer sample into a vial dedicated to turbidity measurements "cell." **Do not dilute the samples.**
    - Always use clean sample cells in good condition. Properly clean cells between measurements. Do not use a brush on the sample cell, always use Kimwipes or equivalent optical wipes to dry the cells.
    - Dirty, scratched, or damaged cells can cause inaccurate readings. Handle cells only by the top to minimize dirt, scratches and fingerprints in the light path.
2. Cap the sample cell to prevent spillage of sample into the instrument.
3. Avoid settling of sample prior to measurement. Allow samples to degas but do not allow settling of solids.
4. Thoroughly clean the outside of cell with Kimwipes, apply one drop of silicone oil if needed, and wipe with oiling cloth. Oil is not needed if the sample cells are properly maintained.
    - The silicone oil is used to eliminate the effects of fine scratches in the glass cell. If the vial has any large visible scratches, discard and use another cell.
    - Avoid excess coating of oil.
5. Place the sample cell into the compartment so that the diamond aligns with orientation mark on the turbidimeter. Close the lid.
6. Place the instrument on a level, stationary surface. It should not be held in the hand during measurement.
7. Press the Read button.
8. If 9.99 or 99.9 are flashing on display, press 'Range' button to change range of meter.
9. Record the displayed value in the bench logbook.
10. Do not leave a sample cell in the cell compartment for extended periods of time. This may compress the spring in the cell holder.
11. Always close the sample compartment lid during storage. Remove sample cell and batteries from instrument if the instrument is stored for extended time period (more than a month).

Quality Control

- QC activities that will help ensure the accuracy and precision of this method include:
    - **Using optically matched (or single) cells for Low Level Turbidity** - Precise measurements of low turbidity (< 2 NTU) samples require using a single cell for all measurements or using optically matched cells – *see Hach instruction manual Section 2.3.3 pages 22-25*.
    - **Use dedicated cells –** The use of cells dedicated to turbidity measurement is recommended.

- **Removing trapped gases** - *See Hach instruction manual Section 2.3.3 pages 22-25.* This would only be a problem for samples that exhibit foaming or where gas bubbles are observed.
- **Do not dilute the samples**.
- The calibration of the turbidimeter must be verified, using the more convenient Gelex® secondary standards, at the beginning of each day and any time the turbidity reading does not make sense. The turbidimeter must be fully calibrated using Formazin primary standards every three months as per manufacturer standards, and also whenever the daily Gelex check standards fail to meet the +/- 5% quality control (QC) criteria.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Nitrate Analysis by Hach Method 8171
Number: SOP-L13_Rev01
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for analysis of nitrate (NO_3^--N).

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach DR 4000V spectrophotometer or equivalent
- pH meter
- Reaction vessel and cap or means of sealing the reaction vessel– (Hach sample cell, 50 mL beaker, vial capable of holding 30 mL, and parafilm if the vessel doesn't have a cap)
- 1 packet of NitraVer® 5 Reagent per sample
- 25 mg/L nitrate (NO_3^--N) (working) standard
- 0.45 µm filter disc fitted to a disposable 50 mL syringe (syringe filter)
- Deionized (DI) water
- Timer

Procedure

1. For each lot of reagents, analyze a reagent blank. Transfer 25 mL of DI water into a reaction vessel and follow steps 4 through 12 below. Sample concentration may need to be adjusted based on the reagent's contribution. If the concentration is greater than 0.25 mg/L call the Project Chemist (Shawn Duffy) at 530-229-3303.
2. Collect the sample(s) following the appropriate SOP (see below). Nitrate samples should be analyzed as soon as possible (within 24 hours).
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
    - SOP-A4 – Depth-Specific Surface Water Sampling
    - SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes

- SOP-A14 – Pore Water Sampling
- SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
- SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
- Remedy-SOP-01 – Process Water Sampling

3. Measure the pH of the raw sample. Record the results in the NO_3^--N Bench Logbook.
4. Verify the spectrophotometer is set for Nitrate (Hach DR/4000V, program 2520) and verify all reagents are for 25 mL sample size (or adjust accordingly).
5. Transfer 25 mL of the sample into a reaction vessel. (Note: the sample cell or vessel must be able to be sealed with a cap or parafilm.)
6. Add 1 packet of NitraVer® 5 Reagent.
7. Start the 1 minute timer.
8. Shake the sample for the entire 1 minute, using a 90° rotation of the wrist and back to the original position with a timing of once per second.
9. After the 1 minute shake time set the sample down and start the 5 minute reaction timer.
10. Run a blank: Use a syringe filter to filter 25 mL of the raw sample, and then use the raw sample to "zero" the spectrophotometer. Note: if the sample needs dilution, then use the same dilution water for the blank.
    - Transfer 25 mL of raw filtered sample into the pour-through-cell funnel.
    - Allow the meter to stabilize and press the Zero button.
11. After 5 minute timer, use a syringe filter to filter the sample with the reagent added and transfer the sample into the pour-through-cell funnel (the sample port of the Hach DR/4000V). Analyze within 2 minutes.
12. Record the instrument reading in the NO_3^--N Bench Logbook.
13. If the result is out of range for the spectrophotometer, reanalyze the sample using a dilution.

    Note: if a dilution is required, the spectrophotometer should be zeroed using a sample from the same dilution.

    Common dilutions:

    - 1:2 dilution: 25 mL of sample are diluted with 25 mL of DI water; multiply the instrument reading (result) by 2 for the adjusted value.

      Example: instrument reading is 3.54
      x 2
      = 7.08 mg/L (final result)

- 1:5 dilution: 10 mL of sample are diluted with 40 mL of DI water; multiply the instrument reading (result) by 5 for the adjusted value.

  Example: instrument reading is 3.54
  x 5
  = 17.7 mg/L (final result)

- 1:10 dilution: 10 mL of sample are diluted with 90 mL of DI water; multiply the instrument reading (result) by 10 for the adjusted value.
- 1:20 dilution: 5 mL of sample are diluted with 95 mL of DI water; multiply the instrument reading (result) by 20 for the adjusted value.

Quality Control (QC)

- With the first analysis of Nitrate each shift, **analyze a Continuing Calibration Verification (CCV) standard** as a **Quality Control** check:
  - Carefully measure 24 mL of DI water into a sample cell.
  - Add 1 mL of 25 mg/L Nitrate (NO_3^--N) standard.
  - Add 1 packet of NitraVer® 5 Reagent at the same time you add the reagent to your samples.
  - Follow the remaining procedures as listed above for the samples (steps 7 through 12). The Blank for the CCV should be DI water.
  - **Record the CCV results in the NO_3^--N Bench Logbook.** If the instrument reading is not between 0.75 mg/L and 1.25 mg/L re-prepare the standard and reanalyze.
- Periodic **Matrix Spikes (MSs)** should be analyzed. Any time a sample result appears anomalous, consider analyzing an MS of that sample.
  - Determine what dilution, if any, is required for the MS (Note: you will be adding 1.0 mg/L to the sample concentration [the instrument reading]). If you have difficulty determining the dilution needed, call the Project Chemist (Shawn Duffy) at 530-229-3303.
  - Carefully measure 24 mL of filtered sample (diluted if required) into a reaction vessel (sample cell/vial).
  - Add 1 mL of 25 mg/L Nitrate (NO_3^--N) standard to the 24 mL of filtered sample—this is your MS**.**
  - Add 1 packet of NitraVer® 5 Reagent at the same time you add the reagent to your samples.
  - Follow the remaining procedures as listed above for the samples (steps 7 through 12), use a 25 mL aliquot of the same dilution water for the blank (use to zero the spectrophotometer).
  - Record the instrument reading in the NO_3^--N Bench Logbook.
  - Check the recovery of the MS:

Example: Matrix Spike (3.17 mg/L) - Sample (2.06 mg/L) = 1.11 mg/L

Concentration of MS Standard = 1.00 mg/L

% recovery is = 1.11/1.00 = 111%

Note: MS % recovery must be between 75 – 125% or you will need to reanalyze.

If the CCV or MS are still not between 0.075 mg/L and 0.125 mg/L after reanalyses, call the Project Chemist (Shawn Duffy) at 530-229-3303.

Known Interferences

- Chloride concentrations above 100 mg/L will cause low results.
- Ferric iron at all levels
- Highly buffered samples or extreme sample pH may exceed the buffering capacity of the Reagents.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Sulfate Analysis by Hach Method 8051
Number: SOP-L14_Rev1
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for analysis of sulfate (SO_4^{2-}).

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach DR 4000V spectrophotometer or equivalent
- Vacuum filter apparatus: 47 mm magnetic filter funnels, 1000 mL Erlenmeyer flask, and vacuum pump. Use a 0.45 µm, 47 mm diameter filter membrane.
- pH meter
- Reaction vessel and cap (Hach sample cell)
- 1 packet of SulfaVer® 4 Reagent per sample
- 70 mg/L Sulfate (SO_4^{2-}) (working) standard
- Timer
- Deionized (DI) water

Procedure

1. For each lot of reagent, analyze a reagent blank. Transfer 25 mL of DI water into a reaction vessel and follow steps 4 through 11 below. Sample concentration may need to be adjusted based on the reagents contribution. (Do not dilute or filter this sample.)
2. Collect the sample(s) following the appropriate SOP (see below). Sulfate samples should be analyzed within 24 hours. If the sample is held for more than 24 hours, store at 4°C and allow the sample to equilibrate to room temperature prior to analysis.
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
    - SOP-A4 – Depth-Specific Surface Water Sampling
    - SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes

- SOP-A14 – Pore Water Sampling
- SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
- SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
- Remedy-SOP-01 – Process Water Sampling.

3. Measure the pH of the raw sample (record the results in the SO_4^{2-} Bench Logbook).
4. Verify the spectrophotometer is set for Sulfate (Hach DR 4000V, program 3450) and verify all reagents are for 25 mL sample size (or adjust accordingly).
   - **Note: Turbid or colored samples (e.g. noticeable by eye) must be filtered.**
     - Filtering can be performed using an inline filter at the time of sampling (see SOP–A6, Sample Field Filtration and Preservation for Metals Analyses) or in the laboratory by vacuum filter.
     - Set up the vacuum filter apparatus.
     - Filter ~100 mL of sample.
5. Due to the high concentration of sulfate, all samples will start with a 1:25 dilution.
   - Add 1 mL of sample to 24 mL of DI water.
   - Mix the sample by swirling or shaking the sample.
6. Add 1 packet of SulfaVer® 4 Reagent.
7. Swirl to mix until the reagent powder is dissolved. (Note that the reaction will generate a white particulate that can be confused with the Reagent powder so pay close attention to what the Reagent powder looks like.)
8. Start the 5-minute reaction timer. **Do not disturb the sample cell during this time.**
9. After the 5 minutes has elapsed, run a blank. If the sample was filtered, use the filtered sample to "zero" the spectrophotometer.
   - **Note: do not use flow-through cell or Sipper Cell Modules.**
   - Wait until the 5 minute timer beeps before placing the blank into the cell holder and zeroing the instrument.
10. Analyze the samples immediately. **Note: do not filter at this stage.**
11. Record the instrument reading in the Lab SO_4^{2-} Bench Logbook.
12. Multiply the instrument reading by the dilution factor (25) and record in the result column.

    If the result is out of range for the spectrophotometer, reanalyze; if still out of range call the Project Chemist (Shawn Duffy) at 530-229-3303.

    Note: if an additional dilution is required, the spectrophotometer should be zeroed using a sample from the same dilution.

Quality Control (QC)

- With the first analysis of sulfate each shift, **analyze a Continuing Calibration Verification (CCV) standard** as a **Quality Control** check:
  - Transfer 25 mL of 70 mg/L Sulfate standard into a sample cell.
  - Add 1 packet of SulfaVer® 4 Reagent at the same time you add the reagent to your samples.
  - Follow steps 7 through 11 listed above (swirl, timer, blank, analyze, record). **Note:** The Blank for the CCV should be DI water.
  - **Record the CCV results in the SO_4^{2-} Bench Logbook.** If the instrument reading is not between 52.5 mg/L and 87.5 mg/L, re-prepare the standard and reanalyze.

    If the CCV is still not between 52.5 mg/L and 87.5 mg/L after reanalyses, call the Project Chemist (Shawn Duffy) at 530-229-3303.

Known Interferences

- Calcium at concentrations greater than 20,000 mg/L as $CaCO_3$.
- Chloride at concentrations greater than 40,000 mg/L as Cl.
- Magnesium at concentrations greater than 10,000 mg/L as $CaCO_3$.
- Silica at concentrations greater than 500 mg/L as SiO_2.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Alkalinity Analysis
Number: SOP-L15_Rev1
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for analysis of alkalinity.

Equipment and Supplies

- Safety glasses
- Latex gloves
- pH meter
- Phenolphthalein Indicator Solution
- Bromcresol Green-Methyl Red Indicator Solution
- Sulfuric acid standard solution, 0.020 N (Titrant)
- Buret, buret clamp and stand
- 250-mL Erlenmeyer flask
- Graduated cylinder – 50-mL or 100-mL
- Magnetic stir plate and magnetic stir bar

Procedure

1. Collect the sample(s) following the appropriate SOP (see below). Alkalinity samples should be analyzed within 24 hours. If the sample is held for more than 24 hours, store at 4°C and allow the sample to equilibrate to room temperature prior to analysis.
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
    - SOP-A4 – Depth-Specific Surface Water Sampling
    - SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
    - SOP-A14 – Pore Water Sampling
    - SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
    - SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
    - Remedy-SOP-01 – Process Water Sampling

2. Measure the pH of the raw sample (record the results in the Alkalinity Bench Logbook).
3. Fill the buret to the zero mark with 0.020 N Sulfuric Acid standard solution (Titrant).
4. Use the graduated cylinder to transfer 50 mL of the sample into an Erlenmeyer flask.
5. Add a clean stir bar.
6. Start the stir plate at a moderate rate (fast enough to stir the sample, but not fast enough to cause a vortex to form).

If the pH of the raw sample was greater than 8.3, proceed to Phenolphthalein Step (step 7 below). If the pH was equal to or less than 8.3, proceed directly to the Total Alkalinity Step (step 10).

Phenolphthalein Step:

7. Add six drops of Phenolphthalein Indicator Solution. Allow to mix with sample. Sample will be pink if Phenolphthalein alkalinity is present. If the sample does not turn pink, proceed to Total Alkalinity Step (step 10).
8. Slowly open the stop-cock allowing the Titrant to drip into the sample and mix. Stop the flow of Titrant as soon as the sample color changes from pink to colorless. (Note: the end point has not been reached until the sample remains colorless.)

   Calculate:
   mg/L phenolphthalein alkalinity as $CaCO_3$ = mL Titrant used × 20.

9. Record the phenolphthalein alkalinity in the Alkalinity Bench Logbook. Proceed to Total Alkalinity Step.

Total Alkalinity Step:

10. Add six drops of Bromcresol Green-Methyl Red Indicator Solution. Allow to mix with sample. There is no color change at this stage.
11. Slowly open the stop-cock allowing the Titrant to drip into the sample and mix. Stop the flow of Titrant as soon as the sample color changes from colorless to a light pink. (Note: the end point has not been reached until the sample remains light pink.)

    Calculate:
    mg/L Total alkalinity as $CaCO_3$ = total mL Titrant used × 20.

12. Record the Total alkalinity in the Alkalinity Bench Logbook.

    Note: if the sample's pH was 8.3 or less, the Total Alkalinity = Bicarbonate Alkalinity. If the pH was greater than 8.3, use the table below[1] to calculate the Carbonate, Bicarbonate, and Hydroxide Alkalinity.

[1] Table source: Hach Water Analysis Handbook, Fourth Edition, Rev. 2. Alkalinity, Buret Titration Method 8221. DOC316.53.01151.

Total alkalinity primarily includes hydroxide, carbonate, and bicarbonate alkalinities. The concentration of these types in a sample may be determined when the phenolphthalein and total alkalinities are known (*Alkalinity relationship* table).

Table 35 Alkalinity relationship

Row	Result of Titration	Hydroxide Alkalinity Equals:	Carbonate Alkalinity Equals:	Bicarbonate Alkalinity Equals:
1	Phenolphthalein Alkalinity equal to 0	0	0	Total Alkalinity
2	Phenolphthalein Alkalinity equal to Total Alkalinity	Total Alkalinity	0	0
3	Phenolphthalein Alkalinity less than one-half of Total Alkalinity	0	Phenolphthalein Alkalinity times 2	Total Alkalinity minus two times Phenolphthalein Alkalinity
4	Phenolphthalein Alkalinity equal to one-half of Total Alkalinity	0	Total Alkalinity	0
5	Phenolphthalein Alkalinity greater than one-half of Total Alkalinity	2 times Phenolphthalein Alkalinity minus Total Alkalinity	2 times the difference between Total and Phenolphthalein Alkalinity	0

Use the *Alkalinity relationship* table with the following procedure:

1. Does the phenolphthalein alkalinity equal zero? If yes, use Row 1.
2. Does the phenolphthalein alkalinity equal total alkalinity? If yes, use Row 2.
3. Divide the total alkalinity by 2 to calculate one-half the total alkalinity.
4. Select Row 3, 4 or 5 based on comparing the result of step c (one-half total alkalinity) with the phenolphthalein alkalinity.
5. Perform the required calculations if any.
6. Check your results. The sum of the three alkalinity types will equal the total alkalinity.

If you have any questions, call the Project Chemist (Shawn Duffy) at 530-229-3303.

Known Interferences

- Highly colored or turbid samples may mask the color change at the end points.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Total Organic Carbon Analysis by Hach Method 10129
Number: SOP-L16_Rev01
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for analysis of total organic carbon (TOC).

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach DR 4000V spectrophotometer or equivalent
- Spectrophotometer manufacturer's manual
- Test 'N Tube™ adapter for the spectrophotometer
- pH meter and pH paper (capable of measuring down to pH 2)
- TOC Bench Logbook
- Chemical oxygen demand (COD) Reactor or similar digestion block
- Stir plate and magnet stir bar
- Low Range TOC Acid Digestion Solution vials (Acid Digestion vials)
- Low Range TOC Indicator Ampules (indicator ampules)
- Sulfate Buffer Solution
- TOC Persulfate Powder Pillow
- Pipet: 0.1 – 1.0 mL, and a 1 – 5 mL or 1 – 10 mL.
- 50 mL Erlenmeyer flask
- 0.45 µm filter disc fitted to a disposable 50 mL syringe (syringe filter)
- Deionized (DI) water
- Kimwipes
- Paper towels
- Timer
- Fine point Sharpie (indelible ink pen)
- Small funnel (comes with each batch of TOC Acid Digestion vials)
- Test tube rack
- 10 mg/L TOC Working Standard

Procedure

1. Collect the sample(s) following the appropriate SOP (see below). TOC samples should be analyzed as soon as possible (within 48 hours if possible).

    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method

- SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
- SOP-A4 – Depth-Specific Surface Water Sampling
- SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
- SOP-A14 – Pore Water Sampling
- SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
- SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
- Remedy-SOP-01 – Process Water Sampling

2. Measure the pH of the raw sample. Record the results in the TOC Bench Logbook.
3. Turn on the COD reactor and make sure it's set at 105°C.
4. Transfer 10 mL of sample into a 50 mL Erlenmeyer flask containing a magnetic stir bar.
5. Add 0.4 mL of Sulfate Buffer Solution (use pH paper to verify the pH is 2.0 or below – if needed add additional buffer, 0.1 mL at a time until pH ≤2).
6. Place the flask on a stir plate and set at a moderate speed for 10 minutes (swirls the sample but does not form a vortex). Steps 7 through 10 may be performed while the flask is being stirred.
7. Remove the number of Low Range TOC Acid Digestion Solution vials you'll need from the manufacture's packaging and place in the test tube rack (remember one for the reagent blank).
8. Label the Acid Digestion vials for the samples, including the reagent blank.
9. Using the funnel provided with the Acid Digestion vials, add the contents of one TOC Persulfate Powder Pillow to each vial (labeled in step 7).
10. Using a pipet add 3 mL of organic-free water (use DI water) to the reagent blank vial.
11. After the 10 minutes for stirring the 50 mL Erlenmeyer flask have elapsed, use a pipet to transfer 3 mL of prepared sample (sample in the Erlenmeyer flask) to the labeled vial(s) with the persulfate powder already added.
12. Holding the blue Indicator Ampule by the top, carefully rinse with DI water and wipe dry with a Kimwipe.
13. Lower the unopened ampule into one of the labeled Acid Digestion vials. Align the score mark (the score mark is in the narrowed "neck" of the ampule) with the top of the vial and snap off the top of the ampule allowing the ampule to drop into the Acid Digestion vial.
    - **Do not** tip or tilt the vial after the ampule is in the vial. **You do not want the indicator solution mixing with the sample.**
14. Repeat steps 12 and 13 for each sample and the reagent blank.

15. Cap the vials tightly and place in the COD Reactor. Start the reactor timer (2 hours). Verify the reactor is at 105°C.
16. After the 2 hour timer, remove the vials from the COD Reactor and place in the test tube rack, being careful to handle the vials by their caps which will have remained cool.
17. Allow the vials to cool for one hour.
18. Verify the Test 'N Tube™ adapter is installed in the spectrophotometer (see the manufacturer's manual for instructions).
19. Verify that the spectrophotometer is set for Low Range TOC (Hach DR/4000V, program 3655).
20. Holding the vial by its cap wipe the reagent vial with a damp paper towel and then with a dry Kimwipe to remove any fingerprints or other marks.
21. Use the reagent blank to "zero" the spectrophotometer.
    - Place the vial in the adapter and close the light shield.
    - Allow the meter to stabilize and press the Zero button.
22. After the spectrophotometer has been zeroed, repeat step 20 for each vial, place the vial in the adapter, close the light shield, allow the meter to stabilize, and record the instrument reading in the TOC Bench Logbook.
23. If the result is out of range for the spectrophotometer, reanalyze the sample using a dilution.

    Common dilutions:

    - 1:2 dilution: 25 mL of sample are diluted with 25 mL of DI water; multiply the instrument reading (result) by 2 for the adjusted value.

      Example: instrument reading is 3.54
      x 2
      = 7.08 mg/L (final result)

    - 1:5 dilution: 10 mL of sample are diluted with 40 mL of DI water; multiply the instrument reading (result) by 5 for the adjusted value.

      Example: instrument reading is 3.54
      x 5
      = 17.7 mg/L (final result)

    - 1:10 dilution: 10 mL of sample are diluted with 90 mL of DI water; multiply the instrument reading (result) by 10 for the adjusted value.
    - 1:20 dilution: 5 mL of sample are diluted with 95 mL of DI water; multiply the instrument reading (result) by 20 for the adjusted value.

Quality Control (QC)

- With the first analysis of TOC each shift, **analyze a Continuing Calibration Verification (CCV) standard** as a **Quality Control** check:
  - Carefully measure 9 mL of the DI water into a 50 mL Erlenmeyer flask containing a magnetic stir bar.
  - Add 1 mL of 10 mg/L TOC Working Standard to the DI water—this is your CCV**.**
  - Follow steps 5 – 22 with your "other" samples.
  - Check the recovery of the CCV. The concentration should be between 0.75 and 1.25 mg/L.
- Periodic **Matrix Spikes (MSs)** should be analyzed. Any time a sample result appears anomalous, consider analyzing an MS of that sample.
  - Determine what dilution, if any, is required for the MS (Note: you will be adding 1.0 mg/L to the sample concentration [the instrument reading]). If you have difficulty determining the dilution needed, call the Project Chemist (Shawn Duffy) at 530-229-3303.
  - Carefully measure 9 mL of the sample (diluted if required) into a 50 mL Erlenmeyer flask containing a magnetic stir bar.
  - Add 1 mL of 10 mg/L TOC standard to the sample—this is your MS**.**
  - Follow steps 5 – 22 with your "other" samples.
  - Check the recovery of the MS:

    Example: Matrix Spike (1.60 mg/L) - Sample (0.36 mg/L) = 1.24 mg/L

    Concentration of MS Standard = 1.0 mg/L

    % recovery is = 1.24/1.00 = 124%

    Note: MS % recovery must be between 75 – 125% or you will need to reanalyze.

    If the CCV or MS are still not between 0.75 mg/L and 1.25 mg/L after reanalyses, call the Project Chemist (Shawn Duffy) at 530-229-3303.

Known Interferences

- Many metals can cause interference at concentrations above 10 mg/L.
- Manganese above 1 mg/L.
- Alkalinity greater than 600 mg/L (reduce the pH to <7 with sulfuric acid); call the Project Chemist (Shawn Duffy) at 530-229-3303 before proceeding.
- Chloride above 500 mg/L.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Orthophosphate Analysis by Hach Method 8048
Number: SOP-L17_Rev01
Revision Date: 10/13/2015

Scope

Standard operating procedure (SOP) for analysis of orthophosphate (PO_4^{3-}).

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach DR 4000V spectrophotometer or equivalent
- pH meter
- PO_4^{3-} Bench Logbook
- Reaction vessel and cap or means of sealing the reaction vessel– (Hach sample cell, 50 mL beaker, vial capable of holding 30 mL, and parafilm if the vessel doesn't have a cap)
- 1 packet of PhosVer 3 Reagent per sample
- 5 mg/L phosphate (PO_4^{3-}) (working) standard
- 0.45 µm filter disc fitted to a disposable 50 mL syringe (syringe filter)
- Deionized (DI) water

Procedure

1. Collect the sample(s) following the appropriate SOP (see below). Orthophosphate samples should be analyzed as soon as possible (within 24 hours).
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
    - SOP-A4 – Depth-Specific Surface Water Sampling
    - SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
    - SOP-A14 – Pore Water Sampling
    - SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method

- SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
- Remedy-SOP-01 – Process Water Sampling

2. Measure the pH of the raw sample in accordance with SOP-L9—pH Measurement. Record the results in the PO43- Bench Logbook.
3. Verify that the spectrophotometer is set for Reactive Phosphoros (Hach DR/4000V, program 3025) and verify all reagents are for 25 mL sample size (or adjust accordingly).
4. Transfer 25 mL of the sample into a reaction vessel. (Note: the sample cell or vessel must be able to be sealed with a cap or parafilm.)
5. Transfer 25 mL of DI water into a reaction vessel (this will be the "Blank").
6. Add 1 packet of PhosVer 3 Reagent to the blank and to each sample.
7. Shake the blank and the sample(s), using a 90° rotation of the wrist and back to the original position with a timing of once per second; until the powder is dissolved.
8. Start the 2 minute reaction timer.
9. After the 2 minute timer, use a syringe filter to filter any reagent powder that has not dissolved from the blank and then use the blank to "zero" the spectrophotometer.
    - Transfer the blank into the pour-through-cell funnel.
    - Allow the meter to stabilize and press the Zero button.
10. After the spectrophotometer has been zeroed, use a syringe filter to filter any reagent powder that has not dissolved from the sample(s) and transfer the sample into the pour-through-cell funnel (the sample port of the Hach DR/4000V). Analyze as soon as possible.
11. Record the instrument reading in the PO_4^{3-} Bench Logbook.
12. If the result is out of range for the spectrophotometer, reanalyze the sample using a dilution.

    Common dilutions:

    - 1:2 dilution: 25 mL of sample are diluted with 25 mL of DI water; multiply the instrument reading (result) by 2 for the adjusted value.

        Example: instrument reading is 3.54
        x 2
        = 7.08 mg/L (final result)

    - 1:5 dilution: 10 mL of sample are diluted with 40 mL of DI water; multiply the instrument reading (result) by 5 for the adjusted value.

        Example: instrument reading is 3.54
        x 5
        = 17.7 mg/L (final result)

    - 1:10 dilution: 10 mL of sample are diluted with 90 mL of DI water; multiply the instrument reading (result) by 10 for the adjusted value.

- 1:20 dilution: 5 mL of sample are diluted with 95 mL of DI water; multiply the instrument reading (result) by 20 for the adjusted value.

Quality Control (QC)

- With the first analysis of orthophosphate each shift, **analyze a Continuing Calibration Verification (CCV) standard** as a **Quality Control** check:
  - Carefully measure 24 mL of DI water into a sample cell.
  - Add 1 mL of 5 mg/L Phosphate (PO_4^{3-}) standard.
  - Add 1 packet of PhosVer 3 Reagent (include the CCV with your other samples).
  - Follow the remaining procedures as listed above for the samples (steps 6 through 10).
  - **Record the CCV results in the PO_4^{3-} Bench Logbook.** If the instrument reading is not between 0.15 mg/L and 0.25 mg/L, re-prepare the standard and reanalyze.
- Periodic **Matrix Spikes (MSs)** should be analyzed. Any time a sample result appears anomalous, consider analyzing an MS of that sample.
  - Determine what dilution, if any, is required for the MS (Note: you will be adding 0.2 mg/L to the sample concentration [the instrument reading]). If you have difficulty determining the dilution needed, call the Project Chemist (Shawn Duffy) at 530-229-3303.
  - Carefully measure 24 mL of filtered sample (diluted if required) into a reaction vessel (sample cell/vial).
  - Add 1 mL of 5 mg/L Phosphate (PO_4^{3-}) standard to the 24 mL of filtered sample—this is your MS**.**
  - Add 1 packet of PhosVer 3 Reagent at the same time you add the reagent to your "other" samples.
  - Follow the remaining procedures as listed above for the samples (steps 6 through 10).
  - Record the instrument reading in the PO_4^{3-} Bench Logbook.
  - Check the recovery of the MS:

    Example: Matrix Spike (1.60 mg/L) - Sample (1.36 mg/L) = 0.24 mg/L

    Concentration of MS Standard = .20 mg/L

    % recovery is = 0.24/0.20 = 120%

    Note: MS % recovery must be between 75 – 125% or you will need to reanalyze.

    If the CCV or MS are still not between 0.075 mg/L and 0.125 mg/L after reanalyses, call the Project Chemist (Shawn Duffy) at 530-229-3303.

Known Interferences

- Metal concentrations above 100 mg/L.
- Highly buffered samples or extreme sample pH may exceed the buffering capacity of the Reagents (sample pH should be between 2 and 10).

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Manganese Analysis by Hach Method 8149
Number: SOP-L18_Rev01
Revision Date: 10/13/2015

Scope

Standard Operating Procedure (SOP) for the analysis of manganese (Mn).

Equipment and Supplies

- Safety glasses
- Latex gloves
- Hach DR 4000V spectrophotometer or equivalent
- Fume hood
- Vacuum filter apparatus: 47 mm magnetic filter funnels, 1,000 mL Erlenmeyer flask, and vacuum pump (use a 0.45 µm, 47 mm diameter filter membrane)
- 0.45 µm filter disc fitted to a disposable 50 mL syringe (syringe filter)
- pH meter
- Reaction vessel and cap or means of sealing the reaction vessel (Hach sample cell and Parafilm if the vessel doesn't have a cap)
- Deionized (DI) water
- 1 packet of Ascorbic Acid Reagent powder per sample
- Rochelle Salt Solution
- Alkaline-Cyanide Reagent Solution
- 0.1% PAN Indicator Solution
- 1 mg/L Manganese (working) standard
- Manganese Bench Log Book
- HNO_3 pH<3 (preservative if the samples can't be analyzed within 24 – 48 hours)

Safety

Caution and special procedures must be maintained when performing this analysis. The alkaline cyanide solution contains cyanide so **the waste must be collected and disposed of as a Reactive waste**.

To prevent the release of hydrogen cyanide gas, the cyanide waste should be stored in a caustic solution with pH >11. The waste must be stored as a base until properly disposed of.

Because the analysis has the potential of releasing hydrogen cyanide gas, **all solutions/reagents must be added in a fume hood.**

Procedure

1. Collect the sample(s) following the appropriate SOP (see list below). Samples should be analyzed as soon as possible. If the samples can't be analyzed within 24 – 48 hours, preserve with HNO_3 pH<3 until ready to analyze. Before starting the analyzing adjust the pH to a pH 4 – 5. **Note: all samples must be filtered prior to preservation/analysis**.
    - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
    - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
    - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
    - SOP-A4 – Depth-Specific Surface Water Sampling
    - SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
    - SOP-A14 – Pore Water Sampling
    - SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
    - SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
    - Remedy-SOP-01 – Process Water Sampling
2. Filtering can be performed using an inline filter at the time of sampling (see SOP–A6, Sample Field Filtration and Preservation for Metals Analyses) or in the laboratory by vacuum filter:
    - Set up the vacuum filter apparatus.
    - Filter ~100 mL of sample.
3. Measure the pH of the raw sample in accordance with SOP-L9— pH Measurement (**Record the results in the Mn Bench Log Book**). Adjust the pH (see step #1 above).
4. Verify that the spectrophotometer is set for **Manganese (Mn) (Hach DR/4000V program 2260)** and verify all reagents are for 10 mL sample size (or adjust accordingly).
5. In the fume hood, transfer 10 mL of filtered sample into a reaction vessel. Use DI water for a blank.
6. Add one packet of Ascorbic Acid Reagent powder to each sample (including the blank). Swirl to mix.
7. Add ten drops of Rochelle Salt Solution to each sample (including the blank). Swirl to mix.

8. Add 15 drops of Alkaline-Cyanide Reagent Solution to each sample (including the blank). Swirl to mix.
9. Add 21 drops of PAN Indicator Solution, 0.1%, to each sample (including the blank). Swirl to mix.
10. Start the 2 minute reaction timer.
11. After the 2 minute timer has sounded, use the blank to "zero" the spectrophotometer.
12. After zeroing the spectrophotometer analyze each sample.
13. Record the instrument reading in the Mn Bench Log Book.
14. If the result is out of range for the spectrophotometer, reanalyze the sample using a dilution.

    Common dilutions:

    - 1:2 dilution: 25 mL of sample are diluted with 25 mL of DI water; multiply the instrument reading (result) by 2 for the adjusted value.

      Example: instrument reading is 0.304
      x 2
      = .608 mg/L (final result)

    - 1:5 dilution: 10 mL of sample are diluted with 40 mL of DI water; multiply the instrument reading (result) by 5 for the adjusted value.

      Example: instrument reading is 0.304
      x 5
      = 1.52 mg/L (final result)

    - 1:10 dilution: 10 mL of sample are diluted with 90 mL of DI water; multiply the instrument reading (result) by 10 for the adjusted value.
    - 1:20 dilution: 5 mL of sample are diluted with 95 mL of DI water; multiply the instrument reading (result) by 20 for the adjusted value.

Quality Control (QC)

- With the first analysis of manganese each shift, **analyze a CCV** (Continuing Calibration Verification) standard as a **Quality Control** check:
  - Carefully measure 9 mL of DI water into a reaction vessel.
  - Add 1 mL of 1 mg/L Mn Standard. Swirl to mix.
  - Analyze with the samples - follow steps 6 – 13 above.
  - **Record the CCV results in the Mn Bench Log Book.** If the instrument reading is not between 0.075 mg/L and 0.125 mg/L, re-prepare the standard and reanalyze.

- Periodic **Matrix Spikes (MSs)** should be analyzed. Any time a sample result appears anomalous, consider analyzing an MS of that sample.
  - Determine what dilution if any is required for the matrix spike (note: you will be adding 0.1 mg/L to the sample concentration [the instrument reading]).
  - Carefully measure 9 mL of filtered sample (diluted if required) into a reaction vessel.
  - Add 1 mL of 1 mg/L Mn Standard to the 9 mL of filtered sample. Swirl to mix (this solution is called the MS)**.**
  - Analyze with the other samples - follow steps 6 – 13 above.
  - Record the instrument reading in the Mn Bench Log Book.
  - Check the recovery of the MS:

    Example: Matrix Spike (0.117 mg/L) - Sample (0.006 mg/L) = 0.111 mg/L

    Concentration of Spike Standard = 0.100 mg/L

    % recovery is = 0.111/0.100 = 111%

    MS % recovery must be between 75 – 125% or you will need to reanalyze.
  - If the CCV or MS are still not between 0.075 mg/L and 0.125 mg/L after reanalyses, call the Project Chemist (Shawn Duffy) at 530-229-3303.

Standard Operating Procedure – Laboratory
PG&E Topock Program

Title: Total Dissolved Solids Analysis
Number: SOP-L19_Rev01
Revision Date: 10/13/2015

Scope

This Standard Operating Procedure (SOP) covers the determination of Total Dissolved Solids (TDS) in groundwater or process water samples. The practical range of the method is 10 mg/L to 20,000 mg/L. If TDS concentrations are greater than 20,000 mg/L, then the sample can be diluted. If the sample is suspected to have a TDS concentration greater than 100,000 mg/L, the site analyst will consult with the Project Chemist.

Summary

A sample is passed through a filter, weighed, and then placed in an oven at 180°C until dried. The sample is allowed to cool in a desiccator, and then weighed to determine the dry weight of the original sample.

Safety

Extreme caution should be used when working around the drying oven (risk of severe burns).

Because of the high temperature of the drying oven the associated glassware is more prone to break on impact (risk of broken glass).

Equipment and Supplies

- Safety glasses
- Latex gloves
- Drying oven (capable of 180°C)
- Analytical balance (capable of measuring weights of 0.1 mg)
- Vacuum pump or other source of applying a vacuum
- Vacuum filter apparatus and filters (glass fiber filter discs, 47 mm, without organic binder, Reeve Angel type 934-AH, Gelman type A/E, or equivalent)
- 250 mL Pyrex glass beakers or equivalent
- Deionized (DI) water
- Conductivity meter
- Desiccator (capable of holding 5 – 6 250 mL Pyrex glass beakers
- Oven mitt or metal tongs (to transfer the hot beakers from the drying oven to the desiccator)

- Graduated cylinder(s) 20 mL, 50 mL, 100 mL
- TDS Bench Log Book

Procedure

1. Preparation of the evaporation vessels (beaker) must be performed ahead of time:
   - Thoroughly clean and dry a 250 mL Pyrex glass beaker.
   - Heat the clean vessel to 180° +/- 2°C for one hour.
   - Carefully transfer the hot beaker to the desiccator with the oven mitt or tongs for cooling and storage until needed.
2. Collect the sample(s) following the appropriate SOP (see list below). The samples should be analyzed within 7 days.
   - SOP-A1 – Purging and Sampling of Groundwater Monitoring Wells, Well-Volume Method
   - SOP-A2 – Purging and Sampling of 1-inch-diameter Groundwater Monitoring Wells, Modified Well-Volume Method
   - SOP-A3 – Purging and Sampling of Active and Inactive Water Supply Wells
   - SOP-A4 – Depth-Specific Surface Water Sampling
   - SOP-A5 – Groundwater Sampling from Sonic Drilling Boreholes
   - SOP-A14 – Pore Water Sampling
   - SOP-A18 – Purging and Sampling of Groundwater Monitoring Wells Minimal Drawdown Method
   - SOP-A19 – Sampling of Groundwater Monitoring Wells HydraSleeve No Purge Method
   - Remedy-SOP-01 – Process Water Sampling
3. Measure the Conductivity using SOP-L4 – Conductivity Analysis by Hach Method 8160. Refer to Table 1 for sample volume.

Table 1
Conductivity vs. Sample Volume Table

Conductivity of Sample	Sample Volume to Use for TDS
<1,500 µS/cm	100 mL
≥1,500 µS/cm and <4,700 µS/cm	50 mL
≥4,700 µS/cm	20 mL

4. Filter the sample in the laboratory using a vacuum filter:
    - Assemble the vacuum filter holder/flask assembly using a clean vacuum flask.
    - Place a 47-mm filter disc (see Equipment and Supplies section above for type of filter) in the filter holder and add the funnel.
    - With vacuum applied to the flask, wash the filter with three separate 20-mL volumes of DI water.
    - Continue applying vacuum for two to three minutes after the water has passed through the filter to ensure that all traces of the water are removed from the filter.
    - Disconnect the vacuum and discard the water from the flask.
    - Reconnect the filter holder/flask assembly to the vacuum.
    - Shake the sample vigorously.
    - Use a clean graduated cylinder to transfer the volume of sample determined from Table 1 above to the filter apparatus. Record the volume used in the TDS Bench Log Book.
    - Filter the sample through the glass fiber filter.
    - Rinse the filter with three 10 mL portions of DI water and continue to apply vacuum for about 3 minutes after filtration is complete to remove as much water as possible.
5. Retrieve a clean 250 mL Pyrex glass beaker from the desiccator and weigh to the nearest tenth of a milligram (0.1 mg); record the weight in the TDS Bench Log Book.
6. Transfer the filtered sample from the vacuum flask to the beaker. Rinse the flask with three 10 mL portions of DI water and pour into the beaker with the sample.
7. Place the sample in the drying oven; verify the oven is set at 180° +/- 2°C.
8. Allow the sample to reach complete dryness (4 hours or more).
9. Cool in a desiccator to approximately room temperature, and weigh the beaker (record the weight in the TDS Bench Log Book).
10. Repeat steps 7 through 9 (drying, cooling, desiccating, and weighing until a constant weight is obtained or until the change in weight is less than 0.5 mg between the consecutive cycles) and record the final weight in the TDS Bench Log Book.
11. Calculate the TDS using the formula shown below and record in the TDS Bench Log Book.

$$\text{mg total dissolved solids/L} = \frac{(A - B) \times 1000}{\text{sample volume, mL}}$$

where:

A = final weight of dried sample + dish (mg)
B = weight of dish (mg).

VOC	volatile organic compound

SECTION 1

Introduction

This *Pacific Gas and Electric Company Program Quality Assurance Project Plan* (QAPP), Revision 2 was prepared to ensure that data of appropriate quality are collected and used for multiple sites for Pacific Gas and Electric Company (PG&E) projects that CH2M HILL supports. Each project will have a sampling and analysis plan (SAP), this QAPP, and QAPP addenda required to meet the project-specific requirements.

1.1 Background

CH2M HILL has been providing services to PG&E since the 1970s. Currently, CH2M HILL and affiliate companies are working at approximately 35 sites for PG&E. CH2M HILL provides services for the following:

- **Site management.** Projects include soil and groundwater monitoring, site characterization, and remediation design systems.
- **Remediation construction.** Projects include soil excavation, disposal, and treatment system construction.
- **Ecosystems and permitting.** Projects include proponent's environmental assessments, California Environmental Quality Act documentation, and other permitting and planning projects.
- **Engineering design.** Projects include computer-aided design and support and structural analysis.

1.2 PG&E Program Objectives

1.2.1 PG&E Program Objectives and Scope

This QAPP presents the quality assurance (QA) and quality control (QC) requirements designed to ensure that environmental data collected for the PG&E Program will be of the appropriate quality to achieve the objectives defined in the project-specific SAPs or QAPP addenda, unless otherwise defined. Specific protocols for sampling, sample handling and storage, chain-of-custody (CoC), laboratory analyses, data handling, and data evaluation and assessment are discussed. Requirements for performance evaluations, corrective actions, and preventive maintenance of equipment are specified. The elements included in this QAPP are consistent with those specified in the *EPA Requirements for Quality Assurance Project Plans* (U.S. Environmental Protection Agency [EPA], 2001a) and *EPA Requirements for Quality Management Plans* (EPA, 2001b) (note that the latter was reissued in March 2006). The objectives of this QAPP are as follows:

- Ensure that data collection and measurement procedures are standardized among all participants.

- Monitor the performance of the various measurement systems within the PG&E Program to maintain statistical control and provide rapid feedback so that corrective measures, if needed, can be implemented before data quality is compromised.
- Periodically assess the performance of these measurement systems and their components.
- Verify that reported data are sufficiently complete, comparable, representative, unbiased, and precise so that they are suitable for their intended use.

This QAPP is intended for use by CH2M HILL and its subcontractors that provide services associated with the environmental data collection effort. The QAPP supplements all SAPs and any other project-specific documents. The PG&E Program quality officer and the program chemist are primarily responsible for implementation of this QAPP.

1.2.2 PG&E Program QAPP versus SAPs and QAPP Addenda

Elements such as the general description, sources of contamination, information from previous investigations, and proposed investigations are addressed in project or site-specific SAPs or QAPP addenda. PG&E Project-specific QAPP addenda will cover items not included in this QAPP or any in conflict with it. The guidance set forth in this QAPP will be followed in the absence of site specific SAPs or QAPP addenda.

The PG&E project-specific SAPs or QAPP addenda should specify project-specific analytes and analytical methods that differ from the QAPP. The project manager or a designee will determine the reporting limit (RL) requirements, evaluate the QAPP specifications to make certain they meet those requirements, and address any differences in a QAPP addendum. The QAPP addendum will be included as part of the project-specific documents when project requirements dictate variance from the QAPP.

Project-specific preliminary cleanup goals or action levels will be included in the SAPs or QAPP addenda, if available. The project-specific documents will indicate sources for the preliminary cleanup goals or action levels. In cases where available technology does not offer analytical methods that are sufficiently sensitive to detect concentrations at or below the reference levels cited by the source, the method RLs will be used as the preliminary cleanup goals or action levels. All goals are subject to revision and will be documented.

Appendix A presents the analytical requirements for Reporting Limits, Accuracy, and Precession Limits.

1.2.3 Analytical Project Planning

The PG&E Program has a laboratory procurement process, modeled after the Air Force Center for Engineering and the Environment (AFCEE) (formerly the Air Force Center for Environmental Excellence), EPA, the U.S. Navy, and other federal programs. The process balances the PG&E Program quality, defensible data, and costs. The model has identified three steps in planning the analytical needs of a project:

1. **Determine the requirements.** To determine project-specific requirements, the program chemist should attend kick-off meetings (or equivalent) to understand the project goals and help develop the analytical scope of work.

2. **Determine the laboratory needs and select the laboratory.** Factors influencing the selection of analytical, geotechnical, radiochemistry laboratories include the matrices sampled; laboratory capabilities, recent performance, and location; and price. The program chemist ensures that the laboratory selected is appropriate to meet project objectives. The more information regarding the project objectives given to the chemists, the better chance they have to control liabilities related to analytical work.
3. **Decide what level of data validation is required to provide defensible data at the appropriate level of QC.** See Section 6.3 for descriptions of the data validation process. When a request for proposal is received from PG&E, there is a kickoff meeting of key people, including the project manager, the responsible contract administrator, the program chemist (or sometimes a project-specific chemist), a representative from project delivery, and others, depending on the type of project. Laboratory scope is discussed and a plan is determined that will provide the appropriate analytical services.

1.2.4 Data Quality Objectives

The specific needs for the data collected during each activity will be examined to ensure that project objectives for each investigation will be optimally achieved. A graded approach will be used in developing the project data quality objectives (DQO) to ensure that the DQO process will be appropriate for the nature, size, cost, and risk associated with the task or project. All projects will begin by examining EPA's seven-step DQO process (EPA, 2000); based on the level of project complexity and intended use of the data, the level of detail and applicability of the seven-step process will be assessed. The DQO process should consider the following steps (if applicable):

1. **State the problem.** Concisely describe the problem to be investigated. This determines the need for data collection. Review existing information to define the problem.
2. **Identify the decision**. Identify the decision that will solve the problem by using the data to be collected.
3. **Identify the inputs to the decision**. Identify the information and environmental measurements that are needed to support the decision.
4. **Define the study boundaries**. Specify the times, spatial areas, and other conditions (e.g., target analytes) that determine when and where data should be collected.
5. **Develop a decision rule**. For each decision, define the conditions that would cause the decision maker to choose between alternate actions (the decision rule is usually in the form of an "if…then" statement).
6. **Specify tolerable limits for decision errors**. Define how much uncertainty can be tolerated by the decision maker. Determine the acceptable error rates based on the consequences of making an incorrect decision.
7. **Optimize the design**. Evaluate information from the previous steps and choose the most resource-efficient design for data collection that will support a reliable decision.

SECTION 2

PG&E Program Organization and Responsibility

2.1 PG&E Program Organization

The PG&E Program management team has been structured with a program manager, program quality control manager, program health and safety manger and a program chemist to ensure that the goals of the PG&E Program are met.

2.2 Project/Task Organization

The organization chart and descriptive text identifying task managers and individuals charged with specific responsibilities for each project can be found in project-specific SAPs. Lines of authority and the scope of authority given to each key member of the project team, including the authority to initiate and approve corrective actions, are discussed in the SAPs. All subcontractors and scopes of work are also identified in the project- or site-specific SAPs.

2.3 Training and Certification Requirements

All personnel engaged in field activities will have completed the Occupational Safety Health Administration, 40-hour health and safety training that meet the requirements of Title 29 Code of Federal Regulations Section 1910.120 and Title 8 Code of California Regulations Section 5192. All CH2M HILL personnel working on the PG&E Program will read applicable project-specific health and safety plans. Documentation will be maintained to demonstrate that all requirements of the plan are followed.

All laboratories contracted for analytical services will be certified under the California Department of Health Environmental Laboratory Accreditation Program, when appropriate and where accreditation is afforded under the California program. No analyses may be performed or reported if accreditation is revoked. Any loss or suspension of accreditation must be communicated to CH2M HILL within 24 hours of notification. Laboratory managers will ensure that all laboratory personnel have been properly trained and are qualified to perform the assigned tasks.

SECTION 3

Sampling Procedures

3.0 Standard Operating Procedures

All sample collection and related activities will follow the appropriate standard operating procedure (SOP). SOPs are located in the project work plan, SAP, QAPP addendum, or other project documents.

3.1 Sampling Design

The number and location of samples are specific to each site and are discussed in the project-specific SAPs. The rationale for the sampling design is also described in the SAPs as part of the project DQOs. The sampling design is a function of the medium sampled, information about the sampling site, the type of data to be collected, and how the data are to be used.

All projects should use the field database and provide a planned sample table (PST), CoC forms, and other database-generated paperwork whenever possible. All samples collected for offsite laboratories will be documented on a CoC form.

The procedures described in the following sections may be superseded or supplemented by the project-specific SAPs or QAPP addenda.

3.2 Sampling Method Requirements

This section addresses the requirements for soil and groundwater sampling. Many projects will require site-specific SOPs because of unique conditions that should be addressed in the project-specific work plan, SAP, QAPP addenda or other project-specific documents. Small projects will need to have sampling SOPs, but may find an existing SOP that can be adopted for the specific needs of the project.

3.2.1 Field Calibration

Field equipment will be calibrated before the start of work and recorded in the field notebook or daily calibration log. Any instrument drift from prior calibration should be noted. Calibration will be in accordance with procedures and schedules in the particular instrument's operations manual.

Calibrated equipment will be uniquely identified by using the manufacturer's serial number or other means. A label with the identification number and the date when the next calibration is due (scheduled calibrations) will be physically attached to the equipment. If this is not possible, records traceable to the equipment (e.g., showing the equipment identification) will be readily available for reference. Instrument identification and the results of calibrations and records of repairs will also be recorded in the logbook or daily calibration log.

Scheduled periodic testing equipment calibration does not relieve field personnel of the responsibility of using properly functioning equipment. If equipment malfunction is suspected, the device shall be removed from service, tagged so that it is not inadvertently used, and the appropriate personnel notified so that a recalibration can be performed or substitute equipment can be obtained. Equipment that fails calibration or becomes inoperable during use will be removed from service and either segregated to prevent inadvertent use or tagged to indicate it is out of calibration. Such equipment will be repaired and satisfactorily recalibrated. Equipment that cannot be repaired will be replaced.

3.2.2 Soil Sampling

Sampling locations will be specified in the project-specific SAPs, but the exact locations will be determined in the field based on such factors as accessibility and topography. The exact locations will be recorded in the field logbook or on the field sampling form when sampling is completed. A sketch of the sampling location will be entered into the logbook, if necessary, with reference points labeled including distances to the sampling location. Location of the sampling point by a global positioning system may be required.

Soil sampling using decontaminated equipment will be performed as described in the following sections. Each sample container will be closed as soon as it is filled; it will be chilled and processed for shipment to an offsite laboratory to allow laboratory analysis within the applicable holding time.

ALL SOILS SAMPLE RESULTS WILL BE REPORTED IN DRY WEIGHT UNLESS OTHERWISE SPECIFIED IN THE SAP.

3.2.2.1 Surface Soil Sampling

Surface soil sampling will follow the project-specific SOPs, but generally, samples will be collected as grab samples at the depth interval specified in the project-specific SAP for each location. Samples will be collected using a decontaminated stainless steel or nonmetallic hand trowel or equivalent equipment (sampling equipment should be chosen based on the analyte of concern for the specific sample). A Terra Core sampler, EasyDraw Syringe, cutoff disposable syringe or equivalent equipment will be used for volatile organic compounds (VOC), as described in Section 3.2.1.4. Samples to be analyzed for VOCs will be collected first. Samples to be analyzed for all other analytes should be placed in a sample-dedicated, 1-gallon, disposable pail or a decontaminated stainless steel bowl. The samples will be homogenized (using the trowel), and transferred to the appropriate containers. To prevent potential contaminant migration from the sample, sample containers will be filled to the top, taking care to prevent soil from remaining in the lid threads prior to being sealed.

3.2.2.2 Subsurface Soil Sampling

Subsurface soil sampling will follow the project-specific SOPs, but generally, samples will be collected by boring to the depth specified in the project-specific SAP using an appropriately sized hand auger or equivalent equipment. Once the specified depth is reached, the hand auger will be removed, and accumulated soil will be set aside in a sample-dedicated disposable pail or tarp. A different, clean hand auger will be inserted into the hole to collect the sample (decontamination of the boring implement is sufficient if multiple boring implements are not available). Other sampling devices, such as push tubes or split-spoon

samplers, may be used. A Terra Core sampler, EasyDraw Syringe, cutoff disposable syringe, or equivalent equipment will be used for VOCs, as described below. Samples to be analyzed for VOCs will be collected first. Samples to be analyzed for all other analytes should be placed in a sample-dedicated, 1-gallon, disposable pail or a decontaminated stainless steel bowl. The samples will be homogenized (using the trowel) and transferred to the appropriate containers. To prevent potential contaminant migration from the sample, sample containers will be filled to the top, taking care to prevent soil from remaining in the lid threads prior to being sealed.

3.2.2.3 Confirmation Sampling for Soil Excavation

This procedure is outlined in the project-specific SOPs. Confirmation sampling will be performed prior to closure of any excavation. Confirmation samples are usually collected from the bottom and sides of the excavation. The number and type of samples collected should be of sufficient quantity to be representative of the excavated site. The project- or site-specific SAP should address the number, type, and quantity of samples to be collected. All confirmation samples should be analyzed by the analytical methodology specified herein or in the project-specific QAPP addendum (collection of soil samples for determination of VOCs shall be in accordance with Section 3.2.1.4.). Field or laboratory screening data should not be used to verify that contamination has been removed below project action levels unless specifically approved by the overseeing regulatory agency.

3.2.2.4 Soil Sampling for Volatile Organic Compounds

See project-specific SOP for procedure. Guidelines for collecting soil samples for VOC analysis are provided in Method SW5035B. These sampling techniques are applicable to analysis by methods SW8260B or C and SW8015B or D (volatile parameters). Sampling for VOCs may be accomplished by using an EasyDraw Syringe, a Terra Core sampler, a cutoff plastic syringe, or any equivalent sampling device.

VOC samples will be collected into pre-tarred vials with or without preservatives. Preserved samples will be chilled and sent to the lab in accordance with the appropriate SOP. Unpreserved VOC samples will be frozen or chilled in the field. If chilled to 4 degrees Celsius (°C) (±2°C), the samples will be shipped by overnight express delivery (or courier) the same day they are collected. If frozen, appropriate measures should be taken to ensure that frozen samples remain frozen until receipt by the laboratory. If samples remain frozen, the laboratory has 14 days from date of collection to analyze the samples. If samples thaw to temperatures higher than 4°C (±2°C), they must be analyzed within 48 hours of collection. If the temperature does not exceed 4°C (±2°C), the laboratory may (1) freeze the samples between -7 and -20°C within 48 hours of collection and keep them frozen or (2) preserve them in sodium bisulfate or methanol within 48 hours of collection. Either of these procedures will extend the holding time to 14 days.

Sampling Using Cutoff Syringe. A disposable syringe capable of measuring 1 to 5 milliliters (ml) (±0.5 ml) is required. Calibration in the field will be needed for the specific soil type and the type of syringe to determine the proper setting on the syringe to collect the samples. For example, the plunger is set to 5 ml, and the sample is collected and weighed; if 5 grams (±0.5 gram) are not obtained, the process is repeated until the correct plunger setting is identified. The same procedure is repeated for the 1-gram sample. Once the volume setting

is identified, all soils of similar type will be collected at this volume. Samples can be collected with or without field preservation. When field preservation is chosen, the samples are collected into vials pre-preserved with methanol or sodium bisulfate. Otherwise, samples can be collected into vials without preservative, and preservation can be performed by the laboratory upon receipt of the samples within 48 hours of collection.

Sampling with Terra Core Sampler or EasyDraw Syringe. The sample is collected into the Terra Core or equivalent sampler following the manufacturer's instructions. A minimum of three samples will be collected. Two aliquots are needed for low-level analysis and reanalysis if necessary. The third aliquot is needed for extraction in methanol by the laboratory in case high-concentration analysis is indicated. Exposure to air must be minimized.

Sampling with Field Preservation. Before using this option, determine if the soil is amenable to the sodium bisulfate preservative. Soil samples that contain carbonate minerals may effervesce upon contact with the preservative. If the amount of gas generated is small (little if any effervescence with the preservative), field preservation may be used. If rapid or vigorous gas generation is observed, the sample should be collected without field preservation. If the sample is amenable to field preservation, it is collected using one of the methods listed above and quickly transferred into a VOC vial with preservative. The vial should be quickly sealed to avoid significant loss of volatiles components. The laboratory will supply a minimum of three preweighed VOC vials with 5 ml of aqueous sodium bisulfate preservative as described in Method SW5035B, as well as a single preweighed VOC vial without the preservative for each sample to be analyzed for VOCs. Two 5-gram aliquots in bisulfate are required for low-concentration analysis and reanalysis, when necessary. One 5-gram aliquot without sodium bisulfate is required for extraction in methanol by the laboratory in case high-concentration analysis is indicated by a low-concentration or screening analysis of the sample. One 1-gram sample in bisulfate is needed because the possibility exists that neither the 5-gram sample intended for low-concentration analysis, nor the 5-gram sample intended for high-concentration analysis, will have all target analyte concentrations within the calibration range. Exposure of the sample to air must be minimized.

If VOC analyses are the only analyses being performed for samples collected from any location; an additional 2- or 4-ounce soil sample must also be collected to analyze for percent moisture.

Sampling without Field Preservation. The samples will be collected using one of the methods listed above and quickly transferred into a minimum of three preweighed, vials without preservative supplied by the laboratory. These preweighed vials may be empty, they may contain reagent water, or they may be preserved with methanol, depending on whether the contaminant concentration is at low- or high-level concentration. Two 5-gram aliquots are needed for low-concentration analysis and reanalysis, when necessary. In addition, one 5-gram aliquot is required for extraction in methanol by the laboratory in case high-concentration analysis is indicated by a low-concentration or screening analysis of the sample. One 1-gram sample is also recommended because the possibility exists that neither the 5-gram sample intended for low-concentration analysis, nor the 5-gram sample intended for high-concentration analysis, will have all target analyte concentrations within the calibration range. Exposure of the sample to air must be minimized. Freezing the samples

between -7 and -20° C within 48 hours and keeping them frozen until analysis allows a 14-day holding time.

If VOC analyses are the only analyses being performed for samples collected from any location; an additional 2- or 4-ounce soil sample must also be collected to analyze for percent moisture.

3.2.3 Groundwater Sampling

3.2.3.1 Water Level Measurement

See project specific SOP for procedure. Field meter probes and water level sounding equipment will be decontaminated before and after each use at each well. Water levels in wells that are known or suspected to be least contaminated will be measured first. Water levels in wells that are known or suspected to have the highest contamination will be measured last.

If well heads are accessible, all wells will be sounded from the top of the casing to determine the depth to water and total well depth prior to purging. An electronic sounder, accurate to ±0.01 foot, will be used to measure depth to water in each well. Annual calibration documentation shall be maintained on file. The serial number of the meters shall be recorded in the sampling logbook. When using an electronic sounder, the probe will be lowered down the casing to the top of the water column, and the graduated markings on the probe wire or tape will be used to measure the depth to water from the surveyed point on the rim of the well casing. (Typically, the measuring device emits a constant tone when the probe is submerged in standing water. Most electronic level sounders have a visual indicator consisting of a small light bulb or diode that turns on when the probe encounters water.) The total well depth will be sounded from the surveyed top of the casing by lowering the weighted probe to the bottom of the well. The weighted probe will sink into silt, if present, at the bottom of the well screen. The total well depth will be measured by recording the depth to the nearest 0.1 foot.

3.2.3.2 Well Purging

See project specific SOPs for procedure. All wells will be purged prior to sampling. All equipment that will contact the sample during purging and sampling will be decontaminated prior to each use.

Low-flow Purge. One option for well sampling is low-stress (low-flow) purging using a pump capable of a purge rate of 1 liter per minute or less. Typically, a pneumatic or small electric submersible pump is used. The water level should be monitored approximately every 5 minutes. The flow rate should be started at the minimum flow capacity of the pump, then gradually increased until initial drawdown is observed. The flow rate should then be reduced slightly to achieve a stabilized pumping level. This reduced rate should become the maximum purge rate for the well. Each adjustment to the flow rate and the water level measured after each adjustment should be recorded. The flow rate should not exceed 1 liter per minute. Care should be taken to maintain pump suction and avoid entrapment of air in the tubing.

Casing Volume Purge. Another option for well sampling is three casing volume (macro-purging) using a pump capable of purging 1 to 5 gallons per minute, usually an electrical

submersible pump. Purging will be conducted at a flow rate sufficient to remove water from the entire screened interval of the well. However, the purge rate should not result in substantial drawdown, which is defined as 5 percent of the water column or the top of the screened interval. Purging will consist of the removal of a minimum of three casing volumes of water.

For low-yield wells (wells that exhibit less than 80 percent recovery [%R], within 2 hours), one casing volume of water shall be removed. If pump capability allows, the well will be purged at a rate of less than 1 gallon per minute. The well will then be allowed to recover to 80 percent and sampled within 24 hours of purging.

Water Quality Parameter Stabilization. To ensure representative sampling, water quality parameters (dissolved oxygen, pH, redox potential, specific conductance, and turbidity) must be stable before samples are collected, regardless of purge technique. Parameters will be measured approximately every 3 to 5 minutes, depending on the rate and duration of the purge. Purging is considered complete when the following water quality parameters are stable (i.e., for three consecutive readings):

- The pH varies by no more than 0.1 pH unit.
- Specific conductance readings are within 10 percent of the average.
- The redox potential varies by no more than 10 millivolts.
- The dissolved oxygen readings are within 10 percent of the average.

The water used to make measurements will not be used to fill sample bottles.

If the macro-purge technique is used, three casing volume well purges must be complete **and** the water quality parameters must be stable before the sample is collected. The total amount of water purged will be recorded in the field logbook or well-specific purge and sample collection form.

Grab-sample Collection. In some instances, it is appropriate to collect a grab sample from a monitoring well. For example, when a low-yield well has been purged and allowed to recharge. A bailer can be used to collect the sample without additional purge, eliminating the need to deploy a well pump for sample collection.

If a bailer is used to collect samples, a sufficient volume of water must be collected to fill the sample bottles and perform one measurement of water quality parameters. The water quality parameters will be recorded in the field logbook or well-specific purge and sample collection form.

3.2.3.3 Well Sampling

See project specific SOPs for procedure. Prior to sampling each well, the water level will be measured and the well purged, as previously described. All wells will be sampled within 24 hours of purging. Wells without a dedicated pump will be sampled using a bailer of appropriate material, such as Teflon or stainless steel. Wells with a dedicated pump will be sampled directly from the tap closest to the well head. All aerators, strainers, and hoses will be removed from the tap prior to sample collection. The flow will be adjusted so that a gentle stream is obtained. To minimize volatilization, a flow rate of less than 100 milliliters per minute is recommended for samples to be analyzed for VOCs.

At each sampling location, sample bottles designated for a particular analysis will be filled sequentially before bottles designated for other analyses are filled. Vials for VOCs will be filled first to minimize aeration of water in the well. All vials for VOCs will be provided, pre-preserved by the subcontract laboratory. The vials will be filled directly from the tap. Each vial will be inverted and checked for air bubbles and checked for headspace. If a pea-size or larger air bubble appears, the cap can be removed and additional sample added to eliminate the air space. If there is any likelihood of contamination being introduced into the sample, the vial contents will be emptied into the container used to measure purge volumes, the vial discarded, and a new sample collected in a new vial.

If a duplicate sample is to be collected, all sample bottles designated for a particular analysis for both duplicates will be filled sequentially before bottles for another analysis are filled. For example, duplicate samples will be collected sequentially for semivolatile organic compounds (SVOC), followed by duplicate samples collected sequentially for metals. EPA recommends the following collection order:

1. Volatile organic compounds and total organic compounds
2. Dissolved gasses and total organic carbon
3. Semivolatile compounds – Acid/Base extractables, pesticides, and PCBs
4. Metals and general chemistry
5. Radionuclides

It is considered good management practice to plan sample collection from the least to the most contaminated area of the site to decrease the risk of cross contamination (assuming no other factors that drive the priority of sampling location order).

Groundwater samples will be transferred from the bailer, tap, or pump tubing directly into the appropriate pre-preserved sample containers, if required. When transferring samples, care must be taken not to touch any nondedicated equipment to the sample container. The containers will be chilled and processed for shipment to the laboratory.

3.3 Equipment Decontamination

See project specific SOPs for procedure. Sampling equipment must be consistently decontaminated to ensure the quality of the samples collected. All equipment that comes into contact with potentially contaminated soil or water samples will be decontaminated. Disposable equipment intended for one use will not be decontaminated but will be packaged for appropriate disposal. In addition, equipment that is dedicated for repeated use at only one location does not need to be decontaminated. Equipment decontamination will occur prior to each use.

The following decontamination sequence is recommended:

1. Nonphosphate detergent and tap water wash, using a brush if necessary
2. Tap water rinse
3. Two rinses with deionized/distilled water

4. Organic-free water rinse (high-performance liquid chromatography grade) for organic samples

Large and bulky sampling equipment might need to be steam cleaned. Equipment will be decontaminated in a predesignated area on pallets or plastic sheeting. The cleaned equipment will be wrapped or covered to prevent contamination and stored in an uncontaminated area.

3.4 Disposal of Investigation-derived Wastes

The disposal of investigation-derived waste (IDW) should be addressed in the project-specific SAP. Each project or task can have different IDW disposal requirements, depending on site-specific conditions and the work performed. The following potentially contaminated IDW might be generated during field activities:

- **Used personal protective equipment (PPE) and disposable equipment.** Used PPE will be double-bagged and placed in a municipal refuse dumpster onsite. PPE and disposable equipment that is still serviceable will be rendered unusable before disposal into the dumpster.
- **Decontamination fluids.** Decontamination fluids include dilute nitric acid, deionized water, residual contaminants, and water with nonphosphate detergent. These fluids will be collected and disposed of in accordance with site requirements and applicable regulatory requirements
- **Soil cuttings.** Soil cuttings generated during subsurface sampling will be collected and disposed of in accordance with site requirements and applicable regulatory requirements.
- **Purged groundwater and excess groundwater collected for sample container filling.** These wastes will be collected and disposed of in accordance with site requirements and applicable regulatory requirements.

Each project SAP should address IDW. Any samples collected for waste characterization should include IDW in the sample identifier (ID).

3.5 Field Quality Control Samples

QC samples will be collected to monitor accuracy, precision, and the potential presence of field contamination for analytical methods to be performed in the offsite laboratory. All field QC samples, except matrix spike/matrix spike duplicates (MS/MSD), will be sent blind to the laboratory along with regular field samples. These blind samples will be labeled similar to regular field samples to disguise them. Sampling frequencies may vary according to the project needs, as defined in the project-specific SAP or QAPP addendum. The recommended frequency of collection for QC samples is discussed in the following sections and should be reviewed and updated to achieve project-specific DQOs.

3.5.1 Field Duplicate Samples

A field duplicate (FD) is an independent sample collected as close as possible to the original sample, from the same source, and under identical conditions. FDs are used to document sampling and analytical precision. FDs will be collected at a minimum frequency of 10 percent or one per sampling event, whichever is more frequent, for each matrix and type of analysis. The sampling procedures described in Section 3.2 will be followed. The sampling locations for FD samples will be recorded in the field logbook or field sampling form, or both.

3.5.2 Equipment Blanks

Equipment blanks (EB) will be collected to evaluate field sampling and decontamination procedures by pouring deionized or organic free water over the decontaminated equipment. EBs will be collected at a frequency of one EB per day for each non-dedicated equipment type per sampling team. The EBs will be preserved, packaged, and shipped in the same manner described for the environmental samples. A separate sample ID will be assigned to each EB sample, and the sample will be submitted blind to the laboratory. EBs will be analyzed in the offsite laboratory for the same parameters specified for the corresponding matrix or for the main contaminate of potential concern (COPC).

3.5.3 Field Blanks

Field blanks (FB) (also known as ambient blanks [AB]) are collected to evaluate (or to monitor) whether contaminants have been introduced during sampling because of ambient conditions. FBs will be collected by pouring deionized water (or organic free water for organic samples) into a sample container at the sampling location and leaving the sample exposed to the atmosphere during the time a sample is collected. FBs will be collected at a frequency of one per location that warrants concern because of environmental conditions or project-specific QC concerns, as determined by the project chemist or project manager. Generally, FBs need to be collected if the analyte concentrations are high enough to allow mobile contaminants to affect the sample results and field conditions such as upwind environments cannot be controlled. FB will be analyzed for the same parameters specified for the associated samples.

3.5.4 Trip Blanks

Trip blanks (TB) are used to monitor contamination during sample shipping and handling and for cross contamination through VOC migration among the collected samples. They are prepared in the laboratory by pouring American Society for Testing and Materials (ASTM) Type II or organic-free water into a VOC sample container. They are then sealed, transported to the field, stay sealed while VOC samples are taken, and transported back to the laboratory in the same cooler as the VOC samples. One TB should accompany each VOC sample cooler.

3.5.5 Matrix Spike/Matrix Spike Duplicate

A MS/MSD consists of duplicate field sample aliquots spiked by the laboratory with analytes of concern to evaluate the effects of the matrix on the recoveries of these analytes. For every 20 field samples of each matrix collected at each site, additional duplicate aliquots

of one of the samples should be collected for each analysis and designated on the CoC form for use as an MS/MSD by the laboratory. Separate line entries are not required for matrix spikes. The increased number of sample containers should be noted. The duplicate aliquots for MS/MSD analyses should be collected simultaneously or in immediate succession with the parent sample. They will be treated in exactly the same manner as the parent sample during storage and shipment. The sampling locations for the MS/MSD will be documented in the field logbook or the field sampling form, or both if the MS/MSD are specifically requested by the project; if not, document the extra volume on the CoC and in the field logbook or on the field sampling form.

3.5.6 Split Samples

Split samples may be collected periodically for comparison of data between analytical laboratories. A split sample is collected from a thoroughly homogenized original sample and is used to document analytical precision. Split samples will be collected for each matrix and for each analytical method, except those for volatiles when project objectives dictate the need. The sampling procedures described in Section 3.2 or those described in the project- or site-specific SAPs or QAPP addenda will be followed. The sampling locations will be recorded in the field logbook or field sampling form, or both. Split samples will be sent to a second certified laboratory, and results will be compared with those from the primary laboratory.

SECTION 4

Sample Handling and Custody

4.1 Sample Documentation and Tracking

Projects with large sampling events should take advantage of the field database to provide a PST, CoCs, and sample container labels. The use of Mobil Integrated Sample Tracking (MIST) and the field database are recommended. All projects must keep sample documentation.

The laboratories will provide pre-preserved sample containers with labels identifying the preservative, unless approved by the project chemist. Laser-printed labels and indelible ink pens will be used whenever possible to complete sample labels. Immediately prior to sample collection, the sample ID, date, time of sampling and sampler's initials will be recorded onto the waterproof label. Samples will be placed into resealable bags, and ice used in shipping containers double bagged. Vital information regarding the collection of each sample will be recorded into a field logbook, field sampling form, or CoC form.

A separate logbook will be used for each project. It will be bound with consecutively numbered pages. All entries will be legibly written in black ink and signed and dated by the individual making the entries. Factual and objective language will be used. All entries will be complete and accurate to allow reconstruction of each field activity. A line will be placed through any portion of a field notebook that is unused. One line strike-through will be used to show corrections to entries. The strike-through will be initialed and dated. No correction fluid will be used. The following information for each sample will be recorded into the field logbook, field sampling form, or CoC form, whichever is appropriate:

- Sampling location and description. (Sketch and measured distances from reference points will be recorded if there is no established identification for the sample location.)
- Sample ID.
- Sampler's name.
- Date and time of sampling.
- Sample designation as composite or grab.
- Sample matrix.
- Type and ID of sampling equipment.
- Field measurement data (e.g., pH, temperature, conductivity).
- Field observations that may be relevant to the analysis or sample integrity (e.g., odor, color, and weather conditions).
- Associated QC blanks.

- Preservative used.
- CoC form number, custody seal number, and lot numbers of sample containers (when appropriate).
- Shipping details. (If the laboratory is providing courier service, the courier must sign and date the CoC forms. Copies of the signed CoC forms should be transmitted to the office as soon as practical. If Federal Express, United Parcel Service, or other courier is used, include shipping information for each shipment.)
- Destination laboratory.

4.2 Containers and Preservatives

The contracted analytical laboratory will provide the required sample containers for all samples including QC samples. All sample containers for PG&E projects will be pre-cleaned and certified to EPA standards. No sample containers will be reused. The contracted laboratory will add preservatives, if required, prior to shipping the sample containers to the field or supply the preservative as appropriate. The laboratory, upon receipt of the samples, will verify and record the adequacy of preservation and will add additional preservative, if necessary. For VOCs, the sample label or CoC will indicate the presence of preservative and the laboratory will verify and record the pH after the analysis. The containers, minimum sample quantities, required preservatives, and maximum holding times for many parameters are shown in Table 4-1 (tables appear at the end of the section in which they are first referenced). The project- or site-specific SAP or QAPP addendum will contain the specific containers required for each project if they differ from the containers listed in Table 4-1.

4.3 Chain-of-Custody

Collecting data of known quality begins at the point of sample collection. Legally defensible data are generated by using proven evidentiary procedures. These procedures are described in the following sections and must be followed to preserve and ensure the integrity of all samples from the time of collection through analysis. Sample custody records must be maintained in the field and subcontractor laboratory. A sample is considered to be in custody if it is either in physical possession or view, locked up, or kept in a secured and restricted area. Until the samples are shipped, custody will be the responsibility of the sampling team leader.

CoC forms document sample collection and shipment to the laboratory. CoC form(s) will be completed for each sampling event. The original copy will be provided to the laboratory with the sample shipping cooler, and a copy will be retained in the field documentation files. The CoC form will identify the contents of each shipment and maintain the custodial integrity of the samples. All CoC forms will be signed and dated by the responsible sampling team personnel, as applicable. The “Relinquished By” field will be signed by the responsible sampling team personnel, with the date, time, and air bill number noted on the CoC form. The laboratory will provide a PDF copy of the CoC forms, with the sample login information included, within 48 hours of sample receipt, along with information related to

the condition of receipt of the samples. The laboratory will also include the original or a copy with the final hardcopy report (the final "hardcopy" can be in a paper or PDF format or both, depending on project-specific requirements).

A self-adhesive custody seal will be placed across the lid and side of each sample to maintain its integrity until the laboratory opens it. The shipping coolers containing the samples will be sealed with a custody seal any time they are not in an individual's possession or view before shipping. All custody seals will be signed and dated by the responsible sampling team personnel.

At a minimum, the CoC form must include the following information:

- Project information such as project number or identification of investigation monitoring program, Project Manager, etc.
- Unique sample ID
- Date and time of sample collection
- Source of sample (including name, location, sample type, and matrix)
- Number of containers
- Designation of MS/MSD (if applicable)
- Preservative used
- Analyses required
- Name of sampler
- Custody transfer signatures, dates, and times of sample transfers from the field to transporters and to the laboratories
- Bill of lading or transporter tracking number (if applicable)

4.4 Laboratory Responsibilities

After the samples reach the laboratory, they shall be checked against information on the CoC form for anomalies. The condition, temperature, and appropriate preservation of samples shall be checked and documented on the CoC form or a sample receipt checklist. Checking an aliquot of each sample container, at the time of receipt, using litmus paper is an acceptable procedure to determine the pH of all sample containers received, except VOCs. The pH check should be conducted in the sample receiving area or in the appropriate laboratory department. Samples for VOC analysis require that the pH check be performed after the vial has been opened for analysis; the pH shall be recorded at the time of analysis in the department log books. Anomalies in the received samples and their resolution shall be documented in laboratory records and summarized in the final analytical report case narrative. All sample information shall then be entered into a tracking system, and unique analytical sample IDs shall be assigned. A copy of this information shall be reviewed by the laboratory for accuracy. Sample holding time tracking begins with the collection of samples and continues until the analysis is complete.

Samples not preserved or analyzed in accordance with the requirements in this QAPP or the project-specific SAP or QAPP addendum may be resampled and analyzed at no additional cost to CH2M HILL. Any subcontracted analyses shall be documented on a CoC form by the laboratory and noted in the case narrative. Internal laboratory CoC procedures shall also be documented and implemented by the laboratory. Sample custody within the laboratory will, at a minimum, include storage of samples in a secure, restricted access area when not in use; samples must be checked out and checked back in by the analysts who use them. Internal custody records must be maintained by the laboratory as part of the documentation file for each sample. Specific instructions concerning the analysis specified for each sample shall be communicated to the analysts. Analytical batches shall be created, and laboratory QC samples shall be introduced into each batch.

While in the laboratory; samples shall be stored in controlled-access, temperature-applicable areas. Refrigerators, coolers, and freezers shall be monitored for temperature 7 days a week. Acceptance criterion for the temperatures of the refrigerators and coolers is 4°C ±2°C. Acceptance criterion for the temperatures of the freezers shall be between -7°C and -20°C. All of the cold-storage areas shall be monitored by using thermometers that have been calibrated with a National Institute of Standards and Technology approved traceable thermometer. As indicated by the calibration results, correction factors shall be applied to each thermometer.

Records that include acceptance criteria shall be maintained. Samples for volatile organics analysis shall be stored separately from other samples, standards, and sample extracts. Samples shall be stored after analysis until disposed of in accordance with applicable local, state, and federal regulations. Disposal records shall be maintained by the laboratory.

The following information shall be documented on the CoC form, the sample receipt form, or the sample login form (or on more than one of these forms, as applicable):

- Date samples received
- CH2M HILL sample ID
- Laboratory sample ID
- Analytical tests requested for the sample batch
- Sample matrix
- Number of samples in the batch
- Container description and location in the laboratory
- Verification of sample preservation

All of the information must be retained and traceable in the laboratory sample tracking system, with summary information provided in the analytical reports.

SOPs describing sample control and custody shall be maintained by the laboratory.

4.5 Sample Packaging and Transport

The following sections provide guidelines for sample packaging and transport that may be superceded, amended, or replaced in the project- or site-specific SAPs or QAPP addenda.

4.5.1 Sample Container Preparation

The following procedures shall be implemented:

- Labels will be checked for completeness and comparability with the COC.
- Container lids will be checked for tightness; if the container is not full, the sampler will note the COC, field notebook, or field sampling form.
- Sample bottles will be double-bagged in heavy-duty plastic. Glass sample containers will be covered with bubble wrap to prevent breakage.

4.5.2 Shipping Cooler Preparation

The following procedures shall be implemented:

- All previous labels and broken custody seals used on the sample shipping cooler will be removed.
- Drain plugs will be sealed with fiberglass or similar tape (outside and inside) to prevent melting ice from leaking.
- A cushioning layer of packing material, such as bubble wrap (approximately 1 inch thick), will be placed at the bottom of the cooler to prevent breakage during shipment.
- The cooler will be lined with a large plastic bag (same type used to contain samples).
- All ice will be double-bagged in zip-lock plastic bags.

4.5.3 Placing Samples in the Cooler

The following procedures shall be implemented:

- The CoC form will be placed in a zip-lock bag and taped inside the top of the cooler if shipment is to be made through commercial carrier.
- Samples will be placed in an upright position in the cooler. Sample containers will never be placed onto their side, except for a soil VOC that is to be frozen.
- Ice will be placed on top of samples and between samples. Ideally, ice will be placed in resealable plastic bags in duplicate to minimize leakage of ice melt into the cooler.
- Void space between samples should be filled with packing material or ice packs (vermiculite is not acceptable packing material unless required by DOT).

4.5.4 Closing the Cooler

The following procedures shall be implemented if the cooler is to be shipped by commercial carrier:

- The cooler lid will be taped with strapping tape, encircling the cooler several times.
- Custody seals should also be affixed to the cooler lid to further ensure the integrity of the samples. Custody seals should be initialed and dated.

4.5.5 Transport

Sample coolers will be transported to the laboratory immediately after sample collection. An overnight courier may be used to transport the samples. Intermediate stops should be avoided, except for emergencies, in which case, the situation should be noted in the field notebooks. The laboratory should be notified that samples are being shipped.

TABLE 4-1
Sample Containers, Preservation, and Holding Times
PG&E Program Quality Assurance Project Plan

Analyte	Method	Container and Minimum Quantity		Preservation	Holding Time
		Water	Soil/Sediment		
Metals (except hexavalent chromium)	SW6010B or C, SW6020A, EPA200.7, EPA200.8, SM3120B, EPA245.1, SW7000 series methods	1-liter P or G	8-oz/P, G, or T	Water: Add HNO_3 to pH<2; soil/sediment: None	28 days for mercury; 180 days for all others
Hexavalent Chromium	SW7199		4-oz/P, G, or T	Soil/sediment: Chill to 4°C (±2°C)	Soil: 30 days to extraction, 7 days to analysis
Hexavalent Chromium	EPA218.6	250-ml P	Not applicable	chill to ≤6°C Laboratory or field filtration within 24 hours. After filtration adjust the pH to 9–9.5 by adding $(NH_4)_2SO_4$/ NH_4OH buffer solution	28 days
Hexavalent Chromium	SM3500-Cr B	250-ml P	Not applicable	chill to ≤6°C Laboratory or field filtration within 24 hours. After filtration adjust the pH to 9–9.5 by adding $(NH_4)_2SO_4$/ NH_4OH buffer solution	28 days
Purgeable TPH	SW8015B, C or D Preparation methods: SW5035B (soil) SW5030B (water)	Three 40-ml G-TLC	Three 40-ml G-TLC	Water: Add HCl to pH<2; chill to 4°C (±2°C) Soil/sediment: Chill to 4°C (±2°C) or: • Frozen in 48 hours • Frozen onsite • Sodium bisulfate • Methanol	Water: 14 days (preserved); 7 days (unpreserved) Soil: 48 hours unless preserved within 48 hours 14 days if solid samples preserved by the following methods: • 4ºC/frozen in 48 hours • Frozen onsite • Sodium bisulfate • Methanol

TABLE 4-1
Sample Containers, Preservation, and Holding Times
PG&E Program Quality Assurance Project Plan

Analyte	Method	Container and Minimum Quantity		Preservation	Holding Time
		Water	Soil/Sediment		
Extractable TPH	SW8015B, C or D	Two 1-liter G	8-oz/G or T	Chill to 4°C (±2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis
Pesticides	SW8081A or B	Two 1-liter G	8-oz/G or T	Chill to 4°C (±2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis 90 days to extraction if frozen to -10°C (±2°C)
PCB	SW8082 or SW8082A	Two 1-liter G	8-oz/G or T	Chill to 4°C (±2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis 90 days to extraction if frozen to -10°C (±2°C)
VOCs	SW8260B or C Preparation methods: SW5035B (Soil) SW5030B (Water)	Three 40-ml G-TLC	Three 40-ml G-TLC	Water: Add HCl to pH<2; chill to 4°C (±2°C) Soil/sediment: Chill to 4°C (±2°C) or: • Frozen in 48 hours • Frozen onsite • Sodium bisulfate • Methanol	Water: 14 days (preserved); 7 days (unpreserved) Soil: 48 hours unless preserved with 48 hours 14 days if solid samples preserved by the following methods: • 4ºC/frozen in 48 hours • Frozen onsite • Sodium bisulfate • Methanol
SVOC	SW8270C or D	Two 1-liter G	8-oz G or T	Chill to 4°C (±2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis
Herbicides	SW8151A	Two 1-liter G	8-oz G or T	Chill to 4°C (± 2°C)	Water: 7 days to extraction; 40 days to analysis Soil: 14 days to extraction; 40 days to analysis

Analyte	Method	Container and Minimum Quantity		Preservation	Holding Time
		Water	Soil/Sediment		
Dioxins and furans	SW8290	Two 1-liter Amber G	8-oz G	Chill to 4°C (±2°C)	Water and Soil: 30 days to extraction; 45 days after extraction to analysis Soils: 365 days to extraction if frozen to -10°C (±2°C)
Dioxins and furans (Drinking water)	EPA1316B	Two 1-liter Amber G		Chill to 4°C (±2°C)	7 Days to extraction 40 days after extraction to analysis
Asbestos	Water: EPA 100.1/100.2-TEM	1-liter sonicated P		Chill to 4°C (±2°C)	Water: 48 hour holding time
	Soil: PLM/BULK (present/absent); CARB435/PLM; TEM		4-oz G	Chill to 4°C (±2°C)	Soil: I year

TABLE 4-1
Sample Containers, Preservation, and Holding Times
PG&E Program Quality Assurance Project Plan

Analyte	Method	Container and Minimum Quantity: Water	Container and Minimum Quantity: Soil/Sediment	Preservation	Holding Time

Notes:

>	=	greater than
<	=	less than
≤	=	less than or equal to
BTEX	=	benzene, toluene, ethylbenzene, and xylene
CF-IRMS	=	continuous-flow isotope ratio mass spectrometry
DOC	=	dissolved organic compounds
G	=	glass
G-TLC	=	glass with teflon-lined cap
H_2PO_4	=	phosphoric acid
H_2SO_4	=	sulfuric acid
HCl	=	hydrochloric acid
HNO_3	=	nitric acid
NaOH	=	sodium hydroxide
NH_4	=	ammonium
NH_4OH	=	ammonium hydroxide
$(NH_4)_2SO_4$	=	ammonium sulfate
oz	=	ounce
P	=	polyethylene
PCB	=	polychlorinated biphenyls
PLM	=	Polarized light microscopy
PNA	=	polynuclear aromatic hydrocarbons
SIM	=	selected ion monitoring
SO_4	=	sulfate
T	=	brass sleeves in the sample barrel (sometimes called California brass)
TDS	=	total dissolved solids
TEM	=	Transmission Electron Microscopy
TKN	=	total kjeldahl nitrogen
TLC	=	teflon lined closure
TOC	=	total organic compounds
TPH	=	total petroleum hydrocarbons
TSS	=	total suspended solids

SECTION 5

Method Quality Objectives and Quality Assurance Program

Programmatic method quality objectives (MQOs) are defined in this section but may differ in individual projects, as specified in the project-specific QAPP addenda. MQOs are the basis for ensuring that the quality of the data collection meets the project-specific DQOs of the plan. They specify the type, quality, and quantity of QA/QC data to be collected and how the data are to be used to make the appropriate decisions for the project. The final output of the data must meet the qualitative and quantitative needs of the project.

5.1 Data Categories

Both screening and definitive data may be generated. Screening data are generated by rapid analytical methods, and calibration and QC requirements are less rigid than those required for definitive data. Quantitation from a screening method is usually imprecise. Definitive data are generated by rigorous analytical methods using standardized calibration and QC and are reported on specified deliverables. The data are analyte-specific, and both identification and quantitation are confirmed.

In general, screening data will be confirmed by definitive data for use in decision making for the PG&E Program. However, screening data may be used for decision making purposes on a project-specific basis, depending upon the DQOs. The project-specific documents will describe the advantages of collecting screening data that might be less precise but will more adequately define the characteristics of the site by increasing the number of samples collected. This approach can reduce overall error in the data collection process.

5.2 Precision, Accuracy, Representativeness, Completeness, and Comparability

Data quality will be evaluated for precision, accuracy, representativeness, completeness, and comparability (PARCC). Both definitive and screening data will be subject to PARCC requirements. PARCC objectives for screening methods may be identical to those for definitive data, or they may be less stringent depending on the project-specific objectives. Sampling frequencies may vary according to the project needs, as defined in the project-specific SAPs or QAPP addenda.

5.2.1 Precision

Precision is a measure of reproducibility of analytical results. It can be defined as the degree of mutual agreement among individual measurements obtained under similar conditions. Total precision is a function of the variability associated with both sampling and analysis. Precision will be evaluated as the relative percent difference (RPD) between field duplicate

sample results or between the MS and MSD results. Field duplicates will comprise 10 percent of the sampling effort. MS/MSD samples will be analyzed at a 5-percent frequency. The MS/MSD samples will be field designated, if so required by project specific requirements. Laboratory-generated precision control limits can be used for data evaluation; however, all precision control limits listed in Appendix A and Tables 5-3 through 5-15 must be met.

5.2.2 Accuracy

Accuracy is the degree of agreement between a measured value and the "true" or expected value. It represents an estimate of total error from a single measurement, including both systematic error, or bias, and random error that may reflect variability due to imprecision. Accuracy is evaluated in terms of percent recovery (%R) determined from results of MS/MSD and laboratory control sample (LCS) analyses. Surrogate recoveries from samples analyzed for organic parameters are also used to assess accuracy. Laboratory-generated accuracy control limits can be used for data evaluation; however, the accuracy control limits listed in Appendix A and Tables 5-3 through 5-15 must be met.

5.2.3 Representativeness

Representativeness is the degree to which sample data accurately reflect the characteristics of a population of samples. It is achieved through a well-designed sampling program and by using standardized sampling strategies and techniques and analytical procedures. Factors that can affect representativeness include site homogeneity, sample homogeneity at a single point, and available information around which the sampling program is designed.

5.2.4 Completeness

Completeness is the number of valid measurements compared with the total number of measurements generated. Completeness will be determined for each method, matrix, and analyte combination. The completeness goals of each project are optimized to meet the DQOs. The goals for the PG&E Program are 95 percent for aqueous samples and 90 percent for soil samples.

5.2.5 Comparability

Comparability is the confidence with which one data set can be compared to another. It is achieved by maintaining standard techniques and procedures for collecting and analyzing samples and reporting the analytical results in standard units. Results of performance evaluation samples and systems audits will provide additional information for assessing comparability of data among subcontracting laboratories.

5.3 Method Detection Limits, Reporting Limits, and Instrument Calibration Requirements

5.3.1 Method Detection Limits

The method detection limit (MDL) is the minimum concentration of a substance that can be measured and reported with 99 percent confidence that the analyte concentration is greater

than zero. Each participating laboratory will determine the MDL for each method, matrix, and analyte for each instrument that will be used to analyze samples. The MDLs will be initially determined prior to analyzing samples and again at least once every 12 months; a quarterly MDL verification can be substituted for the annual MDL study. The following steps should be followed:

1. Estimate the MDL using one of the following:
   - The concentration value that corresponds to an instrument signal/noise ratio in the range of 2.5 to 5
   - The concentration equivalent of three times the standard deviation of replicate measurement of the analyte in reagent water
   - The region of the standard curve where there is a significant change in sensitivity (i.e., a break in the slope of the standard curve)
2. Prepare (e.g., extract and digest) and analyze seven samples of an MS (ASTM Type II water for aqueous methods; Ottawa sand for soil methods; 1-mm glass beads, or smaller, for metals) containing the analyte of interest at a concentration three to five times the estimated MDL.
3. Determine the variance for each analyte by using Equations 1 and 2:

$$S^2 = \frac{1}{n-1}\left[\sum_{i=1}^{n}\left(x_i - \bar{x}\right)^2\right] \quad (1)$$

where:

S^2 = variance
x_i = the nth measurement of the variable x and
$\bar{x}$ = the average value of x

$$\bar{X} = \frac{1}{n}\sum_{i=1}^{n} x_i \quad (2)$$

4. Determine the standard deviation(s) for each analyte by using Equation 3:

$$s = (S^2)^{1/2} \quad (3)$$

5. Determine the MDL for each analyte by using Equation 4:

$$MDL = 3.14(s) \quad (4)$$

   Note: 3.14 is the one-sided t-statistic at the 99-percent confidence level appropriate for determining the MDL using seven samples.

6. If the spike level used in Step 2 is more than 10 times the calculated MDL, repeat the process using a smaller spiking level.

CH2M HILL requires a verification check be performed on the calculated MDLs for each target compound (AFCEE, 2006). The MDL check standard shall be spiked at approximately two times the current reported MDL. The MDL is verified if the check standard produces a

response at least 3 times above the instrument's noise level and greater than the blank associated with the MDL verification study. If the verification response is too low, spike at a successively higher concentration until verification criteria are met, and use the first successful concentration as the reported MDL. The MDL verification check will be sent to CH2M HILL for review and approval.

5.3.2 Reporting Limits

In general, RLs must be greater than two times the calculated MDL. RLs used by the laboratory should not be greater than the reporting limit objectives listed in Appendix A.

When calibrating instruments, a standard at a concentration equal to or less than the RL must be included. In the project-specific SAP or QAPP addendum, reporting of analytical data will be addressed. One of the following options will be selected when establishing reporting requirements for each project:

- Analytes at concentrations greater than the laboratory MDL but less than the RL will be flagged "J" and reported as an estimate. Analytes that are not detected at or above the laboratory MDL will be flagged "U" and reported as not detected at the RL.
- Only analytes at a concentration greater than the project-specific RL will be reported. Analytes detected at less than the RL will be flagged "U" and reported as not detected at the RL.

For consistency, RLs and sample results shall be reported to two significant figures if less than 10 micrograms per liter (µg/L) (parts per billion) and to three significant figures otherwise.

RLs shall be reported on a dry-weight basis for soil samples.

5.3.3 Instrument Calibration

Laboratory instruments shall be calibrated by qualified personnel prior to sample analysis according to the procedures specified for each method. Calibration shall be verified at method-specified intervals throughout the analysis sequence. The frequency and acceptance criteria for calibration are specified for each analytical method in Tables 5-3 through 5-15, with supplemental requirements defined in the following sections for organic methodologies. When multipoint calibration is specified, the concentrations of the calibration standards should bracket those expected in the samples. Samples should be diluted, if necessary, to bring analyte responses within the calibration range. Data that exceed the calibration range cannot be reported by the laboratory. The initial calibration (ICAL) curve shall be verified as accurate with a standard purchased or prepared from an independent second source. ICAL verification involves the analysis of a standard containing all the target analytes, typically in the middle of the calibration range, each time the ICAL is performed. Quantitation based on extrapolation is not desirable.

Calibration requirements

In the initial calibration (for all instruments), a standard at a concentration equal to or less than the RL must be included.

Initial calibration must be re-established if the following conditions exist:

- The last calibration was established more than 1 year prior to the start of a sample's analysis [gas chromatography, gas chromatography-mass spectrometry, inductively coupled plasma, and inductively coupled plasma-mass spectrometry (ICPMS)]
- The last calibration was established more than 2 weeks prior to the start of a sample's analysis for hexavalent chromium by ion chromatography.
- Two consecutive continuing calibration standards fail
- The operating conditions change; for example, any of the following:
  - Major maintenance is performed
  - The fluid or gas "carrier" type changes
  - The instrument requires relocation
  - The analytical column is replaced

5.3.3.1 Initial Calibration Models for the Determination of Organic Compounds

Organic methodologies often provide multiple options for ICAL curve fits and associated acceptance criteria for use. The following sections describe the required laboratory practices that will be employed by the laboratory. The hierarchy that the laboratory will use when selecting the calibration curve fit for use in quantitation of sample results is described in the following section.

Calibration Techniques. The following procedures will be implemented:

- The analyst will verify that correct instrument operating conditions and routine maintenance as specified in the method and laboratory SOP are employed. All maintenance activities will be documented in a laboratory notebook for troubleshooting and scheduling of future routine, periodic maintenance.
- Ensure that the instrument is free of contamination prior to calibration. **Do not** perform any blank subtraction.
- The entire ICAL must be performed and meet method performance criteria prior to sample analyses. The calibration standards must be analyzed in sequential order from the lowest to highest concentration. If **one** calibration standard fails to meet criteria, it may be reanalyzed at the end of the calibration sequence. Justification for removing a calibration point from the selected curve fit includes circumstances such as, improper purge, injection failure, nonspiked level, or other obvious failures. The failure of multiple standards suggests an instrument problem or operator error and corrective action is required.
- Only the lowest or the highest calibration points can be removed from the calibration curve without justification. If the lowest calibration point is removed, the RL for that compound increases to the level of the next lowest calibration point. Approval to elevate RLs greater than the project-specific objectives **must** be approved by the program or project chemist. If the highest calibration point is removed, the linear range is shortened for that compound.

- The lowest calibration point in the calibration curve must be at or below the required RL.
- The other standard concentrations must define the working range of the instrument or the expected range of concentrations found in the samples.
- Either external or internal calibration can be employed for methods not involving mass spectrometry detectors. Internal calibration must be used when a mass spectrometry detector is employed.
- A minimum of five calibration points must be used for the calibration curve for gas chromatography/mass spectrometry and gas chromatography methods.
- Most compounds tend to be linear, and a linear approach should be favored when linearity is suggested by the calibration data. Nonlinear calibration should be considered only when a linear approach cannot be applied. It is not acceptable to use an alternate calibration procedure when a compound fails to perform in the usual manner. When this occurs it is indicative of instrument issues or operator error.
- If a nonlinear calibration curve fit is employed, a minimum of six calibration levels must be used for second-order (quadratic) curves, and a third order polynomial requires a minimum of seven calibration levels.
- When more than five levels of standards are analyzed in anticipation of using second- or third-order calibration curves, all calibration points **must** be used regardless of the calibration option employed. The highest or lowest calibration point may be excluded to narrow the calibration range and meet the requirements for a specific calibration option. Otherwise, unjustified exclusion of calibration data is expressly forbidden.
- Using the average (mean) relative standard deviation (RSD) of all analytes to meet ICAL criteria is **not** acceptable.

Calibration Options. This section describes the acceptable calibration options and the hierarchy that the laboratory should use when selecting a specific option. The choice of calibration option may also be based on previous experience or prior knowledge of detector response.

The following are calibration options:

- **Linear calibration using average calibration or response factors.** Calibration factors for external calibrations or response factors for internal calibrations must have RSDs not exceeding 20 percent or 15 percent, respectively, for quantitation. A minimum response factor of 0.05 for most target analytes or 0.01 for the least responsive target analytes must be achieved to ensure detectability.
- **Linear calibration using a linear regression equation (y=mx+b).** The correlation coefficient must equal 0.995 or better. The line should **not** be forced through the origin. The equation and a plot of the linear regression must be included in the raw data generated by the laboratory and made available in the data package upon request.
- **Nonlinear calibration.** This model may be a second-order or third-order polynomial. The model must be continuous without a break in the function and should **not** be forced through the origin. The coefficient of determination of the nonlinear regression must be

0.99 or better. The equation and a plot of the nonlinear regression must be included in the raw data generated by the laboratory and made available in the data package upon request. This method of calibration **must** be approved by the program or project chemist prior to analysis and is intended for nonlinear responding compounds only.

5.3.3.2 Continuing Calibration

Periodic verification of the ICAL is essential in generating analytical data of known quality. The continuing calibration verification analyses ensure that the instrument has not been adversely affected by the sample matrix or other instrument failures that would increase or decrease the sensitivity or accuracy of the method. The laboratory will perform continuing calibration for all methods in accordance with the specific requirements in the method and laboratory SOP.

Method SW8000B allowed the use of the average of all analytes percent difference or drift (%D) to meet the continuing calibration requirements for the method. Method SW8000B will not be allowed for the PG&E Program QAPP. Using the average (mean) %D to meet continuing calibration criteria is **not** acceptable. All analytes must meet the continuing calibration criteria for %D (see Method SW8000C).

5.4 Elements of Analytical Quality Control

Laboratory QC checks indicate the state of control that prevailed at the time of sample analysis. QC checks that involve field samples, such as matrix and surrogate spikes and field duplicates, also provide an indication of the presence of matrix effects. Field-originated blanks (see Section 3.5) provide a way to monitor potential contamination that field samples are subjected to. The QAPP specifies requirements for method blanks, LCSs, surrogate spikes, and MS/MSD that must be followed by subcontracting laboratories.

A laboratory QC batch is defined as a method blank, LCS, MS/MSD, or a sample duplicate (depending upon the method) and 20 or fewer environmental samples of similar matrix that are extracted or analyzed together. For gas chromatography/mass spectrometry volatile analyses, a method blank, LCS, and MS/MSD must be analyzed in each 12-hour calibration period. The number of environmental samples allowed in the laboratory QC batch is defined by the remaining time in the method-prescribed 12-hour calibration period divided by the analytical run time. Each preparation or analytical batch should be identified in a way that will associate environmental samples with the appropriate laboratory QC samples.

5.4.1 Method Blanks

Method blanks are used to monitor each preparation or analytical batch for interference or contamination from glassware, reagents, and other potential contaminant sources in the laboratory. A method blank is an analyte-free matrix (laboratory reagent water for aqueous samples or Ottawa sand for soil samples) to which all reagents are added in the same amount or proportions as are added to samples. It is processed through the entire sample preparation and analytical procedures along with the samples in the batch. There should be at least one method blank per preparation or analytical batch. If a target analyte is found at a concentration that exceeds the RL, corrective action must be performed to identify and eliminate the contamination source. **All** associated samples must be re-prepared or

reanalyzed, or both, after the contamination source has been eliminated if the compounds detected in the associated blank are also present in the field samples. No analytical data may be corrected for the concentration found in the blank (no blank correction).

5.4.2 Laboratory Control Sample

An LCS consists of an analyte-free matrix (laboratory reagent water for aqueous samples and Ottawa sand or glass beads for soil samples) spiked with known amounts of analytes that come from a source different than that used for calibration standards. A **complete target analyte list** for each method specified in the QAPP will be spiked into the LCS. The spike levels should be less than or equal to the midpoint of the calibration range. If LCS results are outside the specified control limits, corrective action must be taken, including sample re-preparation or reanalysis, or both, if appropriate. Documentation of the re-preparation or reanalysis, or both, must be provided in the analytical report. If more than one LCS is analyzed in a preparation or analytical batch, the results for each of the LCSs analyzed must be reported. Any LCS recoveries that are above or below the QC limits affect the accuracy for the entire batch and require corrective action.

5.4.3 Surrogates

Surrogates are organic analytes that behave similarly as the analytes of interest but are not expected to occur naturally in the samples. They are spiked into the standards, the samples, and QC samples prior to sample preparation. Surrogate recoveries are used as an indicator of accuracy, method performance, and extraction efficiency. If surrogate recoveries are outside the specified control limits, corrective action must be taken, including sample re-preparation or reanalysis, or both, if appropriate. Documentation of the re-preparation or reanalysis, or both, must be provided in the analytical report.

5.4.4 Matrix Spike/Matrix Spike Duplicate

An MS is a sample matrix fortified with known quantities of specific compounds; it is subjected to the same preparation and analytical procedures as the native sample. Target analytes are spiked into the sample. MS recoveries are used to evaluate the effect of the sample matrix on the recovery of the analytes of interest. An MSD is a second fortified sample matrix. The RPD between the results of duplicate MSs measures the precision of sample results. One MS/MSD (MSD where appropriate) per 20 project-specific samples will be analyzed. A complete target analyte list for each method specified in the QAPP will be spiked into the MS/MSD (with the exception of PCBs; see Appendix A -notes). Project-specific samples designated on the CoC form will be spiked. The spike levels will be less than or equal to the midpoint of the calibration range. Exceedances of control limits should be flagged in the analytical report.

5.4.4.1 Matrix Spike for Hexavalent Chromium Analyses

Interference from groundwater is known to reduce the sensitivity of MethodEPA218.6. This can result in an incorrect assessment of the analyte identification or the specific RL if the "Matrix Spike and Dilution Protocol" is not followed. Samples being analyzed by Method EPA218.6 may be required to follow the protocol in the following section.

Matrix Spike and Dilution Protocol. Matrix interference has been encountered that affects the sensitivity for hexavalent chromium by ion chromatography methods. CH2M HILL shall direct the laboratories to perform an additional QA/QC analyses to aid in assessing any effect on method sensitivity for each project due to the sample matrix.

For nondetect sample results, the laboratory will analyze an MS by spiking the samples with 1 µg/L of hexavalent chromium to ensure that identification is accurate and verify that false negatives are detected. For samples with detected results, the laboratory will analyze an MS by spiking the sample with hexavalent chromium at a level not less than 25 percent of the sample concentration. Laboratories will follow the standard protocol of 1 MS and 1 laboratory sample duplicate per 20 samples, unless directed by the project chemist to analyze the MS more frequently.

If the MS is not recovered or the peak is outside of the established retention time window for either detected or nondetect results, the laboratory will make a fivefold dilution of two aliquots of the sample. The first aliquot will be analyzed without the spike; the second aliquot will be spiked with hexavalent chromium at a concentration consistent with the concentrations previously listed and the recovery and peak retention times evaluated. If this MS recovery is not within laboratory QC limits or the peak is not within the laboratory retention time window, the laboratory will dilute two additional aliquots of the sample tenfold, spike one of the aliquots, and analyze the sample/MS. This procedure will be performed at successively greater dilutions of 25:1, 50:1, or 100:1 until the peak identified in the post spike analysis is within the established retention time window for hexavalent chromium and the recovery of the spike is within the laboratory QC limits listed in Appendix A.

The detected result that is reported by the laboratory on the final data package will be chosen from the dilution where both the peak detected in the unspiked and the spiked sample are within the appropriate retention time and the MS is recovered within the QC control limits. The RLs will be raised to the level of the appropriate dilution.

For nondetect results, the dilution selected by the laboratory for reporting will be taken from the smallest dilution that yields an MS recovery within QC control limits and within the appropriate retention time window.

5.4.5 Internal Standards

Internal standards are compounds that have similar properties as the analytes of interest but are not expected to occur naturally in the samples. Some methods require the use of internal standards to compensate for losses during injection or purging or losses due to viscosity. A measured amount of the internal standard is added to the standards, the samples, and QC samples following preparation. When the internal standard results exceed the control limits, corrective action must be taken, including sample reanalysis, if appropriate. Corrective action must be documented in the analytical report.

5.4.6 Laboratory Sample Duplicate

For some methods, a laboratory duplicate is performed instead of a matrix spike duplicate. A laboratory sample duplicate is a sample duplicate selected by the laboratory. It is subjected to the same preparation and analytical procedures as the native sample. The RPD

between the results of the native sample and laboratory sample duplicate measures the precision of sample results. The data collected may also yield information regarding whether the sample matrix is homogenous or heterogeneous.

5.4.7 Interference Check Samples

Interference check samples are used in inductively coupled plasma (ICP) analyses to verify background and interelement correction factors. They consist of two solutions, A and AB. Solution A contains the interfering analytes, and Solution AB contains the analytes of interest and the interfering analytes. Both solutions are analyzed at the beginning and at the end of each analytical sequence. When the interference check sample results exceed the control limits, corrective action must be taken, including sample reanalysis, if appropriate.

5.4.8 Retention Time Windows

Retention time windows for gas and liquid chromatographic analyses must be established by replicate injections of the calibration standard over multiple days as described in SW846 8000B, analytical method, or appropriate laboratory SOP. The absolute retention time of the calibration verification standard at the start of each analytical sequence will be the centerline of the window. For an analyte to be reported as positive, its elution time must be within the retention time window.

5.5 Additional Quality Control Requirements

5.5.1 Holding Time

The holding time requirements specified in this QAPP (see Table 4.1) must be met. For methods requiring both sample preparation and analysis, the preparation holding time will be calculated from the time of sampling to the completion of preparation. The analysis holding time will be calculated from the time of completion of preparation to the time of completion of the analysis, including required dilutions, confirmation analysis, and reanalysis. For methods requiring analysis only, the holding time is calculated from the time of sampling to completion of the analysis, including required dilutions, confirmation analysis, and reanalysis.

5.5.2 Confirmation

Confirmation analysis must be performed as specified for specific organic methods when the result is at or above the RL. Both the primary and confirmation results will be reported. Unless one of the analysis is specifically designated as the confirmation by the method, the more concentrated result will be reported as the sample result and the lesser concentration result as the confirmation. All calibration and QC requirements must be met when confirmation analysis is performed.

5.5.3 Cleanup Procedures to Minimize Matrix Effects

To maintain the lowest possible RLs, appropriate cleanup procedures should be employed when it is indicated by the method to remove or minimize matrix interference. Methods for sample cleanup include, but are not limited to, gel permeation chromatography, silica gel,

alumna, florisil, mercury (sulfur removal), sulfuric acid, and acid/base partitioning. Method blanks, MS/MSDs, and LCSs must be subjected to the same cleanup procedures performed on the samples to monitor the efficiencies of these procedures.

5.5.4 Sample Dilution

Dilution of a sample results in elevated RLs and ultimately affects the usability of the data related to potential actions at the sampling site. It is important to minimize dilutions and maintain the lowest possible RLs. When dilutions are necessary because of high concentrations of target analytes, lesser dilutions should also be reported to fully characterize the sample for each analyte. The level of the lesser dilution should be such that it will provide the lowest possible RLs without having a lasting deleterious effect on the analytical instrumentation.

When a sample exhibits characteristics of matrix interference that are identified through analytical measurement or visual observation, appropriate cleanup procedures specified in Section 5.5.3 must be proven ineffective or inappropriate prior to proceeding with dilution and analysis. Any analyses conducted at a dilution where all analytes will be reported as non-detect above the QAPP RL, must be discussed with the project chemist prior to finalizing the report.

5.5.5 Standard Materials and Other Supplies and Consumables

Standard materials must be of known high purity and traceable to an approved source. Pure standards must not exceed the manufacturer's expiration date or 1 year after receipt if no expiration date is provided. Solutions prepared by the laboratory from the pure standards must be used within the expiration date specified in the laboratory's SOP.

All other supplies and consumables must be inspected prior to use to ensure that the supplies meet the requirements specified in the appropriate SOP. The laboratory's inventory and storage system should ensure their use within the manufacturer's expiration date and storage under proper conditions.

5.5.6 Manual Integration

The laboratory is required to provide all analysts performing methods that rely on interpretation of chromatographic data with training on appropriate software or manual integration practices. The laboratory also will make every effort to minimize the use of manual integration of data. If the need arises to use manual integration to correct a software autointegration error, the manual integration will be clearly identified in the instrument data. Before and after enlargements of the region of the chromatogram where the manual integration was performed will be provided on an appropriate scale that allows an independent reviewer to evaluate the need and quality of the manual integration. The analyst will also document the reason for the manual integration on the chromatogram along with their date and initials. The laboratory manager or designee will approve the manual integration by dating and initialing the chromatogram.

5.5.7 Laboratory Quality Assurance Program

The laboratory will maintain a quality assurance manual or equivalent document. The manual must include all of the requirements provided in the California Environmental Laboratory Accreditation Program (ELAP), and, if applicable, the National Environmental Laboratory Accreditation Program (NELAP). The manual will define the laboratory's internal procedures for QA/QC as follows:

- QA policies, objectives, and requirements
- Organization and personnel
- Document control
- SOPs (analytical methodology and administrative)
- Data generation
- Software verification
- Quality assurance
- Quality control
- Nonconformance/corrective action procedures
- Data review

5.5.7.1 Laboratory Standard Operating Procedures

The laboratory will maintain SOPs for all analytical methods and laboratory operations. The format for SOPs will conform with the following:

- *Test Methods for Evaluating Solid Waste, Physical and Chemical Methods, SW-846, Third Edition, Update III, Section 1* (EPA, 1996)
- "Good Laboratory Practices" in *Principles and Guidance to Regulations for Ensuring Data Integrity in Automated Laboratory Operations* (EPA, 1995)

All SOPs must have a unique identification number that is traceable to previous revisions of the same document. SOP review must be completed annually.

5.5.7.2 Demonstration of Capability

Laboratory QA department personnel will maintain records documenting the ability of each analyst to perform applicable method protocols. Documentation will include annual checks for each method and analyst. In addition, internal, blind performance evaluation samples for each method and matrix demonstrating overall laboratory performance must be submitted annually. The laboratory may receive additional blind performance evaluation samples in conjunction with the PG&E Program.

5.6 Analytical Procedures

The allowed sample preparation methods are presented in Table 5-2. Any changes or alternatives to this list will be included in site-specific SAPs or QAPP addenda. Analytical and preparation methods for SW7000 series are provided in Table 5-2 as alternate methods to SW6020 (with the exception of mercury and soil hexavalent chromium, the SW 7000 series must be approved by the project chemist). These methods will be allowed, provided the RL

objectives are met. After a method is chosen, it must be used throughout the duration of a specific project to maintain data comparability.

This QAPP includes common analytical procedures that may be required for the PG&E Program. Appendix A, Tables A -1 through A -3 contain representative lists of the analytes of concern, the methods to be used, and the RL objectives. Some of the listed analytes may not necessarily be of concern for a particular project; project-specific SAPs or QAPP addenda will list the analytes of concern. The RLs included herein reflect quantifiable levels that are attainable with a specified degree of confidence using the specified methods. The RLs should meet most preliminary cleanup goals or action levels. If changes to the methods or RLs are necessary to meet cleanup goals, the QAPP will be updated or amended by addendum.

General QC requirements are discussed in Section 5.3.3. The calibration and QC requirements specified for each method will be followed and are included in Appendix A and Tables 5-3 through 5-15. Appropriate corrective action will be taken when acceptance criteria are not met. If corrective action is not effective, and data quality is potentially degraded, the occurrence must be documented in a corrective action report and in the data package case narrative. The laboratory manager or a designated person must notify the project chemist.

Analytical services will be provided by laboratories contracted by CH2M HILL or its subcontractors. Analytical laboratories will be accredited, in accordance with the California ELAP, for all parameters where accreditation is available. Subcontract laboratories will be required to follow the SAP and QAPP addenda that are applicable to specific projects or activities and must be approved by the CH2M HILL project chemist.

Field measurements will be performed or supervised directly or indirectly by CH2M HILL field personnel.

5.7 Title 22 Metals

The California Code of Regulations - Title 22, Division 4.5 – Environmental Health Standards for the Management of Hazardous waste has a waste characterization protocol that specifies the following stepped procedure for determining hazardous waste disposal:

1. If the sample is suspected of containing high levels of metals, analyze for the Title 22 metals – total threshold limit concentration (TTLC) (see Appendix A, Table A-3).
2. Compare the TTLC sample results with column G of Appendix A, Table A-3.
3. If the TTLC sample results are greater than the concentrations listed in column G of Appendix A, Table A-3, extract and analyze the samples using the waste extraction test (WET) [only required for analytes that exceed the concentrations listed in column G of Appendix A, Table A-3].
4. If the soluble threshold limit concentration (STLC) sample result, from the waste extraction test extraction, is greater than the concentration listed in column H of Appendix A, Table A-3 for any of the Resource Conservation and Recovery Act metals listed in column E of Appendix A, Table A-3., extract the sample by toxicity

characteristic leaching procedure (TCLP) Method 1311 and analyze for the specific metals that exceeded the STLC threshold.

TABLE 5-1
Maximum Concentrations for Title 22 – Organic Compounds – SW8000 Series
PG&E Program Quality Assurance Project Plan

Constituent	CAS	Method
Mirex	2385-85-5	SW8081
Methyl chloromethyl ether (Chloromethyl methyl ether)	107-30-2	SW8021B
2-Acetylaminofluorene (2-AAF)	53-96-3	SW8270C
Acrylonitrile	107-13-1	SW8260B
4-Aminodiphenyl (4-Aminobiphenyl)	92-67-1	SW8270C
Benzidine and its salts	92-87-5	SW8270C
bischloromethyl ether (BCME)	542-88-1	SW8270C
1,2-Dibromo-3-chloropropane (DBCP)	96-12-8	SW8270C
4-Dimethylaminoazobenzene (DAB)	60-11-7	SW8270C
Ethyleneimine (EL)	151-56-4	
ALPHA-NAPHTHYLAMINE (1-NA)	134-32-7	SW8270C
BETA-NAPHTHYLAMINE (2-NA)	91-59-8	SW8270C
4-Nitrobiphenyl (4-NBP)	92-93-3	SW8270C
N-Nitrosodimethylamine (DMN)	62-75-9	SW8270C
beta-Propiolactone (BPL)	57-57-8	SW8260B

Note:

If the sample contains any of the compounds listed in this table at a single or combined concentration equal to or exceeding 0.001 percent by weight, the sample is considered to be toxic under CA Title 22 Section 66261.24 (Characteristic of Toxicity)

TABLE 5-2
Extraction and Digestion Methods
PG&E Program Quality Assurance Project Plan

Analytical Method	Parameter	Preparatory Methods
SW6010B	Trace metals by ICP	SW3005A, SW3010A, SW3015, SW3050B, SW3051
SW6020	Trace metals by ICP-MS	SW3005A, SW3010A, SW3015, SW3050B, SW3051
SW7000 Series[a]	Various elements (unless specified separately) Does Not include Mercury or soil Hexavalent chromium	SW3015, SW3020A, SW3050B, SW3051
EPA200.7 and EPA200.8	Trace metals by ICP/ICP-MS	See analytical method
SW7470A, SW7471A, and EPA245.1	Mercury by cold vapor atomic adsorption	See analytical method
SW7196A, SW7199, and EPA218.6	Hexavalent chromium	See analytical method for water, Use SW3060A for soil preparation prior to SW7199
SW8015B or D	TPH volatile and extractable (water and soil)	Volatiles: SW5030BB, SW5031, SW5035 Extractables: SW3510C, SW3520C, SW3545C, SW3541, SW3545, SW3550B
SW8081A	Organochlorine pesticides (water and soil)	SW3510C, SW3520C, SW3540C, SW3541, SW3545, SW3550B
SW8082	PCBs (water and soil)	SW3510C, SW3520C, SW3540C, SW3541
SW8151A	Chlorinated herbicides (water and soil)	SW3510C, SW3520C, SW3540C, SW3541, SW3550B
SW8260B	Volatile organics (water and soil)	SW3585, SW5021, SW5030B, SW5031, SW5032, SW5035
SW8270C and SW8270C SIM	Semivolatile organics (water and soil)	SW3510C, SW3520C, SW3535, SW3540C, SW3541, SW3545, SW3550B

TABLE 5-4
Calibration and QC Requirements for Metals – SW6010B and EPA200.7
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
ICAL (a blank and at least one standard)	When modifications are made to the system, or when continuing calibration verification fails.	If more than one standard is used, correlation coefficient must be >0.995.	Not applicable.
Second-Source Calibration Verification	Immediately following each ICAL.	All analytes within ±10% of expected value for SW6010B and within ±5% of expected value for EPA200.7.	Correct problem and repeat ICAL.
Calibration Blank	After every second-source or continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem and reanalyze previous 10 samples.
Continuing Calibration Verification	After every 10 samples and at the end of the analysis sequence.	All analytes within ±10% of expected value for SW6010B and within ±10% of expected value for EPA200.7.	Recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Interference Check Standard	At the start and end of each analytical sequence or twice during an 8-hour period, whichever is more frequent.	All analytes within ±20% of expected value.	Correct the problem, recalibrate, and reanalyze ICS and all affected samples.

TABLE 5-4
Calibration and QC Requirements for Metals – SW6010B and EPA200.7
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
MS/MSD	One set per 20 project-specific samples. MSD is optional if a laboratory sample duplicate is performed.	All analytes within limits specified in Appendix A.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified in Appendix A.	Correct the problem, re-prepare and reanalyze the LCS and all samples in the analytical batch.
Postdigestion Spike Addition	When MS/MSD fails.	Recovery within 75 to 125% of expected value.	None.
Dilution Test	Each new sample matrix. Or when the PDS fails	Result from 1:5 dilution must be within ±10% of the undiluted sample result (applies only if undiluted sample result is at least 25 times the RL).	Perform postdigestion spike addition.
Linear Range Calibration Check Standard	Once per quarter.	All analytes within +10% of expected value.	Correct problem and reanalyze or reset linear range.

TABLE 5-5
Calibration and QC Requirements for Metals – SW6020 and EPA200.8
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
ICAL (a blank and at least one standard)	Before initial sample analysis, when modifications are made to the analytical system, or when continuing calibration verification fails.	Not applicable	Not applicable
Second-source Calibration Verification	Immediately following each ICAL.	All analytes within ±10% of expected value.	Correct problem and repeat ICAL.
Calibration Blank	After every Second-source or Continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem and reanalyze previous 10 samples.

TABLE 5-5

QC Check	Frequency	Criteria	Corrective Action
Continuing Calibration Verification	After every 10 samples and at the end of the analysis sequence.	All analytes within ±10% of expected value.	Recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Interference Check Standard	At the start and end of each analytical sequence or twice during an 8-hour period, whichever is more frequent.	All analytes within ±20% of expected value.	Correct the problem, recalibrate and reanalyze ICS and all affected samples.
MS/MSD	One set per 20 project-specific samples. MSD is optional if a laboratory sample duplicate is performed.	All analytes within limits specified in Appendix A.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified in Appendix A.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
Postdigestion Spike Addition	When MS/MSD fails.	Recovery within 75 to 125% of expected value.	None.
Dilution Test	Each new sample matrix. Or when the PDS fails	Result from 1:5 dilution must be within ±10% of the undiluted sample result (applies only if undiluted sample result is at least 25 times the RL).	Perform postdigestion spike addition.

TABLE 5-6
Calibration and QC Requirements for Metals – SW7000 Series and EPA245.1
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (a blank and at least five standards)	Before initial sample analysis, when modifications are made to the analytical system, or when continuing calibration verification fails.	Correlation coefficient of linear regression is ≥0.995.	Correct the problem and repeat the ICAL.
Second-source Calibration Verification	Immediately following each ICAL.	All analytes within ±20% of expected value.	Correct the problem and repeat ICAL.
Calibration Blank	After every second-source or continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem, then reanalyze previous 10 samples.
Continuing Calibration Verification	After every 10 samples and at the end of the analysis sequence.	All analytes within ±20% of expected value.	Recalibrate and reanalyze all samples since the last accept-able continuing calibration verification.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
MS/MSD	One set per 20 project-specific samples. MSD is optional if a laboratory sample duplicate is performed.	All analytes within limits specified in accuracy and precision table.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified Appendix A.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
Recovery Test (PDS)	When MS/MSD fails.	Recovery within 85 to 115% of expected value.	Analyze all samples by MSA.
Dilution Test	Each new sample matrix. Or when the PDS fails	Result from 1:5 dilution must be within ±10% of the undiluted sample result (applies only if undiluted sample result is at least 25 times the RL).	Perform recovery test.

Note:
MSA = method of standard addition

TABLE 5-7
Calibration and QC Requirements for General Chemistry and Other Parameters[a]
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (a blank and at least five standards); Does Not Apply to Titrimetric Method	Before initial sample analysis, when modifications are made to the analytical system, or when continuing calibration verification fails.	Correlation coefficient of linear regression is ≥0.995.	Correct the problem and repeat the ICAL.
Second-source calibration verification	Immediately following each ICAL.	Analytes within ±15% of expected value (±10% for SW9056/EPA300.0).	Correct the problem and repeat ICAL.
Calibration blank; does not apply to titrimetric method	After every second-source or continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem, then reanalyze previous 10 samples.
Continuing calibration verification	After every 10 samples and at the end of the analysis sequence.	Within ±15% of expected value (±10% for SW9056/EP300.0).	Recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Method blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
MS/MSD	One set per 20 project-specific samples. MSD is optional if a laboratory sample duplicate is performed.	All analytes within limits specified in Appendix A.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified in Appendix A.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
IPC (EPA314.0 only)	Daily, before sample analysis.	Conductance within 10% of original value (original value within ±10% of MCT). $PD_{A/H}$ <25%, instrument response within ±20% of expected response. Retention time shifts <5%, or overall retention time <80% of original recorded value.	Prepare fresh IPC solution. Redetermined MCT or correct problem and reanalyze IPC. Correct problem, clean or replace column.

TABLE 5-7
Calibration and QC Requirements for General Chemistry and Other Parameters[a]
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
ICAL Verification (ICCS) (EPA314.0 only)	Daily, before sample analysis or when eluent is changed.	Instrument response within ±25% of expected value using a standard at or below the RL.	Correct problem then repeat ICAL.
Pretreated Laboratory Reagent Blank (EPA314.0 only)	Required in any analytical batch which includes samples that have been pretreated to reduce the common anion levels.	Perchlorate must be ≤½ RL.	Correct problem, re-prepare, and analyze method blank and all samples processed with the contaminated blank.
Low-level MDL Check Standard (EPA314.0 only)	Weekly and with ICAL.	Must meet QC acceptance criteria, 50 to 150% of its true concentration.	Reanalyze low-level MDL check standard, if still out of criteria, repeat ICAL.

[a]Unless calibration and QC requirements are specified for an individual method.

Notes:

ICCS = initial calibration check standard

IPC = instrument performance check

MCT = matrix conductivity threshold

TABLE 5-8
Calibration and QC Requirements for Hexavalent Chromium – SW7199 and EPA218.6
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (a blank and at least five standards)	Before initial sample analysis, when modifications are made to the analytical system, or when continuing calibration verification fails.	Correlation coefficient of linear regression is ≥0.999.	Correct the problem and repeat the ICAL.
Second-source Calibration Verification	Immediately following each ICAL.	All analytes within ±10% of expected value.	Correct the problem and repeat ICAL.
Calibration Blank	After every second-source or continuing calibration verification analysis.	No analytes detected at or above the RL.	Correct the problem, then reanalyze previous 10 samples.
Continuing Calibration Verification	After every 10 samples and at the end of the analysis sequence.	All analytes within ±10% of expected value for SW7199 and within ±5% of expected value for EPA218.6.	Recalibrate and reanalyze all samples since the last accept-able continuing calibration verification.
Low-level Calibration verification at the RL of 0.2µg/L	Immediately following each ICAL.	Result within ±20% of expected value.	Correct the problem and repeat ICAL.
Duplicate Sample Injections (SW7199 only)	Every sample.	RPD between injections must be <20%.	Correct the problem, re-prepare, and reanalyze all associated samples.

TABLE 5-8
Calibration and QC Requirements for Hexavalent Chromium – SW7199 and EPA218.6
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
MS	One per 20 project-specific samples.	All analytes within limits specified in Appendix A.	None.
Laboratory Sample Duplicate	Once per analytical batch if MSD not performed.	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%. One sample result <RL and a difference of ±2 times the RL.	None.
LCS	At least one per analytical batch.	All analytes within limits specified in Appendix A.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
pH Buffer Solution Modification	As needed because of sample matrices that cause the analytical column to overload. All QC samples and analyses will use the modified buffered solution when needed.	A modified pH-adjustment buffer that contains 10 times less ammonium sulfate (33 g/L) but the same concentration of ammonium hydroxide as the buffer prescribed in SW7199/ EPA218.6.	None.
MS Dilute and Spike (see Section 5.3.3.1)	As directed in Section 5.3.3.1.	Spike recovery 85 to 115% and peak within RT window.	Dilute two aliquots 1:5, spike one with 1 μg/L of hexavalent chromium and analyze the other unspiked. Continue the procedure using successively greater dilutions of two aliquots until RT and recovery criteria are met.

Note:
RT = retention time

TABLE 5-9
Soil Preparation Method SW3060A for Method SW7199
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
2.5 grams sample to a final volume of 100 ml must be used for each sample	Each sample in the preparation batch.	Follow method preparation for all samples, method blank, and QC samples.	
Method Blank	One per preparation batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
LCS	One per preparation batch.	Spike at concentration specified in method. Recovery range 80 to 120%.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
Soluble Matrix Spike	One per preparation batch.	Spike at concentration specified in method. Recovery range 75 to 125%.	None.
Insoluble Matrix Spike	One per preparation batch.	Spike at concentration specified in method. Recovery range 75 to 125%.	None.
Post Digestion Spike	One per preparation batch.	Spike at concentration specified in method. Recovery range 85 to 115%.	None.

TABLE 5-10
Calibration and QC Requirements for Stable Isotopes[a]
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Instrument Standardization	Daily, prior to sample analysis.	Laboratory SOP.	Perform instrument maintenance.
Laboratory Sample Duplicate	Every sample analyzed five times.	Laboratory SOP.	Perform instrument maintenance and reanalyze samples.

[a] ^{18}O and deuterium

TABLE 5-11
Calibration and QC Requirements for TPH, BTEX, Herbicides, and Dissolved Gases – SW8015B, SW8021B, SW8151A, and RSK-175S
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (minimum 5 points)	Prior to sample analysis, or when calibration verification fails.	If the %RSD is ≤20%, the average RRF may be used for quantitation; otherwise use calibration curve with coefficient of correlation or determination ≥0.99.	Correct the problem and repeat the ICAL.
Continuing Calibration Verification	At the start of each analytical sequence and after every 10 samples, and at the end of the sequence.	Analytes within ±15% of expected value.	Correct the problem, recalibrate, and reanalyze all samples since the last acceptable continuing calibration verification.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Surrogate Spike	Every standard, sample, method blank, MS/MSD, and LCS.	All surrogates in samples, method blank, MS/MSD, and LCS within limits specified in Appendix A.	Correct the problem and reanalyze (re-prepare if necessary).
MS/MSD	One set per 20 samples.	Full target list spike required within limits specified in Appendix A. Not applicable for RSK-175.	None.
LCS	At least one per analytical batch.	Full target list spike required within limits specified in Appendix A.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.
Second Detector or Second Column Confirmation (does not apply to SW8015B or RSK-175)	All samples with results above the RL objectives must be confirmed within the holding time.	Confirmation to be done using a second detector, or second column of dissimilar phase and retention characteristics (or gas chromatography/mass spectrometry if sample concentration is sufficiently high). All calibration and QC acceptance criteria specified for primary analysis must be met in the confirmation analysis.	Failure to perform confirmation will result in potential resampling and analysis at no cost to the project.

Note:
RRF = relative response factor

TABLE 5-12
Calibration and QC Requirements for Pesticides and PCBs – SW8081A and SW8082
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Multipoint ICAL (minimum 5 points) for single-response pesticides; single-point calibration for toxaphene and chlordane; multipoint calibration for Aroclors 1016 and 1260 only, but include midpoint standard for all other Aroclors for pattern recognition; if a specific Aroclor is found in any sample, quantitation for that Aroclor must be done using 5-point calibration	Prior to sample analysis or when calibration verification fails.	To use average RRF for quantitation of any analyte, % RSD must be ≤20%; otherwise use calibration curve with coefficient of correlation or determination ≥0.99.	Correct the problem and repeat the ICAL.
Second-source calibration verification – pesticides and Aroclors 1016 and 1260 (or Aroclors identified in samples)	Once for each multipoint ICAL.	All analytes within ±15% of expected value.	Correct the problem, then recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Continuing calibration verification – pesticides and Aroclors 1016 and 1260 (or Aroclors identified in samples)	At the start of each analytical sequence; after every 12 hours or 10 samples, whichever is more frequent; and at the end of the sequence.	All analytes within ±15% of expected value.	Correct the problem, then recalibrate and reanalyze all samples since the last acceptable continuing calibration verification.
Endrin/DDT breakdown check (not applicable when analyzing for Aroclors/PCBs only)	At start of each 12-hour period.	Breakdown of either endrin or DDT ≤15%.	Evaluate injector port and take corrective action; recalibrate and reanalyze affected samples if necessary.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Surrogate Spike	Every standard, sample, method blank, MS/MSD, and LCS.	At least one of the surro-gates in samples, method blank, MS/MSD, and LCS within limits specified in Appendix A.	Correct the problem and reanalyze (re-prepare if necessary).
MS/MSD	One set per 20 project-specific samples.	Full target list spike required within limits specified in corresponding Appendix A.	None.
LCS	At least one per analytical batch.	Full target list spike required within limits specified in corresponding Appendix A.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.

TABLE 5-12
Calibration and QC Requirements for Pesticides and PCBs – SW8081A and SW8082
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Second Column Confirmation	All samples with results above the RL objectives must be confirmed within the holding time.	Confirmation to be done using second column of dissimilar phase and retention characteristics (or gas chromatography/mass spectrometry if sample concentration is sufficiently high). All calibration and QC acceptance criteria specified for primary analysis must be met in the confirmation analysis.	Failure to perform confirmation will result in potential resampling and analysis at no cost to the project.

Note:

DDT = dichloro-diphenyl-trichloroethane

TABLE 5-13
Calibration and QC Requirements for VOCs – SW8260B
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
BFB Tuning	Prior to ICAL and calibration verification (every 12 hours).	Refer to criteria listed in the method.	Retune instrument and verify.
Multipoint ICAL (minimum 5 points)	Prior to sample analysis, or when calibration verification fails.	SPCCs average RRF ≥0.30a and %RSD for RRFs for CCCs ≤30% and one of the following options: Option 1 Linear – RSD for each analyte <15%. Use of the mean %RSD for all analytes ≤15% may **not** be used. Option 2 Linear – least squares regression r ≥0.995. Option 3 Nonlinear – coefficient of determination ≥0.99 (6 standards to used for a second order; 7 standards to be used for a third order).	Correct the problem and repeat the ICAL.
Second-source Calibration Verification	Once for each multipoint ICAL.	All analytes within ±25% of expected value.	Correct the problem and repeat ICAL.

TABLE 5-13
Calibration and QC Requirements for VOCs – SW8260B
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
Continuing Calibration Verification	At the start of each analytical sequence and every 12 hours thereafter.	SPCCs average RF ≥0.30c and %D for RFs for CCCs ≤20%. All other analytes within ±20% of expected value.	Correct the problem, recalibrate, and reanalyze all samples since the last acceptable continuing calibration verification.
Retention Time Window Calculated for Each Analyte	Each analyte.	Relative retention time of each analyte within ±0.06 relative retention time units of the ICAL.	Not applicable (used for identification of analyte).
Internal Standards	Each sample and QC sample, method blank, MS/MSD and LCS.	Continuing calibration verification retention time within ±30 seconds from retention time of the ICAL midpoint standard. Sample retention time within ±30 seconds from retention time of the daily continuing calibration verification. Continuing calibration verification EICP area within –50% to +100% of the internal standard responses in the ICAL midpoint standard. Sample EICP area within –50% to +100% of the daily continuing calibration verification.	Inspect mass spectrometer and gas chromatography for malfunctions; reanalyze all affected samples.
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Surrogate Spike	Every standard, sample, method blank, MS/MSD and LCS.	All surrogates in samples, method blank and LCS within limits Appendix A.	Correct the problem and reanalyze (re-prepare if necessary).
MS/MSD	One set per 20 project-specific samples.	Full target list spike required within limits specified in Appendix A.	None.
LCS	At least one per analytical batch.	Full target list spike required within limits specified in Appendix A.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.

[a]SPCC average RRF ≥0.10 for bromoform, chloromethane, and 1,1-dichloroethane.

Notes:
BFB = bromofluorobenzene
CCC = calibration check compounds
EICP = extracted ion current profile SPCC

TABLE 5-14
Calibration and QC Requirements for Semivolatile Organic Compounds – SW8270C
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
DFTPP Tuning	Prior to ICAL and calibration verification (every 12 hours).	Refer to criteria listed in the method.	Retune instrument and verify.
Multipoint ICAL (minimum 5 points)	Prior to sample analysis, or when calibration verification fails.	SPCCs average RF ≥0.050 and %RSD for RFs for CCCs ≤30% and one of the following options: Option 1: Linear – RSD for each analyte <15%. Use of the mean %RSD for all analytes ≤15% may **not** be used. Option 2: Linear – least squares regression r ≥0.995. Option 3: Nonlinear – coefficient of Determination ≥0.99 (6 standards to used for a second order; 7 standards to be used for a third order).	Correct the problem and repeat the ICAL.
Second-source Calibration Verification	Once for each multipoint ICAL.	All analytes within ±25% of expected value.	Correct the problem and repeat ICAL.
Continuing Calibration Verification	At the start of each analytical sequence and every 12 hours thereafter.	SPCCs average RF ≥0.050 and %D for RFs for CCCs ≤20%. All other analytes within ±20% of expected value.	Correct the problem, recalibrate, and reanalyze all samples since the last acceptable continuing calibration verification.
Retention Time Window Calculated for Each Analyte	Each analyte.	Relative retention time of each analyte within ±0.06 relative retention time units of the ICAL.	Not applicable (used for identification of analyte).
Internal Standards	Each sample and QC sample, method blank, MS/MSD and LCS.	Continuing calibration verification retention time within ±30 seconds from retention time of the ICAL midpoint standard. Sample retention time within ±30 seconds from retention time of the daily continuing calibration verification. Continuing calibration verification EICP area within -50% to +100% of the internal standard responses in the ICAL midpoint standard.	Inspect mass spectrometer and gas chromatography for malfunctions; reanalyze all affected samples.

TABLE 5-14
Calibration and QC Requirements for Semivolatile Organic Compounds – SW8270C
PG&E Program Quality Assurance Project Plan

QC Check	Frequency	Criteria	Corrective Action
		Sample EICP area within -50% to +100% of the daily continuing calibration verification.	
Method Blank	At least one per analytical batch.	No analytes detected at or above the RL.	Correct the problem, re-prepare, and reanalyze all associated samples.
Surrogate Spike	Every standard, sample, method blank, MS/MSD and LCS.	At least two surrogates per fraction in samples, method blank and LCS within limits specified in Appendix A.	Correct the problem and reanalyze (re-prepare if necessary).
MS/MSD	One set per 20 project-specific samples.	Full target list spike required within limits specified in Appendix A.	None.
LCS	At least one per analytical batch.	Full target list spike required within limits specified in Appendix A.	Correct the problem, re-prepare, and reanalyze the LCS and all samples in the analytical batch.

Note:
DFTPP = decafluorotriphenylphosphene

SECTION 6

Data Reduction, Validation, and Reporting

6.1 Laboratory Data Management

Data reduction will be performed manually or by using appropriate computer software. Quantitation procedures specified for each method must be followed. If data reduction is performed manually, the documentation must include the formulas used. Computer software used for data reduction must have been previously verified by the laboratory for accuracy. Documentation of the software verification must be maintained in the laboratory. All data reduction documentation must allow re-creation of the calculations.

All data will undergo a minimum of three levels of review at the laboratory prior to release. The analyst performing the tests shall initially review 100 percent of the data. After the analyst's review has been completed, 100 percent of the data shall be reviewed independently by a senior analyst or by the section supervisor for accuracy, completeness and compliance with calibration, QC requirements, and holding times. Analyte identification and quantitation must be verified. Calibration and QC results will be compared with the applicable control limits. RLs should be reviewed to make sure they meet the project objectives. Results of multiple dilutions should be reviewed for consistency. Any discrepancies must be resolved and corrected. Laboratory qualifiers will be applied when there are nonconformances that could potentially affect data usability. These qualifiers must be properly defined as part of the deliverables. All issues that are relevant to the quality of the data must be addressed in a case narrative. The laboratory QC manager will review a minimum of 10 percent of data or deliverables generated for the PG&E Program against the project-specific requirements. A final data review will be conducted by the laboratory manager or client services representative to ensure that all required analyses were performed and that all documentation is complete.

The hardcopy and electronic data deliverable (EDD) laboratory reports for all samples and analyses will contain the information necessary to perform data evaluation.

The PG&E Program will request four types of deliverables from the laboratory, depending upon the DQOs of the individual project. The following is a synopsis of when it is appropriate to use each type deliverable:

- **Level 1.** Appropriate for screening-level sampling results. Noncritical project decisions are made using this data.
- **Level 2.** Appropriate for investigative sampling results that will be replaced with confirmatory data or results used for disposal purposes. Less critical project decisions are made using this data.

- **Level 3.** Appropriate for investigative, confirmatory, or closure results. Critical project decisions may be made using this data.
- **Level 4.** Appropriate for investigative, confirmatory, or closure results. Critical decisions may be made using this data and should be used for projects that require a high degree of confidence in the accuracy of the data.

Hardcopy deliverables (and a electronic copy in portable document format [PDF]), in summary format, equivalent to those specified in the latest versions of EPA *Contract Laboratory Program Statements of Work for Organics and Inorganics Analyses* are preferred. The laboratory data report should be organized in a format that facilitates identification and retrieval of data. Alternate reporting formats require approval from the program chemist or project chemist.

A Level 1 report will include, at a minimum, the following information (when applicable):

- Cover letter with the following information:
  - Title of report and laboratory unique report identification (e.g., sample delivery group number)
  - Project name and site location
  - Name and location of laboratory and second-site or subcontracted laboratory
  - Client name and address
  - Statement of authenticity and official signature and title of person authorizing release of the report
- Table of contents
- Summary of samples received that correlates field sample IDs with the laboratory IDs
- Laboratory qualifier flags and definitions
- Field identification number
- Date received
- Date prepared
- Date analyzed (and time of analysis if the holding time is less than or equal to 48 hours)
- Preparation and analytical methods
- Result for each analyte (dry-weight basis for soils)
- Percent solids results for soil samples
- Dilution factor (provide both diluted and undiluted results when available)
- Sample-specific RL adjusted for sample size, dilution/concentration

- Sample-specific MDL adjusted for sample size, dilution/concentration (when project objectives require reporting less than the RL)
- Units of measure
- Applicable flags for data associated with QC that are outside of control limits
- CoC forms

A Level 2 report will consist of all the elements included in a Level 1 deliverable plus the following:

- Case narrative that addresses the following:
  - Sample receipt discrepancies (e.g., bubbles in VOA samples or temperature exceedances)
  - Descriptions of all nonconformances in the sample receipt, handling, preparation, analytical and reporting processes, and the corrective action taken for each occurrence
  - Identification and justification for sample dilution
  - Serial dilution recoveries, if applicable (required in hardcopy format only)
  - Postdigestion spike recoveries, if applicable (required in hardcopy format only)
- Surrogate %Rs
- MS/MSD and LCS spike concentrations, native sample results, spiked sample results, %R, and RPDs between the MS and MSD results; associated QC limits must also be provided
- Method blank results
- Analytical batch reference number that cross references samples to QC sample analyses
- Completed sample receipt checklist

A Level 3 report will consist of all the elements included in Level 1 and 2 reports plus the following:

- Analytical sequence or laboratory run log that contains sufficient information to correlate samples reported in the summary results to the associated method QC information, such as initial and continuing calibration analyses
- Confirmation results
- Calibration blank results for inorganic analyses (required in hardcopy format only)
- ICP and ICP/MS interference check sample results that include true concentrations, measured concentrations, and the calculated %R of the elements included (required in hardcopy format only)
- Method of standard addition results, if applicable (required in hardcopy format only)

- Internal standard recovery and retention time information, as applicable
- ICAL summary, including standard concentrations, response factors, average response factors, RSDs or correlation coefficients, and calibration plots or equations, if applicable (required in hardcopy format only)
- Continuing calibration verification summary, including expected and recovered concentrations and percent differences (required in hardcopy format only)
- Instrument tuning and mass calibration information for gas chromatography/mass spectrometry and ICP/MS analyses
- Any other method-specific QC sample results

A Level 4 report will include all elements for Levels 1 through 3 and all of the associated raw data. It is imperative that the relative scale used for all chromatographic and other instrument data be supplied in a scale that facilitates review from hardcopy. Enlargements of sufficient size and clarity for complex areas of sample chromatograms will be provided. Additional information to be supplied includes the following:

- Sample preparation logs that include the following:
  - Preparation start and end times
  - Beginning and ending temperatures (e.g., water baths and digestion blocks)
- Each algorithm and an example calculation for at least one sample for each matrix analyzed
- Reconstructed total ion chromatograms or selected ion current profiles for each sample (or blank) analyzed and mass spectra(s) for each compound identified including the following:
  - Raw compound spectra
  - Enhanced or background spectra
  - Laboratory generated library spectra (for tentatively identified compounds, provide the reference mass spectra from software spectra library)
- Ion ratio information for dioxin/furan methods

6.2 Hardcopy and Electronic Deliverables

Within the timeframe specified in the laboratory statement of work, contract, or purchase order from sample receipt, the laboratory shall deliver two hardcopies and one PDF of documentation, as specified in this QAPP. In addition, the laboratory shall deliver one electronic copy of the data (i.e., EDD), as specified in the format described in Table 6-1 (or as directed in the project-specific addendum), on CD-ROM or by e-mail (in ASCII format) within the same timeframe (LabSpec-7 format [see Table 6-1]).

All electronic data files shall match the final hardcopy results. CH2M HILL requires receipt of final hardcopy results with electronic files.

All raw data will be maintained in the laboratory and will be available upon request, if not required by the project-specific deliverable. Complete documentation of sample preparation and analysis and associated QC information will be maintained in a manner that allows easy retrieval if additional validation or information is required. Appropriate back-up procedures must be implemented by the laboratory for data that are stored electronically. All data generated using gas chromatography/mass spectrometry must be maintained on COD-ROM or equivalent format and provided to CH2M HILL upon request. All documentation must be retained for a minimum of 5 years after data acquisition.

The primary responsibility for implementing these procedures in the laboratory will reside with the laboratory manager or equivalent. The laboratory manager will approve laboratory reports before submittal.

6.3 Data Validation and Verification

Depending on the project-specific objectives, the analytical results of the data collection effort will be validated by CH2M HILL. In general, there will be different levels of validation employed for the PG&E Program that correspond to the reports described in Section 6.1. In some instances a Level 3 or Level 4 data package may be obtained from the laboratory, but only a Level 1 or Level 2 validation may be conducted. Specific validation levels will be identified in the site-specific SAP or QAPP addendum. Validation of Levels 1 through 4 will always be performed by the project chemist or designee. The levels are summarized as follows:

Level 1 Import the laboratory results into the project database; use automated data validation (AutoDV), as applicable, to the project database. Verify that samples were analyzed by the methods requested, and review the data for outliers and anomalies. Prepare a brief summary validation report.

Level 2 Import the laboratory results into the project database; use AutoDV as applicable, to the project database. Verify that samples were analyzed by the methods requested, review the laboratory case narrative for events in the laboratory that affect the accuracy or precision of the data, review QC indicator data, and perform a cursory review of the data. Prepare a summary validation report.

Level 2B Import the Laboratory results into the project database; use AutoDV, as applicable, to the project database. Verify that samples were analyzed by the methods requested, review the laboratory case narrative for events in the laboratory that affect the accuracy or precision of the data, review QC indicator data, and perform a cursory review of the data. Review specific raw data, as specified in the QAPP addendum, and compare the current data with historical data. Prepare a summary validation report.

Level 3 Import the laboratory results into the project database; use AutoDV, as applicable, to the project database. Validate the analytical data, as described in the following sections, without reviewing any raw data or analyte verification. Prepare a summary validation report.

Level 3B Import the laboratory results into the project database; use AutoDV, as applicable, to the project database. Validate the analytical data as described in the following sections with review of specific raw data, as specified in the QAPP addendum, and compare the current data with historical data. Prepare a summary validation report.

Level 4 Import the laboratory results into the project database; use AutoDV, as applicable, to the project database. Validate analytical data as described in the following sections, including a review of the analytical raw data, and compare the current data with historical data. Prepare a summary validation report.

6.4 Level 3 and 4 Validation Procedures

Personnel involved in the data validation function will be independent of any data generation effort. The project chemist will have responsibility for oversight of the data validation effort. Data validation will be performed when the final data packages are received from the laboratory. Data validation will be performed on an analytical batch basis within each analytical report using the summary results of calibration and laboratory QC and the results from associated field samples. Data packages will be reviewed for all constituents of concern. Raw data will be reviewed when deemed necessary by the project chemist or as specified in QAPP addenda. Data validation procedures will include the following:

- Review of the data package for completeness
- Review of CoC records for discrepancies that might degrade data quality
- Review for compliance with holding time and QC frequency requirements
- Evaluation of all calibration and QC summary results against the project requirements
- Verification of analyte identification and calculations for at least 10 percent of the data
- Qualification of the data using appropriate qualifier flags, as necessary, to reflect data usability limitations
- Initiation of corrective actions, as necessary, based on the data review findings

Data validation will be patterned after the *Contract Laboratory National Functional Guidelines for Inorganic Data Review* (EPA, 2002) and *Contract Laboratory National Functional Guidelines for Organic Data Review* (EPA, 1999), substituting the calibration and QC requirements specified in this QAPP for those specified in the guidelines. The national functional guidelines will primarily be used as a guidance document for the application of data qualification criteria. The level of validation will be defined in the SAP or QAPP addendum.

The flagging criteria presented in Tables 6-2 and 6-3 will be used; the qualifier flags are defined in Table 6-4. Qualifier flags, if required, will be applied to the electronic sample results. A summary table of the data qualifications will be provided in the validation report. If multiple flags are required for a result, the most severe flag will be applied to the electronic result. The hierarchy of flags, from the most severe to the least severe, will be as follows: R, UJ, J, U.

A validation report will be generated for each method and sample delivery group. A copy of the validation report will be retained with the data package in the project chemistry file. The project chemist will be notified of any significant data quality problems.

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
1	VersionCode	Text	15	R	Yes	Code identifying the version of the EDD deliverable.
2	LabName	Text	10	R	Yes	Identification code for the laboratory performing the work. This value is used to distinguish between different facilities.
3	SDG	Text	15	R	No	Sample delivery group designation; always populated for all samples, including QC.
4	FieldID	Text	30	R	No	Client sample ID as appears on CoC forms with optional laboratory-assigned suffixes or prefixes to make it unique. If the sample ID on the CoC form and the prefix or suffix is more than 20 characters, abbreviate the value but make it unique. For laboratory QC samples (e.g., method blanks and laboratory control samples), use a unique laboratory sample ID.
5	NativeID	Text	30	R	No	Client sample ID, **exactly** as on CoC forms. **No prefix or suffix allowed** in client sample IDs. Used to identify the native sample from which other samples are derived (e.g., QAQCType = LR, MS, or SD). For laboratory QC samples (i.e., method blanks and laboratory control samples), use the FieldID value that was assigned. However, for laboratory blank spike duplicate samples, use the FieldID value that was assigned to the associated laboratory blank spike sample.
6	QAQCType	Text	2	R	Yes	The code for the sample type. Any field sample that is not used as laboratory QC and is not otherwise marked on the CoC forms should have the designation of “N” (normal field sample). No suffix allowed (i.e., do not add numbers as suffixes to the QAQCType values as called for in the ERPIMS guidelines). If all analyses for a given sample are diluted, the first dilution should be designated as the normal sample. If more dilutions are required, the next dilution should be designated as the first true dilution with a QAQCType value of “LR” and a LRType value of “DL” (see LRType,).

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
7	LRType	Text	3	C	Yes	This is the code for laboratory replicate sample type. Values are as follows: • Blank (if QAQCType value is not LR) • DL (dilution) • RE (re-analysis) • D (inorganic duplicate) • CF (confirmation) For multiple dilutions or reanalyses of the same sample, append the replicate number after the LRType value (e.g., RE, RE2, and RE3).
8	Matrix	Text	5	R	Yes	Sample matrix code. Valid values are as follows: “AIR”, “WATER”, or “SOIL” unless otherwise provided by the project data manager and marked on CoC forms. The use of other terms (e.g., “liquid” or “solid”) for laboratory QC is not allowed.
9	LabSampleID	Text	12	R	No	Laboratory sample ID assigned by the laboratory. Prefix or suffix is allowed. Dilutions or re-extractions are noted here. For example, “D97-11111RE” is acceptable.
10	AnalysisMethod	Text	20	R	Yes	Analysis method code. This is the ID of the analytical method performed on the sample. For example, “SW8260A.” Generic names such as “EPA” should not be used.
11	ExtractionMethod	Text	20	R	Yes	Preparation method code. A value in this field is required. If the preparation is described in the method, use “METHOD”. If there is no separate preparation required, use “NONE”. Total and dissolved metal analyses are differentiated by the value in this column. Total, TCLP, and SPLP analyses are differentiated by the value in the LeachMethod column (see below).
12	SampleDate	Date		C	No	Date of sample collection. A value is required for all samples sent to the laboratory and samples derived from those samples. Format = mm/dd/yyyy.
13	SampleTime	Time		C	No	Time of sample collection. A value is required for all samples sent to the laboratory and samples derived from those samples. Twenty-four-hour format (hh:mm).
14	ReceiveDate	Date		C	No	Date of sample receipt in the laboratory. A value is required for all samples sent to the laboratory and samples derived from those samples. Format = mm/dd/yyyy.

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
15	ExtractDate	Date		C	No	Date of sample preparation (extraction or digestion). A value is required if the ExtractionMethod field value is other than “NONE”. Format = mm/dd/yyyy
16	ExtractTime	Time		C	No	Time of sample preparation. A value is required if the ExtractionMethod field value is other than “NONE”. Twenty-four-hour format (hh:mm).
17	AnalysisDate	Date		R	No	Date of sample analysis. A value is required for all records. Format = mm/dd/yyyy
18	AnalysisTime	Time		R	No	Time of sample analysis. A value is required for all records. Twenty-four-hour format (hh:mm).
19	PercentSolids	Number		R	No	Percent solids within the sample; should be zero for water samples.
20	LabLotCtlNum	Text	10	C	No	ID for an autonomous group of environmental samples and associated QC samples prepared together. For example, the value can be a digestion or extraction batch ID. If there is no separate extraction or preparation performed, the field is left blank.
21	CAS	Text	20	R	No	CAS registry number of analyte, if available.
22	ParamID	Text	12	R	Yes	Parameter ID code for the parameter listed in the Analyte field.
23	Analyte	Text	60	R	No	Name of analyte, chemical name.
24	Result	Text	10	R	No	Result of the analysis. Surrogate analytes are reported in units of percent. All others are reported in sample concentration units. If undetected, report the adjusted MDL or adjusted RL, depending on the project. (Reported as a text field to preserve significant figures.)
25	ExpectedValue	Number		C	No	Report “100” for surrogates; report “0” for blanks; spike level plus parent result for LCS, and MS/MSD; parent value for laboratory duplicate.
26	Units	Text	10	R	Yes	Units of measure used in the analysis. Report “PERCENT” for surrogate analytes; report concentration units for all others.
27	Dilution	Number		R	No	Total dilution reported in the analysis. Default value is “1”. This value reflects changes to sample preparation amounts as defined by the method (e.g., less sample used for standard VOC analysis).

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
28	MDL	Number		C	No	Minimum detection limit adjusted for preparation and dilution. This value may be the method detection limit or the instrument detection limit, depending on the method and the project requirements. This value is **not** adjusted for percent moisture.
29	RL	Number		C	No	Reporting limit adjusted for preparation and dilution. Value is **not** adjusted for percent moisture. Equivalent to PQL.
30	LabQualifier	Text	6	R	No	Laboratory qualifier for the results, as reported on the hardcopy. Use "=" as first (or only) qualifier value for detected results if there are no other qualifiers for the result.
31	Surrogate	Text	1	R	Yes	If the chemical is a surrogate = Y; if not = N.
32	Comments	Text	240	O	No	Comment field.
33	ParValUncert	Text	16	C	No	Radiological parameter value uncertainty.
34	Recovery	Number		C	No	Percent recovery for MS, SD, LCS, LCSD, and surrogate compounds.
35	LowerControlLimit	Number		C	No	Lower control limit value for spiked compounds, expressed in units of percent. A value in this field is required if there is a value in the Recovery field (Field 34).
36	UpperControlLimit	Number		C	No	Upper control limit value for spiked compounds, expressed in units of percent. A value in this field is required if there is a value in the Recovery field (Field 34).
37	Basis	Text	1	R	Yes	Weight basis for soil (or solid) sample analysis; D = dry-weight basis, W = wet-weight basis, and X = not applicable.
38	ConcQual	Text	1	R	Yes	Concentration qualifier. Use "=" for detects, "J" for estimated value (value between detection limit and reporting limit), "U" for undetected result, and "E" for exceeded result.
39	MDLAdjusted	Number		C	No	Minimum detection limit adjusted for preparation, dilution **and percent moisture**. See the description of the MDL field (Field 28) for an explanation of the contents of this field.
40	RLAdjusted	Number		C	No	Reporting limit adjusted for preparation, dilution **and percent moisture**. Equivalent to PQL

TABLE 6-1A
Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Number	Field Name	Data Type	Data Length	Requirement	Valid Values[a]	Description and Comments
41	SampleDescription	Text	30	C	No	Full sample ID as it appears on CoC forms. In some cases, this may be the name of the sampling location instead of the sample. Required for all samples that are either collected in the field and specified on CoC forms, or derived from samples that are collected in the field and specified on COC forms.
42	LeachMethod	Text	20	R	Yes	Analytical method used for leaching the sample; applies to TCLP, SPLP, or other leaching or pre-extraction leaching procedures. Use “NONE” if the sample was not leached.
43	LeachDate	Date		C	No	Date that the leaching method was performed (use the start date for multidate leaching procedures). Value is required if the LeachMethod field value is other then “NONE”. Format = mm/dd/yyyy.
44	LeachTime	Time		C	No	Time that the leaching procedure started. Value is required if the LeachMethod field value is other then “NONE”. Twenty-four-hour format (hh:mm).
45	LeachLot	Text	10	C	No	ID of an autonomous group of environmental samples and associated QC samples **leached** at the same time. Value is required if the LeachMethod field value is other then “NONE”. If the sample was not leached, the field is left blank.
46	AnalysisLot	Text	10	R	No	ID of an autonomous group of environmental samples and associated QC samples **analyzed** together. A value in this field is required (i.e., it should not be blank).
47	CalRefID	Text	10	C	No	ID of a group of environmental and QC samples linked by a common set of calibration records. All results with the same CalRefID value will have had the same initial calibration run.

[a]For a list of valid values see Table 6-1B.

Notes:
The EDD file from the laboratory will be a comma-delimited ASCII file in the format listed above. There will be one EDD file per hardcopy report and the filename of the EDD file will be in the format REPORTID.csv, where REPORTID is the hardcopy report ID of sample delivery group.
C = Conditionally Required
EPRIMS = Environmental Restoration Program Information Management System
R = Required

TABLE 6-1B
Values for Data Guidelines for Electronic Data Deliverables
PG&E Program Quality Assurance Project Plan

Field Name	Valid Values	Meaning
VersionCode	4.20AFCEE3	Format 4.20, AFCEE data values. LabQualifier field contains the laboratory qualifier values defined in the AFCEE QAPP, Version 3.0.
VersionCode	4.20EPACLP	Format 4.20, EPA data values. LabQualifier field contains the standard EPA CLP laboratory qualifiers.
QAQCType	N	Normal, environmental sample
QAQCType	LB	Laboratory method blank
QAQCType	MS	Laboratory matrix spike sample
QAQCType	SD	Laboratory matrix spike duplicate
QAQCType	LR	Laboratory replicate (dilution, re-analysis, duplicate)

Flagging Conventions for Organic Methods
PG&E Program Quality Assurance Project Plan

Quality Control Check	Evaluation	Flag	Samples Affected
Field Duplicates	Concentration of reported analytes are >5 times the RL in either sample and RPD >UT (30% for water samples; 50% for soil samples)	J = positive results	Field duplicate pair
	One or both sample results <5 times the RL and a difference of ±2 times the RL for water (±4 times for soil).	J = positive; UJ = nondetect	
Confirmation (SW8015B; SW8021B,SW8081A; SW8151A;)	RPD between primary and confirmation results > 25%	J = positive results	Sample

Notes:

All QA/QC criteria are included in Tables 5-3 through 5-15 and Appendix A and will be used for validation criteria.

Organic methods include SW8015B, SW8081A, SW8082, SW8151A, SW8260B, SW8270C, and SW8270C SIM.

Spike recovery limits do not apply when sample concentration exceeds the spike concentration by a factor of four or more.

For methods requiring confirmation, the qualifications apply to primary analysis results (either of the two columns/detectors may be designated as the primary column/detector).

Where one MS recovery meets acceptance criteria and the other MS of the pair does not, professional judgment may be used to determine if the parent sample should be qualified for matrix effects by comparing the MS recoveries to other QC results within the batch or sample site.

Qualifier may not apply in cases where a surrogate coelutes with a nontarget analyte.

Qualifier may not apply in cases where low surrogate recoveries are due to sample dilution.

< = less than
> = greater than
%R = percent recovery
LT = lower tolerance
UT = upper tolerance

TABLE 6-3
Flagging Conventions – Minimum Data Evaluation Criteria for Inorganic Methods

Equipment Blank			All samples, same site, matrix and date
MS/MSD	%R >UT	J = positive results	MS analytes in parent sample and field duplicate if applicable
	%R <LT	J = positive results; UJ = nondetects	
	%R <10%	J = positive results; R = nondetects	
	RPD >UT	J = positive results	

TABLE 6-3
Flagging Conventions – Minimum Data Evaluation Criteria for Inorganic Methods
PG&E Program Quality Assurance Project Plan

Quality Control Check	Evaluation	Flag	Samples Affected
MS Dilute and Spike for hexavalent chromium by Methods SW7199 or EPA218.6 (see Section 5.3.3.1)	Spike recovery 85-115% and peak within recovery time window. If criteria are not met, the laboratory is required to dilute two aliquots 1:5, spike one with 1 μg/L of hexavalent chromium and analyze the other unspiked. Continue the aforementioned procedure using successively greater dilutions of two aliquots until recovery time and recovery criteria are met.	Choose the dilution where the RT/recovery criteria are met. If RT/recovery criteria are met at a 1:1 dilution, data qualification is not required for detected or nondetected results. If RT/recovery criteria met at dilution greater than a 1:1, elevate the RL for nondetected results and qualify the data U at a level equal to the RL multiplied by the dilution factor of the acceptable analysis (apply ValAdj validation reason). If RT/recovery criteria are not met: a) Analysis performed only at a 1:1 dilution: J positive results (apply LabA&P validation reason) UJ or R nondetects determined in conjunction with Project Chemist (apply LabA&P validation reason) b) Analysis performed at subsequent dilutions and criteria are still not met: J flag positive apply LabA&P validation reason) Elevate RL - UJ or R nondetects, determined in conjunction with project chemist (apply LabA&P validation reason)	Sample
Post digestion Spikes/Recovery Test (Metals only) (Step 1 - following MS/MSD, only required if the MS/MSD fails)	Spike results indicate performance of Dilution Test required (i.e. MS/MSD Failed), but Dilution Test not done.	J = positive results, UJ = nondetects	All samples in digestion batch if Dilution test not performed
	%R >UT	J = positive	
	%R <LT	J = positive results, UJ = nondetects	

TABLE 6-3
Flagging Conventions – Minimum Data Evaluation Criteria for Inorganic Methods
PG&E Program Quality Assurance Project Plan

Quality Control Check	Evaluation	Flag	Samples Affected
Dilution Test (Step 2 - following Post digestion spike, only required if the PDS fails)	If concentration is >25 times the RL and percent difference >UT	J = positive results UJ = nondetects	Analytes in parent sample if analytical spike not performed
MSA (GFAA only) for samples where postdigestion spike (performed as a result of unacceptable serial dilution) fails	r <0.995	J = positive results	Sample
Field Duplicates Laboratory Sample Duplicates	Concentration of reported analytes are >5 times the RL in either sample and RPD >20%	J = positive results	Field duplicate pair
	One or both sample results <5 times the RL and a difference of ±2 times the RL	J = positive results; UJ = nondetects	

Notes:

< = less than

> = greater than

All QA/QC criteria are included in Tables 5-3 through 5-15 and Appendix A and will be used for validation criteria.

Spike recovery limits do not apply when sample concentration exceeds the spike concentration by a factor of four or more.

CCB = continuing calibration blank

ICB = Initial calibration blank

LabA&P = laboratory accuracy and precision criteria not met

LT = lower tolerance

MSA = method of standard addition

UT = upper tolerance

ValAdj = Value reported by laboratory adjusted because of matrix issues.

TABLE 6-5
Qualifier Flag Definitions
PG&E Program Quality Assurance Project Plan

Flag	Definition
J	Analyte was present but reported value may not be accurate or precise.
R	The result has been rejected.
U	Analyte was analyzed for but not detected at the specified detection limit.
UJ	Analyte was not detected above the detection limit objective; however, the reported detection limit is approximate and might not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

SECTION 7

Performance Evaluations

To assess sample and data collection procedures, performance evaluations will be conducted that include of technical systems audits and performance audits.

7.1 Technical Systems Audits

7.1.1 Laboratory Audits

The laboratories participating in the data collection effort will be prequalified by the project management teams. A surveillance audit program that requires routine technical system audits will be instituted. Laboratory prequalification and the surveillance audits may also be undertaken by regulatory agencies. Laboratory prequalification audits may be performed as onsite audits, desk audits, or a combination of both, depending on the scale and sensitivity of the project.

7.1.1.1 Onsite Laboratory Prequalification Audit

An onsite laboratory prequalification audit in conjunction with a desk audit (see Section 7.1.1.2) is the preferred audit when using a new laboratory. The onsite laboratory audit will start with a pre-audit meeting during which the auditor will discuss with the laboratory staff the purpose of the audit, the schedule and areas to be audited, and the procedures that will be followed. The meeting may include a brief tour of the laboratory. The audit will then be conducted. The auditor will assemble the findings at the conclusion of the audit and discuss the findings with laboratory staff.

Critical items that will be addressed in a technical system audit include, but may not be limited to, the following:

- Calibration procedures and documentation
- Treatment and handling of standards
- Completeness of data forms, notebooks, and other reporting requirements
- Data review and verification procedures
- Data storage, filing, and recordkeeping procedures
- Sample custody procedures
- QC procedures, tolerances, and documentation
- Operating conditions of facilities and equipment
- Documentation of staff training and instrument maintenance activities
- Systems and operations overview

A written audit report will be sent to the laboratory within a specified time. A copy of the audit report will be sent to the project manager, and a copy will be retained in the project files.

The need for follow-up action will be determined based on the laboratory's responses. If an audit identifies an unacceptable condition or unacceptable data, the laboratory will be responsible for developing and initiating corrective action to resolve the situation. The project manager will be notified if the nonconformance impacts the project and requires resources not normally available to the project team. In such cases, the project manager will decide whether resources to pursue corrective action will be made available.

7.1.1.2 Desk Prequalification Audit

In part, a prequalification audit is performed to provide a perspective of the laboratory operations and the internal auditing and data review processes. Noncritical samples, split samples, or performance evaluation samples will be sent to the laboratory as part of the prequalification audit to ascertain the laboratory's ability to produce quality data. Generally, this process starts by sending guidance documents (e.g., QAPP, SAP, and SOW) to the laboratory for review. After a review and confirmation, the laboratory will follow the guidance documents to the best of their ability and to the project chemist's satisfaction. The auditor will request copies of accreditation audits (e.g., ELAP, NELAP, or AFCEE), SOPs, an example data package, and the laboratory's quality assurance manual. After a review of the laboratory's documentation (including instrument output, analytical reports, and other documentation specific to a batch of samples), samples can be sent to the laboratory. The data will be validated by using the Level 4 protocol described in Section 6.3 and reviewing the laboratories QC documentation. The corrective actions described in Section 7.1.1.1 may also apply.

7.1.2 Field Audits

Field audits will be performed annually to verify the performance of field procedures. The audit will evaluate the following:

- Sample containers and preservatives
- Sample collection and identification procedures
- Sample custody, handling, and shipping procedures
- Equipment decontamination procedures
- Calibration of field instruments and performance of field tests
- Documentation of field activities, maintenance of field records, and document control

7.2 Performance Audits

7.2.1 Performance Evaluations

Laboratories are required to participate in a performance evaluation program, in accordance with the California ELAP. Any method or analyte failure in a performance evaluation that affects the certification status of the laboratory with the National Environmental Laboratory Accreditation Program or the state of California must be immediately communicated to the program chemist.

Blind performance evaluation samples will be submitted to the laboratories as deemed necessary by the project chemist or project team.

7.2.2 External Audits

Announced and unannounced audits of the field operations and laboratories may be conducted by CH2M HILL during any stage of the project.

7.2.3 Internal Audits

Annual audits of the laboratory shall be conducted by the laboratory's quality assurance officer. The audits shall verify, at a minimum, that written SOPs are being followed; standards are traceable to certified sources; documentation is complete; data review is being done effectively and is properly documented; and data reporting, including electronic and manual data transfer, is accurate and complete. All audit findings shall be documented in QA reports to management. Necessary corrective actions shall be taken within a reasonable timeframe. The quality assurance office shall verify that such actions are effective and complete and document their implementation in an audit closeout report to management.

SECTION 8

Preventive Maintenance

The primary objective of preventive maintenance is to promote the timely and effective completion of a data collection effort. The maintenance program should be designed to minimize the downtime of crucial sampling and analytical equipment caused by component failures. The maintenance program should establish the following:

- Maintenance responsibilities
- Maintenance schedules
- An adequate inventory of critical spare parts and equipment

8.1 Maintenance Responsibilities

Laboratory instrument maintenance is the responsibility of the participating laboratory. Generally, the laboratory manager or supervisor is responsible for the instruments in their work areas; they will establish maintenance procedures and schedules for each instrument. Laboratories should maintain service agreements with instrument manufacturers or a reputable service company to minimize downtime if there is an instrument malfunction.

Maintenance responsibilities for field equipment are assigned to the field team leader for specific sampling tasks. However, the field team using the equipment is responsible for checking the status of the equipment prior to use and reporting any problems encountered. The field team is also responsible for ensuring that critical spare parts are included as part of the field equipment checklist. Nonoperational field equipment should be removed from service and a replacement obtained. All field instruments will be properly protected against inclement weather conditions during the field investigation.

8.2 Maintenance Schedules

The effectiveness of any maintenance program depends, to a large extent, on adherence to specific maintenance schedules for each piece of equipment. Nonroutine maintenance activities are conducted as needed. Manufacturers' recommendations should provide the primary basis for establishing maintenance schedules. Service contracts may be used to implement maintenance schedules.

Each analytical instrument should be assigned an instrument logbook; all maintenance activities for will be the documented instrument in the logbook. Logbooks should contain the following information:

- Date of service
- Person performing the service
- Type of service performed and the reason for service
- Replacement parts installed, if appropriate
- Date of next scheduled service
- Any other useful information

8.3 Spare Parts

An adequate inventory of spare parts is required to minimize equipment down time. The inventory will include the following:

- Parts and supplies that are subject to frequent failure
- Parts and supplies that have limited useful lifetimes
- Parts and supplies that cannot be obtained in a timely manner should failure occur

Field managers and laboratory managers are responsible for maintaining an adequate inventory of spare parts. In addition to spare parts and supply inventories, an in-house source of backup equipment and instrumentation should be available.

SECTION 9

Data Assessment

9.1 Data Quality Assessment

All laboratory data will be evaluated according to the QA acceptance criteria specified in Tables 5-3 through 5-15 and Appendix A Limitations regarding data usability will be assigned, if appropriate, in accordance with the validation process described in Section 7. Field data will be evaluated according to the appropriate SOP.

9.2 Reconciliation with Project Objectives

The PG&E Program includes projects and sites with varying tasks and objectives. The procedure for data reconciliation will be a function of the project-specific objectives and will be addressed in the project-specific documents.

SECTION 10

Corrective Action

Corrective action may be required as a result of deviations from field or analytical procedures. Deficiencies identified in audits and data quality evaluations may also call for corrective action. All project personnel have the responsibility to identify, report, and solicit approval for corrective actions to resolve conditions that are adverse to data quality.

Tables 5-3 through 5-15 specify the corrective actions to be taken when deviations from calibration and QC acceptance criteria occur. Field and laboratory staff may encounter conditions requiring immediate corrective action that are not addressed in this QAPP, the SAPs, or QAPP addenda. These staff will document conditions and the results of corrective actions in a field logbook or laboratory nonconformance report and communicate their actions as soon as feasible to the appropriate people (field team leader, laboratory supervisor, project chemist, project manager, and if necessary, the PG&E Program quality manager) for immediate input. A mechanism must be in place to allow for supervisory review or client input, or both, for all deviations or deficiencies. A corrective action reporting system that requires immediate documentation of deviations or deficiencies and for supervisory review of the actions taken to correct them will be established. At a minimum, the corrective action report should include the following information:

- The type of deviation or deficiency
- The date of occurrence
- The impact of the deviation or deficiency, such as samples affected
- The corrective action taken
- Documentation that the process has been returned to control

The only time that a corrective action report may be waived is when a deviation or deficiency is immediately corrected and its impact is precluded. An example would be an unacceptable ICAL that is repeated before samples are analyzed.

Each corrective action report must be reviewed and approved by a person of authority, such as the field team leader or laboratory supervisor. The ultimate responsibility for the laboratory corrective action process is the QC manager, who must ensure that proper documentation, approval, and close out of all out-of-control or nonconformance events is performed. A nonconformance report will summarize each nonconformance condition. Corrective action reports that could potentially affect data quality must be brought to the attention of the project chemist. Report disposition will be the responsibility of the project chemist. The project manager may be notified about a particular report at the project chemist's discretion. Copies of corrective action reports must be maintained in the laboratory or field project files.

SECTION 11

Quality Assurance Reports

Where specified in the SAP, work plan, or QAPP addendum, a QA report or data quality evaluation will be submitted by the project chemist to the project manager on a predetermined interval established in the SAP or QAPP addendum. The report will summarize the results of the data validation and the data assessment. The results should be presented in a manner that facilitates decision making. For example, temporal data may be more effectively presented if supplemented by a time plot. Any significant quality problems and recommended solutions should be included in the report. Limitations on data usability identified during data validation should be highlighted. Results of the data assessment should be reconciled with the project objectives.

SECTION 12

Data Management

Electronic data associated with CH2M Hill projects will be used to generate validation reports, risk assessment calculations, modeling results, data summary tables, maps, and other figures. The data management will follow CH2M HILL standard procedures for environmental data collection. Other consultants or contractors may use other electronic data management programs, which will be described in the SAP or QAPP addendum. However, any system used must be capable of storing and managing the information as follows:

- Simple procedures to get rapid access to stored data
- Data entry methods of known accuracy and efficiency
- Well-documented validation procedures for electronic databases
- Sampling data management using unique sample IDs
- A sampling inventory of newly collected data and methods of sample inventory reconciliation
- Sample-specific attributes, including location IDs, sample type and media, and sample date
- Reporting and delivery formats to support data analysis and reduction

12.1 Archiving

Hardcopy and electronic versions will be archived in project files and on electronic archive tapes for the duration of the project, as specified in contractual agreements, or for a minimum of 5 years. All electronic data will be subject to routine back-up until it is archived for long-term retention.

12.2 Data Flow and Transfer

The data flow from the laboratory and field to the project staff and data users will be sufficiently documented to ensure that data are properly tracked, reviewed, and validated.

12.3 Record Keeping

In addition to the data management procedures for analytical data provided in Section 6.1, the laboratory will maintain electronic and hardcopy records sufficient to re-create each analytical event. At a minimum, laboratory will maintain the following records:

- Raw data, including instrument printouts, bench work sheets, and chromatograms, with compound identification and quantitation reports
- Laboratory-specific, written SOPs for each analytical method and QA/QC function implemental during the analysis of project samples

Notes:

Please keep in mind, Screening Levels are constantly revised by the EPA. The appropriate Screening levels are specific to the project, the location, the agency providing oversight, and the overall Goals of the project.

mg/kg = milligrams per kilogram
ug/kg = micrograms per kilogram
µmhos/cm = micromhos per centimeter

All soil results (with the exception of Waste characterization) must be reported as dry weight
SW 7199 soil analysis must be accompanied by a SW 3060A extraction
PCB - LCS, MS, and MSD only require Aroclor-1016 and Aroclor-1260 spikes

[1] For soil, most stringent of:
EPA Regional Screening Levels - 2008 and May 2012
CHHSL = California Human Health Screening Levels, January 2005
DTSC = California Department of Toxic Substance Control, January 2005

Notes:

Please keep in mind, Screening Levels are constantly revised by the EPA. The appropriate Screening levels are specific to the project, the location, the agency providing oversight, and the overall Goals of the project.

mg/L = milligrams per liter
ug/L = micrograms per liter
µmhos/cm = micromhos per centimeter
pCi/L = picocuries per liter
PCB - LCS, MS, and MSD only require Aroclor-1016 and Aroclor-1260 spikes

[1] For groundwater, most stringent of:
EPA Regional Screening Levels - 2008 and May 2012
Federal Drinking Water Standards, MCLs
*Secondary Federal Drinking Water Standards, MCLs
California Drinking Water Standards, MCLs

Addendum to the PG&E Program Quality Assurance Project Plan for the Topock Groundwater Remedy

1.0 Introduction

This Addendum to the *PG&E Program Quality Assurance Project Plan* (QAPP) Revision 2 (CH2M HILL 2012) has been prepared to address any variations from the QAPP or specifications associated with the Topock Groundwater Remedy (the project) that are not included or defined in the QAPP document. The laboratories will be required to adhere to the QAPP and then use the specific information outlined within this Addendum to supersede the QAPP information.

In compliance with the 1996 Corrective Action Consent Agreement (CACA) (California Department of Toxic Substances Control [DTSC] 1996) and the Remedial Design/Remedial Action (RD/RA) Consent Decree (DOI 2013), the sampling and analytical procedures set forth in the QAPP (CH2M HILL 2012), this Addendum, as well as the Sampling and Monitoring Plan (Volume 2 of the Operation and Maintenance Manual) will be followed during remedy operation.

Over the decades-long operation and optimization of the remedy, updates to the aforementioned documents may be necessary for a variety of reasons (e.g., changes driven by field conditions, changes driven by regulations, etc.). As with current practice and required by the QAPP, Standard Operating Procedures (SOPs) will be reviewed on annual basis, at a minimum, and PG&E will inform the agencies of material and substantive changes to the SOPs, as well as the rationale for the changes, prior to implementation.

2.0 Project Organization and Responsibility

2.1 Project Organization

For information on project organization refer to the Operation and Maintenance (O&M) Manual, Main Text, Section L2, and the Construction/Remedial Action Work Plan Section 2.1.

2.2 Certification Requirements

All laboratories participating in analytical services will have a documented Quality System and be certified under the National Environmental Laboratory Accreditation Program (NELAP) or the State of California Environmental Laboratory Accreditation Program (ELAP). Laboratories in California will be required to be certified under the ELAP. Additional accreditation may also be required. The laboratory managers will be responsible for ensuring that all laboratory personnel have been properly trained and are qualified to perform their assigned tasks.

3.0 Sampling Procedures

3.1 Sampling Design

Sampling and monitoring activities are needed for compliance purposes and for effective operation and maintenance of the groundwater remedy. The rationale for the sampling design (sampling locations, frequency, and analytes) and the Data Quality Objectives (DQO) process is documented in the O&M Manual, Volume 2, Sampling and Monitoring Plan.

3.2 Field Sampling Procedures

The groundwater remedy will use the project-specific field database, planned sample tables, chain-of-custody (CoC) forms, and other database-generated paperwork (e.g., purge forms, calibration log books). All sample collection and related activities will follow the SOPs provided in Appendix A of the Sampling and Monitoring Plan. Exhibit 3-1 lists the relevant SOPs for the remedy. Over the decades-long operation of the remedy, SOPs may be updated. The Field Lead and Project Chemist will ensure that the sampling is performed in accordance with the updated SOPs.

Information from SOP-L11 was incorporated into SOP-L9; SOP-L11 was deleted.
Information from SOP-L12 was incorporated into SOP-L1 and SOP-L2; SOP-L12 was deleted.

3.3 Additional or Revised QC Steps for Hexavalent Chromium

The following quality control (QC) steps will be implemented for all samples related to the groundwater remedy:

1. Additional QC Step – All equipment blanks will be blind (versus being identified to the laboratory as “blank”, or “EB” for equipment blanks), with the exception of additional well-specific equipment blanks for the floodplain wells (see Step 2 in Section 3.4).

2. Additional QC Step – Certified filters will be purchased for groundwater and surface water samples. These filters are packaged with manufactures’ testing data and certification. If uncertified filters must be used, each lot (if lot information is available) will be analyzed for hexavalent chromium (Cr[VI]). If no lot number information is available, one filter per day will be analyzed for Cr(VI).

3. Revised QC Step – The following protocol for Cr(VI) has been established using the ammonium sulfate buffer solution for Cr(VI) sample preservation in the field:

    - Within 2 weeks prior to any field event requiring preservation for Cr(VI), fresh buffer solution will be made and the purity checked by the laboratory; the resulting chromatogram will be emailed to the CH2M HILL project chemist for verification.

    - All Cr(VI) samples will be field-filtered and preserved to a pH range of 9.3 to 9.7 with ammonium sulfate buffer solution.

    - The laboratory will confirm preservation at the time of sample receipt.

    - The Topock groundwater remedy will use EPA Methods E218.6 or SM3500-Cr (use of Methods SW7199 and SW7196 are restricted and must be approved by the project chemist) for Cr(VI) analyses. The use of these methods was approved by DTSC in 2008 (DTSC 2008).

3.4 Additional QC Steps for Hexavalent Chromium in Select Floodplain Well Samples

In addition to the QC steps discussed in Section 3.3, the additional QC steps outlined in this section will be followed during sampling of a) monitoring wells located in or near the floodplain (as defined in Exhibit 3-2) that are currently non-detect (or detected at less than 5 parts per billion) for Cr(VI), and b) future wells located in or

near the floodplain as determined by the CH2M HILL project chemist. As water quality changes, the list of wells in Exhibit 3-2 will be reviewed periodically (initially on an annual basis) and updated as applicable.

EXHIBIT 3-2
Floodplain Wells Recommended for Additional Quality Control Steps
Addendum to the PG&E Program Quality Assurance Project Plan for the Topock Groundwater Remedy

MW-21	MW-33-040	MW-43-075	MW-52S
MW-27-020	MW-34-055	MW-43-090	MW-53D
MW-27-060	MW-34-080	MW-44-070	MW-53M
MW-27-085	MW-36-070	MW-49-135	MW-54-85
MW-28-025	MW-39-040	MW-49-275	MW-54-140
MW-28-090	MW-42-055	MW-49-365	MW-54-195
MW-29	MW-42-065	MW-52D	MW-55-45
MW-32-020	MW-43-025	MW-52M	MW-55-120
MW-32-035			

The additional QC steps for the wells listed in Exhibit 3-2 are as follows:

1. Two Cr(VI) sample containers will be filled for each floodplain well listed in Exhibit 3-2, field filtered, and preserved. The duplicate sample will be placed on hold at the laboratory and will not be analyzed unless needed to investigate an anomalous result.
    - Cr(VI) will be analyzed by method E218.6R.
    - The sample labels will have a designation of “1 of 2” and “2 of 2”.
    - The sample identifier (ID) will be recorded and the existence of two sample containers will be indicated on the CoC form.
2. For each of the wells listed in Exhibit 3-2 that have non-dedicated pumps, an extra equipment blank will be collected after decontaminating the pump and prior to lowering the pump down the well. For example, if sampling has just been completed at MW-42-055 and the next well is MW-42-065, the sampling team will need to decontaminate the portable pump and then collect MW-42-065-XXX-EB before placing the pump in MW-42-065.
    - The well-specific equipment blanks (e.g., MW-42-065-XXX-EB) will be placed on hold and will not be analyzed unless needed to investigate an anomalous result.

The additional QC steps were put into place due to the sensitive nature of the sample locations, where low level detections could have large implications if shown to be correct. These additional QC steps are of little use for wells in the uplands where slight differences of a few ppb are of less concern, especially where the sample concentration is less than the background concentration. At the same time, samples with concentrations greater than 10 – 15 ppb can have sufficient variability within the analytical methods to exceed the possible influence from contamination sources or colloidal suspension concentrations.

Extra containers and EBs prescribed in Steps 1 and 2 above are collected to help determine the source for any possible anomalous results found in the wells listed in Exhibit 3-2. All the wells located near the river (specifically those around the active reducing zone) are susceptible to colloidal suspension of chromium which can cause a high variability between the Cr(T) and Cr(VI) results. The special EBs are collected to eliminate the possibility of cross-contamination between the wells (i.e., to verify that carry-over is not occurring).

Note that the MW-55 and MW-21 wells are not necessarily in the floodplain, but are located in areas “near” the river where the “normal” results are either non-detect or low concentrations. In the event results are “detected”

higher than normal or where the Cr(T) and Cr(VI) concentrations differed more than is considered normal, PG&E works to determine the likely causes and provide the analysis in the report where the results are reported.

3.5 Additional QC Steps for Cr(T) and Cr(VI) — River Samples

In addition to the QC steps discussed in Section 3.3, all river samples (shoreline and in-channel) will require the following additional QC steps:

1. For surface water sampling events; three analyte-specific sample containers will be collected from each sample location for both total chromium (Cr[T]) and Cr(VI). The laboratory will analyze the initial sample aliquot; if that result is an anomalous result (any detected concentration in the river will be considered anomalous), corrective action will be implemented and an additional aliquot of the original sample will be reanalyzed along with an aliquot from each of the additional sample volumes for comparison purposes. In addition, the agencies will be notified immediately if anomalous Cr(T) or Cr(VI) results are detected in river samples which require reanalysis.
    - Cr(VI) will be analyzed by method E218.6R. Cr(T) will be analyzed by SW-6020A.
    - The sample labels will have a designation of “1 of 3”, “2 of 3”, and “3 of 3”.
    - The sample ID will be recorded and the existence of three sample containers will be indicated on the CoC form.
2. Blank samples will be collected daily from two sets of randomly selected dedicated equipment (tubing).
3. In addition, one atmospheric (ambient) blank will be collected at the PG&E Topock site per day of river sampling. The atmospheric blank and the dedicated equipment blanks will be placed on hold at the laboratory, and analyzed only in event of river sample detections.
4. The laboratory is required to ensure that the buffer solution and initial calibration method blank concentrations are less than the method detection limit (MDL) prior to proceeding with sample analysis. In all cases in which corrective actions are applied, the CH2M HILL project chemist will be notified to aid in the corrective action process.
5. In the event corrective action is taken due to an anomalous result, the laboratory will document (in detail) the procedure in the analytical report’s case narrative. The narrative must include, at a minimum, the identity of each “anomalous” detection, the result from each analysis, the basis for what likely caused the detection if the detection is found unrelated to the actual sample (e.g., background contamination), and any future corrective action that will be implemented to resolve the identified problem(s).

3.6 Additional Laboratory QC Steps

To ensure precision and accuracy for the project, analytical laboratories will conduct the following additional QC steps for Cr(T) analyses, Cr(VI) analyses, and all other analyses.

All Cr(T) Analysis

1. The laboratory must use the average of three scans/injections to calculate relative standard deviation (RSD) for the analysis of all metals.
2. All reported detections must have a %RSD of less than or equal to 15% for the triplicate inductively coupled plasma/matrix spike injections.
3. All groundwater and soil samples will be digested using an appropriate method.
4. The laboratory may be asked to investigate situations where the Cr(T) and Cr(VI) results differ by more than 20% relative percent difference (RPD) for samples with concentrations > 4 ppb.

All Cr(VI) Analysis

1. The laboratory will analyze a QC sample (low level check standard) after the initial calibration, at the reporting limit (RL) concentration.
2. The laboratory is required to ensure that the buffer solution, initial calibration blank, and method blank concentrations are less than the MDL prior to proceeding with sample analysis. Sample analysis will only proceed after the buffer solution and method blank concentrations are less than the MDL.
3. Initial calibration must be re-established if any of the following occur:
   - The last calibration was established more than 2 weeks prior to the start of a sample's analysis.
   - Two consecutive continuing calibration standards fail.
   - Any of the following operating conditions change:
     - Major maintenance is performed.
     - The system fluid is changed.
     - The instrument requires relocation.
     - The analytical column is replaced.
4. The laboratory will establish a retention time window and monitor the samples for exceedances.
5. If any calibration blank other than the initial calibration blank (see number 3 above) has a detection greater than the RL, and if there are detections in any sample, the laboratory records will document the concentrations and corrective action will be performed. The corrective action will include sample reanalysis and may also include change of reagents, eluate, and/or standards; and/or optimizing instrumentation. In all cases in which corrective actions are applied, the CH2M HILL project chemist will be notified to aid in the corrective action process.
6. If any calibration blank other than the initial calibration blank (see number 3 above) has a detection greater than the MDL but below the RL, and if there are detections in any sample, the laboratory records will document the concentrations and corrective action will be performed. However, the manner of reporting results will remain unchanged (i.e., results less than the RL will be reported as a non-detected result at 0.2 µg/L). Corrective action may include sample reanalysis; change of reagents, eluate and/or standards; and/or optimizing instrumentation. In all cases in which corrective actions are applied, the CH2M HILL project chemist will be notified to aid in the corrective action process.

All Other Analyses

1. The laboratory will supply sample containers that are pre-cleaned and certified to EPA-specified standards for low level chemical analysis for all PG&E programs.
2. In all cases in which corrective actions are applied, the CH2M HILL project chemist will be notified to aid in the corrective action process.

4.0 Method Quality Objectives and Quality Assurance Program

The data quality goal for the groundwater remedy is to achieve defensible data with the highest quality possible, given the variability of parameters for the groundwater remedy. The final output is a data set designed and validated to meet the qualitative and quantitative needs of the project. See Tables 4-1 through 4-3 at the end of this Addendum for project-specific reporting level requirements and EPA/California screening-level information that may differ from the QAPP.

4.1 Analytical Requirements

This Addendum specifies project-specific analytes and analytical methods that differ from the QAPP. All methods, analytes, or QC parameters specified in this Addendum that may differ from the QAPP supersede the criteria in the QAPP.

4.1.1 Reporting Limits

RLs should be a minimum of two times greater than the calculated MDLs. RLs used by the laboratory should not be greater than the RL objectives listed in Tables 4-1 through 4-3. Note that in Table 4-1, the 0.4 mg/kg RL used for this project is currently the lowest RL achievable using SW7199/3060A and is well below the industrial soil screening level. Screening levels are established by use of statistical analysis and are not based on the analytical capabilities of laboratories or methods.

Only analytes detected at concentrations greater than the project-specific RL will be reported. Analytes detected at less than the RL will be flagged "U" and reported as not detected at the RL.

RLs and sample results shall be reported to two significant figures if less than 10 micrograms per liter (µg/L) (parts per billion) and to three significant figures otherwise.

4.1.2 Calibration

In the initial calibration (for all instruments), a standard at a concentration equal to or less than the RL must be included.

Initial calibration must be re-established if any of the following conditions exist:

- The last calibration was established more than 1 year prior to the start of a sample's analysis (gas chromatography, gas chromatography-mass spectrometry, inductively coupled plasma, and inductively coupled plasma-mass spectrometry)
- The last calibration was established more than 2 weeks prior to the start of a sample's analysis (ion chromatography, and other "wet" chemistry analytical instruments)
- Two consecutive continuing calibration standards fail
- The operating conditions change; for example, any of the following:
  - Major maintenance is performed
  - The fluid or gas "carrier" type changes
  - The instrument requires relocation

4.1.3 Matrix Spike for Hexavalent Chromium Analyses

Interference from Topock groundwater is known to reduce the sensitivity of Method EPA 218.6. This can result in an incorrect assessment of the analyte identification or the specific RL if the Matrix Spike and Dilution Protocol is not followed (see Section 5.4.4.1 of the QAPP). All Topock groundwater and surface water samples analyzed by Method EPA 218.6 will follow the Matrix Spike and Dilution Protocol.

4.1.4 Matrix Spike and Dilution Protocol

Matrix interference has been encountered that affects the sensitivity for hexavalent chromium by ion chromatography methods. CH2M HILL shall direct the laboratories to perform an additional quality assurance/ quality control (QA/QC) analyses to aid in assessing any effect on method sensitivity for each project due to the sample matrix. All Topock groundwater and surface water samples analyzed by Method EPA218.6 will follow the Matrix Spike and Dilution Protocol.

The analytes and analytical requirements are presented in Tables 4-1 through 4-3.

4.2 Data Validation

The validation for this QAPP Addendum will follow the Level 3B designation from the QAPP and will be performed by the project chemist and designees.

5.0 Retention of Records

Hardcopy and electronic versions will be archived in project files, on electronic archive tapes, and/or other electronic storage media for the duration of remedy operation plus 10 years, as specified in contractual agreements. All electronic data will be subject to routine back-up until it is archived for long-term retention.

The PG&E Construction Manager, or designee, is responsible for ensuring that training and certification requirements of the QAPP are satisfied. The Construction Headquarters will serve as the primary repository for records during construction.

Notes:

Please keep in mind, Screening Levels are constantly revised by the EPA. The appropriate Screening levels are specific to the project, the location, the agency providing oversight, and the overall Goals of the project.

mg/kg = milligrams per kilogram
ug/kg = micrograms per kilogram
µmhos/cm = micromhos per centimeter

All soil results (with the exception of Waste characterization) must be reported as dry weight
SW 7199 soil analysis must be accompanied by a SW 3060A extraction
PCB - LCS, MS, and MSD only require Aroclor-1016 and Aroclor-1260 spikes

[1] Screening levels are established by use of statistical analysis and are not based on the analytical capabilities of labortories or methods. The 0.4 mg/kg RL used for hexavalent chromium for this project is currently the lowest RL achievable using SW7199/3060A and is well below the industrial soil screening level.
[2] For soil, most stringent of:
EPA Regional Screening Levels - 2008 and May 2012
CHHSL = California Human Health Screening Levels, January 2005
DTSC = California Department of Toxic Substance Control, January 2005

Notes:

Please keep in mind, Screening Levels are constantly revised by the EPA. The appropriate Screening levels are specific to the project, the location, the agency providing oversight, and the overall Goals of the project.

mg/L = milligrams per liter
ug/L = micrograms per liter
µmhos/cm = micromhos per centimeter
pCi/L = picocuries per liter
PCB - LCS, MS, and MSD only require Aroclor-1016 and Aroclor-1260 spike

[1] Screening levels are established by use of statistical analysis and are not based on the analytical capabilities of labortories or methods. For groundwater, most stringent of:
EPA Regional Screening Levels - 2008 and May 201
Federal Drinking Water Standards, MCLs
*Secondary Federal Drinking Water Standards, MCLs
California Drinking Water Standards, MCLs

1.0 Introduction

This volume of the Operation and Maintenance (O&M) Manual presents the contingency plans for the Pacific Gas and Electric Company (PG&E) Topock Compressor Station (TCS) groundwater remedy, as required by the 1996 Consent Agreement (California Department of Toxic Substances Control [DTSC] 1996) and the 2013 Consent Decree (U.S. Department of the Interior [DOI] 2013). Contingency planning was conducted as a part of the final groundwater remedy design process to anticipate potential risks and organize plans to mitigate these risks. A contingency plan such as this one is typically used during the design phase as a tool to anticipate potential risks and to develop methods to mitigate these risks either within the design or as part of the future system operations. The contingency planning is done using a method termed Failure Mode Effect Analysis (FMEA). The FMEA tool provides an analytical and systematic approach to reviewing potential failure modes and their associated causes, and therefore helps to assess which risks pose the greatest concern and to prioritize risk management in order to prevent problems before they arise. The objective of the FMEA process is to outline possible failures that could cause unacceptable conditions in the groundwater remedy. Mitigation measures in design and operation are focused on these issues first and foremost. The FMEA also identifies conditions that, while not unacceptable, are issues that PG&E will strive to avoid or minimize. The following types of unacceptable conditions have been identified:

- **Category A: Unacceptable Remedy Performance** — The Remedial Action Objectives (RAOs) are not met. Specifically, this could include migration of unacceptable concentrations of constituents of concern to the Colorado River, permanent expansion of the target remediation area, or not achieving the numeric cleanup goals of the RAOs.
- **Category B: Schedule** — Failures that cause the schedule to achieving the groundwater remedy RAOs to be extended by more than 5 to 15 years.
- **Category C: Cost** — Failures that cause the cost of achieving the groundwater remedy RAOs to be increased by more than $10,000,000 to $50,000,000.
- **Category D: Significant Change to Impact** — Changes (such as visual impact) that necessitate additional California Environmental Quality Act (CEQA) analysis.
- **Category E: Significant Health and Safety (H&S) or Compliance Incident** — A health and safety incident that results in lost work time for remedy or Compressor Station staff or the public; an environmental compliance Notice of Violation (other than related to remedy performance); or violation of the requirements in the Applicable or Relevant and Appropriate Requirements (ARARs).

The mitigation measures described in the FMEA tables in this Contingency Plan are taken to minimize or eliminate the likelihood, or severity, of these unacceptable conditions. The FMEA also identifies potential failures that could cause conditions that, while not unacceptable as defined above, should be prevented or minimized.

Causes of potential failures are mitigated in the design process (e.g., select equipment to accommodate a range of anticipated operational conditions), in adaptive operations (e.g., adjusting flow rates and/or carbon substrate dosing; installation of future provisional remediation, freshwater supply, and/or monitoring wells; etc.), and/or in corrective action/contingency response planning (e.g., installing additional wells). Operational mitigation descriptions include the condition that an operator would observe and the action he/she would take. A preventative maintenance schedule is proposed as an overall mitigation step to minimize risk of unexpected failures.

Contingency planning has been prepared for six key elements of the groundwater remedy:

- In-Situ Remediation System (Section 2.1)
- Remedy-produced Water Management System (Section 2.2)
- Freshwater Supply (Section 2.3)

- Power Supply (Section 2.4)
- Remedy Supervisory Control and Data Acquisition (SCADA), Control Systems, and Instrumentation (Section 2.5)
- Enhanced Evaporation at TCS Evaporation Ponds (Section 2.6)

Each system's analysis in this FMEA includes an evaluation of the likelihood and severity of each type of potential failure to help prioritize mitigation. The severity scoring is shown in Table 1.0-1 (tables are presented at the end of each section). It should be noted that the "Severity of Effect" column denotes the implication of the effect if it were to occur, which should be unlikely since the mitigation measures are being taken. As shown in Table 1.0-1, unacceptable conditions are those with a severity score of 4 or above. The type of unacceptable condition is only indicated in the FMEA tables where there is a severity score of 4 or above. A potential failure may result in a 6-month schedule increase (severity score of 2), for example, without constituting an unacceptable condition and therefore the type of unacceptable condition would not be indicated in the FMEA table for this example. Quantifiable thresholds have not been defined for condition Categories A (remedy performance), D (change to impact), and E (H&S/compliance) to distinguish between different severity scores. Severity of effect for these categories is assessed qualitatively on a relative scale. For example, an H&S incident (Category E) with a severity score of 5 is expected to be the most serious with comparatively more lost work time, injury to personnel, etc. than a severity-level 4 H&S incident. The likelihood score is also relative, with 5 being the highest likelihood, though not necessarily highly likely.

The RAOs for the final groundwater remedy are to:

1. Prevent ingestion of groundwater as a potable water source having hexavalent chromium (Cr[VI]) in excess of the regional background concentration of 32 micrograms per liter (µg/L).
2. Prevent or minimize migration of total chromium (Cr[T]) and Cr(VI) in groundwater to ensure concentrations in surface water do not exceed water quality standards that support the designated beneficial uses of the Colorado River (11 µg/L Cr[VI]).
3. Reduce the mass of Cr(T) and Cr(VI) in groundwater at the site to achieve compliance with ARARs in groundwater. This RAO will be achieved through cleanup goal of regional background of 32 µg/L of Cr(VI).
4. Ensure that the geographic location of the target remediation area does not permanently expand following completion of the remedial action.

Compliance monitoring will include groundwater and surface water sampling and will focus on confirming that the final groundwater remedy is achieving these RAOs. Compliance monitoring is primarily designed to ensure that the remedy is meeting RAOs 2, 3, and 4, relating to controlling migration and reducing mass to an adequate degree.

The Contingency Plan anticipates potential issues that may occur with the remedy and identifies design and adaptive operations elements to mitigate those issues, which have been incorporated into the 100% Design Submittal. The adaptive operations framework is presented in data quality objectives in the Sampling and Monitoring Plan presented in Volume 2 of this O&M Manual (see also figures in Section 2 of Volume 2) and is referenced in the FMEA for the IRZ. Additional mitigations identified in the FMEA that may be required and are not covered by design or adaptive operations constitute contingency actions, as outlined in this plan.

TABLE 1.0-1

Severity Scoring Used in Failure Mode and Effects Analysis
Groundwater Remedy Operation and Maintenance Manual
Volume 3: Contingency Plan
PG&E Topock Compressor Station, Needles, California

	Category				
Severity of Effect	**A - Unacceptable Remedy Performance**	**B - Schedule**	**C - Cost**	**D - Change to Impact**	**E - H&S or Compliance**
Unacceptable Conditions					
5	Remedy does not meet RAOs, cleanup goals, design objectives, or otherwise perform as required.	Very significant schedule increase more than 15 years	Very significant cost increase more than $50M	Additional CEQA analysis required	• Serious H&S incident • ARARs, mitigation measures, or other compliance Notice of Violation event
4	Not defined	Schedule increase more than 5 years	Cost increase more than $10M	Not defined	Not defined
Other Conditions					
3	Remedy performance, operational, or other issue that prompts remedy (or portions thereof) to be temporarily shut down, but does not constitute unacceptable condition as defined above	Schedule increase 1-5 years	Cost increase $1M - $10M	Not defined	Not defined
2	Less significant/nuisance issues with remedy	Schedule increase 6 mo. - 1 year	Cost increase $0.5M - $1M	Not defined	Not defined
1	An incident that has an impact in one or more of the five categories, but less than defined above.				

Notes:
ARAR = applicable or relevant and appropriate requirement
H&S = health and safety
RAO = remedial action objective

2.0 Contingency Planning

2.1 In-Situ Remediation System

The in-situ remediation system includes the following components, as described above and in Section 3.2 of the Final (100%) Basis of Design Report:

- National Trails Highway In-Situ Reactive Zone (NTH IRZ): Line of wells that may be used as both injection and extraction wells to circulate groundwater and distribute an organic carbon source to promote reduction of Cr(VI) to trivalent chromium (Cr[III]).
- Inner Recirculation Loop (IRL):
  - River Bank Extraction Wells along the Colorado River to provide hydraulic capture of the plume, clean up floodplain downgradient of the IRZ, enhance the flow of contaminated groundwater through the NTH IRZ line, and control migration of IRZ-generated by-products.
  - IRL Injection Wells to re-inject groundwater extracted from the River Bank Extraction Wells (which may be amended with an organic carbon source) and/or fresh water into wells in the upgradient portion of the Cr(VI) plume to flush the plume through the NTH IRZ.
- Freshwater Injection Wells to inject fresh water into wells upgradient of the Cr(VI) plume to control and confine the plume migration to the west, to assist with flushing the chromium plume through the NTH IRZ, and to constrain westward spread of carbon-amended water and in-situ byproducts from the Inner Recirculation Loop.
- TCS Recirculation Loop:
  - East Ravine Extraction Wells in the eastern (downgradient) end of the East Ravine to provide hydraulic capture of contaminated groundwater in bedrock and Transwestern Bench Extraction Wells in the area northeast of the TCS to accelerate capture of Cr(VI) impacted groundwater from the alluvial deposits located downgradient of the TCS.
  - TCS Injection Wells located upgradient of the TCS for the re-injection of groundwater extracted from the East Ravine Extraction Wells and Transwestern Bench Extraction Wells, which will be amended with an organic carbon source, to promote reduction of the Cr(VI) to Cr(III) and remove elevated Cr(VI) groundwater concentrations from the alluvial aquifer in the vicinity of the TCS.

Table 2.1-1 presents the results of the FMEA for the in-situ remediation system.

Potential failures identified include possible ways in which the remedy may not perform per the original intent. This risk is mitigated through design (including pilot testing, predictive simulations/modeling, additional design efforts, and designing in flexibility) and operational flexibility (as described in the Decision Rules/Operational Framework included in Volume 2 of this O&M Manual). The FMEA includes references to elements of the 100% design submittal that provide additional details on how remedy risks are being mitigated in the design and operational strategy. Other potential failures include operational and safety issues involved with mechanical equipment and chemicals for which PG&E has set as a design criterion that two levels of protection would have to fail simultaneously for a failure to be considered significant enough to be included in the FMEA.

2.2 Remedy-produced Water Management System

The final groundwater remedy is reliant on several dozen wells used for the IRZ, freshwater and carbon-amended water injection, and groundwater extraction. For all wells, especially the injection and IRZ wells, regular maintenance such as backwashing and rehabilitation is vital to ensure efficient and effective operations during the 30-year projected life of the remedy. Well maintenance will also prevent or reduce the need for drilling new replacement wells. These maintenance activities will produce an ongoing water stream that must be managed as

part of the remedial action. Other types of produced water with smaller volumes will also need to be managed, such as monitoring well sampling and development purge water, equipment decontamination wastewater, and rainfall that collects in remedy facility secondary containment. Providing a reliable means of managing this wastewater is a necessary supporting component of the overall remedy.

The Remedy-produced Water Management System includes the generation, transportation, conditioning, reuse and disposal of conditioned water. The system is described in Section 2.3 of the Operation and Maintenance Plan (Volume 1 of this O&M Manual).

Table 2.2-1 presents the FMEA matrix for the Remedy-produced Water Management System. Two main failure types were identified. The first type of failure is the system a) not having capacity to condition the produced water due to produced water flow being greater than forecasted, or b) experiences downtime which could be caused by a range of events (vandalism, acts of God, equipment failure, etc.). This would result in having to truck some or all of the produced water off-site for management. This would increase costs and traffic-related impacts of the remedy. However, it would not impact remedy performance. To mitigate this risk, the conditioning system has been conservatively sized and space has been reserved for build-out of additional equipment if needed. Also, multiple disposal/reuse options were established to reduce the risk of disposal/reuse limiting produced water management.

The second type of failure is the conditioning system effluent causing performance problems with wells or pipelines used for re-injecting the water. Problems could range up to the possibility of well fouling or scaling requiring replacement of the wells. Water quality issues that could hurt well performance include high suspended solids, high or low pH, or constituents/ions that precipitate out and scale the well. Loss of wells due to fouling or scaling could slow the remedy performance until the wells are rehabilitated or replaced. This risk is mitigated by including fine-particle filtration and in-line monitoring of pH and turbidity in the design. Operational mitigations will include frequent monitoring of the conditioning system performance and of the injectivity of the wells used for re-injecting treated water.

In response to comments on the 60% design documents (RTC #757 DTSC-239, Tribes' comment #341 [see Appendix I of the 100% Basis of Design Report]), a contingent system is included in this Contingency Plan to remove scale-forming ions from remedy-produced water prior to injecting, if needed. The design basis for the contingent system, referred to herein as the dissolved metals removal system (DMRS), is included in Appendix A of this Contingency Plan. The DMRS would be integrated into the remedy-produced water conditioning A-side process, downstream of the A-side filters (see Volume 1, O&M Plan, of the O&M Manual, Sections 2.5 and 3.3). Effluent water from the DMRS would be sent to the remedy-produced water A-side Conditioned Water Tank Farm (TNK-RTP01-1401 and TNK-RTP01-1402), pumped from there to the conditioned water frac tank (T-IRZ00-0620) at the MW-20 Bench, and then returned to the NTH IRZ injection wells via the conditioned water injection pump (PMP-IRZ00-0648) and piping.

The implementation of the contingent DMRS could be triggered by significant performance losses in pipelines and/or wells due to heavy scaling of calcium, iron, magnesium, and/or manganese that cannot be adequately mitigated using planned preventative measures including the clean-in-place (CIP) loop (see Section 5.1 of Volume 1), routine pipeline maintenance procedures (Sections 5.2 and 5.3 of Volume 1), and the well maintenance program (Section 4 of Volume 1).

The DMRS is designed to be fully integrated into the planned conditioning process for remedy-produced water and has space allocated for it in the design, thereby allowing for installation without expansion of the building footprint if required in the future. The DMRS would be primarily located on the second floor of the planned Remedy-produced Water Conditioning Plant. Certain treatment chemicals will be stored on the first floor of the planned Remedy-produced Water Conditioning Plant.

2.3 Freshwater Supply System

The Freshwater Supply System will provide water for the freshwater injection wells used in the groundwater remedy. The freshwater injection is to control and confine the plume migration to the west, assist with flushing

the chromium plume through the IRZ, and constrain westward spread of carbon-amended water and in-situ byproducts from the IRL. The objective of the freshwater supply system is to provide sufficient water of acceptable quality for successful implementation of the remedy. The quantity and quality requirements are defined in Section 3.3 of the Basis of Design Report. Fresh water for the remedy will be supplied from well HNWR-1A, located in Arizona, with the HNWR-1 well as a secondary source and the Topock-2/-3 and Site B wells as contingent sources. To provide maximum flexibility and reliability in the remedy freshwater supply, provisions to plumb and operate the HNWR-1, Topock-2/-3, and Site B wells, if needed in the future, are provided in the final design. For well water quality protection, Volume 2 of the O&M Manual discusses in detail the proposed monitoring plan for the HNWR-1A well and results of a recent source assessment. Table 2.3-1 presents the FMEA matrix for the supply of fresh water.

Per DTSC direction (comment RTC #21 DTSC-2 on the 60% design), a contingent arsenic treatment system is included in the design and is identified herein as the freshwater pre-injection treatment system (FWPTS). The design basis for the FWPTS is included in Appendix B of this Contingency Plan. Space is reserved for the FWPTS next to the planned Remedy-produced Water Conditioning Plant.

The triggering step for implementation of this contingency system was outlined in a letter from the California State Water Resources Control Board (SWRCB) (2013) to DTSC. The SWRCB letter requires that if the leading edge of the arsenic plume above the 10 μg/L water quality objective extends more than 150 feet away from injection locations, PG&E must immediately reassess its modeling calculations and quickly identify interim actions it can take to limit the migration of the arsenic plume. The letter further directs the cessation of the injection of untreated fresh water if the arsenic concentration caused by injection of fresh water is detected above the water quality objective (10 μg/L) at 225 feet from the injection locations. The letter states that at this point, DTSC should either (i) require pretreatment to remove arsenic prior to injection or (ii) require another source of fresh water in order to meet the water quality objective.

2.4 Power Supply System

The power supply system will provide electricity for the groundwater remedy. The design objective of the system is to reliably provide sufficient electricity to power the groundwater remedy's electrically driven components such as pumps, controls, and lighting.

The primary power supply source for the remedy facilities in California will be power generated by the PG&E Topock Compressor Station. A portable, rental backup generator similar to the existing IM-3 back-up generator (Isuzu Model 6WG1X) will be mobilized onsite as needed during project implementation to provide power. A connection panel is included in the final design (see Basis of Design Report Appendix D, Drawing E-00-61, Detail 4) and space has been reserved for the portable rental generator. The power supply for the new water recirculation system and transfer pumps at the TCS evaporation ponds will be a new natural gas-fueled reciprocating internal combustion engine (RICE) electrical power generator housed in a new enclosed utility building located within the TCS evaporation ponds fence line. Auxiliary equipment planned for installation at the TCS evaporation ponds (e.g., lighting, controls, sensors, security cameras, and valve actuators) will be supplied with 24-volt direct current (VDC) power by new thermoelectric generators (TEGs) installed in a secure fenced area adjacent to the new utility building. A transfer switch will provide for the flexibility of supplying power to the auxiliary equipment from the RICE.

For the freshwater supply well (HNWR-1A) in Arizona, the power supply source will be power provided by Mohave Electric Cooperative. The primary power supply for the long-term remedy support area at Moabi Regional Park will be provided by the City of Needles.

Secondary power supply will be power generated from small photovoltaic solar panels at the workshop building and parking shade structure at Moabi Regional Park for the long-term remedy support area at Moabi Regional Park, and at select remote well locations. Backup power will also be provided for the long-term remedy support area at Moabi Regional Park, if needed, via an on-site diesel generator (Kohler Power Systems 200REOZJF) with an integral, double-walled fuel tank.

A potential failure is the temporary loss of power to the groundwater remedy infrastructure such as pumps and control systems. This could be caused by damage to the power generation equipment or transmission system. The failure modes anticipated would all be repairable in a period of days to weeks. Because the remedy performance is not anticipated to be affected significantly by equipment outages of that duration, the power supply failure modes evaluated are not anticipated to significantly affect remedy schedule or performance.

To mitigate the risk of even temporary power outages, the electrical equipment used in the remedy is designed for the site conditions; site security is provided to minimize risk of vandalism, and an uninterruptible power supply (UPS) is provided for key equipment such as control systems.

Table 2.4-1 presents the FMEA matrix for the power supply system.

2.5 Remedy SCADA, Control Systems, and Instrumentation

The Remedy SCADA system provides operator control, remote access, data logging, and alarm notification for the groundwater remedy. Field instrumentation measures various process data and transmits these data to programmable logic controllers (PLCs). PLCs are industrial computerized controllers that gather this process data and use process-specific algorithms to provide automated control of the groundwater remedy system. Additionally PLCs are used to concentrate hardwired data signals and transmit them to the central SCADA control center via communications network links. The operator interface terminals (OITs) or human/machine interfaces (HMIs) provide graphical displays representing current and historical process data and provides for operator interaction with the process, adjustment to the automation system, and trending of historical data. The final remedy will include field instrumentation and PLCs for each process area or well site tied together via wires, fiber optic communications, radio transmission, or other wireless communications methods, as well as multiple OITs/HMIs to allow operators to interact with various aspects of the groundwater remedy system.

The design objectives of the Remedy SCADA, instrumentation, and control systems are to reliably provide automatic and remote control/monitoring of the groundwater remedy system components, and to reliably record data that are needed for operations and compliance reporting.

A potential failure evaluated is damage to the Remedy SCADA system that causes temporary loss of the ability to view system performance, send/receive control signals from the control room, and log system data. This could have various causes such as hardware or software failures due to site environmental conditions or vandalism, power outages, or damage to communication wiring. Such potential failures are not anticipated to significantly affect remedy schedule or performance.

To mitigate the risk of even temporary loss of Remedy SCADA, instrumentation, and controls systems functions, the Remedy SCADA and instrumentation equipment used in the remedy will be designed for the site conditions, equipment spares will be stocked on-site for critical control equipment, site security to protect against vandalism will be provided, and externally powered instruments will be connected to UPS-fed circuits.

Table 2.5-1 presents the FMEA matrix for the Remedy SCADA, control systems, and instruments.

2.6 Enhanced Evaporation at TCS Evaporation Ponds

One of the management options identified for remedy-produced water is disposal at the existing TCS evaporation ponds (other options include injection into the IRZ wells, re-use in cooling towers, and off-site disposal). Water accumulated in the ponds will evaporate over time. In the event that the ponds are full (i.e., water level in the ponds reaches the maximum level allowed by the Regional Water Quality Control Board), and injection into the IRZ wells and re-use in the cooling towers are not feasible or available, water can also be trucked off-site via the truck loading station at the ponds (or other stations at TCS, Transwestern Bench, MW-20 Bench, or the point of generation [i.e., well sites, etc.]). The preferred method of water disposal is evaporation; therefore, a new drip system and agitators will be installed to enhance evaporation at the ponds. Further, the existing truck loading station will also be improved to support off-site trucking of water or discharge of water to the ponds, if needed. Table 2.6-1 presents the FMEA matrix for the evaporation pond enhancements system.

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations				Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition					Notes
			Mitigation	Observable Condition		Action if Cause Occurs				A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Change to Impact	E. H&S or Compliance NOV (other than related to remedy performance)	
				Remedy SCADA	Human										
Conveyance (General)															
Release from conveyance pipeline. Effect Without Mitigation: Potential release of water with Cr(VI), carbon substrate, and/or well/pipeline maintenance chemicals.	Differential thermal expansion or settlement, deterioration, vandalism, puncture; pressure exceedance; fabrication failure.	Overall pipeline design for durability over project lifetime; secondary containment (double-wall pipe or concrete trench box) with appropriately-designed leak detection systems (see Appendix C - Design Criteria, Section C.5.1 - Piping); redundant/spare pipe installed (or spare space provided for additional pipe); pipe installed within concrete trench box or direct buried without stacking to facilitate access.	Flow monitoring	Alarm conditions - secondary containment sump alarms; out-of-range process alarms (i.e., pipeline flows or pressures)	Observe leak	Stop pipeline operation, switch to spare pipeline and/or repair /replace pipeline, resume operation.	4	1	4					X	Type E unacceptable condition associated with potential environmental release.
Conveyance fouling/clogging. Effect without Mitigation: Potentially insufficient capacity to support remedy.	Solids buildup (i.e., scaling, biofouling).	Overall system/pipeline design to minimize solids buildup; clean-in-place system and cleanouts for pipeline maintenance (see Operations and Maintenance Plan, Section 5 - Pipeline Maintenance); redundant/spare pipe installed (or spare space provided for additional pipe); pipe installed within concrete trench box or direct buried without stacking to facilitate access.	Pipeline pressure/flow monitoring	Pipeline pressure/flow monitoring and data-logging	Significant increase in pipeline pressure or decrease in flow; observed clogging	Stop pipeline operation, switch to spare pipeline and/or clean/repair /replace pipeline, resume operation.	2	3	6						
Pipeline maintenance chemical/fluid release to wells. Effect without Mitigation: Release of chemicals, solids, etc. into wells and groundwater.	Valving between wells and conveyance not closed during pipeline maintenance.	Clean-in-place system programmed to require automated wellhead valves to be closed prior to operation.	Operator training; wellhead/pipeline inspection during maintenance	Well pressure/flow monitoring and data-logging; wellhead valve position monitoring	Loss of pipeline maintenance solution; observed well flows during pipeline maintenance	Well rehab (Operations and Maintenance Plan, Section 4 - Well Maintenance)	2	2	4

Remediation Wells (General) - see also Table 2.2-1, Failure Mode Effect Analysis Matrix - Remedy-produced Water Management System															
Extraction well failure. Effect without Mitigation: The well will not be able to contribute to meeting extraction rate/remedy goals.	Capacity declines over time due to fouling or other well issues.	See Appendix C - Design Criteria (Remediation Well Design and Field Construction Approach) and Operations and Maintenance Plan, Section 4 - Well Maintenance - Extraction wells designed to optimize performance - Extraction wells designed to facilitate periodic well rehab - Remedy operations to minimize substrate and remedial by-product concentrations at extraction wells to minimize fouling	Remediation/monitoring well performance monitoring; periodic well rehab (Operations and Maintenance Plan, Section 4 - Well Maintenance)	Well water level/flow monitoring and data-logging	Insufficient capacity of produced water based on remediation/ monitoring well performance monitoring and evaluation	If well maintenance efforts ineffective - stop well operation, repair or replace, resume operation.	2	3	6						
	Well collapse or casing/screen failure (from deterioration, corrosion, etc.), vandalism, accidental damage, etc.	See Appendix C - Design Criteria (Remediation Well Design and Field Construction Approach) - Overall well design for durability over project lifetime - materials selection for resistance against corrosion, deterioration, and damage during routine operation and well rehab - Wells secured within vaults for protection	Visual well inspections	Alarm condition - out-of-range well operation	Observe damage	Stop well operation, repair or replace, resume operation.	2	1	2						
Injection well failure. Effect without Mitigation: The well will not be able to contribute to meeting injection rate/remedy goals.	Capacity declines over time.	See Appendix C - Design Criteria (Remediation Well Design and Field Construction Approach) and Operations and Maintenance Plan, Section 4 - Well Maintenance - Injection wells designed to optimize performance - drop tubes to minimize air entrainment - Injection wells designed to facilitate routine backwashing and periodic well rehab	Remediation/monitoring well performance monitoring; periodic well backwashing and rehab (Operations and Maintenance Plan, Section 4 - Well Maintenance)	Well water level/pressure/flow monitoring and data-logging	Insufficient capacity of injected water based on remediation/ monitoring well performance monitoring and evaluation	If well maintenance efforts ineffective - stop well operation, repair or replace, resume operation.	2	3	6						
	Well collapse or casing/screen failure (from deterioration, corrosion, etc.), vandalism, accidental damage, etc.	See Appendix C - Design Criteria (Remediation Well Design and Field Construction Approach) - Overall well design for durability over project lifetime - materials selection for resistance against corrosion, deterioration, and damage during routine operation and well rehab - Wells secured within vaults for protection	Visual well inspections	Alarm condition - out-of-range well operation	Observe damage	Stop well operation, repair or replace, resume operation.	2	1	2						
Release from wellhead, piping, or vault. Effect Without Mitigation: Potential release of water with Cr(VI), carbon substrate, and/or well/pipeline maintenance chemicals.	Differential thermal expansion, deterioration, vandalism, puncture; pressure exceedance; fabrication failure.	Overall wellhead design for durability over project lifetime; wells secured within vaults for protection; leak detection level switch in vault sump to alarm/stop well operation	Visual well/vault inspections	Alarm condition - well vault sump level switch; out-of-range well operation	Observe leak	Stop well operation, repair, resume operation.	4	1	4					X	Type E unacceptable condition associated with potential environmental release.
	Injection well overflows.	Downwell pressure transducer to shut off well if excessive water level/pressure increase; leak detection level switch in vault sump to alarm/stop well operation; overall injection system designed for flow/pressure balancing across network to minimize potential for well overflow	Visual well/vault inspections; preventative well maintenance (Operations and Maintenance Plan, Section 4 - Well Maintenance)	Alarm condition - well vault sump level switch; out-of-range well operation	Observe leak	Stop well operation, make repairs (as necessary), troubleshoot injection well capacity issues, as necessary - rehab/redevelop well (Operations and Maintenance Plan, Section 4 - Well Maintenance)	4	1	4					X	
Remediation well equipment, valving, instrumentation failure (other than above). Effect without Mitigation: Potential well damage or undesired operation.	Mechanical or electrical failure; general wear and tear; temperature.	Valves/instruments designed to fail in safest position; redundant controls/alarms; well casing relief valves to protect injection wells in case of excess pressure; common equipment/onsite spares for wells to facilitate troubleshooting	Preventative maintenance schedule; visual well/vault inspections	Alarm condition - well vault sump level switch; out-of-range well operation	Observe leak or out-of-range well operation	Stop well operation, repair, resume operation.	2	2	4

Carbon Amendment System (MW-20 Bench)															
General carbon amendment system failure. Effect without Mitigation: Unable to operate parts or all of groundwater recirculation and carbon amendment systems to support remedy.	Equipment, valving, instrumentation failure	Valves/instruments that can result in a release if a fail-safe return is not provided are designed to fail in safest position; redundant controls/alarms; common equipment/onsite spares to facilitate troubleshooting; secondary containment at bench systems.	Visual inspections and preventative maintenance schedule	Alarm condition - out-of-range system operation; sump level alarm	Observed failure condition	Stop system operation, repair, resume operation.	3	2	6						
Carbon substrate storage and/or feed system failure. Effect without Mitigation: Potential release of flammable liquid; unable to amend recirculated groundwater with carbon substrate; potential over-dosing of carbon substrate to injection wells.	Human error	See Appendix C - Design Criteria, C.5.7 - Fire Protection Equipment and Final Basis of Design Report, Section 3.2.1.1 - Description of NTH IRZ (Organic Carbon Substrate Amendment System [MW-20 Bench]) - System designed in accordance with all applicable codes for flammable liquids - Overall system design for durability over project lifetime, including materials selection for compatibility, corrosion control, impact/damage protection - Storage tank has impact-resistant construction and double-wall construction with integral interstitial zone for leak detection monitoring - Instrumentation to include: tank interstitial space fluid level sensors, primary tank level transmitter with manual gauging port for operator verification, primary tank fluid temperature sensor, visible beacon/audible alarm within bench areas to notify operators of high level during tank filling, pipeline secondary containment leak detection system - Double-wall tank and piping systems with additional secondary containment in process/filling area - Valves/instruments designed to fail in safest position - Redundant controls/alarms - Fire extinguishers to be located at bench system in accordance with applicable codes - Security fencing/traffic bollards	Visual inspections and preventative maintenance schedule; operator training	Alarm condition - leak detection/ secondary containment alarm; tank overfill alarm; out-of-range system operation (i.e., over- or under-dosing)	Observe failure condition	Stop system operation, repair, replace, or otherwise resolve failure, resume system operation; manual carbon substrate dosing at system or individual wells, if necessary	5	2	10			X		X	Type C/E unacceptable conditions associated with potential cost/H&S issues with flammable liquid storage and handling.

NTH IRZ															
IRZ is not effective at removing Cr(VI) from groundwater as designed. Effect without Mitigation: Potential schedule/cost increase or other issues with achieving RAOs as designed.	More rapid utilization of carbon substrate after injection than anticipated.	Design included pilot testing, predictive simulations/modeling, and additional design efforts; system designed with flexibility for range of operating flow rates and carbon substrate types and dosing strategies; future provisional wells have been included in the design, if needed; flexibility retained in the design to adjust locations of provisional wells; manual carbon substrate dosing can target individual wells if needed to supplement IRZ-wide dosing; River Bank Extraction Wells are designed to capture downgradient Cr(VI), TOC, and/or byproducts, as needed; system designed with flexibility to re-direct extracted water from TCS Recirculation Loop to NTH IRZ (if system is flow limited)	See Sampling and Monitoring Plan, Decision Rules/Operational Framework (Figures 2.2-2 and 2.2-3) for IRZ performance troubleshooting and operational adaptability philosophy to be conducted based on remedial performance monitoring/evaluation and using the designed system flexibility - operational adjustments may include flow rates, carbon substrate type and dosing strategy, number and location of operating wells, injection of water from the TCS Recirculation Loop into the NTH IRZ (if system is flow limited), etc. River Bank Extraction Wells, Inner Recirculation Loop Injection Wells, and Freshwater Injection Wells may be slowed or shut down to slow groundwater flow rate during NTH IRZ troubleshooting.		See Sampling and Monitoring Plan and Operations and Maintenance Plan for summary of remedy monitoring and how data will be evaluated/applied to remedy system optimization	If operational adjustments outlined in Sampling and Monitoring Plan, Decision Rules/Operational Framework (Figures 2.2-2 and 2.2-3) are not successful in establishing IRZ effectiveness - additional extraction/injection wells or water sources (if system is flow limited) will be considered	4	2	8	X	X	X	X		Unacceptable conditions associated with potential increased level of effort required to achieve remedy performance objectives.
	Well spacing or screen placement is inadequate.						4	2	8	X	X	X	X		
	Recalcitrant mass in immobile porespace.						4	2	8	X	X	X	X		
	Unexpected hydrogeologic conditions (e.g., preferential flow paths allow water to pass through IRZ without adequate treatment).						4	3	12	X	X	X	X		
	Extraction/injection flow limited.						4	2	8	X	X	X	X		
Extraction of organic carbon and/or significant byproducts. Effect without Mitigation: Potential to increase well/pipeline maintenance required to meet remedy goals.	Carbon substrate dosing greater than required.					If operational adjustments outlined in Sampling and Monitoring Plan, Decision Rules/Operational Framework (Figures 2.2-2 and 2.2-3) are not successful in managing organic carbon or by-product concentrations at extraction wells - additional wells or water sources (if system is flow limited) will be considered; treatment of riverbank extracted groundwater prior to re-injection will be considered.	4	2	8			X			
	By-product generation greater than expected/attenuation slower than expected						4	2	8			X

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations: Mitigation	Mitigation - Operations: Observable Condition: Remedy SCADA	Mitigation - Operations: Observable Condition: Human	Mitigation - Operations: Action if Cause Occurs	Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition: A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Change to Impact	E. H&S or Compliance NOV (other than related to remedy performance)	Notes
Inner Recirculation Loop - see also Table 2.3-1, Failure Mode Effect Analysis Matrix - Freshwater Supply															
Unacceptable migration of Cr(VI) or byproducts. Effect without Mitigation: Potential for Cr(VI) or byproducts to enter the Colorado River; potential plume expansion.	Unexpected hydrogeologic conditions.	Design included pilot testing, predictive simulations/modeling, and additional design efforts; system designed with flexibility for range of operating flow rates and carbon substrate type and dosing strategy; Inner Recirculation Loop Injection Wells designed for flexibility to inject freshwater and/or riverbank extracted groundwater[1]; future provisional wells have been included in the design, if needed; flexibility retained in the design to adjust locations of provisional wells	See Sampling and Monitoring Plan, Decision Rules/Operational Framework (Figures 2.2-4 and 2.2-5) for IRL performance troubleshooting and operational adaptability philosophy to be conducted based on remedial performance monitoring/evaluation and using the designed system flexibility - operational adjustments may include flow rates, carbon substrate type and dosing strategy, number and location of operating wells, injection of freshwater and/or riverbank extracted groundwater into Inner Recirculation Loop Injection Wells[1], etc.		See Sampling and Monitoring Plan and Operations and Maintenance Plan for summary of remedy monitoring and how data will be evaluated/applied to remedy system optimization	If operational adjustments outlined in Sampling and Monitoring Plan, Decision Rules/Operational Framework (Figures 2.2-4 and 2.2-5) are not successful in establishing adequate plume control or plume flushing - additional extraction/injection wells (including wells to the south of RB-5), River Bank Extraction Well pumping from shallow zones, or additional water sources (if system is flow limited) will be considered, as needed, to limit new large-capacity extraction wells; additional mitigation measures, including potential treatment of riverbank extracted groundwater prior to re-injection, will be considered; construction sequence may also be changed to prioritize installation of River Bank Extraction Wells (with possible carbon amendment and injection of extraction groundwater into the NTH IRZ), if needed	4	3	12	X		X	X		Unacceptable conditions associated with potential increased level of effort required to achieve remedy performance objectives.
	Well spacing or screen placement is inadequate.						4	2	8	X		X	X		
	New large-capacity wells (e.g., water supply wells) are installed near the site (e.g., at Park Moabi or elsewhere along the Colorado River).						4	2	8	X		X	X		
Flushing of plume through NTH IRZ not as effective as designed. Effect without Mitigation: Potential schedule delay.	Unexpected hydrogeologic conditions.						4	3	12		X	X	X		
	Well spacing or screen placement is inadequate.						4	2	8	X		X	X		
	Lack of adequate supply of injection water (e.g., River Bank Extraction Well produced water contains unacceptably high concentrations of byproducts/other constituents).						4	2	8		X	X	X		
Natural reducing rind near river is negatively-impacted by pumping resulting in inadequate reducing buffer in floodplain. Effect without Mitigation: Could affect ability to rely on MNA for residual contamination when active remediation ends.	Oxic water from the river being pulled into floodplain by extraction wells near the river	Design included pilot testing, predictive simulations/modeling, and additional design efforts; system designed with flexibility for range of operating flow rates; River Bank Extraction Well pumping planned for deeper zones only				If operational adjustments are not successful in adequately maintaining the natural reducing rind - assess potentially required remedy modifications	2	2	4						

TABLE 2.1-1

PG&E Topock Compressor Station, Needles, California

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations: Mitigation	Mitigation - Operations: Observable Condition: Remedy SCADA	Mitigation - Operations: Observable Condition: Human	Mitigation - Operations: Action if Cause Occurs	Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition: A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Change to Impact	E. H&S or Compliance NOV (other than related to remedy performance)	Notes
TCS Recirculation Loop															
Transwestern Bench Extraction Well network does not provide adequate volume or mass removal. Effect without Mitigation: Potential schedule delay as impacted water near TCS not treated as rapidly as planned.	Unexpected hydrogeologic conditions.	Design included pilot testing, predictive simulations/modeling, and additional design efforts; system designed with flexibility for range of operating flow rates and carbon substrate type and dosing strategy; future provisional wells have been included in the design, if needed; flexibility retained in the design to adjust locations of provisional wells; River Bank Extraction Wells are designed to capture downgradient Cr(VI), TOC, and/or byproducts, as needed; system designed with flexibility to re-direct extracted water from TCS Recirculation Loop to NTH IRZ (if system is limited by ability to inject into TCS Injection Wells)	See Sampling and Monitoring Plan, Decision Rules/Operational Framework (Figures 2.2-6 to 2.2-8) for TCS Recirculation Loop performance troubleshooting and operational adaptability philosophy to be conducted based on remedial performance monitoring/evaluation and using the designed system flexibility - operational adjustments may include flow rates, carbon substrate type and dosing strategy, number and location of operating wells, etc.; Transwestern Bench and East Ravine extracted groundwater may be injected into NTH IRZ (if system is limited by ability to inject into TCS Injection Wells).		See Sampling and Monitoring Plan and Operations and Maintenance Plan for summary of remedy monitoring and how data will be evaluated/applied to remedy system optimization	If operational adjustments outlined in Sampling and Monitoring Plan, Decision Rules/Operational Framework (Figures 2.2-6 to 2.2-8) are not successful in achieving design objectives - additional extraction/injection wells or water sources (if system is flow limited) will be considered, including the use of fresh water to supplement injections into the TCS Injection Wells - a plan for constructing arsenic monitoring wells and establishing baseline arsenic conditions including prior carbon injections in the area would be required prior to injecting fresh water into the TCS Injection Wells.	4	3	12		X	X	X		
	Well spacing or screen placement is inadequate.						4	2	8		X	X	X		
	Extraction/injection flow limited.						4	2	8		X	X	X		
East Ravine Extraction Well network does not provide capture of targeted groundwater, as designed. Effect without Mitigation: Potential expansion of plume or Cr(VI) release to Colorado River.	Unexpected hydrogeologic conditions.						4	3	12	X	X	X	X		Unacceptable conditions associated with potential increased level of effort required to achieve remedy performance objectives.
	Well spacing or screen placement is inadequate.						4	2	8	X	X	X	X		
	Extraction/injection flow limited.						4	2	8	X	X	X	X		
Cr(VI) treatment by TCS Injection Well network not as effective as designed. Effect without Mitigation: Potential schedule delay.	Unexpected hydrogeologic conditions.						4	3	12		X	X	X		
	More rapid utilization of carbon substrate after injection than anticipated.						4	2	8		X	X	X		
	Well spacing or screen placement is inadequate.						4	2	8		X	X	X		
	Extraction/injection flow limited.						4	2	8		X	X	X		

TABLE 2.1-1

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations: Mitigation	Mitigation - Operations: Observable Condition: Remedy SCADA	Mitigation - Operations: Observable Condition: Human	Mitigation - Operations: Action if Cause Occurs	Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition: A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Change to Impact	E. H&S or Compliance NOV (other than related to remedy performance)	Notes
Freshwater Injection System - see also Table 2.3-1, Failure Mode Effect Analysis Matrix - Freshwater Supply															
Flushing of plume through NTH IRZ not as effective as designed. Effect without Mitigation: Potential schedule delay.	Unexpected hydrogeologic conditions.	Design included pilot testing, predictive simulations/modeling, and additional design efforts; system designed with flexibility for range of operating flow rates	See Sampling and Monitoring Plan, Figure 2.2-9 Freshwater Injection System Decision Rules/Operational Framework for freshwater injection performance troubleshooting and operational adaptability philosophy to be conducted based on remedial performance monitoring/evaluation and using the designed system flexibility - operational adjustments may include flow rates, number and location of operating wells, etc.; TCS injections may be adjusted or shut down if FW-02 is not operating as intended		See Sampling and Monitoring Plan and Operations and Maintenance Plan for summary of remedy monitoring and how data will be evaluated/applied to remedy system optimization	If operational adjustments outlined in Sampling and Monitoring Plan, Figure 2.2-9 Freshwater Injection System Decision Rules/Operational Framework are not successful in achieving design objectives - additional injection wells will be considered	4	3	12		X	X	X		Unacceptable conditions associated with potential increased level of effort required to achieve remedy performance objectives.
	Well or screen placement is inadequate.						4	2	8		X	X	X		
	Lack of adequate supply of injection water.						4	2	8		X	X	X		
Insufficient FW-02 performance to maintain control of southwestern plume margin. Effect without Mitigation: Potential plume expansion.	Unexpected hydrogeologic conditions.						4	3	12	X					
	Well or screen placement is inadequate.						4	2	8	X					
	Lack of adequate supply of injection water.						4	2	8	X					
Analytical data collected from freshwater arsenic monitoring wells located 225 feet from freshwater injection locations indicate arrival of arsenic plume above the 10 µg/L water quality objective. Effect without Mitigation: Per the California State Water Resources Control Board (SWRCB) letter to DTSC (SWRCB 2013), PG&E is required to cease injection of untreated water and either 1) add pre-treatment or 2) use a freshwater source without arsenic if data collected from freshwater arsenic monitoring wells located 225 feet from freshwater injection locations indicate arrival of arsenic plume above the 10 µg/L water quality objective. Modeling calculations will be re-assessed and these or other actions may also be considered for implementation if data collected from freshwater arsenic monitoring wells located 150 feet from freshwater injection locations indicate arrival of the leading edge of the arsenic plume above the 10 µg/L water quality objective.	Unexpected hydrogeologic/ geochemical conditions.	Design included pilot testing, predictive simulations/modeling and additional design efforts; system designed with flexibility for range of operating flow rates	Sampling of freshwater arsenic monitoring wells located 150 feet from freshwater injection locations. If data from these wells indicate arrival of the leading edge of the arsenic plume above the 10 µg/L water quality objective, modeling calculations will be re-assessed and operational adjustments may include flow rates, number and location of Inner Recirculation Loop Injection Wells operating with fresh water versus riverbank extracted groundwater[1], aeration of fresh water prior to injection to reduce arsenic mobility, etc. (see Sampling and Monitoring Plan, Section 2.2.4)		See Sampling and Monitoring Plan and Operations and Maintenance Plan for summary of remedy monitoring and how data will be evaluated/applied to remedy system optimization	If operational adjustments/interim actions discussed in Sampling and Monitoring Plan, Section 2.2.4 are not successful in achieving design objectives - implementation of the freshwater pre-injection treatment system (see also Section 2.3) for freshwater arsenic treatment and/or additional/alternative freshwater sources will be implemented per the SWRCB letter to DTSC (SWRCB 2013).	4	2	8		X	X			Type B/C unacceptable condition associated with potential schedule/cost increases.

TABLE 2.1-1
Failure Mode Effect Analysis Matrix - In-Situ Remediation System
Groundwater Remedy Operation and Maintenance Manual
Volume 3: Contingency Plan
PG&E Topock Compressor Station, Needles, California

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations			Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition					Notes
			Mitigation	Observable Condition		Action if Cause Occurs									
				Remedy SCADA	Human										
In-Situ Remediation System (General)															
Aerial or vertical extent of Cr(VI) plume greater than currently defined. Effect without Mitigation: Potential expansion of remedy footprint.	Inadequate characterization of Cr(VI) in groundwater	Groundwater characterization efforts to date indicate it is unlikely that significant Cr(VI) concentrations exist outside of currently-defined plume footprint. Remedy system design includes some flexibility to expand outside of planned footprint, if needed. See Chapter 5 of the Construction/Remedial Action Work Plan for the Construction Contingency Plan/Procedures.	Installation of remediation and monitoring wells will be conducted in a step-wise manner with a focus on first gathering lithologic data, then water quality data, before finalizing well locations/well screen intervals and installing wells. Well construction will also consider previous well data to ensure the latest data is used in the well installation process.			Assess potentially required remedy modifications, including system expansion	4	2	8			X	X		Unacceptable conditions associated with potential cost increase/additional CEQA analysis required due to expansion of remedy footprint.
Cr(III) re-oxidation to Cr(VI) after in-situ treatment. Effect without Mitigation: Potential issues with achieving RAOs as designed.	Unexpected high availability of reactive MnO_2 surfaces along groundwater flow path.	Design included pilot testing, predictive simulations/modeling, and additional design efforts that indicated significant re-oxidation of Cr(III) to Cr(VI) is unlikely	See Sampling and Monitoring Plan, Decision Rules/Operational Framework (Figures 2.2-2 to 2.2-9) for remedy performance troubleshooting and operational adaptability philosophy to be conducted based on remedial performance monitoring/evaluation and using the designed system flexibility such as adjusting operational flow rates, organic carbon dosing strategy, etc.		See Sampling and Monitoring Plan and Operations and Maintenance Plan for summary of remedy monitoring and how data will be evaluated/applied to remedy system optimization	Assess potentially required remedy modifications	1 to 4	1	1 to 4	X	X	X	X		Unacceptable conditions associated with potential increased level of effort required to achieve remedy performance objectives.
Changes in aquifer pH not adequately buffered. Effect without Mitigation: Potential issues with achieving RAOs as designed.	Inadequate groundwater and/or biogeochemical characterization	Design included pilot testing and predictive simulations/modeling that indicated significant change in pH is unlikely				Assess potentially required remedy modifications	1 to 3	1	1 to 3						
In-situ remedy byproduct (arsenic) concentrations do not sufficiently attenuate. Effect without Mitigation: Potential issues with achieving RAOs as designed.		Design included pilot testing, predictive simulations/modeling, and additional design efforts that indicate sufficient byproduct attenuation following remedy operation				Assess potentially required remedy modifications, including potential treatment of extracted riverbank groundwater prior to re-injection	1 to 3	1	1 to 3						
In-situ remedy byproduct (manganese) concentrations do not sufficiently attenuate. Effect without Mitigation: Potential issues with achieving RAOs as designed.							1 to 3	1	1 to 3						
In-situ remedy byproduct (iron) concentrations do not sufficiently attenuate. Effect without Mitigation: Potential issues with achieving RAOs as designed.							1 to 3	1	1 to 3

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations			Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition					Notes
			Mitigation	Observable Condition		Action if Cause Occurs									
				Remedy SCADA	Human				A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Change to Impact	E. H&S or Compliance NOV (other than related to remedy performance)	
Natural Disaster														
Seismic damage. Effect without Mitigation: Damage to remedy infrastructure may cause shutdown of parts or all of remedy.	Earthquake	See Appendix C - Design Criteria, C.3.5 - Seismic Loads - Structures will be designed in accordance with applicable seismic codes		Alarm conditions will shut system down if significant damage	Observed failure condition	Stop system operation, inspect system, repair/replace system infrastructure (as needed), resume system operation	varies	1	varies		X	X			Type B/C unacceptable condition associated with potential schedule/cost increases.
Flooding. Effect without Mitigation: Damage to remedy infrastructure may cause shutdown of parts or all of remedy; potential loss of access.	Rising water levels in Colorado River and/or extreme rain events	Remedy infrastructure located outside of ordinary high water mark and 100-year floodplain to the extent possible; system can be operated/shutdown remotely if access limited	Preventative system shutdown or other action if flood conditions predicted	Alarm conditions will shut system down if significant flooding (sump levels)/ damage	Observed failure condition		varies	1	varies		X	X			Type B/C unacceptable condition associated with potential schedule/cost increases.
Fire damage. Effect without Mitigation: Damage to remedy infrastructure may cause shutdown of parts or all of remedy.	Wildfires/vegetation fires; Compressor station or gas pipeline explosion	System can be operated/shutdown remotely if access limited	Routine vegetation clearing/housekeeping in remedy facility areas; preventative system shutdown or other actions if fires in area	Alarm conditions will shut system down if significant damage	Observed failure condition		varies	1	varies		X	X			Type B/C unacceptable condition associated with potential schedule/cost increases.
Freezing conditions. Effect without Mitigation: Potential damage to remedy infrastructure may cause shutdown of parts or all of remedy.	Cold temperatures	Site conditions/temperatures unlikely to be cold enough to cause issues.	Preventative system shutdown and system/pipeline draining if freezing temperatures predicted	Alarm conditions will shut system down if significant freezing/ damage	Observed failure condition		1	1	1						
Wind-blow dust damage. Effect without Mitigation: Potential damage to remedy infrastructure may cause shutdown of parts or all of remedy.	Dust, sands, etc. blown by high desert winds	Most remedy infrastructure located within enclosed buildings or vaults.	Preventative maintenance and visual inspection schedule to observe damage	Alarm conditions will shut system down if equipment failure due to dust damage	Observed damage or failure condition		1	2	2						

Abbreviations:
PLC - process logic controller
DOI - United States Department of the Interior
DTSC - Department of Toxic Substances Control
EIR - environmental impact report
H&S - health and safety
NOV - notice of violation
RAO - remedial action objective
TW - Transwestern
IRZ - In-Situ Reactive Zone
NTH - National Trails Highway
TCS - Topock Compressor Station
IRL - Inner Recirculation Loop
MNA - monitored natural attenuation
Cr(VI) - hexavalent chromium
Cr(III) - trivalent chromium
MnO_2 - manganese dioxide
P/V - pressure/vacuum
SWRCB - State Water Resources Control Board
TOC - total organic carbon

Notes:
1. Under the nominal operational scenario, riverbank extracted groundwater will be injected into the lower two-thirds of the saturated interval at IRL-1 and IRL-2. Changes in the wells and/or intervals into which riverbank extracted groundwater is injected will first be discussed with the DTSC and DOI.

TABLE 2.2-1
Failure Mode Effect Analysis Matrix — Remedy-produced Water Management System
Groundwater Remedy Operation and Maintenance Manual
Volume 3: Contingency Plan
PG&E Topock Compressor Station, Needles, California

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations				Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition					Notes
			Mitigation	Observable Condition		Action if Cause Occurs				A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Significant Change to Impacts (Additional CEQA Analysis)	E. H&S or Compliance NOV (other than related to remedy performance)	
				Remedy SCADA	Human										
1. Conditioning System Capacity Insufficient [2,3] Effect without Mitigation: Some water will not be able to be conditioned or re-used/ disposed on-site.	a. Generate more water that must be managed in a single backwash event – Short- term capacity condition	Plant designed for 35 gpm capacity and safety factor applied in sizing storage tanks	Temporarily decrease backwash frequency which would cause an increase in water level in the injection well	Influent flow measurements	N/A	Adjust operations to reduce backwash Investigate root cause and re-evaluate well O&M procedures	1	1	1						In cases resulting in loss of well performance, see the SOPs in the O&M Manual for diagnostic and maintenance procedures.[4]
	b. Wells need more maintenance then anticipated – Long-term capacity condition	Plant designed for 35 gpm capacity and safety factor applied in sizing storage tanks. Process is divided into 2 sides (Remedy A-side and Freshwater B-side) to allow for flexibility in managing conditioned water.	Investigate root cause, re-evaluate well operations, and maintenance procedures (see Section 4). If needed, evaluate the need and methods to increase plant capacity.	Flow transmitters, High well operating level	N/A	Adjust operations to reduce backwash Investigate root cause and re-evaluate well O&M procedures	3	2	6						See Note [1]. Severity depends on downtime and cost.
	c. Excessive load of solids on filters. Frequent filter change-outs	Install tanks to settle solids and turbidity analyzers on conditioned water tanks. Design coarse, then fine filter and standby filters on each train and instrumentation to measure pressure across the filters.	Conduct jar testing for alternative coagulants, to improve settling in tanks. Normal operation is flow through 2-stage filters. Standby filters put into service if operating filter is fouled. Stock spare filters on site	Quick increase in differential pressure across cartridge filters Alarms	Scheduled inspections, check water chemistry for scaling conditions	Well sampling to evaluate influent solids concentrations; Replace cartridges. If scaling, change pH target or add antiscalant	2	1	2						In cases resulting in loss of well performance, see the O&M Manual, Volume 1, Section 4 for diagnostic and maintenance procedures.[4]
	d. Grit build-up in tank	Design capability to pump solids from these tanks to phase separators. Design capability to use vac truck to remove solids.	Operators to monitor solids level	N/A	Operators to monitor solids level	Operators to hose down solids so they'll pump out, or remove by vac truck	1	1	1						
	e. Phase separator bins cannot be removed due to problems with hauling contractor and solids fill up in system. Plant capacity limited or stopped.	N/A	Have backup destination for disposal planned	N/A	N/A	Store full bins on site or at other PG&E facilities	1	1	1						

TABLE 2.2-1
Failure Mode Effect Analysis Matrix — Remedy-produced Water Management System
Groundwater Remedy Operation and Maintenance Manual
Volume 3: Contingency Plan
PG&E Topock Compressor Station, Needles, California

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations				Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition					Notes
			Mitigation	Observable Condition		Action if Cause Occurs				A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Significant Change to Impacts (Additional CEQA Analysis)	E. H&S or Compliance NOV (other than related to remedy performance)	
				Remedy SCADA	Human										
	f. IRZ and other on-site reuse/disposal options do not have the capacity to take all treated water – Short term condition	N/A	Storage	N/A	N/A	Adjust operations	2	1	2						
	g. IRZ and other on-site reuse/disposal options do not have the capacity to take all treated water – Long term condition	N/A	Evaluate alternative re-use options	N/A	N/A	Trucking	3	1	3						.
	h. More wells or higher flow rates are needed to achieve RAOs, which produces more water to manage	Reserve space for additional storage and/or conditioning equipment	N/A	N/A	N/A	N/A	2	1	2						See Note 3.
2. Poor Quality Water to Wells: High or low pH Effect without Mitigation: Out of Spec Water may cause increased well or formation fouling or geochemical changes releasing minerals which could affect IRZ performance or plume composition. Excessive pH either high or low could reduce or change microorganism populations, which in turn could also reduce IRZ performance.	a. Tank eductor failure, and poor mixing of conditioning chemicals	Install redundant tank eductors	N/A	N/A	If chemical addition loses effectiveness at altering pH. Will do periodic visual inspections of educators	Repair or replace	1	1	1						
	b. pH Analyzer Failure	Install analyzers on influent and conditioned water tanks	Periodic calibration and system inspections	High and low alarm	Scheduled inspections and monitoring with handheld meter	N/A	1	1	1						
3. Poor Quality Water to Wells: High Suspended Solids Effect without Mitigation: Increase potential for well fouling which could result in increased well maintenance	Cartridge filter rupture or operator not install cartridge	Install turbidity analyzers on conditioned water tanks	Injection well performance monitoring SOP and RPWC System SOPs.[4] Normal operation is flow through 2-stage filters. Standby filter put into service if operating filter is fouled	Alarms on analyzers	Equipment inspections	Follow well maintenance procedures (Section 4), replace cartridges	2	1	2						

TABLE 2.2-1
Failure Mode Effect Analysis Matrix — Remedy-produced Water Management System
Groundwater Remedy Operation and Maintenance Manual
Volume 3: Contingency Plan
PG&E Topock Compressor Station, Needles, California

Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation - Operations: Mitigation	Observable Condition: Remedy SCADA	Observable Condition: Human	Action if Cause Occurs	Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	Type of Unacceptable Condition: A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Significant Change to Impacts (Additional CEQA Analysis)	E. H&S or Compliance NOV (other than related to remedy performance)	Notes
4. Poor Quality Water to Wells: Presence of scaling ions: (Ca, Mg, Mn, Fe, etc.) or high pH water Effect without Mitigation: Scaling in pipelines and wells	Presence of ions in well water	Reserve space to add conditioning units, if needed. These contingent units are described in Section 2.2 of this Contingency Plan. Pipe blowoffs and cleanouts are included in the pipelines. May need to add anti-scalants continuously or use other chemical cleaners.	Monitor effluent quality and injection well performance (see additional information in the Notes column).	N/A	N/A	Follow well maintenance procedures (Section 4)	2	2	4						System is not designed for removing dissolved metals. Modify conditioning process if dissolved ions and metals pose or are causing declining well performance. Addition of conditioning methods may be required if pH increase is not effective in removing constituents. More frequent rehabs or backwash at wells that are fouling due to poor effluent water quality.
5. Equipment Failure Effect Without Mitigation: Leak, contamination, personnel exposure	a. Pipe rupture	Select piping material that is appropriate for the liquid being conveyed and is rated for the anticipated operating pressure.	N/A	N/A	Visual	Follow SOPs,[4] and perform repair	2	1	2						
	b. Tank Failure	Install tank vents, barriers to prevent vehicle impact, seismic supports, coatings, corrosion protection system, and secondary containment for tanks	Preventive maintenance	N/A	Visual	Follow SOPs,[4] and perform repair	2	1	2						
	c. Pump Failure	Mech. seals, drainage for leaks and drips, evaluate seal flush system destination, evaluate cavitation potential on low suction head pumps.	Preventive maintenance	Run fail indication	N/A	Follow SOPs[4] for pump and seals, and perform repair	1	1	1						
	d. Filter failure	Install instrumentation to measure pressure across the filters and alarm. Install 2-stage filters (coarse and fine). Set vessel pressure rating to contain “deadhead” pump condition.	Preventive maintenance	Increased pressure across filters	N/A	Follow SOPs,[4] and perform repair/ replace cartridges	1	1	1						
	e. Eductor failure	Install multiple tank eductors. Monitor vacuum on educator to evaluate erosion or fouling.	Preventive maintenance and inspection. Do routine maintenance and adjust procedures and equipment accordingly.	N/A	Visual inspections/ maintenance	Follow SOPs[4] and perform repair/ replace educators.	1	1	1

			Mitigation - Operations							Type of Unacceptable Condition					
				Observable Condition											
Potential Failure and Effect without Mitigation	Potential Cause	Mitigation - Design	Mitigation	Remedy SCADA	Human	Action if Cause Occurs	Severity (1 Low - 5 High)	Likelihood (1 Low - 5 High)	Severity x Likelihood	A. Unacceptable Remedy Performance	B. Significant Schedule Increase	C. Significant Cost Increase	D. Significant Change to Impacts (Additional CEQA Analysis)	E. H&S or Compliance NOV (other than related to remedy performance)	Notes
6. Freezing Effect without mitigation: No fluid flow	Low ambient temperature	Install heat trace for some chemical piping and storage tanks.	Drain system. Other responses include heat tape, wrapping lines with cloth or rags, or placing heat lamps.	N/A	Weather forecast and anticipated outage schedule.	Upgrade freeze protection or change chemical strength or type	2	1	2						Not been a problem historically at TCS or IM-3
7. Spills Effect without Mitigation: Exposure and contamination of soil	Equipment or pipe failure	Provide adequate secondary containment	SOP[4] and training and alarms (also in HMBP, BMPs, SWPPP)	Alarm for pump running and no flow. Secondary containment level alarms	Visual inspections	Drain system, pump to influent storage tanks. Repair leak.	2	1	2						
8. Unexpected constituents/ material by-product in conditioned water Effect without Mitigation: Carry over contaminant to cooling tower or injection wells	a. Not following RPWC SOPs[4]	N/A	Follow the Operation and Maintenance Manual and SOPs	N/A	N/A	Reinforce/training	1	1	1						Examples include, iron, manganese, silica, calcium, magnesium, and biological materials
	b. Unexpected material enters system	N/A	Investigate root cause, re-evaluate well operations, and maintenance procedures (see Section 4)	N/A	N/A	Revise SOPs[4] or process as needed, could modify monitoring procedures.	2	1	2						
9. Lightning Strike Effect without mitigation: Damage to plant may cause shutdown of system. May cause release of produced water or conditioning chemicals	Lightning	Provide lightning protection and adequate secondary containment for tanks and equipment	Maintain appropriate spare parts to minimize downtime. If necessary, can truck offsite or stop backwashing to mitigate downtime of conditioning system.	N/A	Add inspections into SOPs[4] to watch for leaks or overfilling after a strike	Inspect and assess site for damage / mechanical integrity or repair. If necessary, can truck offsite or stop backwashing until repair is done.	2	1	2						
10. Seismic Damage Effect without Mitigation: Damage to plant may cause shutdown of system	Earthquake	Design in accordance with structural design criteria in 90% Basis of Design Report, Appendix C. Provide adequate secondary containment for tanks and equipment	If necessary, can truck offsite or stop backwashing to mitigate downtime of conditioning system.	N/A	N/A	Inspect and assess site for damage / mechanical integrity or repair. If necessary, can truck offsite or stop backwashing until repair is done.	3	1	3						
11. Fire Effect without Mitigation: Damage to plant may cause shutdown of system	Fire	Fire hydrant in proximity of building. Provide adequate secondary containment for equipment and tanks.	Fire water/pumps at station. If necessary, can truck offsite or stop backwashing to mitigate downtime of conditioning system.	N/A	N/A	Contact Fire Dept. Inspect, assess damage, begin repairs, startup. If necessary, can truck offsite or stop backwashing until repair is done.	2	1	2

12. System is damaged due to vandalism Effect without Mitigation: Damage to wells could result in increased trucking or well repair/ replacement. Plant is off-line for weeks to months while being re-built.	Vandalism	Facilities within the TCS will be secured by current TCS security system. Controls built into the system (alarms, containment, automatic cutoffs and shutdowns) are designed to help mitigate uncontrolled releases or discharges following several types of due to vandalism	Periodic inspections of all equipment inside and outside conditioning system and wells. TCS access control and security will help protect plant.	N/A	N/A	Inspect and assess site for damage / mechanical integrity or repair.	2	1	2						

Notes:

[1] Anticipated annual remedy-produced water volume is 7.6 million gallons (MG) per year. With provisional wells this volume could increase to 10 MG per year. The automated backwashing and conditioning system has been designed to accommodate this range of anticipated volume of wastewater. If the system functions as designed, the amount of trucking needed during O&M would be minimal, and within the range analyzed in the certified EIR (DTSC 2011; see Section 3.5.3, page 3-26).

[2] Current estimated annual flow is 7.6 MG; with provisional wells could be 10 MG/yr. Peak design flow is 35 gpm (18.4 MG/yr.).

[3] Space is reserved to allow for increase storage and system conditioning capacity if needed.

[4] Standard Operating Procedures are presented in O&M Manual Volume 1, Operation and Maintenance Plan, Appendix B.

Acronyms and Abbreviations:

ARAR = Applicable or Relevant and Appropriate Requirements
BMP = Best Management Practices
EIR = Environmental Impact Report
H&S = Health & Safety
HMBP = Hazardous Materials Business Plan
IM-3 = Interim Measure No. 3
NOV = Notice of Violation
N/A = Not Applicable
O&M = Operation and Maintenance
RAO = Remedial Action Objective
RPWC = Remedy-Produced Water Conditioning
SCADA = Supervisory Control and Data Acquisition
SOP = Standard Operating Procedure
SWPPP = Storm Water Pollution Prevention Plan
TCS = Topock Compressor Station

TABLE 2.3-1
Failure Mode Effect Analysis Matrix — Freshwater Supply
Groundwater Remedy Operation and Maintenance Manual
Volume 3: Contingency Plan
PG&E Topock Compressor Station, Needles, California

	Failure Mode	Likely Causes for Failure	Effects of Failure	Operational Actions	Possible Contingency Measures
Failure Modes Associated with HNWR-1A Source	Well yield declines below the minimum required for optimal remedy operation[1]	• Pump failure • Extraction well fouling • Excessive drawdown due to competing water users	• Delay in reaching Remedial Action Objectives	• Replace pump • Rehab well • Replace well • Bring HNWR-1 online	• Supplement flow with water from Topock 2/3 or bring Site B well online. Blend Site B water with water from Topock-2/3 and/or HNWR-1/1A. Potentially implement a contingent arsenic treatment system per State Water Resources Control Board letter (SWRCB 2013)[2].
	Quality of water in freshwater well declines over time	• Pumping draws in saline water from below or geochemically reduced water containing iron and manganese	• Could result in shutting down remedial action if water quality is not suitable for injection	• Isolate the upper well screen interval from the lower screen interval (e.g., using an in-well packer) • Aerate freshwater prior to injection (note that this option requires a small amount of piping changes and addition of fittings) • Increase riverbank extraction (note that this option could only be used to offset a marginal reduction in freshwater supply)	• Supplement flow with water from Topock 2/3 or bring Site B well on line. • Potentially implement a contingent arsenic treatment system per State Water Resources Control Board letter (SWRCB 2013)[2]
	Freshwater pumping causes adverse effects on water quality or capacity in nearby wells	• Over pumping of aquifer in areas with marginal groundwater quality / transmissivity	• Could result in shutting down remedial action if affected water users cannot be made whole	• None	• Bring Site B well on line. Blend Site B water with water from Topock-2/3 and/or HNWR-1/1A. Potentially implement a contingent arsenic treatment system per State Water Resources Control Board letter (SWRCB 2013)[2]

Notes:

[1] PG&E provided a response to a two-part question regarding the potential effects of a prolonged drought on Arizona water supply and the remedy process via an email from Yvonne Meeks/PG&E to Doug Bonamici/Colorado River Indian Tribes, titled Re; February TWG Action Item and dated March 24, 2015. The questions and responses are stated as follows:

"1.) Are you saying severe drought will not adversely affect remedy flow characteristics as it operates, and,

PG&E Response: That's correct, PG&E professional judgment is that potential future drought conditions would not be expected to significantly impact the remedy flow characteristics as it operates, and therefore the remedy performance or simulated timeframes. The remedy doesn't depend on local precipitation for its function.

2) That a prolonged drought is unlikely to reduce/impair the availability of Arizona freshwater supply so much that it would jeopardize the remedy process?

PG&E Response: Again correct, as long as there is flow in the Colorado River, then the remedy is expected function as designed (including the availability of freshwater from Arizona). The aquifer on both sides of the river Topock is fed by the Colorado River and the river is

TABLE 2.3-1
Failure Mode Effect Analysis Matrix — Freshwater Supply

Failure Mode	Likely Causes for Failure	Effects of Failure	Operational Actions	Possible Contingency Measures

highly controlled by the dams upstream. So as long as there is some water flowing in the Colorado River, there would be adequate water in the aquifer to support the pumping associated with the remedy.

Although it has never happened, in an extreme drought there could possibly be curtailments on water usage in the Colorado River basin. That could cause PG&E, along with other water users, to have to reduce pumping – although we have water rights well in excess of planned pumping needs. A reduction in pumping would not result in a failure of the remedy. The natural hydraulic gradient would continue to move the plume through the IRZ even in the absence of pumping, just at a slower rate."

[2] The referenced letter provides the SWRCB's findings and conditions for allowing injection of fresh water containing naturally occurring arsenic above the maximum contaminant level (MCL) without pre-treatment. The letter requires that if the leading edge of the arsenic plume above the 10 parts per billion [μg/L] water quality objective extends more than 150 feet away from injection locations, PG&E must immediately reassess its modeling calculations and quickly identify interim actions it can take to limit the migration of the arsenic plume. The letter further directs the cessation of the injection of untreated fresh water if the arsenic concentration caused by injection of fresh water is detected above the water quality objective (10 μg/L) at 225 feet from the injection locations. The letter states that at this point, DTSC should either (i) require pretreatment to remove arsenic prior to injection or (ii) require another source of fresh water in order to meet the water quality objective.

Contingent Dissolved Metals Removal System Conceptual Design Basis

Contingent Dissolved Metals Removal System Conceptual Design Basis
PG&E Topock Compressor Station, Needles, California

PREPARED FOR: Pacific Gas and Electric Company

PREPARED BY: CH2M HILL

DATE: August 14, 2014

1.0 Introduction

In response to the California Department of Toxic Substances Control's (DTSC's) comment #757 DTSC-239 and the Tribes' comment #341 on the 60% Basis of Design Report for Pacific Gas and Electric Company's (PG&E's) Final Groundwater Remedy for the Topock Compressor Station (TCS), a contingency plan to remove scaling ions from remedy-produced water is presented in this technical memorandum (TM). The information contained herein includes a description of the contingent removal system along with an estimate of the system footprint, chemical use, electricity use, and waste generation.

The contingent system, referred to herein as the dissolved metals removal system (DMRS), will be located entirely in the planned Remedy-produced Water Conditioning Building inside the TCS. No additional footprint is required for installation of this contingency system. The DMRS is designed to be fully integrated into the currently planned conditioning process for remedy-produced water, thereby allowing for easy installation if required in the future.

The DMRS will be primarily located on the second floor of the Remedy-produced Water Conditioning Building. Certain treatment chemicals will be stored on the first floor of the planned Remedy-produced Water Conditioning Building. For additional information on Remedy Produced Water management, see Appendix F of the Basis of Design Report (CH2M HILL, 2014).

2.0 Water Quality, Treatment Goals, and Design Flow Rates

This conceptual basis of design is based on Topock-specific groundwater data collected from Floodplain Area monitoring wells and in-situ pilot test wells, as well as experience in designing and operating iron, manganese, calcium, and magnesium groundwater treatment systems on non-Topock projects. Once the Final Groundwater Remedy is up and running, this basis of design should, at a minimum, be verified with actual water quality information and any adjustments to the conceptual design should be made accordingly.

Prior to implementation, bench-scale and pilot-scale tests should be conducted using actual remedy-produced water to determine the final design of the DMRS and finalize equipment selection.

2.1 Design Influent Water Quality

For the purpose of this conceptual design, it is assumed that the quality of remedy-produced water generated from the future National Trails Highway (NTH) In-situ Reactive Zone (IRZ) injections wells will be similar to the groundwater quality data of the existing Floodplain Area monitoring wells that are considered to be anoxic (that is, low oxygen concentrations representative of anticipated groundwater during IRZ operations). Table 1 (presented at the end of this TM) summarizes the groundwater quality for these Floodplain Area anoxic monitoring wells (data collected through November 2013). The mean concentrations of the parameters in the anoxic Floodplain Area monitoring wells are the primary basis of the "expected" concentrations of DMRS influent water quality parameters. Exhibit 1 summarizes the DMRS influent water quality and flow design basis.

EXHIBIT 1
Conceptual Design Flow Rate, Influent Water Quality, and Treatment Goals
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

Parameter	Units	Expected Influent Value [a]	Upper Expected Influent Value [a]	Target Effluent Value
Process Flow Rate	Gallons per minute	20-35		
pH	pH units	7.4	7.9	6.5-8.5
Alkalinity	mg/L (as $CaCO_3$)	160	330	--
Total Dissolved Solids	mg/L	6,000	12,000	--
Temperature	degrees Celsius	29.0	30.5	--
Iron	mg/L	2.6	8.6	< 0.15
Manganese	mg/L	1.8	2.7	< 0.02
Calcium	mg/L	304	500	< 200[b]
Magnesium	mg/L	99	150	--
Chloride	mg/L	2,600	4,050	--
Sulfate	mg/L	790	1,550	--
CCPP [c]	mg/L	21.2	121	< 0

Notes:
[a] Values are estimated on the basis of existing groundwater data and anticipated changes in groundwater conditions at injection wells. Remedy-produced water quality data collected after the Final Groundwater Remedy is implemented should be compared to these expected values, and the final design should be adjusted accordingly. Bench-scale tests for equipment components should also be conducted using remedy-produced water in the final design.

[b] The target effluent value of calcium is the concentration threshold determined using WaterPro for which the calcium carbonate precipitation potential (CCPP) is less than zero when all other water quality parameters are at their expected concentrations.

[c] CCPP is used as the indicator to evaluate the potential for scaling to occur for this memorandum. CCPP is estimated using WaterPro.

-- = No target value specified

2013 Annual Monitoring Report for the Floodplain Reductive Zone In-Situ Pilot Test, Tables 3 and 4 (ARCADIS, 2013)
Concentrations in Floodplain Area monitoring wells (see Table 1 at the end of this TM).

2.2 Design Flow Rate and Treatment Goals

The design flow rate is equivalent to the design flow rates of the Remedy-produced Water Conditioning System. The DMRS will be designed to treat “A-side” remedy-produced water only, as this is the water that is likely to have high concentrations of scaling compounds. The goal of the DMRS is to minimize precipitation of iron, manganese, calcium, and magnesium in the piping system and the injection wells by removing the metals. Exhibit 1 shows the DMRS design flow rates and the treatment goals.

Concentrations of iron and manganese that will not cause adverse aesthetic effects are defined as secondary maximum contaminant levels (MCLs). Aesthetic effects include such things as scaling and discoloration, but do not cause adverse health effects. The target effluent concentration values for iron and manganese shown in Exhibit 1 are about 50% lower than their respective secondary MCLs in order to provide more protection from scaling. Calcium and magnesium contribute to water “hardness,” and the influent water quality

conditions shown in Exhibit 1 are considered "very hard"(typically water with combined hardness concentrations greater than 300 milligrams per liter [mg/L] as calcium carbonate ($CaCO_3$) is considered very hard [American Water Works Association, 1995]). Under these influent water quality conditions, calcium and magnesium will likely scale the piping and wells, and thus the treatment goal would be to reduce the magnesium and calcium concentrations so they do not precipitate. The degree to which calcium and magnesium precipitate depends on pH, temperature, and dissolved salt concentrations, and the calcium carbonate precipitation potential (CCPP) will be used as the indicator in this conceptual design.

Water!Pro™ [1](WaterPro) modeling software was used to evaluate the design water quality and establish a design treatment goal. The treatment goal for calcium is the concentration threshold determined by WaterPro for which the CCPP is less than zero when all other water quality parameters are at their expected concentrations (note that a measure of CCPP below zero indicates that calcium carbonate is under-saturated in solution, therefore not likely to precipitate).

3.0 Evaluation and Selection of Removal Technologies

For this conceptual design basis, PG&E has identified and evaluated proven treatment technologies for iron, manganese, calcium, and magnesium that have been successfully used by municipalities and industry. Unproven technologies or technologies that have not been widely used in full-scale applications were not considered.

The initial technologies considered included the following:

- For iron and manganese:
  - Oxidation with several oxidants followed by filtration
  - Biological removal
  - Chemical precipitation softening (with lime or caustic)
  - Ion (cation) exchange
  - Adsorption onto manganese oxide-containing media such as manganese dioxide (MnO_2) or greensand
- For calcium and magnesium:
  - Ion (cation) exchange
  - Chemical precipitation softening (with lime, soda ash and/or caustic [sodium hydroxide])
  - Membrane softening with reverse osmosis or nanofiltration membranes

Descriptions of the considered technologies and a discussion of the preferred technology that was selected are presented in the subsections below; the conceptual design is then presented in Section 4.0.

3.1 Iron and Manganese Removal

There are many effective iron and manganese treatment methods available, including oxidation and filtration, chemical precipitation softening, adsorptive filtration, ion exchange, membrane filtration (e.g., reverse osmosis), and biological filtration (Odell, 2009). Membrane filtration was not considered for the DMRS due to the anticipated high energy usage and large volume of wastewater generated. Biological filtration was eliminated because of the potential for treatment upsets with influent pH changes. The methods of oxidation and filtration and ion (cation) exchange were ruled out because they are typically less effective at the relatively high expected concentrations of iron and manganese in influent water. In addition, ion (cation) exchange for iron and manganese removal was eliminated because all of the iron and manganese must be in the reduced form for this process to be effective and some of the iron and manganese in the remedy-produced water is likely to be oxidized.

[1] Corrosion Control & Treatment Process Modeling Program developed by Schott Engineering Associates for use with Microsoft Excel.

Chemical precipitation softening—typically done with lime and less so with caustic—is effective in removing iron and manganese from water, but not typically used due to higher capital costs than other proven technologies; however, it was retained for further consideration as a feasible option.

Adsorptive filtration is a method where the iron and manganese are oxidized, then adsorbed onto one of several available types of high-content manganese oxide-containing mineral surface. Adsorptive filtration with MnO_2 was considered for removing iron and manganese in this conceptual design because of its proven performance, high efficiency, low energy use, low waste generation, and small amount of space needed for equipment.

In this removal method, an oxidant (such as chlorine) is injected just upstream of the filtration vessels. After a short contact time of 15 to 30 seconds, iron and manganese will be oxidized and adsorb onto the surface of the MnO_2 media. The excess chlorine in the process water keeps the MnO_2 media catalytically active by converting the iron and manganese to oxides (ferric hydroxide [$Fe(OH)_3$] and MnO_2), thereby providing additional adsorption sites for oxidation to take place (MWH, 2005). These rapid reactions allow the removal system to be designed with relatively high hydraulic loading rates (i.e., ratio of flow rate to filter cross section area) and small footprint. Any residual chlorine oxidant will be removed to prevent adverse effects when re-injected to the IRZ wells. The filtration vessels are backwashed periodically and any solids that are removed can be settled in a clarifier or decant tank by gravity. Polymers or other settling aids may be needed to improve solids formation. Solids are dewatered before being disposed of off-site. Water can be decanted and recycled back to the head of the process up to 95 percent of the backwash flow.

Another technology that operates using the same principle of oxidation followed by adsorption that has often been used to remove iron and manganese is potassium permanganate oxidation and greensand filtration. However, relative to oxidation followed by MnO_2 adsorption, this technology requires longer contact times, slower loading rates, and larger diameter vessels, and the manganese effluent concentration are more difficult to control (AdEdge, 2004). Potassium permanganate is also not an ideal oxidant because the unreacted permanganate produces pink discoloration of the water and would require removal following treatment. Similar to MnO_2 filtration, the filter beds are backwashed periodically and solids are dewatered and then disposed of off-site.

3.2 Calcium and Magnesium Removal

The technologies considered for calcium and magnesium removal included ion exchange, chemical precipitation softening (with lime, soda ash and/or caustic), and membrane softening with reverse osmosis or nanofiltration membranes. The adsorptive filtration method is effective at removing iron and manganese but ineffective in removing calcium and magnesium, so was discarded.

Ion exchange softening is typically carried out using strong acid cation exchange resins. Using the sodium form of strong acid resin, the sodium ions (Na^+) enter solution and divalent ions such as calcium (Ca^{2+}) and magnesium (Mg^{2+}) are adsorbed to the resin. After a resin bed becomes loaded with Ca^{2+} and Mg^{2+}, it is regenerated with high strength sodium chloride brine solution. The resin bed regeneration involves a sequence of steps consisting of backwashing, brine injection, slow rinse displacement, and fast rinsing. Ion exchange for the anticipated remedy-produced water would result in a large wastewater stream (more than 20 percent of influent flow) and is therefore rejected from further consideration.

Membrane softening with reverse osmosis and nanofiltration membranes was eliminated from consideration because of the high operational costs and the large amount of concentrated brine produced by this alternative (20 percent to 50 percent of the entire plant production).

Chemical softening involves coagulation, flocculation, and sedimentation; these steps occur in one basin, called a solids contact clarifier or reactor clarifier with sludge recirculation (MWH, 2005) or in a package treatment unit. Produced water treated by any of the chemical softening processes needs to be filtered before injecting back into the subsurface.

Lime-soda ash softening, partial (i.e., not fully softened) lime softening, and partial caustic softening are forms of chemical softening in which calcium (Ca^{2+}), magnesium (Mg^{2+}), and a combination of Ca^{2+} and Mg^{2+} along with iron (Fe^{2+}) and manganese (Mn^{2+}) are precipitated by chemical addition to the stream being treated. The chemical reactions are complex but result in primarily solid forms of calcium carbonate, ferric carbonate, and oxides of manganese or manganese hydroxide. If magnesium is precipitated, it would form magnesium hydroxide. Lime-soda ash softening is the most common of these softening processes. Partial (lime or caustic) softening relies on naturally occurring alkalinity in the stream being treated, so no additional soda ash (sodium carbonate) needs to be added.

In the case of the expected influent water quality, the alkalinity (160 to 330 mg/L as $CaCO_3$) is sufficient to precipitate most of the calcium as calcium carbonate using either partial lime or caustic softening. Partial caustic softening has a number of advantages over partial lime softening for calcium removal; for one, addition of caustic, unlike lime, does not introduce additional calcium to the stream that would also need to be removed, and all the alkalinity is used to precipitate calcium from the raw water. Using liquid caustic eliminates the difficulties in handling dry chemical feeding of lime or lime and soda ash. Although caustic is more expensive than lime, the higher cost is partially offset by the reduced labor needed to maintain an all-liquid system. Partial caustic softening also produces less by-product sludge than partial lime softening. Taking all of this into account, partial caustic softening would be the most suitable chemical softening option for calcium and magnesium removal in the DRMS.

3.3 Selected Process

After ruling out all treatment technologies for removal of either iron and manganese or calcium and magnesium that are unsuitable for the DMRS under the anticipated water quality conditions, it is determined that partial caustic softening is the best available option for removing calcium and magnesium as well as iron and manganese. Although not necessarily the least costly alternative for either of the two pairs of target constituents when considered individually, partial caustic softening is the best alternative that will be effective at removing all four constituents from the remedy-produced water stream, obviating the additional costs and design challenges that would be posed by providing two different treatment trains to handle the four constituents. Therefore partial caustic softening was the process selected to carry into the conceptual design stage for removal of calcium and magnesium as well as iron and manganese.

4.0 Contingent Dissolved Metals Removal Process and System Description

This section describes the design philosophy, the removal process, and the conceptual system configuration for a partial chemical softening process using caustic. The process flow diagram (PFD) is shown on Figure 1a and the corresponding mass balance is shown in Figure 1b (figures are presented at the end of this TM).

4.1 System Description

The DMRS is a potential future process addition for the A-side stream of the remedy-produced water conditioning process. The contingent system would be installed downstream of the influent tanks (where batch conditioning including pH adjustment, coagulant addition, solids settling, and sludge draw-off occurs) and the cartridge filters (where suspended solids are removed from the process stream). Exhibit 2 illustrates the contingent dissolved metals removal process and its integration into the planned Remedy produced Water Conditioning System.

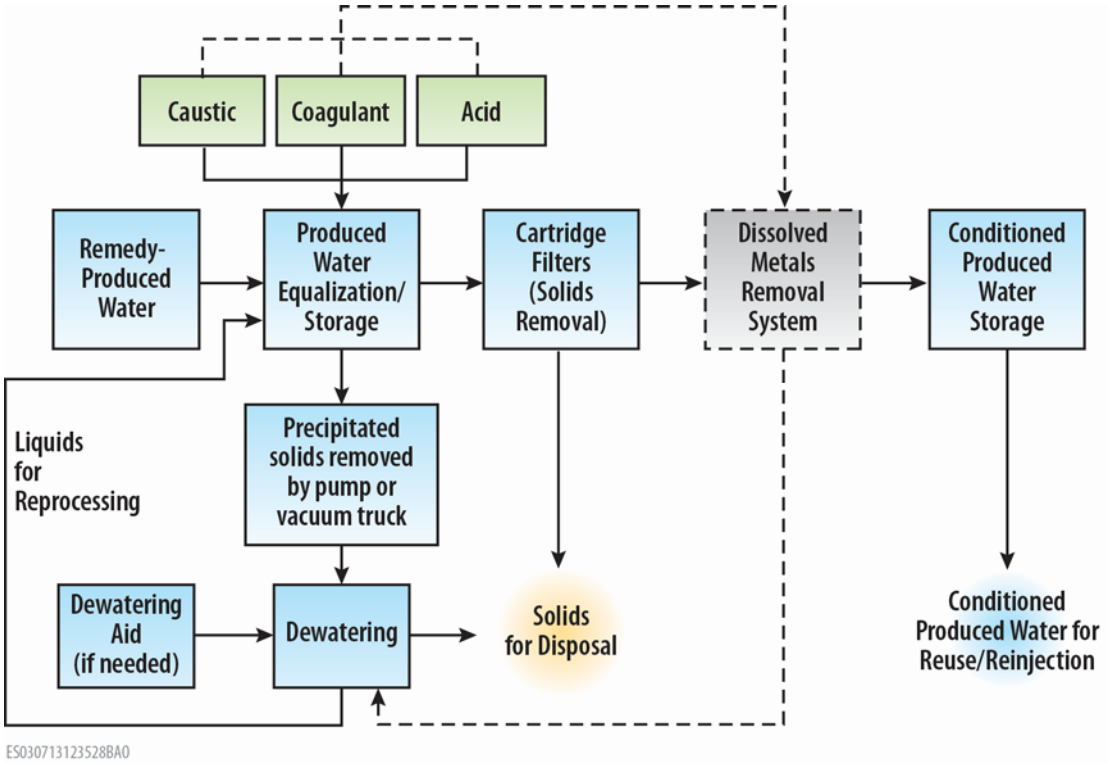

EXHIBIT 2
Dissolved Metals Removal System Schematic Diagram
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

After filtration, the produced water would be fed into a process unit to improve the coagulation/flocculation and enhance solids removal. This unit combines several steps including:

1. Rapid mixing of the chemical agents – Rapid mixing is used to quickly and uniformly disperse the chemical agents throughout the water. Chemical agents will include 25 percent caustic and possibly a coagulant. The need for coagulant would be confirmed during bench-scale testing. Caustic addition would result in a solution pH of 9.7 to 10 to enable sufficient calcium to be removed to achieve a desired CCPP level.
2. Chemical reactions – Calcium forms calcium carbonate, a solid precipitate, by reacting with caustic or sodium carbonate (formed by reaction of carbonic acid with caustic). Magnesium is soluble up to a pH of 11 and so would not be removed to a great extent. Additional residence time is needed in the reaction chamber due to the high dissolved solids concentrations which slow the reaction rate (estimated to be 35 to 40 minutes).
3. Solids formation –The carbonate solids will form as tiny particles initially. A coagulant and also a flocculant may be needed to aid in forming larger masses so as to settle more easily. The use of these chemical agents would be confirmed during bench scale testing
4. Effluent clarification – Carbonate solids would be allowed to settle by gravity to clarify the water. Gravity clarification is often enhanced by the use of parallel plates or tubes to aid in settling the solids. The tubes and plates interfere with the rising solid particles, increasing the rate of agglomeration, thereby causing the solids to settle to the bottom of the process unit. Flocculants can also help with clarification, and if needed would be identified during bench scale testing. A portion of the solids would be recycled

to "seed" the reaction and improve solids settling efficiency. Periodically, solids would be pumped out of the process unit to a dewatering device – in this case the phase separators located in the 1st floor.

As shown on the process flow diagram (Figure 1a), effluent water flows to a clear well and then is pumped through two single or media filter vessels sized for 4 to 6 gallons per minute per square foot (gpm/sq. ft.) hydraulic loading. Both vessels would be in service and the flow would be evenly split between them (parallel configuration). The media beds would be expected to capture any solids escaping the clarifier (15 to 30 mg/L is typical). Iron and manganese removal will be accomplished in the softening step. The filtered water would flow through cartridge filters to a treated water tank and from there be pumped to the conditioned water tank farm. Acid would be added upstream of the media filter vessels to neutralize the pH (to approximately pH 7.5) and to mitigate precipitation of calcium carbonate in the media filters. The neutralized water would be re-injected to the IRZ wells via the clean-in-place (CIP) pump located at the MW-20 Bench.

Filters would be backwashed periodically using filtered water for 10 minutes using a loading rate of 15 gpm/sq. ft. (47 gpm) or 5 minutes using a loading rate of 30 gpm/sq. ft. (94 gpm), depending on the media. The backwash stream would flow to a cone bottom decant tank. The liquid stream would be returned to the influent tanks and solids would be pumped to the phase separators.

4.1.1 Reserved Space for the Contingent DMRS within the Planned Remedy-produced Water Conditioning Plant

Many equipment manufacturers offer solids contact clarifiers with different configurations. These units are sized for larger flows (typically 500,000 gallons per day and larger) than what is anticipated for the DMRS. Some manufacturers offer package treatment units geared for small communities or small industrial facilities for different treatment processes including chemical softening. Solids contact clarifiers typically require a large vertical space to have sufficient mixing, solids accumulation and installation/maintenance for the unit mixers. For the purposes of this conceptual design, a package unit suitable for softening processes (supplied by companies such as Evoqua [formerly Siemens], Veolia, and Infilco Degremont) would be installed in the 2nd floor of the Remedy-produced Water Conditioning Building. The 1st floor has chemical storage and the phase separators for solids dewatering and would be used to support DMRS operations. The general arrangement is shown on Figure 2.

4.1.2 Solid Waste & Wastewater Generation

Solid wastes are generated largely from the solids contact clarifier, with lesser amounts from the filter backwash. Wastewater is generated by daily backwashing of the filter media to reduce pressure losses and maintain uniform bed flow profiles to maintain system performance. Daily backwashing removes precipitated non-hazardous suspended solids including calcium carbonate and precipitated iron and manganese from the media bed. Backwashing is anticipated to occur daily. The solid and liquid portions of the backwash water are separated in the cone bottom decant tank. The liquid portion of the backwash water is expected to have similar qualities to the treated water, with very little soluble scaling ions present. A summary of the waste generation calculations is shown in Exhibit 3.

EXHIBIT 3
Summary of Waste Generation
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

Item	Amount, Units
Backwash wastewater [a]	9,800 gallons per year
Sludge [a]	168 tons per year
Spent filter media	2.6 tons over project life (assume 30 years)

Notes:
[a] Based on assumed volume of 4.67 million gallons per year that would be processed in this system.

The volume of wastewater was estimated based on the following assumptions:

- Backwash rate is 15 to 30 gpm/sq. ft. and vessel cross section area is 3.1 sq. ft, depending on the media provided with the filters.
- Backwashing time is 5 to 10 minutes (5 minutes for the media requiring 30 gpm/sq. ft. and 10 minutes for the media requiring 15 gpm/sq. ft.) resulting in 470 gallons per backwash per vessel.
- Two vessels are backwashed daily.
- 95 percent of the backwash water is recycled to the influent tank farm with the remainder pumped to the evaporation ponds.

The backwash volume of 470 gallons/backwash x 2 vessels/day x 4 days of operation/week x 52 weeks of operation/year x 5% remaining after recycling = 9,800 gallons /year. This volume is small enough that it could be disposed of in the Compressor Station ponds if necessary.

Wastewater sludge is mostly calcium carbonate ($CaCO_3$); for this calculation all of the sludge from the clarifier and backwash filter stream is considered to be $CaCO_3$: 104 mg/L Ca x (1/40 mg/millimole [mmol] Ca) x 1 mmol $CaCO_3$ / mmol Ca x 100 mg $CaCO_3$ /mmol = 260 mg/L.

Pounds of dry solids/million gallons (MG): 260 mg/L x 8.34 lb/MG = 2,170 lb/MG. Assumes the sludge can be dewatered to 3 percent solids.

The amount of dry solids generated per year based on the calculated annual flow (Table 2) is 4.67 MG/yr x 2,170 lb/MG / 0.03 = 337,000 lb / yr = 168 tons/yr.

At 10 tons per phase separator, this results in about 17 phase separator bins being disposed of annually.

The possible disposal of the worn filter media would as also produce a solid waste stream. The filter media has a long service life of typically 10-15 years, but the actual lifespan is project- and system-specific. The mass of solid waste to be managed is estimated based on the following assumptions:

- The media has a specific gravity of 1.92 with water density of 62.4 pounds per cubic foot (cf)
- Each vessel has 11 cf of media
- Two vessels need replacement twice during the project life

Therefore the estimated solid waste generated per year for the DMRS is 2 vessels x 11 cf x 2 replacements = 44 cf x 1.92 x 62.4 lb/cf = 5,270 lb = 2.6 tons.

4.2 Chemical and Media Use

Chemicals will be used in the treatment system for pH adjustment in the partial softening process. WaterPro was used to calculate caustic and hydrochloric acid use. In addition a coagulant and/or flocculent may be necessary for efficient solids removal, and these would be selected during bench-scale testing. The estimated chemical usage is shown in Exhibit 4.

4.3 Electricity Usage

Electricity usage was estimated based on the power consumption from equipment (primarily pumps) usage. The estimated electricity usage of the DMRS is 3,200 kilowatt-hours per year.

EXHIBIT 4
Estimated Chemical Usage
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

Item, Units	25% Caustic	19% Hydrochloric Acid	Coagulant (If needed)	Polymer[b] (If needed)
Calculated dose, mg/L	93	3.6	TBD	1
Pure chemical used, pounds/year [a]	3,600	140	TBD	39
Chemical product usage, gallons/year	340	15	TBD	3.4

Notes:
[a] Based on assumed volume of 4.67 million gallons per year that would be processed in this system.
[b] A polymer if required would be used as a flocculating agent. Its need would be determined during bench scale testing.
mg/L – milligrams per liter
TBD = to be determined

4.4 Controls Philosophy

The system will be automated to reduce the need for continuous operator oversight. Electronic notifications will be sent automatically to on-site operators that notify them of system alarms, shutdown, or other issues. System automation will be controlled using a programmable logic controller that will communicate with the groundwater remedy supervisory control and data acquisition system (SCADA). Remotely controlled valves will have pneumatic actuators if possible for diverting water or stopping flow. Online pH will be incorporated to enable remote process monitoring and control. Iron, manganese, calcium and magnesium cannot be monitored directly using an online analyzer. Grab samples will be collected periodically from sample ports and analyzed using bench-top colorimetric instruments in the sample room (located in the Remedy-produced Water Conditioning Building) to monitor iron, manganese, calcium and magnesium levels.

4.5 Supporting Facilities

As discussed previously, the DMRS would be installed in the Remedy-produced Water Conditioning Building. Electricity will be provided to the Remedy-produced Water Conditioning Building from the Compressor Station. The building will have a heating, ventilation, and air conditioning system for the sample room and electrical equipment room. A programmable logic controller located at the Remedy-produced Water Conditioning Building will control the DMRS with remote monitoring and control accomplished by the groundwater remedy SCADA.

4.6 Contingent DMRS in Relation to the Overall Well Maintenance Program for the Groundwater Remedy

The DMRS, if required, would be a part of the Remedy-produced Water Conditioning System. Effluent water from the DMRS is sent to the A-side conditioned water storage tanks, and from there can be pumped to tank TNK-720 at the MW-20 Bench and returned to the NTH IRZ injection wells via the CIP injection pump and piping that feeds the North and South NTH IRZ headers. If implemented, the blending ratio of the DMRS effluent to total injected water flow is 20-35 gpm to 200-400 gpm. Therefore, the DMRS effluent could account for 5-18 percent of the injected water into the IRZ wells, which is small compared to the amount of groundwater to be injected into the wells. Therefore, routine and non-routine well maintenance procedures will continue to be the primary means to mitigate the effects of scaling/fouling in wells due to dissolved metals. Procedures for well maintenance are described in detail in the Operations and Maintenance (O&M) Plan for the Groundwater Remedy (Volume 1 of the O&M Manual, Section 4 and Appendix B).

4.7 Design Philosophy/Uncertainties in Design

Because this conceptual design was developed absent the actual water quality information of the future groundwater and remedy-produced water and without bench testing the selected equipment and chemicals using remedy-produced water, various uncertainties exist in the design that will need to be confirmed after the Final Remedy is implemented. The design of the DMRS and expected chemical usage, waste production, and electricity usage should be adjusted based on actual water quality information and bench-scale testing results. Some or all of the following testing and bench-scale tests may be needed to confirm the design of the Contingent DMRS:

- Water quality testing of A-side remedy-produced water; this should include testing for key parameters listed in Exhibit 1, as well as other constituents that are prone to causing scaling/fouling of the remedy system.
- Bench-scale testing the process of caustic additions should be conducted using 25 percent caustic (or the final strength/type of caustic selected for the Remedy-produced Water Conditioning Plant) to determine the dose needed to drive the pH of the treated water to the optimal pH between 9.7 and 10 for the chemical softening process.
- Bench-scale testing of the reactor clarifier to determine the effectiveness of the chemical softening processes (coagulation, flocculation, and sedimentation), and what the optimal pH and additional hydraulic residence time is. This testing should also be used to determine if a coagulant or flocculant is needed to aid with solids settling and any possible benefits of solids recycling.
- Bench-scale testing with single or multimedia filters (such as a column test) to determine the effectiveness of the media in lowering levels of iron, manganese, and solids in the clarifier effluent, and to verify the filter sizing, loading rates, and backwash regimen. These results could also affect the size of the treated water tank and cone bottom decant tank.
- Bench-scale testing the process of acidification should be conducted using 19 percent hydrochloric acid (or the final strength/type of acid selected for the Remedy-produced Water Conditioning Plant) to determine the dose needed to drive the pH of the treated water to 7.5 (or an alternative target pH determined from other bench-scale testing).
- Bench-scale testing of media filters backwash water using the Imhoff Cone Test to determine the effectiveness and rate of solids settling in the cone bottom decant tank. Based on these testing results, further analysis should be conducted to determine the necessity of a polymer addition to aid in solids settling. Testing should then be further conducted to determine the appropriate polymer and regimen for use. If the cone bottom decant tank and polymer are unsuccessful, an alternative option such as a low-profile clarifier may be considered.
- Bench-scale testing the process of acidification should be conducted using 19 percent hydrochloric acid (or the final strength/type of acid selected for the Remedy-produced Water Conditioning Plant) to determine the dose needed to drive the pH of the treated water to 7.5 (or an alternative target pH determined from other bench-scale testing).

Based on the results of the tests listed above, the need for additional and/or alternative testing may be determined and should be conducted as warranted. The conceptual design is conservative in assuming that iron, manganese, calcium and magnesium will all contribute to scaling in pipelines. However, if bench-scale testing determines that one or more or the constituents are not affecting remedy performance, equipment and process steps may need to be modified accordingly.

5.0 Design Information

Process calculations used to develop the design criteria were prepared using the estimated water quality in the NTH IRZ injection wells. Conceptual design information is presented in Tables 2 and 3 and on Figures 1a, 1b, and 2 attached at the end of this TM.

Notes:

[1] Data collected from Topock monitoring wells located in the Floodplain Area that are situated in anoxic groundwater conditions, through November 2013. Remedy-produced water entering the DMRS will largely be extracted from wells in the Floodplain Area or wells in anoxic conditions.

[2] The background threshold value (BTV) is the upper limit estimate of the background concentration of the constituent based on statistical analysis.

[3] Data collected from Floodplain Reductive Zone In-Situ Pilot Test from March 2006 to July 2013 (ARCADIS, 2013). Data represent the changing groundwater conditions over time due to the injection of a food-grade reagent mixture into groundwater, which is what will be implemented in the final groundwater remedy.

[4] Data collected from the influent of the Topock Interim Measure 3 (IM-3) groundwater treatment system. Data are from a total of 11 samples collected between June 2009 and June 2012. Wells that feed IM-3 are situated in generally more oxic groundwater conditions than the expected anoxic conditions of the remedy-produced water. Therefore, IM-3 influent data are the least significant of the datasets presented. Nondetect concentrations are included in the minimum, maximum, and mean value calculations at their reporting limits.

NC = Not calculated

-- = Not available

TABLE 2
Conceptual Design Criteria for Contingent Dissolved Metals Removal System
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
OPERATIONAL CRITERIA		
Maximum Process Flow Capacity	35 gpm	
Average Process Flow Capacity	20 gpm	
Average Daily Flow – Well Rehabilitation Period (22 weeks/year)	29,645 gallons	A side water is processed 4 days of the week. Assume annual well rehabilitation takes place for continuous period of time limiting the number of days routine backwashing can occur..
Average Daily Flow – Rest of the year (30 weeks/year)	17,145 gallons	A side water is processed 4 days of the week during normal backwashing operations.
Annual Flow	4,670,000 gallons	
SITE CIVIL		
Location	Remedy-produced Water Conditioning Plant at PG&E Topock Compressor Station near Needles, California.	
Building Finish Floor Elevation	Finished first floor, Elevation 626 feet (NGVD88). Finished second floor, Elevation 640 feet (NGVD88)	
Grading	Longitudinal Slopes: Minimum 1% away from structures (2% desirable).	
Vehicle Access	WB 50 (turning radius for semi-truck and trailer with 50-foot wheel base). Highway truck (wheel loading on access roadways and parking areas). 50-foot minimum turning radius. Designated site accommodates truck circulation. Roads will be constructed at new facility for maintenance activities.	Required for delivery of chemicals, pumps, motors, and fire vehicles.
Site Constraints	Proposed facility located within the boundary of the compressor station. Access to all critical compressor station facilities must be maintained.	No modifications to the perimeter site fence or entrance gate will be made.
Parking	No parking will be required for new facility.	
Pedestrian Traffic	Limited to paved roadways, sidewalks are not located between existing facilities.	
PROCESS EQUIPMENT, MOTORS, VALVES, AND ANCILLARIES		
Treatment Process	Partial caustic softening to remove calcium and magnesium hardness and iron and manganese. This will be accomplished largely in a solids contact clarifier or package treatment unit. Process steps include rapid chemical mixing, softening reaction, coagulation, flocculation, settling, sludge recirculation, and sludge withdrawal. Effluent is filtered in media and cartridge filters to achieve desired effluent quality.	Design criteria listed below are what is expected from planned pre-purchase bid, but not a guarantee of what equipment will be selected. The information in this section will be verified during the detailed design.

TABLE 2
Conceptual Design Criteria for Contingent Dissolved Metals Removal System
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Softening Treatment		
Treatment Objective	Hardness and iron and manganese removal	Primary iron and manganese removal will be through media filters, but some removal will be accomplished in softening step.
Number of Clarifier Units	One	Package treatment unit designed for chemical softening
Number of Media Vessels	Two	Single or multimedia vessels designed for solids removal
Reaction Zone Residence Time	35 to 40 minutes	Allow additional time to counteract reduced rate caused by salty (high TDS) groundwater
Rise Rate	0.75 gpm/square foot	
Materials of Construction	Carbon steel vessels with internal epoxy lining skid-mounted on structural steel frame	
Performance Targets		
Effluent Iron Concentration	< 0.15 mg/L	This performance target is for media filter effluent. Empirical evidence shows that Fe concentrations > 0.15 mg/L cause scaling
Effluent Manganese Concentration	< 0.02 mg/L	This performance criterion is for media filter effluent. Empirical evidence shows that Mn concentrations > 0.02 mg/L cause scaling
Effluent Calcium Concentration	< 200 mg/L	By definition, calcium carbonate precipitation potential (CCPP) < 0 mg/L indicates that calcium carbonate is undersaturated in solution. The WaterPro™ model indicates that CCPP < 0 when calcium concentrations <200 mg/L and with the remaining parameters are at their “expected” values.
Caustic Feed System		
Chemical Feed System	One chemical feeder system— high-density cross-link polyethylene (HDXLPE) tank and pump skid with duplex pumps, controller, and panel with 120 volt receptacle. Sized for up to 10 gph. Tank sized for minimum one month’s storage (approximately 55 gallons)	Assumed able to use all of planned Remedy-produced Water Conditioning caustic feed system.
Safety Equipment	One eyewash and shower unit	Use planned 2nd floor unit
Coatings/Finishes	Chemical resistant coatings in chemical areas	
Controls	Chemical feed pump speed control and tank level controls	

TABLE 2
Conceptual Design Criteria for Contingent Dissolved Metals Removal System
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Acid Feed System		
Chemical Feed System	One chemical pump system —Pump skid with duplex pumps, controller, and panel with 120 volt receptacle. Sized for up to 0.01 gph. Tank not needed due to low demand of 15 gallons per year.	Assumed able to use all of planned Remedy-produced Water Conditioning acid feed system.
Safety Equipment	One eyewash and shower unit	Use planned 2nd floor unit
Coatings/Finishes	Chemical resistant coatings in chemical areas	
Controls	Chemical feed pump speed control and tank level controls	
Backwash Tank and Treated Water Tank		
Number	Two	One cone bottom tank (Backwash Tank) and one flat bottom tank (Treated Water Tank).
Material	Fiberglass Reinforced Plastic (FRP)	An ultra-high molecular weight coating may be considered for the inside surface of the cone bottom tank (Backwash Tank) to improve the slickness of the surface for solids to settle onto.
Capacity	1,000-gallon tanks	Backwash is anticipated to be approximately 470 gallons per vessel (940 gallons total per day) – 10 minutes of backwashing at 15 gpm/ft^2 or 5 minutes of backwashing at 30 gpm/ft^2 depending upon filter media. Backwash tank will have cone bottom to aid in solids recovery and improve backwash recycle rate.
Static Mixer		
Number	As required	
Diameter	2-inch	
Type	Wafer style with integral injection ports	
Piping Materials		
Process	HDPE SDR 11 or CPVC Schedule 80, per ASTM D1784, ASTM D1785, and NSF/ANSI 14 and NSF 61 listed	
Potable Water	Buried: Copper, Type K, per ASTM B88 Exposed: Copper, Type L, per ASTM B88 or CPVC Sch. 80	
Process Piping Installation	Major process piping headers will be installed in pipe trenches inside the treatment building and buried outside the building. Media vessel piping will be aboveground. Actuated valves will be installed above grade whenever possible.

Cooling Load Basis	Building envelope heat gain and internal heat gains from equipment.	
System Type		
Process Building	None.	
PLUMBING		
Lavatory/Toilet Room	No facilities provided.	
Potable Water	Existing emergency shower/eye wash station available on 2nd floor of building.	Per 2010 California Plumbing Code, and ANSI Z358.1.
Non-potable Water	The non-potable water supply will have a reduced pressure backflow preventer. Non-potable water will be supplied for wash down water. Wash down hose valves, hoses and hose racks will be furnished in the area as required.	Per 2010 California Plumbing Code.

TABLE 2
Conceptual Design Criteria for Contingent Dissolved Metals Removal System
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
ELECTRICAL		
Electrical Load	The electrical load will consist of process pumps, motor operated valves, filter system, control panel and instrumentation. Power distribution will be sized in accordance with NFPA 70 (National Electric Code) to operate process and facility loads. Short-circuit current interrupting capacity of power distribution equipment will be coordinated with existing power distribution system.	.
Service Voltage	480V, 3-phase, 3-wire power will be supplied from XFMR 099	
Utilization Voltage	Appendix C, 90% Basis of Design Report (CH2M HILL, 2014)	
Redundancy Requirements	Power distribution system redundancy will be limited to equipment supporting the operation of back-up process and facility equipment (i.e. motor control combination starters, and breakers,). Power distribution system will incorporate spare breakers and fuses. Supporting quick replacement of failed components.	.
Manufacturers of Electrical Equipment, Grounding, Lightning Protection, Illumination, Emergency Lights, Stand-by/Backup Power, Raceways, and Duct Banks	Appendix C, 90% Basis of Design Report (CH2M HILL, 2014)	
SECURITY		
Security	None	All security covered through TCS main facility
CONTROL AND TELEMETRY		
Control and Telemetry Design Criteria	The treatment vessels will be a packaged system with the equipment manufacturer providing a fully configured programmable logic controller based system control panel with panel-mounted operator interface terminal. The control panel will be specified with an uninterruptible power supply to provide true online conditioned power sized to operate the connected load for 30 minutes.	
Communications, Other Networks, Supervisory Control and Data Acquisition, Instrumentation	Appendix C, 90% Basis of Design Report (CH2M HILL, 2014)

TABLE 3
Preliminary Major Equipment List
Contingent Dissolved Metals Removal System Conceptual Design Basis TM
PG&E Topock Compressor Station, Needles, California

Quantity	Name	Description
2	Single or Multimedia Filter Vessels	2 foot diameter carbon steel vessels with internal epoxy lining skid-mounted on a structural steel frame (maximum of 6 gpm/sq. ft. feed hydraulic loading rate and 15 to 30 gpm/sq. ft. backwash hydraulic loading rates)
1	Package treatment unit designed for chemical softening	Carbon steel epoxy coated internals. Functions include softening, coagulation, flocculation, settling, sludge recirculation, and sludge withdrawal. Complete with mixers, scrapers and other mechanical equipment (sludge pump). Automatic operation with built in control panel and digital controller allowing communication/control to Remedy SCADA.
1	Chemical Feed System	No new equipment needed; use planned acid and caustic feed systems
2	Media Filter Feed Pumps	Duplex centrifugal pumps
1	Duplex cartridge filters with replaceable elements	Package unit with differential pressure indication and alarm, automated valves (pneumatic type), and electric actuated purge valves
2	Backwash Recycle Pumps	Duplex centrifugal pumps
1	Treated Water Tank	Flat bottom 1,000 gallon fiberglass reinforced plastic tank
1	Backwash Tank	Cone bottom 1,000 gallon fiberglass reinforced plastic tank provided with tank support
1	Backwash Solids Pump	Air operated diaphragm pump
1	Softener Clearwell	250 gallon HDPE tank, flat bottom
2	Backwash Pumps	Duplex centrifugal pumps
2	Treated Water Pumps	Duplex centrifugal pumps
1	Polymer System (contingency)	Pre-engineered skid with chemical metering pumps for polymer

Figures

Notes:

1. Package unit designed for softening applications includes functions for softening, coagulation, flocculation, settling, sludge recirculation, and sludge withdrawal. Unit is provided with mixers, scrapers and other mechanical equipment. Package unit designed for automatic operation with built-in control panel and digital controller. Polymer and coagulant may be added based on bench-scale testing of produced water and are not shown for clarity.

2. The conditioned water is pumped from the Conditioned Water Tank Farm to the T-720 Frac Tank at the MW-20 Bench where it is re-injected into the IRZ wells.

3. Chemical feed systems are existing and are assumed to have capacity to support this process.

PREPARED FOR: Pacific Gas and Electric Company

PREPARED BY: CH2M HILL

DATE: August 28, 2014

1.0 Introduction

Since the submittal of the 60% design of the Pacific Gas and Electric Company (PG&E) Topock Compressor Station (TCS) (CH2M HILL 2013), the State Water Resources Control Board (State Board) has issued a decision letter on November 20, 2013, and the California Department of Toxic Substances Control (DTSC) has provided direction in its comment on the 60% design (#145 DTSC-50) that will include an arsenic pre-treatment contingency as part of the 90% design. In compliance with this DTSC directive, this technical memorandum (TM) presents the design basis for a potential future pre-treatment option for freshwater.

This option assumes that the primary source is groundwater from well HNWR-1A and the secondary source is groundwater from wells HNWR-1 or Site B. All three freshwater supply wells are located in Arizona. This assumption will be revisited after completion of the alternative freshwater source evaluation—the field work is currently under way. The potential future treatment system, referred to herein as the freshwater pre-injection treatment system (FWPTS), will be located in the vicinity of the planned remedy-produced water-conditioning plant. All components of the FWPTS are located on previously disturbed areas within the PG&E-owned parcel.

The treatment goals of the FWPTS are arsenic removal to concentrations less than the federal and California maximum contaminant level (MCL) of 10 micrograms per liter (µg/L) (California Department of Public Health, 2013). This TM discusses the evaluation of available treatment technologies for arsenic; the selection of technologies for bench-scale testing; the results from bench-scale testing at CH2M HILL's Applied Science Laboratory (ASL) in Corvallis, Oregon; and the design basis/design criteria for the FWPTS. This document also includes a process flow diagram, a preliminary equipment layout, and a preliminary list of key equipment.

The design information presented herein has been developed based on Topock-specific information (that is, bench-scale testing results of HNWR-1 water) and experience in designing and operating arsenic groundwater treatment systems on non-Topock projects. Because of its location, the potential future FWPTS will be designed to achieve a safe, harmonious, and sustainable operation within TCS. Engineering design details of the FWPTS are included in the 90% design.

2.0 Freshwater Water Quality, Treatment Goals, and Design Flow Rates

For the purpose of this conceptual design, it is assumed that the water quality from the future supply well (HNWR-1A) in Arizona is similar to that of the HNWR-1 well. PG&E has collected and analyzed six samples from HNWR-1 starting in November 2010. Analytical results from November 2010 through February 2014 indicate that the naturally-occurring arsenic concentrations in HNWR-1 water were 14-16 µg/L, greater than the federal and California MCL of 10 µg/L arsenic. Tables 1A and 1B summarize available analytical results for HNWR-1 (all tables and figures are presented at the end of this TM). As previously mentioned, the treatment goals for the FWPTS are to remove arsenic to concentrations less than 10 µg/L.

The total freshwater supply flow rates are based on the sum of the modeled freshwater flows into the Freshwater and Inner Recirculation Loop injection wells. The FWPTS will be designed to treat freshwater for remedy injection only. Exhibit 1 shows the FWPTS design flow rates.

3.0 Evaluation and Selection of Treatment Technologies

For this conceptual design basis, PG&E has identified and evaluated proven treatment technologies for arsenic that are United States Environmental Protection Agency (USEPA) Best Available Technologies (USEPA 2001) and have been successfully used by municipalities and industry. Unproven technologies or technologies that have not been used in full-scale applications were not considered.

The initial list included nine technologies: anion exchange, activated alumina (AA) adsorbents, reverse osmosis (RO), electrodialysis reversal (EDR), lime softening, distillation, iron-based adsorbents, titanium-based adsorbents, and coagulation/filtration (see Exhibit 2). These technologies were evaluated and screened in a two-step process: (1) the initial screening was based on the experience of the engineering team with the individual technology, and (2) the second-level screening was based on a set of criteria - namely treatment effectiveness, reliability and flexibility[1], operational complexity, waste generation, footprint, and cost effectiveness. After completion of the technology screening and evaluation process, the AA technology with disposable and regenerable (AA) adsorptive media, coagulation filtration, and iron-based adsorbent granular ferric hydroxide (GFH) were selected for bench-scale testing. For more details of this screening and a description of the evaluation processes, see Attachment A.

EXHIBIT 2
Technologies Considered for Arsenic Removal
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Technology	Evaluation Status
Anion exchange	Screened out, significant waste generation.
AA	Selected for bench-testing
Titanium-based adsorbents	Screened out, similar as other adsorbents considered, with less experience.
Reverse osmosis (RO)	Screened out, significant waste generation.
Electrodialysis reversal (EDR)	Screened out, significant waste generation.
Lime softening	Screened out, significant waste generation.
Distillation	Screened out, significant energy use and capital cost.
Coagulation filtration	Selected for bench-testing
Iron-based adsorbents	Selected for bench-testing

[1] Flexibility is defined as the ability of a system to respond to potential internal or external changes affecting its performance, in a timely and cost-effective manner. Also includes aspects such as handling changes in influent water quality and flowrates.

4.0 Summary of Bench-scale Testing Results

The objectives of bench-scale testing were to: (1) verify the effectiveness of each adsorptive media in removing arsenic from HNWR-1 water to the treatment goals, (2) understand the time to break through (critical for equipment sizing and waste management) for AA and GFH, (3) understand effectiveness of coagulation with a jar test, and (4) understand waste generation amounts. This section summarizes the testing and results to date as it relates to arsenic treatment.

To accomplish the first two objectives, CH2M HILL's ASL employs a testing procedure for evaluating adsorptive media effectiveness in removing arsenic in a small-diameter laboratory column analogous to the rapid small-scale column test method developed for assessing granular-activated carbon in a continuous flow system. This method significantly reduces the amount of time and water required for testing compared to pilot-scale and full-scale systems (USEPA 1996). A jar test was performed to evaluate the effectiveness of ferric chloride as coagulant.

A groundwater sample was continuously pumped, sampled, and collected in three 55-gallon drums from HNWR-1 well in early January 2013 and was shipped to ASL for bench-scale testing. The groundwater sample was processed continuously through the column, and the treated water was sampled and analyzed for arsenic until breakthrough (defined as at least 70 percent of the average influent concentration). After the first breakthrough, the media was regenerated, and the test was repeated. Two treatment cycles (termed Service Cycle 1 and Service Cycle 2) were conducted for regenerable AA (due to fluoride breakthrough caused by the greater affinity of fluoride versus arsenic to AA). Because of time constraints, not all media samples were able to be tested until arsenic breakthrough. In total, 133 liters of HNWR-1 well water were processed using disposable AA and 204 liters using GFH. These samples were tested for as long as time permitted in the laboratory. The rapid small-scale column test results provide information on adsorption capacity (extent of adsorption) and the rate of adsorption (adsorption kinetics), which are the two dominant factors affecting breakthrough in the media columns.

The rapid small-scale column test for arsenic removal was performed using the following media

- Regenerable AA (BASF AA-400G)
- Disposable AA (BASF AA-FS50)
- Alum-impregnated AA (AIAA)
- GFH

Prior to passing the water over the media, the groundwater was pretreated as follows: the pH was adjusted to 6.5 with hydrochloric acid and the water was injected with chlorine to maintain a residual concentration of 1 mg/L for 60 seconds (this is to oxidize any arsenite present in the water to arsenate), and was followed by inline filtration.

Column Testing Treatment Effectiveness and Time to Breakthrough

Figure 1 shows concentrations of arsenic in treated water versus the number of bed-volumes of groundwater passed through (one bed-volume is equivalent to the amount of adsorptive media in the column). During the first service cycle, the regenerable AA performs well, but in the second service cycle the effluent concentration begins to increase more rapidly indicating after the initial service cycle the media loses capacity to adsorb arsenic. Due to this fact and the difficulty in regenerating AA media which requires using strong chemicals like caustic and sulfuric acid increasing safety concerns, cost, and associated wastewater management[2], this method is eliminated from further analysis. The AIAA performed somewhat better than the regenerable AA, but not as well as the disposable AA media. The poorer performance and the additional effort to impregnate the alum onto the AA, eliminates this media from further evaluation. The disposable media performed well to more than 44,000 bed volumes, although the arsenic effluent concentration appears to have increased more than the effluent from the GFH media column.

To ascertain the relative performance of the two media, another figure was prepared (Figure 2), which shows the measured effluent concentration as a function of the amount of arsenic adsorbed on the treatment media. The amount of arsenic absorbed was calculated by multiplying the measured concentration in effluent samples by the volume of water passing through during the sampling interval and dividing by the mass of media in the column.

[2] The estimated wastewater volume ranged from 3.3 to 11 million gallons per year (CH2M HILL 2013).

The effluent concentration in the disposable AA, begins to rise rapidly when the adsorption reaches 0.4 µg/mg media where as in the GFH varies between 0.15 and 0.35 µg/mg media until the test was stopped. These results more clearly indicate GFH will perform better.

Jar Testing Results

Jar testing was performed to test arsenic removal by coagulation with ferric chloride. Water samples were pre-oxidized with free chlorine dosed to provide approximately 1 mg/L free chlorine residual for 60 seconds prior to ferric chloride addition and mixing. Ferric chloride was added to reach doses 5, 10, 15, and 20 mg/L. The mixers were run at 70 revolutions per minute (rpm) for 30 seconds followed by 25 rpm for 20 minutes. The samples were then filtered through a 0.45 micron filter and the filtered water tested for arsenic and pH.

Figure 3 shows the arsenic concentration versus ferric chloride dose applied during testing. Jar testing demonstrated that arsenic could effectively be removed to <10 µg/L with ferric chloride dosed to 5 mg/L.

Process Selection

As shown above, the GFH was effective at removing arsenic to below the treatment goals (the federal and California MCL of 10 µg/L). The effluent remained less than 1 µg/L of arsenic for over 70,000 bed-volumes. The GFH media performed better than the disposable AA offering longer running periods between media change-outs. Coagulation and filtration although effective creates a solid waste stream 5 times greater than GFH that must be transported and disposed of off-site and is more difficult to operate. Based on these reasons, GFH was selected for the FWPTS design.

Section 5 discusses the treatment and backwash process in more details and provides a summary of the sustainability factors.

5.0 Freshwater Treatment Process and System Description

As previously mentioned, GFH was selected as the treatment technology to be carried forward into the design of the FWPTS. GFH is a granular, ferric-based, non-regenerative media that adsorbs arsenic and other heavy metal ions from solution. The USEPA has identified GFH as an effective media to remove arsenic (USEPA 2003). This section describes the design philosophy, the treatment process, and the system configuration envisioned at this stage. This section also discusses the uncertainties with the ongoing design and the work that is currently underway or being planned to address these uncertainties.

5.1 Treatment System Description

Groundwater will be pumped and conveyed from the future water supply well in Arizona to the remedy freshwater storage tank. Water will be pumped from this tank and will be injected with hypochlorite for arsenic oxidation and with acid to reduce pH to 6.5; both hypochlorite and lower pH improve arsenic removal in the media vessels. After chemical injection, water will be passed through cartridge filters to remove solids that would otherwise clog the media, reducing performance and runtime. With the solids removed, the water will be divided into two or three streams (nominal or maximum flow) and each will be processed through a single treatment media vessel (configured in parallel) in a downward flow direction. Automatic valves will divert the flow to the proper vessels and will control the flow rate into each in service vessel. During nominal flow, the third and treatment media vessel will be in standby mode. During maximum flow, three treatment media vessels will be operating.

PG&E evaluated dechlorination alternatives to remove residual chlorine from the treated freshwater. The reason for this step is to prevent the dechlorination chemicals in the freshwater plume from adversely effecting microorganisms in the remediation zones. Dechlorination is often accomplished by addition of commonly used chemicals such as ascorbic acid, calcium thiosulfate, and hydrogen peroxide. The evaluation included cost-effectiveness and safety issues related with handling and storage, and the results showed calcium thiosulfate was the best. The equipment needed include chemical storage tanks or totes, metering pumps, and an inline static mixer. Due to climate condition at Topock, the equipment would be housed in an air-conditioned storage building.

5.2 Media Backwash & Replacement Process

The amount of wastewater generated is primarily a function of backwash frequency. Backwashing prevents over compaction of the media bed enabling good flow conditions. The media bed should be backwashed once a month for proper media maintenance. Backwashing occurs in an upflow mode, the reverse of normal forward down-flow operation. Once the backwash process is complete, normal forward down-flow operation may resume. Each media vessel backwash process is expected take ten minutes.

At some point during treatment operations, the media will lose its adsorptive capacity and will need to be replaced. Based on bench scale testing, this point is anticipated to be after more than 70,000 bed-volumes or about 8 months at maximum flow rates. The actual replacement frequency will be determined during full-scale operation. For the purpose of the conceptual design, it is assumed that the media will be replaced once a year. Spent media will be removed from each vessel and sent to a landfill. Prior experience operating GFH treatment process shows the spent media is not hazardous (Ela 2006). Waste characterization testing will be performed in accordance with state and federal requirements and facility waste acceptance procedures. Virgin media will be placed in the media vessel and normal forward down-flow operation may resume.

Wastewater & Solid Waste Generation

The volume of wastewater needing to be managed is estimated based on the following assumptions:

- Backwash rate is 15 gpm/sq. ft. and vessel cross section area is 50 sq. ft.
- Backwashing time is 10 minutes resulting in 7,550 gallons per backwash
- Four vessels backwashed monthly at 900 gpm and two vessels backwashed monthly at 450 gpm
- 95 percent of the backwash water is recycled to the beginning of the process

At 450 gpm – 7,550 gallons/backwash x 2 vessels per month x 12 months per year x 5% = 9,000 gallons per year

For 900 gpm – 7,550 gallons/backwash x 4 vessels per month x 12 months per year x 5% = 18,000 gallons per year

The remaining (5 percent of the) backwash water can be discharged to the TCS evaporation ponds or disposed offsite at permitted facilities. There is no need to treat or neutralize the pH of the discharged backwash water as it will be within acceptable ranges. Treated water is used for backwashing and no arsenic desorbs from the media during the backwashing process. Discharged backwash water will have more solids compared to the treated water but it will be able to be pumped to the TCS evaporation ponds or disposed offsite without treatment.

Periodic disposal of the spent GFH media would be required also as a solid waste stream. Based on the bench testing, this would be no more frequently than every 8 months, but is expected to be less frequent. For the purposes of this conceptual design, it is assumed that the media will require annual replacement. The mass of solid waste to be managed

- The media has a specific gravity of 1.1 with water density of 62.4 pounds per cubic foot
- Each vessel has 200 cubic feet of media
- Four vessels need replacement at a rate 900 gpm and 2 vessels at a rate of 450 gpm

At 450 gpm – 200 cubic feet/vessel x 2 vessels per year x 1.1 x 62.4 pounds per cubic foot / 2,000 tons/pound = 13.7 tons per year

At 900 gpm – 200 cubic feet/vessel x 4 vessels per year x 1.1 x 62.4 pounds per cubic foot / 2,000 tons/pound = 27.5 tons per year

5.3 Chemical and Media Use

Chemicals will be used in the treatment system. Chlorine in the form of calcium hypochlorite tablets is used to oxidize arsenite to arsenate. Arsenate is more readily removed by the treatment process. Acid is used in pretreatment to improve adsorption by lowering the pH to about 6.5. The estimated chemical use is shown in Exhibit 3.

EXHIBIT 3
Annual Chemical Usage Rates
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Flow Case	Flowrate, gpm	Hypochlorite, pounds/year	93% Sulfuric Acid, gallons/year	Calcium Thiosulfate
Nominal	450	3,500	5,150	2,550
Maximum	900	7,000	10,300	1,275

5.4 Sustainability Summary

For each of the treatment plant operating scenarios (450 and 900 gpm), sustainability parameters such as waste generation, chemical usage, energy use, and greenhouse gas emissions were estimated for the FWPTS as shown on Exhibit 4.

EXHIBIT 4
Sustainability Summary [a]
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

	Operations								Construction	
Treatment Case	Chemical Truck Trips	Solid Waste Truck Trips	Electricity, kw-hr/yr	Wastewater Generation, MG/yr	Solid Waste Generated, tons/ year[b]	Chemical Use, gal/yr	Total Miles/ year	Emissions, CO2 eq, Tons/year[c]	CO2 eq, Tons [d]	Footprint, sf [e]
450 gpm	20	2	280,000	Minimal	17	21,300	7,000	180	210	2,400
900 gpm	39	~3	320,000	Minimal	33	42,500	13,000	200	250	3,900

Notes:
Units: kw-hr/year = kilowatt-hours per year; MG/yr = million gallons per year; gal = gallons; sf = square feet; gpm=gal per minute; CO2 eq – carbon dioxide equivalent
[a] Previously submitted on March 29, 2013. Additional effects for using a dechlorination agent if required will be added to this table in the 90% design submittal.
[b] Solid waste includes spent filter cartridges (500 to 1,000 per year)
[c] Operational emissions include vehicle emission and electricity generation
[d] Construction includes site work, material delivery, and workers travel
[e] Footprint based on foundations for building, process tanks, and chemical storage

5.5 Controls Philosophy

The system will be automated to reduce the need for continuous operator oversight. Electronic notifications will be sent automatically to on-site operators that notify them of system alarms, shutdown, or other issues. System automation will be controlled using a programmable logic controller that will communicate with the groundwater remedy supervisory control and data acquisition system. Pneumatic valves will be automated to control flow. Online pH, turbidity, and conductivity sensors will be incorporated to enable remote process monitoring and control. Arsenic cannot be monitored using an online analyzer. Grab samples will be collected periodically and analyzed using a bench top colorimetric instrument in the sample room (located in the Remedy Produced Water Conditioning Building) to monitor arsenic levels.

5.6 Other Related Systems and Infrastructure

Electricity will be provided from the Compressor Station. The new FWPTS location will have a heating, ventilation, and air conditioning (HVAC) system for only critical equipment such as electrical and controls equipment.

5.7 Design Philosophy/Uncertainties in Design

As previously mentioned, the FWPTS will be designed to achieve a safe, efficient, and sustainable operation within the compressor station over the anticipated decades-long life of the remedy. Most of the uncertainty in the design is related to the bed life and adsorptive capacity of the media. Based on bench testing, it is anticipated that the media will not need to be replaced before 70,000 bed volumes are processed– or every 8 months. The actual adsorptive capacity will need to be determined during full-scale operation and the result will greatly influence the amount of wastewater and solid waste generated by the process.

6.0 Design Information

Process calculations used to develop the design criteria were prepared using the conservative assumption that the treatment vessels each needed to be backwashed once a month and media replaced annually. Conceptual design information is presented in Tables 2, 3, and 4 and on Figures 4, 5, and 6.

TABLE 2

Design Criteria for Arsenic Treatment System

Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
OPERATIONAL CRITERIA		
Maximum Groundwater Injection Flow Capacity	900 gpm	
Minimum Groundwater Injection Flow Capacity	150 gpm	
Average Groundwater Injection Flow Capacity	450 gpm	
SITE CIVIL		
Location	Designated freshwater treatment at PG&E Topock Compressor Station near Needles, California. Next to the Remedy Produced Water Conditioning Building, within the footprint of the planned Decontamination Pad	
Building Finish Floor Elevation	Finished first floor, Elevation 626 feet (NGVD88).	
Grading	Longitudinal Slopes: Minimum 1% away from structures (2% desirable).	
Vehicle Access	WB 50 (turning radius for semi-truck and trailer with 50-foot wheel base). HS 20 (wheel loading on access roadways and parking areas). 50-foot minimum turning radius. Designated site accommodates truck circulation. Roads will be constructed at new facility for maintenance activities.	Required for delivery of chemicals, pumps, motors, and fire vehicles.
Site Constraints	Proposed facility located within the boundary of the compressor station. Access to all critical compressor station facilities must be maintained.	No modifications to the perimeter site fence or entrance gate will be made.
Parking	No parking will be required for new facility.	
Pedestrian Traffic	Limited to paved roadways, sidewalks are not located between existing facilities.	
PROCESS EQUIPMENT, MOTORS, VALVES, AND ANCILLARIES		
Treatment Process	Pre-oxidation, influent pH adjustment, followed by ligand exchange with granular ferric hydroxide for arsenic removal. Periodic backwash of media with treated water and annual media replacement. Treated water will be dechlorinated to limit adverse effects on microorganisms and remedy performance (see Dechlorination System below).	Design criteria listed below is what is expected from planned pre-purchase bid, but not a guarantee of what equipment will be selected.

TABLE 2

Design Criteria for Arsenic Treatment System

Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Granular Ferric Hydroxide (GFH) Treatment		
Treatment Objective	Arsenic removal	
Number of Vessels	Three when operating a maximum flow: Three online. Two online when operating at nominal flow;	Three vessels were included in the 90% design instead of four following a value engineering evaluation. Three vessels on-line will meet treatment requirements and have a very small effect on performance because the total downtime during backwashing (i.e., vessel is off-line) is 30 minutes per month (<0.1% of time).
Residence Time	5 minutes empty bed contact time	USEPA guidance.
Vessel Height	10.5 feet overall	
Vessel Diameter	8 feet	4 to 8 gpm/ft^2 hydraulic loading.
Materials of Construction	Low-carbon steel with epoxy lining that is NSF 61 listed.	
Media	Granular ferric hydroxide	Siemens, Severn Trent, or equal
Performance Limits		
Effluent Arsenic Concentration	< 10 µg/L	
Wastewater Volume	9,000 – 18,000 gal/year	
Chlorine Feed System		
Chemical Feed System	One calcium hypochlorite tablet feeder system—HDXLPE (with oxidation resistant liner) mix tank, feed pump, tablet hopper, controller and panel with disconnect. Sized for 0.2 to 2 lbs/hour of chlorine. Three days' minimum tablet capacity.	Feed system located in a containment area.
Safety Equipment	One eyewash and shower unit	Located in chemical storage area.
Coatings/Finishes	Chemical resistant coatings in chemical areas	
Controls	Chemical feed pump speed control	
Sulfuric Acid Feed System		
Chemical Feed System	One 1,000-gallon carbon steel with baked phenolic lining. Desiccant drier installed on vent. Sulfuric acid tank with tank pad. One chemical feed skid with two controllable chemical feed pumps (up to 2 gal/hour)	Tank will be located in a containment area. Monthly fill frequency is the design basis. Solution concentration will be 93%.
Safety Equipment	One eyewash and shower unit	Located in chemical storage area.
Coatings/Finishes	Chemical resistant coatings in chemical areas	
Controls	Chemical feed pump speed control	
Backwash Tank and Treated Water Tank		
Material	Fiberglass Reinforced Plastic (FRP)	
Number	Two	

TABLE 2

Design Criteria for Arsenic Treatment System

Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Capacity	10,000-gallons tanks	Backwash is anticipated to be just over 7,000 gallons per vessel – 10 minutes of backwashing at 15 gpm/ft^2. Backwash tank will have floating decanter and cone bottom to aid in solids recovery and improve backwash recycle rate. Treated water tank will be flat-bottomed. Both tanks will be equipped with ladders and top access platforms with safety cages and railings.
Dechlorination System		Chemical selected for use in dechlorination is calcium thiosulfate.
Chemical Feed System	Drums or chemical tote compatible with calcium thiosulfate. One chemical feed skid with two controllable chemical feed pumps	Container will be located in a containment area. Monthly fill frequency is the design basis, It is assumed there is sufficient space for this equipment.
Safety Equipment	One eyewash and shower unit	Located in chemical storage area.
Coatings/Finishes	Chemical resistant coatings in chemical areas	
Controls	Chemical feed pump speed control Inline static mixer	
Flow Meters		
Type	Magnetic	
Number	Seven	
Flow Control Strategy	FWPTS will receive raw water from the primary source well (HNWR-1A) into a new freshwater storage tank (10,000 gallons). The secondary sources (HNWR-1 and Site B) may be connected to the pipeline in the future. PG&E is considering augmenting the supply with a gravity flow line from the existing TCS storage tanks only when required.) A booster pump with variable frequency drive will vary the flow through the treatment plant to maintain set point water levels in the treated water tank and prevent pump operating when the remedy freshwater storage tank water levels are below the setpoint. Media vessel inlet control valves equalize flows through each vessel based on flowmeters located downstream of each media vessel.	
Pressure Transmitters	Furnished before/after media vessels.	
Static Mixer		
Number	Two (at the inlet and outlet)	
Diameter	10-inch	
Type	Wafer style with integral injection ports	

TABLE 2

Design Criteria for Arsenic Treatment System

Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Piping Materials		
Process	HDPE SDR 11 or CPVC Schedule 80, per ASTM D1784, ASTM D1785, and NSF/ANSI 14 and NSF 61 listed	
Treatment Media Vessel Manifold	HDPE SDR 11 or CPVC Schedule 80, per ASTM D178, ASTM D1785, NSF/ANSI 14 and NSF-61 listed	
Potable Water	Buried: Copper, Type K, per ASTM B88 Exposed: Copper, Type L, per ASTM B88 or CPVC Sch. 80	
Process Piping Installation	Major process piping headers will be installed in pipe trenches inside the treatment building and buried outside the building. Media vessel piping will be aboveground. Actuated valves will be installed above grade whenever possible.	
Remedy freshwater storage tank Interface	Inlet from Remedy freshwater storage tank	
YARD PIPING		
Design Criteria	Appendix C, Basis of Design Report (CH2M HILL 2014)	
CORROSION CONTROL		
Design Criteria	Appendix C, Basis of Design Report (CH2M HIL, 2014)	
ARCHITECTURAL/STRUCTURAL		
Building Code	Appendix C, Basis of Design Report (CH2M HILL 2014)	
Building Design Concept	Single building adjacent to Remedy Produced Water Conditioning System	
Building Construction Materials	Appendix C, Basis of Design Report (CH2M HILL 2014)	
Loads	Appendix C, Basis of Design Report (CH2M HILL 2014)	
HVAC		
Codes/Standards	Appendix C, Basis of Design Report (CH2M HILL 2014)	
Design Conditions		
Site Elevation	See Section C.2 Civil, Appendix C, Basis of Design Report (CH2M HILL 2014)	
Cooling Load Basis	Building envelope heat gain and internal heat gains from equipment.	
System Type		
Process Building	A free standing electrical and controls equipment panel will be installed. The panel will have dedicated cooling system.	
PLUMBING		
Lavatory/Toilet Room	No facilities provided.	
Potable Water	Emergency shower/eye wash stations.	Per 2010 California Plumbing Code, and ANSI Z358.1.

TABLE 2

Design Criteria for Arsenic Treatment System

Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Non-potable Water	The non-potable water supply will have a reduced pressure backflow preventer. Non-potable water will be supplied for wash down water. Wash down hose valves, hoses and hose racks will be furnished in the area as required.	Per 2010 California Plumbing Code.
ELECTRICAL		
Electrical Load	The electrical load will consist of process pumps, motor operated valves, filter system, control panel and instrumentation, building HVAC, convenience receptacles and interior and exterior lighting. Power distribution will be sized in accordance with NFPA 70 (National Electric Code) to operate process and facility loads. Short-circuit current interrupting capacity of power distribution equipment will be coordinated with existing power distribution system.	.
Service Voltage	480V, 3-phase, 3-wire power will be supplied from XFMR 099	
Utilization Voltage	Appendix C, Basis of Design Report (CH2M HILL 2014)	
Redundancy Requirements	Power distribution system redundancy will be limited to equipment supporting the operation of back-up process and facility equipment (i.e. motor control combination starters, and breakers,). Power distribution system for FWPTS will incorporate spare breakers and fuses. Supporting quick replacement of failed components. Backup power when needed by portable diesel generator located near Remedy Produced Conditioning Building.	.
Manufacturers of Electrical Equipment, Grounding, Lightning Protection, Illumination, Emergency Lights, Stand-by/Backup Power, Raceways, and Duct Banks	Appendix C, Basis of Design Report (CH2M HILL 2014)	
SECURITY		
Security	None	All security covered through TCS main facility
CONTROL AND TELEMETRY		
Control and Telemetry Design Criteria	The treatment vessels will be a packaged system with the equipment manufacturer providing a fully configured programmable logic controller based system control panel with panel-mounted operator interface terminal. The control panel will be specified with an uninterruptible power supply to provide true online conditioned power sized to operate the connected load for 30 minutes.	

TABLE 2

Design Criteria for Arsenic Treatment System

Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Subject	Criteria	Comments/Reason
Communications, Other Networks, Supervisory Control and Data Acquisition, Instrumentation	Appendix C, Basis of Design Report (CH2M HILL 2014)	
Environmental Requirements	Equipment and instrumentation will be suitable for the following conditions: Air-conditioned Spaces: 10°C to 35°C and a relative humidity of 10 to 80 percent. Non-air-conditioned Spaces: 0°C to 50°C and a relative humidity of 10 to 95 percent. Outdoors: 0°C to 60°C and a relative humidity of 5 to 100 percent.	Environmental controls, such as heaters, fans, and air conditioning will be provided to maintain equipment within the operating conditions recommended by the manufacturer.
Standards/References	Appendix C, Basis of Design Report (CH2M HILL 2014)	

TABLE 3
Major Equipment List
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Quantity	Name	Description
3	Treatment Media Vessels	8-feet-diameter low-carbon steel with epoxy lining (4 - 8 gpm/ft^2 hydraulic loading rate)
1	Hypochlorite Feeder	Calcium hypochlorite tablet feeder: HDXLPE (with oxidation-resistant liner) mix tank, feed pump, tablet hopper, controller, and panel with disconnect
1	Sulfuric Acid Tank	1,000-gallon, (93% sulfuric acid), desiccant drier installed on vent. Baked phenolic lining on steel.
1	Acid Feed System	Pre-engineered skid with two chemical metering pumps for 93% sulfuric acid (0.5 to 2 gph)
1	Dechlorination System	Pre-engineered chemical feed skid to pump calcium thiosulfate, storage tote(s) or tanks, and static mixer. Air-conditioned chemical storage shed will be provided to maintain chemical quality.
2	Pre-and post-treatment Wafer-Style Static Mixers	With integral injection ports
2	Booster Pumps	Centrifugal pump with variable frequency drive
2	Filters skids with replaceable elements	Package unit with differential pressure indication and alarm and flow control valves to divert water to the online filter. Cartridge type
2	Backwash Recycle Pumps	Multistage centrifugal pump
2	Backwash Pumps	Centrifugal pump 755 gpm (15 gpm/ft^2 hydraulic loading rate)

Attachment A
Arsenic and Fluoride Treatment Technology Screening

ATTACHMENT A

Arsenic and Fluoride Treatment Technology Screening

As part of the pre-conceptual design work, several treatment technologies were identified and screened to help select an effective and efficient treatment process for two removal processes -- arsenic/fluoride removal and arsenic only removal. After technology identification, the list was screened qualitatively with a more detailed screening was completed on a short list of five technologies. Bench-scale testing was then performed to select the technology to carry forward into design.

A.1 Initial Screening

The United States Environmental Protection Agency, water and wastewater utilities, industrial concerns, research universities and centers, and industry groups have published numerous case studies and reports on testing and performance of these technologies in treating arsenic and fluoride in water (American Water Works Association, 1999; Odell, 2010). The initial list of technologies evaluated for the Topock freshwater pre-injection treatment system was developed from those technologies that have been successfully used by municipalities and industry. Unproven technologies or technologies that have not been used in full-scale applications were not considered in the screening. The initial list included anion exchange, activated alumina (AA), reverse osmosis (RO), electrodialysis reversal (EDR), lime softening, distillation, iron-based adsorbents, titanium-based adsorbents, and coagulation/filtration. The status of selection is summarized in Table A-1.

TABLE A-1
Technologies Considered for Arsenic and Fluoride Removal
Addendum to Freshwater Pre-injection Treatment System Design Basis Memorandum
PG&E Topock Compressor Station, Needles, California

Technology	Status
Anion exchange	Screened out, significant waste generation.
Activated Alumina (AA)	Selected for bench-testing. Primary treatment option is regenerable AA if arsenic and fluoride treatment required.
Titanium-based adsorbents	Screened out, similar as other adsorbents considered, with less experience.
Reverse Osmosis (RO)	Screened out, significant waste generation.
Electrodialysis Reversal (EDR)	Screened out, significant waste generation.
Lime Softening	Screened out, significant waste generation.
Distillation	Screened out, significant energy use and capital cost.
Coagulation Filtration	Screened out, this process does not treat fluoride. If arsenic-only treatment is required, this technology would be screened out due to more residuals are generated, additional chemicals are used, and the process is more complex than iron-based adsorbents. However, it will be retained for bench-scale testing for data collection due to the quick and simple test.
Iron-based Adsorbents	Screened out, this process does not treat fluoride. If arsenic-only treatment required, this process may be used.

A brief process description is provided below.

Anion Exchange. Anions such as fluoride, nitrate, arsenate, selenate, and chromate can be removed from water by using ion exchange with resin. This physical-chemical process involves an easily displaceable ion on the solid phase, exchanging with an unwanted ion in the water that adsorbs to the solid phase. To accomplish the exchange reaction, a packed bed of ion-exchange resin beads is used. Source water is continually passed through the bed in a downflow or upflow mode until the adsorbent is exhausted, as evidenced by the appearance (breakthrough) of the unwanted contaminant at an unacceptable concentration in the effluent.

The most useful ion-exchange reactions are reversible. In the simplest cases, the exhausted bed is regenerated using an excess of the displaceable ion in the form of salt brine. Ideally, no permanent media structural change occurs during the exhaustion/regeneration cycle. This is a proven technology, is widely used, and is easy to automate, but it generates considerable wastewater.

Activated Alumina*.* AA is a semi-crystalline porous inorganic adsorbent, is a proven technology for fluoride removal, and effectively removes arsenic. The removal mechanism, which is one of exchange of contaminant anions for surface hydroxides on the alumina, is generally called adsorption, although ligand exchange is a more appropriate term for the highly specific surface reactions involved. Packed beds of AA are used in water treatment plants in a similar manner to anion exchange. Regeneration is accomplished using a basic solution like sodium hydroxide (caustic). The adsorbent media can be purchased in a disposable form as well. In this case, the spent media is disposed in an offsite facility. This is a proven technology, is widely used, is easy to automate, but it generates considerable wastewater.

Titanium-based adsorbents*.* These are porous adsorbents made with titanium that work similarly to AA in that surface hydroxides exchange with fluoride in the water stream. Similarly, caustic is used to regenerate the adsorbent in the packed beds. This is a newer process with fewer systems in service.

Reverse Osmosis. RO is a membrane water treatment system in which water is pressurized to more than 100 pounds per square inch and is directed through small pores in a synthetic membrane. Treated water is produced through the other side of the small pores while larger particulates are retained on the inlet side of the membrane. RO is effective in removing uranium, radium, arsenic, fluoride, nitrates, microbial contaminants, and many chemicals. Because of the high pressure required for the process, RO systems typically are energy-intensive and have high initial costs. Furthermore, these systems can require more operator attention and can require membrane integrity testing. RO systems also risk fouling and scaling from hard water, colloids, and bacteria. The fouling and scaling increase the pressure drop and result in a shorter lifetime for the membrane or frequent chemical cleaning. In addition, this process generates considerable volumes of wastewater.

Electrodialysis Reversal. EDR is a membrane water treatment process that relies on polarizing electrodes to remove contaminants. The ions in the water are attracted to the membrane by a cathode or anode. Once attracted to the membrane, the ion is transported electrically through the membrane. EDR systems reverse the polarity of the electrodes every 15 to 20 minutes. This process releases accumulated ions and has the following advantages:

- Breaks up scale and reduces the potential for scaling.
- Reduces microbiological growth on the membrane.
- Reduces membrane cleaning frequency.

EDR systems operate at higher pressures than most water treatment systems but not as high as RO systems. They are maintenance intensive and generate considerable volumes of wastewater.

Lime Softening. Hardness in water is characterized by elevated levels of magnesium and calcium. Lime softening removes the hardness by mixing lime (slaked or hydrated) during the treatment process. The lime addition increases the pH of the water and causes the magnesium and calcium to precipitate out. Flocculation and sedimentation units are employed to provide a sufficient time and space to accumulate solids. Magnesium requires a higher pH than calcium to cause precipitation and results in water with a pH as high as 11. Carbon dioxide is used commonly to reduce the pH back to desired levels. This process, although used often, requires

careful chemical dosing and process monitoring, requires large amounts of chemicals, and generates large amounts of waste sludge.

Distillation. To distill water, water is heated until boiling and vaporized. The resulting steam is collected and condensed in a clean storage tank. Distillation is effective in removing metals, hardness, and particulates because they do not vaporize with the water. The boiling process also kills bacteria and some viruses. Distillation is ineffective in removing contaminants with a lower boiling point than water, such as benzene. These contaminants must be removed before condensation or recontamination will occur. This process is straightforward to operate but uses high amounts of energy and requires costly metal alloys for construction.

Coagulation Filtration. Coagulation is a process in which smaller particles in suspension attach to one another through electrostatic forces. As the particles attach to one another, larger particles start to form. Aluminum and ferric salts are the most commonly used compounds to enhance coagulation because aluminum or iron hydroxide is formed. Once finished with the coagulation process, the water is filtered through a media filter or microfilter to remove the aggregated particles. Coagulation filtration has been found very effective in removing arsenic from water. While often some form of pretreatment is needed (usually chlorine oxidation), coagulation filtration systems can achieve over a 90 percent reduction in arsenic. However, this process does not treat fluoride. The process is relatively easy to operate.

Iron-based Adsorbents. Contaminated water is passed through a pressure vessel that contains iron based adsorbents that remove arsenic. Granular ferric hydroxide is a common example that is in an amorphous crystalline form. Iron-based adsorbents have been shown effective in removing arsenic (not fluoride) at pH levels normally found in drinking water; however, best performance happens at lower pH levels. Lower pH levels may result in the need for more operator attention and the possibility of handling hazardous chemicals. Once the media has been lost its adsorbent capacity, the spent media is replaced.

A.1.1 Initial Screening Results

As a result of the screening, four technologies were retained for further evaluation:

- AA adsorption – disposal media and regenerable media
- Iron-based adsorbents
- Coagulation/filtration

The following technologies were rejected based on the reasons listed below.

- **Anion exchange, EDR, and RO:** processes generate large residual wastewater streams that must be disposed of.
- **Lime softening:** generates large volume of waste sludge that is difficult and costly to dispose of.
- **Titanium-based adsorbents:** effective at very low pH or with expensive rare earth metals and has the fewest number of operating systems.
- **Distillation:** high cost for energy use.

A.2 Second-level Screening

The two remaining technologies were screened at a second level with AA divided into regenerable and disposable forms. The screening criteria were as follows:

1. Treatment Effectiveness
   - Ability to achieve treatment goals
2. Reliability and Flexibility
   - Ability to allow variation in influent water
   - Expandability

3. Operational Complexity
   - Ease of operation
   - Safety
4. Waste Generation
   - Quantity and quality
5. Footprint
6. Cost Effectiveness

As a result of the screening, anion exchange was not carried forward and was dropped from further consideration because of its lower effectiveness, greater operational complexity, the wastewater volumes generated, and its higher operating cost. The four processes— regenerable AA and disposable AA, iron-based adsorbents, and coagulation/filtration —were advanced to bench-scale testing.

A.3 Bench-scale Testing

As described in the body of the Design Basis Technical Memorandum, bench-scale testing was performed after the technology screening. Testing showed that regenerable AA and iron-based adsorbent were the technologies that best met design needs if both arsenic and fluoride removal, or arsenic removal alone is required Disposable AA was eliminated from further evaluation.

SECTION 1

Introduction

Pacific Gas and Electric Company (PG&E) is implementing the selected groundwater remedy to address chromium contamination in groundwater at the Topock Compressor Station (Compressor Station) in San Bernardino County, Needles, California. In addition, after receipt of approval from the California Department of Toxic Substances Control (DTSC), with the U.S. Department of the Interior's (DOI's) concurrence, PG&E will decommission and remove the Interim Measure No. 3 (IM-3) Groundwater Extraction and Treatment System (referred to herein as the "IM-3 system"). The IM-3 Treatment Plant and MW-20 Bench Facility (a portion of which is part of the IM-3 system) areas have been identified as investigation areas (Areas of Concern [AOCs] 29 and AOC 30, respectively) in the concurrent Soil RCRA Facility Investigation/Remedial Investigation (RFI/RI) program.

The mitigation measure HAZ-2c set forth in the certified environmental impact report (EIR) (DTSC 2011) adopted by the DTSC for the groundwater remediation project requires that contaminated soil identified during ground disturbance activities be managed and disposed of in accordance with a project-specific Soil Management Plan (SMP) and Health and Safety Plan (HSP). If activities involve stockpiling of excavated hazardous soil, this would trigger the need for compliance with the California action-specific applicable or relevant and appropriate requirement (ARAR) #86: Waste piles for RCRA hazardous waste (22 CCR, Div 4.5, Ch. 14, Article 12) (DOI 2010), which is addressed in this SMP.

At the final design stage of the groundwater remediation project, proposed remedy infrastructure (excluding future provisional wells) is within 20 feet of or overlaps with twenty-four Soil Investigation Areas that are undergoing investigations as part of the Soil RFI/RI (see Figure 1.0-1 located at the end of this section). As shown in Figure 1.0-1, the overlap between the groundwater remediation project and ongoing soil investigations (or areas within 20 feet of these investigation areas) occurs in the following areas:

- Soil Investigation Areas inside the Compressor Station:
  - SWMU 5 – Sludge Drying Beds
  - SWMU 6 – Chromium Reduction Tank
  - SWMU 9 – Transfer Sump
  - AOC 7 – Hazardous Materials Storage Area
  - AOC 8 – Paint Locker
  - AOC 13 – Unpaved Areas within the Compressor Station
  - AOC 17 – Onsite Septic System
  - AOC 18 – Combined Hazardous Waste Transference Pipelines
  - AOC 21 – Round Area by Sludge Drying Beds
  - AOC 22 – Unidentified Three-sided Structure
  - AOC 33 – Potential Former Burn Area near AOC 17
  - Unit 4.3 – Oil/Water Holding Tank
- Soil Investigation Areas outside Compressor Station:
  - SWMU 1 – Former Percolation Bed
  - AOC 1 – Area Around Former Percolation Bed
  - AOC 4 - Debris Ravine
  - AOC 9 – Southeast Fence Line (Outside Visitor Parking Area)
  - AOC 10 – East Ravine
  - AOC 11 – Topographic Low Areas
  - AOC 12 – Fill Areas
  - AOC 27 – MW-24 Bench
  - AOC 28 – Pipeline Drip Legs
  - AOC 30 – MW 20 Bench

- Perimeter Area outside of but adjacent to the Compressor Station fence line
- Storm Drain System

In compliance with the aforementioned EIR mitigation measure and action-specific ARAR, this SMP includes procedures and protocols for the management and disposal of potentially contaminated and contaminated soil displaced during drilling, construction, operation and maintenance (O&M) of the groundwater remedy, and the decommissioning and removal of the IM-3 system. Potentially contaminated and contaminated soil is expected to be limited to within and near the boundaries of the Soil RFI/RI Investigation Areas. This SMP is Volume 4 of the O&M Manual, which is Appendix L of the Basis of Design Report for the final design. The HSP for O&M activities is Volume 5 of the O&M Manual. The HSP for groundwater remedy construction activities was submitted as part of the Construction/Remedial Action Work Plan (CH2M HILL 2015). Details of the decommissioning and removal of the IM-3 system are submitted as part of the IM-3 Decommissioning, Removal, and Restoration Work Plan. Soil and material originating in or near Soil RFI/RI Investigation Areas (areas of known or suspected soil contamination) that is displaced as part of the groundwater remediation project will be handled and managed in accordance with this SMP and the HSPs for construction and O&M activities. Displaced soil and material originating outside areas of known or suspected contamination will be pre-characterized prior to remedy construction to identify areas potentially impacted by nearby current and former roadways (polycyclic aromatic hydrocarbons [PAHs] and lead). Displaced soil from areas outside of known or suspected contamination areas that is impacted with PAHs and lead will be handled and managed in accordance with this SMP and the HSPs for construction and O&M activities. Uncontaminated soil will be reused as backfill into the same trench or excavation area, if practicable. Uncontaminated soil that cannot be immediately used as backfill may be reused in other areas within the Area of Potential Effects (APE), or stockpiled for future reuse within the APE. The stockpiled uncontaminated soil will be managed following the Construction and Operations Best Management Practices (BMPs) Plan for Soil Storage that is summarized in Section 3.1.2 of this SMP, the Construction/Remedial Action Work Plan (CH2M HILL 2015), and the Groundwater Remedy O&M Storm Water Pollution Prevention Plan (also called the Industrial SWPPP) (Appendix E of Volume 1 of the O&M Manual).

In addition, handling and management of displaced soil and material from Soil RFI/RI Investigation Areas, and soil displaced as part of the decommissioning and removal of the IM-3 system will be performed in accordance with this SMP and the IM-3 Decommissioning, Removal, and Restoration Work Plan. Soil generated from Soil RFI/RI work activities will follow the protocols for handling of soil specified in the Revised Final Soil RFI/RI Work Plan (CH2M HILL 2013).

1.1 Soil Management Plan Purpose and Objectives

The purpose and objectives of this SMP are as follows:

1. Ensure that soil is handled in a manner that complies with ARARs and the EIR mitigation measures.
2. Ensure that displaced soil from in and near Soil RFI/RI Investigation Areas that are generated during drilling, construction, decommissioning, removal, and O&M activities is handled in a manner that is protective of human health (including construction workers) and the environment within the framework of appropriate federal, state, and local requirements, and consistent with United States Environmental Protection Agency (USEPA) guidance.
3. Maximize onsite reuse of soil that was displaced during drilling, construction, decommissioning, removal, and O&M activities, following guidelines and protocols of the *Revised Management Protocol for Handling and Disposition of Displaced Site Material, Topock Remediation Project, Needles, California* (PG&E 2015) presented in Appendix B.
4. Minimize offsite transportation and disposal of soil that was displaced during drilling, construction, decommissioning, removal, and O&M.
5. Collect data to help guide future decision-making regarding the disposition of displaced soil and material.

1.2 Site Description, Soil Investigation History, and Findings

The Compressor Station is located adjacent to the Colorado River in eastern San Bernardino County, California, approximately 12 miles southeast of Needles, California, south of Interstate 40 (I-40), in the north end of the Chemehuevi Mountains. The APE for the Topock site is contained within what the Fort Mojave Indian Tribe (FMIT) and other Native American Tribes have identified as a larger area of traditional and cultural importance. The Tribes believe that the environmental, cultural, and spiritual resources may not be physically perceptible. DTSC has concluded within the January 2011 certified EIR that the 779.2-acre project site "appears to qualify as a historic resource under CEQA [California Environmental Quality Act] as an area that is significant in the social and cultural annals of California," and the U.S. Bureau of Land Management (BLM) also has determined that a traditional cultural property or property of traditional religious and cultural significance that is eligible for listing on the National Register of Historic Places exists in the area of the Topock project within the current APE, consisting of 1,600 acres of surface area and a section of the Colorado River (DTSC 2011).

In recognition of this, all remedial activities at the Compressor Station are planned in such a way as to minimize impact to this area. Specifically, impacts to cultural resources will be minimized by implementing the mitigation measures required by the EIR. In addition, mitigation measures will be implemented in accordance with the Programmatic Agreement (PA), the Cultural and Historic Properties Management Plan (CHPMP), and the Cultural Impact Mitigation Program (CIMP), and in consultation with the Tribes. The work will be conducted in a manner that recognizes and respects these resources and the spiritual values of the area.

Since 1996, there have been multiple phases of investigation at the Topock site to collect data to evaluate the nature and extent of contamination at the Solid Waste Management Units (SWMUs), AOCs, and Undesignated Areas (UAs). Results from the RFI/RI at the site are being documented in three volumes:

- **RFI/RI Volume 1**. The *Revised Final RCRA Facility Investigation and Remedial Investigation Report, Volume 1 – Site Background and History* (CH2M HILL 2007a) was completed in August 2007 and was approved by DTSC and DOI. Volume 1 of the RFI/RI identifies the 20 SWMUs, AOCs, and other UAs at the Topock Compressor Station to be carried forward in the Final RFI/RI. An Addendum to the RFI/RI Volume 1 (CH2M HILL 2014) was submitted and approved in May 2014. This Addendum summarizes the history and available data for 15 new units identified since the completion of the RFI/RI Volume 1.
- **RFI/RI Volume 2.** The Revised *Final RCRA Facility Investigation/Remedial Investigation, Volume 2— Hydrogeologic Characterization and Results of Groundwater and Surface Water Investigation Report* (CH2M HILL 2009a) was completed in February 2009 and approved by DTSC and DOI. Volume 2 of the RFI/RI contains the hydrogeologic characterization and results of groundwater and surface water investigations to address historical releases to groundwater from wastewater discharged at Bat Cave Wash and injection well PGE-8 at the Topock Compressor Station. The purpose of the Volume 2 RFI/RI is to complete the RFI/RI requirements for groundwater impacts associated with the past discharge of wastewater from Bat Cave Wash (SMWU 1/ AOC 1) and injection well PGE-8 (SWMU 2). An Addendum to the RFI/RI Volume 2 (CH2M HILL 2009b) was submitted in June 2009. This Addendum included select data and information collected between October 2007 and September 2008, after the data cutoff period for RFI/RI Volume 2.
- **RFI/RI Volume 3.** RFI/RI Volume 3 will include final characterization data to complete the RFI/RI requirements for remaining Topock Compressor Station operations, including results of soils investigations and the current East Ravine (AOC 10) and Compressor Station groundwater investigation. Also included in Volume 3 will be new or additional SWMUs and AOCs that have been identified in the Addendum to the RFI/RI Volume 1.

PG&E will continue to document and notify the Agencies of any new units discovered in the future. The SWMUs, AOCs, UAs, and other investigation areas still being characterized in support of the RFI/RI Volume 3 are presented in Exhibit 1.2-1 and shown on Figure 1.0-1.

Two draft work plans were initially prepared to describe collection of additional soil data to complete site characterization activities at the SWMUs, AOCs, and UAs identified in the Revised Final RFI/RI Volume 1 in support of RFI/RI Volume 3 preparation. Investigation areas outside the compressor station fence line were addressed in

the *Draft RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part A, PG&E Topock Compressor Station, Needles, California* (Draft Soil Part A Work Plan) (CH2M HILL 2006). Investigation areas within the compressor station fence line were addressed in the *Draft RCRA Facility Investigation/Remedial Investigation Soil Investigation Work Plan Part B, PG&E Topock Compressor Station, Needles, California* (Draft Part B Work Plan) (CH2M HILL 2007b).

Soil Investigation Areas		Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure? (Y/N) — List type of infrastructure
Located Outside the Topock Compressor Station Fence Line		
SWMU 1	Former Percolation Bed	Yes - pipes
AOC 1	Area Around Former Percolation Bed	Yes – wells, pipes
AOC 4	Debris Ravine	Yes – pipes
AOC 9	Southeast Fence Line (Outside Visitor Parking Area)	Yes – pipes
AOC 10	East Ravine	Yes – pipes, wells
AOC 11	Topographic Low Areas	Yes – pipes, wells, building
AOC 12	Fill Area	Yes – pipe, wells
AOC 14	Railroad Debris Site	No
AOC 27	MW 24 Bench	Yes – well, pipe
AOC 28	Pipeline Drip legs	Yes – pipes, wells
AOC 29	IM-3 Treatment Plant	No
AOC 30	MW 20 Bench	Yes – pipes, wells, building, tanks
AOC 31	Former Teapot Dome Oil Pit	No
UA 1	Potential Pipe Disposal Area	No
UA 2	Former 300B Pipeline Liquids Tank	No
Located Inside the Topock Compressor Station Fence Line		
SWMU 5	Sludge-Drying Beds	Yes - pipes
SWMU 6	Chromate Reduction Tank	Yes - pipes
SWMU 8	Process Pump Tank	No
SWMU 9	Transfer Sump	Yes - pipes
SWMU 11	Former Sulfuric Acid Tanks	No
AOC 5	Cooling Tower A	No
AOC 6	Cooling Tower B	No
AOC 7	Hazardous Materials Storage Area	Yes – pipes, tanks
AOC 8	Paint Locker	Yes – pipes, tanks
AOC 13	Unpaved Areas within the Compressor Station	Yes – pipes, wells, buildings
AOC 15	Auxiliary Jacket Water Cooling Pumps	No
AOC 16	Sandblast Shelter	No
AOC 17	Onsite Septic System	Yes – pipes
AOC 18	Combined Hazardous Waste Transference Pipelines	Yes – pipes
AOC 19	Former Cooling Liquid Mixing Area and Former Hotwell	No
AOC 20	Industrial Floor Drains	No
AOC 21	Round Depression near Sludge Drying Bed	Yes - pipes

Soil Investigation Areas		Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure? (Y/N) — List type of infrastructure
AOC 22	Unidentified Three-sided Structure	Yes – pipes
AOC 23	Former Water Conditioning Building	No
AOC 24	Stained Area and Former American Petroleum Institute Oil/Water Separator	No
AOC 25	Compressor and Generator Engine Basements	No
AOC 26	Former Scrubber Oil Sump	No
AOC 32	Oil Storage Tanks and Waste Oil Sump	No
AOC 33	Potential Former Burn Area near AOC 17	Yes – pipes
Unit 4.3	Oil/Water Holding Tank	Yes - pipes
Unit 4.4	Oil Water Separator	No
Unit 4.5	Portable Waste Oil Storage Tank	No
Perimeter Area		Yes – pipes, wells
Storm Drain System		Yes – pipes

Subsequent to submitting the two draft work plans, the Part A and Part B work plans were combined into a single work plan: *Draft Soil RFI/RI Work Plan, PG&E Topock Compressor Station, Needles, California* (CH2M HILL 2011a). The Draft Soil RFI/RI Work Plan contains the Part A and B Data Quality Objectives (DQOs) process, data gaps analysis for each SWMU/AOC, and the proposed sampling plan for the next phase of investigation.

A Revised Final Soil RFI/RI Work Plan was prepared to incorporate comments received from Agencies and stakeholders on the Draft Work Plan, and was submitted to Agencies on January 14, 2013 (CH2M HILL 2013) for final review and approval. The Revised Final Soil RFI/RI Work Plan was approved by DTSC and DOI on August 24, 2015.

1.2.1 Soil Investigation History and Findings Outside the Compressor Station Fence Line

Ten investigation areas located outside of the Compressor Station fence line, one new investigation area (AOC 28 – Pipeline Drip Legs), Perimeter Area, and Storm Drains System located outside of the Compressor Station fence line require further investigation in order to satisfy the Part A DQOs. These investigation areas are:

- SWMU 1 – Former Percolation Bed
- AOC 1 – Area Around Former Percolation Bed
- AOC 4 – Debris Ravine
- AOC 9 – Southeast Fence Line (Outside Visitor Parking Area)
- AOC 10 – East Ravine
- AOC 11 – Topographic Low Areas, including the two new areas
- AOC 14 – Railroad Debris Area
- AOC 28 – Pipeline Drip Legs
- AOC 27 – MW-24 Bench Area
- UA-1 – Potential Pipeline Disposal Area
- AOC 31 – Former Teapot Dome Oil Pit
- Perimeter Area
- Storm Drains System

The proposed sampling plan for these units is described in the Revised Final Soil RFI/RI Work Plan (CH2M HILL 2013). Table 1.2-1 (tables are presented at the end of each section) provides a summary of historical activities at the Part A investigation areas, a list of constituents that exceeded interim screening levels, and the proposed analytical suites.

1.2.2 Soil Investigation History and Findings Inside the Compressor Station Fence Line

Twenty-four investigation areas located inside the compressor station fence line require further investigation in order to satisfy the Part B DQOs. These investigation areas are:

- SWMU 5 – Sludge-drying Beds
- SWMU 6 – Chromate Reduction Tank
- SWMU 8 – Process Pump Tank
- SWMU 9 – Transfer Sump
- SWMU 11 – Former Sulfuric Acid Tanks
- AOC 5 – Cooling Tower A
- AOC 6 – Cooling Tower B
- AOC 7– Hazardous Materials Storage Area
- AOC 8 – Paint Locker
- AOC 13 – Unpaved Areas within the Compressor Station
- AOC 15 – Auxiliary Jacket Cooling Water Pumps
- AOC 16 – Sandblast Shelter
- AOC 17 – Onsite Septic System
- AOC 18 – Combined Wastewater Transference Pipelines
- AOC 19 – Former Cooling Liquid Mixing Area and Former Hotwell
- AOC 20 – Industrial Floor Drains
- AOC 21 – Round Depression near Sludge Drying Bed
- AOC 22 – Three-sided Structure
- AOC 23 – Former Water Conditioning Building
- AOC 24 – Stained Area and Former American Petroleum Institute Oil/Water Separator
- AOC 26 – Former Scrubber Sump
- AOC 33 – Potential Former Burn Area Near AOC 17
- Unit 4.3 – Oily Water Holding Tank
- Unit 4.4 – Oil/Water Separator
- Unit 4.5 – Portable Waste Oil Holding Tank

The proposed sampling plan for these units was described in the Revised Final Soil RFI/RI Work Plan (CH2M HILL 2013). Table 1.2-2 provides a summary of historical activities at the Part B investigation areas, a list of constituents that exceeded interim screening levels, and the proposed analytical suites.

1.3 Report Organization

This SMP is organized into the following sections:

- Section 1.0 contains background information, objectives, a summary of the previous investigations conducted at the site, and a list of Soil RFI/RI Investigation Areas within 20 feet of or overlapping groundwater remedy infrastructure.
- Section 2.0 presents details related to soil management activities including identifying areas of potential/ known contamination in the vicinity of the groundwater remedy system and IM-3 system, and the process for soil characterization, soil screening and classification, handling, and storage of soil at the site.
- Section 3.0 describes storage methods, labeling requirements and inspection of soil storage areas.

- Section 4.0 summarizes the employee training required for waste soil management, hazardous waste profiling, transportation, and disposal of the various waste streams.
- Section 5.0 summarizes the records and documents that should be maintained at the site.
- Section 6.0 presents the process for updating the SMP.
- Section 7.0 presents a list of references used in the preparation of this SMP.

TABLE 1.2-1
Historical Activities Summary, Constituents Exceeding Interim Screening Levels for Soil RFI/RI Units Outside the Fence Line, Perimeter Area, and Storm Drains, and Associated Analytical Suites
Groundwater Remedy Operation and Maintenance Manual
Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Interim Screening Levels	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
SWMU 1	SWMU 1 is located outside the facility fence line in the bed of Bat Cave Wash. During the 1950s, the facility discharged wastewater containing chromium (cooling tower blowdown) wastewater into Bat Cave Wash without any impoundment. From about 1964 to approximately 1971, the facility discharged wastewater containing chromium to a percolation bed and allowed water to percolate into the ground and/or evaporate. The chromium-containing wastewater was combined with a small quantity (approximately 5 percent) of treated water from the oily waste treatment system discharged from the station.	As, Ba, Ca, Total Cr, Cr^{+6}, Co, Cu, Pb, Mn, Mo, Ni, K, Se, V, Zn, Ca, Mg, Mn, K	Title 22 metals, hexavalent chromium, VOCs. SVOCs, PAHs, TPH, pH, pesticides, PCBs[2]	Yes
AOC 1	AOC 1 is located in the area surrounding SWMU 1, outside the fence line within Bat Cave Wash. This area comprises property owned by PG&E, Havasu National Wildlife Refuge, and the Bureau of Reclamation. As discussed for SWMU 1, the facility discharged wastewater containing chromium into the Bat Cave Wash until approximately 1964.	As, Ba, Total Cr, Cr^{+6}, Cu, Pb, Mo, Ni, Zn, Mn, Benzo (a) anthracene; Benzo (a) pyrene; Benzo (b) fluoranthene; PAH High Molecular weight; B(a)P Equivalent; Aroclor 1254; Total PCBs	Title 22 metals, hexavalent chromium, VOCs. SVOCs, PAHs, TPH, pH, pesticides, PCBs[2], dioxins and furans	Yes
AOC 4	AOC 4 is located south of the fence line, and is a narrow, steep ravine that drains into the Bat Cave Wash. This area comprises property owned by PG&E and the Havasu National Wildlife Refuge. Operation of the area is not well known, but trash burning has been identified on site. In 2009, a Removal Action and erosion control were conducted.	An, Ba, Cd, Total Cr, Cr^{+6}, Co, Cu, Pb, Hg, Ni, V, Zn, Benzo (a) anthracene; Benzo (a) pyrene; Benzo (b) fluoranthene; Benzo (k) fluoranthene; Indeno (1,2,3-cd) pyrene; PAH High Molecular weight; B(a)P Equivalent; Aroclor 1254; Aroclor 1260, Total PCBs	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, pH, pesticides, PCBs, dioxins and furans	Yes
AOC 9	AOC 9 is located outside the fence line on the east side, south of the visitor parking lot on a steep slope. In 2000, a broken stormwater drainage pipe and stained soil were found in the area. The staining most likely originated from leaks near the Auxiliary Building. The stained soil was excavated, a new stormwater drainage pipe was installed, and the area was backfilled with 1 – 2 feet of clean soil. The exact location of the former storm drain line is uncertain, and the footprint of AOC 9 is sufficiently large to address both potential locations.	Total Cr, Cr^{+6}, Cu, Pb, Hg, Mo, Ni, Tl, Zn, Benzo (a) pyrene; B(a)P Equivalent; 4,4-DDE	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, pH, asbestos, pesticides, PCBs	Yes

TABLE 1.2-1
Historical Activities Summary, Constituents Exceeding Interim Screening Levels for Soil RFI/RI Units Outside the Fence Line, Perimeter Area, and Storm Drains, and Associated Analytical Suites
Groundwater Remedy Operation and Maintenance Manual
Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Interim Screening Levels	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
AOC 10	AOC 10 is the east ravine located on the southeast side, outside of the fence line. This AOC comprises property owned by PG&E and the Havasu National Wildlife Refuge. The ravine is bisected by three constructed berms built between 1916 and the 1950s. AOC 10 receives run-off from the eastern portion of the upper yard of the compressor station, and the station access road.	As, Ba, Total Cr, Cr^{+6}, Co, Cu, Pb, Mo, Ni, Se, V, Zn, Benzo (a) anthracene; Benzo (a) pyrene; Benzo (b) fluoranthene; Benzo (k) fluoranthene; Indeno (1,2,3-cd) pyrene; PAH High Molecular weight; B(a)P Equivalent	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, general chemistry parameters, pesticides, PCBs, dioxins and furans (if burn material present)	Yes
AOC 11	AOC 11 consists of the topographic low areas on the northeast side of the Topock Compressor Station. AOC 11 is located on PG&E and Havasu National Wildlife Refuge property. Multiple storm drains may be discharging to this area, or have discharged to this area in the past. AOC 11 also includes the topographic low area north of the plant access road near the Old Route 66 sign. This area receives run-off from the station access road.	As, Ba, Total Cr, Cr^{+6}, Cu, Pb, Mo, Se, Zn, Al, Mn, K, Benzo (a) anthracene; Benzo (a) pyrene; Benzo (b) fluoranthene; Benzo (k) fluoranthene; PAH High Molecular weight; B(a)P Equivalent; Aroclor 1260; Total PCBs; 4,4-DDE; Dieldrin	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, pH, PCBs, pesticides	Yes
AOC 12	AOC 12, known as the Fill Area, included three areas located near the Transwestern gas pipeline meter station, east of the compressor station. Portions of AOC 12 are located on PG&E and Havasu National Wildlife Refuge property. These areas were identified as locations that may contain buried construction-related debris, but no debris was found in the identified areas during the Soil Part A Phase investigation.	Co, Cu, Se, Zn, Di-N-butyl phthalate; Benzo (a) pyrene; B(a)P Equivalent	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, pH, asbestos, pesticides, PCBs	Yes
AOC 14	AOC 14, the Railroad Debris Site, is located immediately north of I-40. It is bounded by Santa Fe railroad tracks to the north. The area sits approximately 100 feet above the bottom of the Bat Cave Wash. Aerial photos dated from 1947 to 1955 depicted materials and debris scattered in this area, and water softening (lime) sludge is also believed to have been disposed of in this area. An asbestos removal action was completed in 1999, and sampling detected no remaining asbestos. Field observations identified scattered debris and a potential burn layer (visible in the I-40 road cut) in this area.	Total Cr, Cr^{+6}, Cu, Pb, Hg, Mo, Se, Zn, Benzo (a) pyrene; PAH High Molecular weight; B(a)P Equivalent; 4,4-DDE; 4,4-DDT	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, pH, asbestos, pesticides, PCBs, dioxins and furans (if burn material present)	No

TABLE 1.2-1

Groundwater Remedy Operation and Maintenance Manual
Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Interim Screening Levels	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
AOC 27	AOC 27, known as the MW-24 Bench, is located north of the upper yard of the compressor station and south of I-40. During employee interviews conducted by PG&E, a former PG&E Topock Compressor Station employee indicated this area was also used as a potential waste disposal area. In January 2008, during trenching activities in the MW-24 bench area associated with installation of a control panel related to the upland *in-situ* pilot test, debris consisting mostly of treated wood, concrete, and scrap steel/tin (including a possible fragment of a storage tank) were encountered.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, pesticides, PAHs, VOCs, SVOCs, PCBs, TPH, pH, dioxins and furans (if burn material present)	Yes
AOC 28	AOC 28, the Pipeline Drip Legs, consists of three drip legs associated with the 300A and 300B pipelines are located to the east of the compressor station and a drip leg for the 300B pipeline downstream of the compressor station in Bat Cave Wash. A drip leg collects pipeline liquids by gravity. It is connected to a valve used to drain the pipeline liquids to a fixed or portable tank.	No data have been collected in this area.	TPH, PAHs, and PCBs	Yes
AOC 29	AOC 29, the Interim Measure-3 Treatment Plant, is located north of Interstate-40. The Interim Measure-3 provides hydraulic control of the plume boundaries near the Colorado River to maintain a landward gradient. This facility was established and is operated under modern waste management laws, and will be closed pursuant to a decommissioning plan. Investigation of this AOC has been postponed until the plant is closed.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, sodium, chloride	No
AOC 30	AOC 30, the MW 20 Bench, is located between the National Trails Highway and the Colorado River. This area is part of the floodplain reductive zone in-situ pilot test. This facility was established and is operated under modern waste management laws and will be closed in accordance with agency requirements; therefore, investigation of this AOC is postponed until this unit is closed.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, sodium, chloride	Yes

TABLE 1.2-1
Historical Activities Summary, Constituents Exceeding Interim Screening Levels for Soil RFI/RI Units Outside the Fence Line, Perimeter Area, and Storm Drains, and Associated Analytical Suites
Groundwater Remedy Operation and Maintenance Manual
Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Interim Screening Levels	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
AOC 31	AOC 31, the Teapot Dome oil pit, is located on the northeast side of the facility, just outside the compressor station fence line. It is located within and overlaps with the Perimeter Area investigation. Former employees indicated that they had been told that the Teapot Dome restaurant provided oil changes, and that oil from vehicles was dumped into a pit. Potential wastes in this area pre-date the construction of the compressor station.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, TPH, SVOCs, PAHs, and PCBs	No
UA 1	UA 1 is located north of the gas pipeline road near the former evaporation ponds. During site investigations, a former employee identified this area as a possible burial for asbestos-covered metal pipes. In 2008, a geophysical survey did not reveal any presence of the buried pipes, only small metallic anomalies found underground. This area will be investigated further, but no historical data have been documented. UA-1 is located within an especially culturally sensitive area, and the Tribes have expressed their desire to avoid or greatly limit any further activity in this area.	No data have been collected in this area.	Asbestos	No
UA 2	UA 2, the former 300B Pipeline Drip Tank, is located southeast of the plant on a shelf in the hill next to old Route 66. In 1994, investigation found oil-stained soil in a small area underneath and adjacent to this tank. In 1996 the tank was removed, and a cleanup was implemented. Soil was excavated to a depth of 5.5 ft. No further characterization is recommended in this area.	As, Ba, Pb, Zn	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, TPH, pH, pesticides, PCBs	No
Perimeter Area[3]	The Perimeter Area is the area extending from the facility fence line to the toe of the slope. The majority of the Perimeter Area is lower than the station, and these topographically lower areas could have received runoff and incidental spills from the station. The Perimeter Area excludes those portions of the slope that are already part of a designated unit (i.e., portions of SWMU 1, AOC 9, AOC 10, and AOC 11). There has been no previous investigations or sampling in this area.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, TPH, SVOCs, PAHs, and PCBs	Yes

TABLE 1.2-1
Historical Activities Summary, Constituents Exceeding Interim Screening Levels for Soil RFI/RI Units Outside the Fence Line, Perimeter Area, and Storm Drains, and Associated Analytical Suites

Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Interim Screening Levels	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
Storm Drains[3]	Fifteen storm drain outfalls have been visually identified outside the fence line, but little information is known regarding the exact locations of historic lines and drainage to these lines. Contaminants discharged to catch basins within the compressor station would most likely have entered the storm drains and been transported to the outfalls.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs	Yes

Notes:

[1] Analytical suites as presented in the Revised Final Soil RFI/RI Work Plan (CH2M HILL 2013).

[2] PCB analysis only on soil collected between 0 and 2 feet below ground surface.

[3] The Perimeter Area and Storm Drains are being investigated separately from the areas outside (Part A) and within (Part B) the fence line; once the data from the Perimeter Area and Storm Drains investigations have been collected, they will be combined with the appropriate existing Part A or B unit(s) or identified as a hotspot if there is no apparent connection to an existing unit.

Metals: Antimony (An); Arsenic (As); Barium (Ba); Beryllium (Be), Cadmium (Cd); Hexavalent Chromium (Cr^{+6}); Total Chromium (Total Cr); Cobalt (Co); Copper (Cu); Lead (Pb); Mercury (Hg); Molybdenum (Mo); Nickel (Ni); Selenium (Se); Silver (Hg); Thallium (Tl); Vanadium (V); Zinc (Zn)

Inorganics: Aluminum (Al); Calcium (Ca); Iron (Fe); Magnesium (Mg); Manganese (Mn); Potassium (K); Sodium (Na); Cyanide (CN)

Semivolatile Organic Compounds (SVOCs): 4-Methylphenol; Bis (2-ethylhexyl) phthalate; Di-N-butyl phthalate

Volatile Organic Compounds (VOCs): Methyl acetate

Polycyclic Aromatic Hydrocarbons (PAHs): 1-Methyl naphthalene; 2-Methyl naphthalene; Acenaphthene, Anthracene; Benzo (a) anthracene; Benzo (a) pyrene; Benzo (b) fluoranthene; Benzo (ghi) perylene; Benzo (k) fluoranthene; Chrysene; Dibenzo (a,h) anthracene; Fluoranthene; Fluorene; Indeno (1,2,3-cd) pyrene, Naphthalene; Phenanthrene; Pyrene, PAH Low molecular weight; PAH High Molecular weight; B(a)P Equivalent

Polychlorinated biphenyls (PCBs): Aroclor-1016; Aroclor-1254; Aroclor-1260; Total PCBs

Pesticides: 1,1-dichloro-2.2-bis[p-chlorophenyl] ethylene (4,4-DDE); 1,1,1-Trichloro-2,2-bis(4-chlorophenyl)ethane (4,4-DDT)

Total Petroleum Hydrocarbons (TPH): TPH as diesel; TPH as motor oil

TABLE 1.2-2
Historical Area Summary and Constituents Exceeding Background Threshold Value for Soil RFI/RI Units Inside the Fence Line and Associated Analytical Suites
Groundwater Remedy Operation and Maintenance Manual
Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Background Threshold Value	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
SWMU 5	SWMU 5 is located inside the fence line and comprises the two former sludge-drying beds. Both of these beds were approximately 20 feet wide by 50 feet long. Bed 1, constructed in the early 1950s, was used to dehydrate lime sludge generated by the water softening process. From 1964 through 1969, it was used to treat chromium-bearing wastewater in the single-step chromate reduction process. A second bed was constructed in the late 1960s, and from 1969 through 1985, the two drying beds were used to dehydrate chromic hydroxide sludge. Use of these beds ceased in 1985. Closure of the drying beds was accomplished during Phase I of the Hazardous Waste Treatment System Closure, between 1988 and 1989.	Total Cr, Pb, Zn	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs	Yes
SWMU 6	SWMU 6 was the chromate reduction tank located in the southern end of the lower yard. The tank was part of the two-step waste water treatment system installed in 1969 and was in operation through 1985. The tank was approximately 10 feet high and 5 feet in diameter, with a capacity of 1,500 gallons. Closure of this system was completed during Phase I Hazardous Waste Treatment System Closure.	Total Cr, Cr^{+6}, Zn	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs	Yes
SWMU 8	SWMU 8 was located on the southern end of the lower yard in an area that is now covered by the new Fire Pump Building. SWMU 8 was the process pump tank that was part of the two-step waste water treatment system. The tank was approximately 8 feet high and 5.5 feet in diameter. The pump tank was used as a temporary holding tank for treated wastewater discharged from the precipitation tank, before it was pumped to the former percolation bed. In 1985, this unit was removed from service and closure was accomplished during Phase I.	Co, Cu, Ni	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs	No
SWMU 9	SWMU 9, located in the southwestern portion of the lower yard, was the transfer sump that was part of a two-step wastewater treatment system. The sump was a pre-fabricated concrete septic tank that had the capacity of 1,500 gallons. The sump was 3 feet in diameter and 20 feet deep. From 1969 through 1985 effluent from the chromate reduction tank was routed through SWMU 9. In 1989, the transfer sump was removed during Phase 2 of the Hazardous Waste Treatment System Closure.	Be	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs	Yes
SWMU 11	SWMU 11 consists of two 400-gallon sulfuric acid tanks, located in the cooling tower A (AOC 5) and cooling Tower B (AOC 6). These tanks were used to control pH to minimize scale, corrosion, and biological growth. The 1950s through 1984, sulfuric acid was delivered to the facility in drums and pumped directly into the basins. To date, no data have been collected to evaluate any potential concerns related to sulfuric acid tanks.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, and pH	No

TABLE 1.2-2
Historical Area Summary and Constituents Exceeding Background Threshold Value for Soil RFI/RI Units Inside the Fence Line and Associated Analytical Suites
Groundwater Remedy Operation and Maintenance Manual
Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Background Threshold Value	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
AOC 5	AOC 5 is the area surrounding original Cooling Tower A, and encompasses the cooling tower, former chemical shed, and SWMU 11. Most of the area is covered with gravel, but pavement bounds the surrounding area. From 1951 to 1985 chromium-based corrosion inhibitors were used to treat the cooling water, and stored within the chemical shed. Stained soils were observed within the shed during demolition of the shed in 2000. The stained soils were excavated.	Cr^{+6}, total Cr, Cu, Zn	Title 22 metals, hexavalent chromium, and pH	No
AOC 6	AOC 6 is the entire area surrounding Cooling Tower B, and encompasses the cooling tower, former chemical shed, and SWMU 11. Most of the area is covered with gravel, but pavement bounds the surrounding area. From 1951 to 1985 chromium-based corrosion inhibitors were used to treat the cooling water, and stored within the chemical shed. Stained soils were observed within the shed during demolition of the shed in 2000. The stained soils were excavated.	Cr^{+6}, total Cr, Cu, Ni, Zn	Title 22 metals, hexavalent chromium, and pH	No
AOC 7	AOC 7 consists of the hazardous materials storage area and loading dock, and the adjacent Carpenter Shop (former Chemical Storage Building). The current hazardous material storage area has been used since the mid-1980s to store chemical products used at the station. The former Chemical Storage Building was constructed in 1951 as part of the original station configuration.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, PCBs, TPH, and pH	Yes
AOC 8	AOC 8 consists of a small storage locker used for paint storage. The locker is 5 feet wide by 5 feet long and is set back into southern retaining wall at the Compressor Station. The paint locker is constructed of steel with tight fitting doors, and located on pavement. No evidence of release is present.	No data have been collected in this area.	Title 22 metals, VOCs and TPH	Yes
AOC 13	AOC 13 consists of the current and former unpaved areas within the fence line. Many of the former unpaved areas are now paved and covered by buildings. Spills that have occurred at the facility and may have affected unpaved areas.	Be, Cd, Cr+6, Total Cr, Co, Cu, Pb, Mo, Ni, Se, Zn	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos	Yes
AOC 15	AOC 15 consist of the auxiliary jacket cooling water pumps located north of the Auxiliary Building. AOC 15 is part of the closed-loop cooling system for the generator engines. From 1951 through 1985, chromium-based cooling water additives were used in the closed loop cooling systems. Leaks from valve seals and pumps may have affected the soil at AOC 15.	Cr^{+6}, total Cr, Cu, Pb, Mo, Ni, Zn	Title 22 metals, hexavalent chromium, and pH	No

Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Background Threshold Value	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
AOC 16	AOC 16 is the sand blast shelter located in the lower yard. The sandblast shelter was installed in the early 1990s, and used primarily for smaller items (fixed infrastructure and large items are typically sandblasted in place).	No data have been collected in this area.	Title 22 metals	No
AOC 17	AOC 17 is the onsite septic system that serves the Auxiliary Building and nearby buildings. It consists of the septic located northeast of the air dryer building, and the associated leachfield. Wastewater from the facility laboratory of the Auxiliary Building is routed to the septic system. According to informal station drawings, the leachfield consists of 3 100-foot-long lines spaced 6 feet apart. The onsite septic system is believed to have been installed as part of the original compressor station facilities.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs	Yes
AOC 18	AOC 18 consists of the hazardous waste transference pipelines associated with the hazardous waste treatment system, as well as the pipelines conveying the cooling tower blowdown to the lower yard. In the 1980s, the pipelines were uncovered, pressure tested, and removed in accordance with the hazardous waste treatment system closure plan. Visually contaminated soil was removed, confirmation sampling was conducted, and supplemental soil excavation was conducted where needed. Not all sections of the piping could be removed, and active sections were not pressure tested.	Be, Cr^{+6}, Total Cr, Pb, Mo, Ni, Zn	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, and PAHs	Yes
AOC 19	AOC 19 is the Former Cooling Liquid Mixing and Jacket Cooling Water Hot Well Area located east of the Compressor Building. Employee interviews indicated that the hot well periodically overflowed. The hotwell was replaced with surge tanks circa 1967. Remnants of the hotwell were discovered and removed during a construction project in the 1990s. The former cooling liquid mixing area consists of a small concrete pad. Green droplets were noticed on the concrete pad during a routine test of a nearby eyewash fountain/safety shower in 2006. Elevated level of chromium were found in the green water.	Cd, Cr^{+6}, total Cr, Cu, Pb, Mo, Se, Zn	Title 22 metals, hexavalent chromium, and pH	No
AOC 20	AOC 20 consists of the industrial floor drains within the compressor station building and other buildings within the upper yard, as well as the associated pipelines, and the pipelines conveying the drainage to the oily water holding tank in the lower yard. Historically, the pipes associate with AOC 20 were made from vitrified clay.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, TPH, PCBs, and PAHs	No

TABLE 1.2-2
Historical Area Summary and Constituents Exceeding Background Threshold Value for Soil RFI/RI Units Inside the Fence Line and Associated Analytical Suites

Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Background Threshold Value	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
AOC 21	AOC 21 is a former round structure found adjacent to Sludge Drying Bed No. 1. This round structure was filled with white material that was most likely water softener (lime) sludge. The material appears to be similar to the material found in Sludge Drying Bed No. 1. No information is available on the construction of this area, although it appears to be of earthen materials.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, calcium, sodium, and pH	Yes
AOC 22	AOC 22 consists of a three-sided structure located in the upper yard, along the present compressor station fence line. A 1955 aerial photo appears to depict a drum that was near the structure. No further information about this structure is available.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, PCBs, and PAHs	Yes
AOC 23	AOC 23 is the former water conditioning (water softening) building located in the southern part of the upper yard. Currently AOC 23 is used for storage of dry non-hazardous materials. Chemical feed tanks for the water softening process were located inside the building, and the precipitator for the water softening system was located outside the building.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and pH	No
AOC 24	AOC 24 consists of the stained area near the API oil/water separator formerly located northeast of the northern scrubbers, as well as the footprint of the separator. The staining is apparent in 1955 aerial photographs and some plant photographs. The separator was later moved and reused as part of the old oily water treatment system adjacent to Sludge Drying Bed No. 1.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and pH	No
AOC 25	AOC 25 consists of the compressor and generator engine basements. There are 10 compressor engines, 9 of which are still active, and four generators engines. Each of the engines is mounted on a concrete pedestal on a concrete foundation. The pedestal is surrounded by a concrete trench. The trench around the pedestal is known as the basement. Drips and leaks from the engines would discharge into the drains in the basements, and enter AOC 20. Surface and shallow subsurface site investigation and soil removal have been conducted in areas immediately adjacent to the auxiliary and compressor buildings.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos	No

TABLE 1.2-2

Volume 4: Soil Management Plan
PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Background Threshold Value	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
AOC 26	AOC 26 is the location of the former scrubber oil sump located in the lower yard south of the South Scrubbers. The sump received pipeline liquids of the natural gas scrubbers, as well as oil from the oil bath filters until the filters were taken out of service in the 1960s. The scrubber sump was removed in 1996 as part of an upgrade to the waste oil system. The area was investigated and contaminated soil was removed to the degree feasible (excavation was limited by the presence of infrastructure). Residual contamination is present below the maximum excavation depth (approximately 10 feet).	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and pH	No
AOC 32	AOC 32 is the oil storage area in the upper yard immediately west of the visitor parking lot. AOC 32 contains five 7,150-gallon capacity oil storage tanks, the steel-lined waste oil sump, and two 150-gallon capacity lubricating oil surge tanks. The tanks and oil sump are part of the original compressor station installation. The tanks and sump are located within a concrete containment structure. The sidewalls of the containment structure are apparent in a ca. 1956 station photograph; however, it is uncertain if the floor of the oil storage area has always been paved. Associated piping is also located within the containment. The containment structure appears to be in good repair; an inspection conducted in 1994 indicated that it was in good condition at the time. The dirty oil sump receives waste oil from the oil/water separator, and pipeline liquids collected from the scrubbers. It formerly received used oil from the scrubber sump.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, and PCBs	No
AOC 33	AOC 33 is the potential burn area located near AOC 17. This area was identified when PG&E conducted additional interviews with current and former employees to collect new anecdotal information pertaining to historical compressor station practices. Several employees reported that PG&E may have conducted a yearly fire training exercise during which materials were set on fire and employees practiced extinguishing the fire. The employees indicated that these fire extinguishing drills took place in the early 1980s (and may have taken place prior to then) and continued into the 1990s.	No data have been collected in this area.	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, asbestos, and dioxin and furans	Yes
Unit 4.3	Unit 4.3 is the oil/water holding tank that was installed in 1970. It was a cylindrical steel tank 15 feet long by 5 feet in diameter that was used to collect oily water from the compressor floor drainage, engine and steam-cleaning operations, and other activities discharging to AOC 20.	None, sampled only for TPH.	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, and PAHs	Yes

PG&E Topock Compressor Station, Needles, California

Units	Summary of Historical Activities	Constituents Exceeding Background Threshold Value	Analytical Suites[1]	Overlaps or Is within 20 feet of Groundwater Remedy Infrastructure?
Unit 4.4	Unit 4.4 was the oil water separator located adjacent to Unit 4.3 (the API oil/water separator relocated from the area northeast of the north scrubbers. Unit 4.4 was equipped with an underflow weir to control discharge, and the floating oil was transferred by hose to a portable waste oil storage tank.	None, sampled only for TPH.	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, and PAHs	No
Unit 4.5	Unit 4.5 was the portable waste oil storage tank adjacent to the Unit 4.3 and 4.4. Skimmed oil from Unit 4.4 was discharged into Unit 4.5. The portable tank was stationed on a concrete pad; when it was full it was transported to the east side of the facility, and pumped into the waste oil tank. Starting in 1975, the oil was either sold for reuse or transported to a recycling center.	None, sampled only for TPH.	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, and PAHs	No

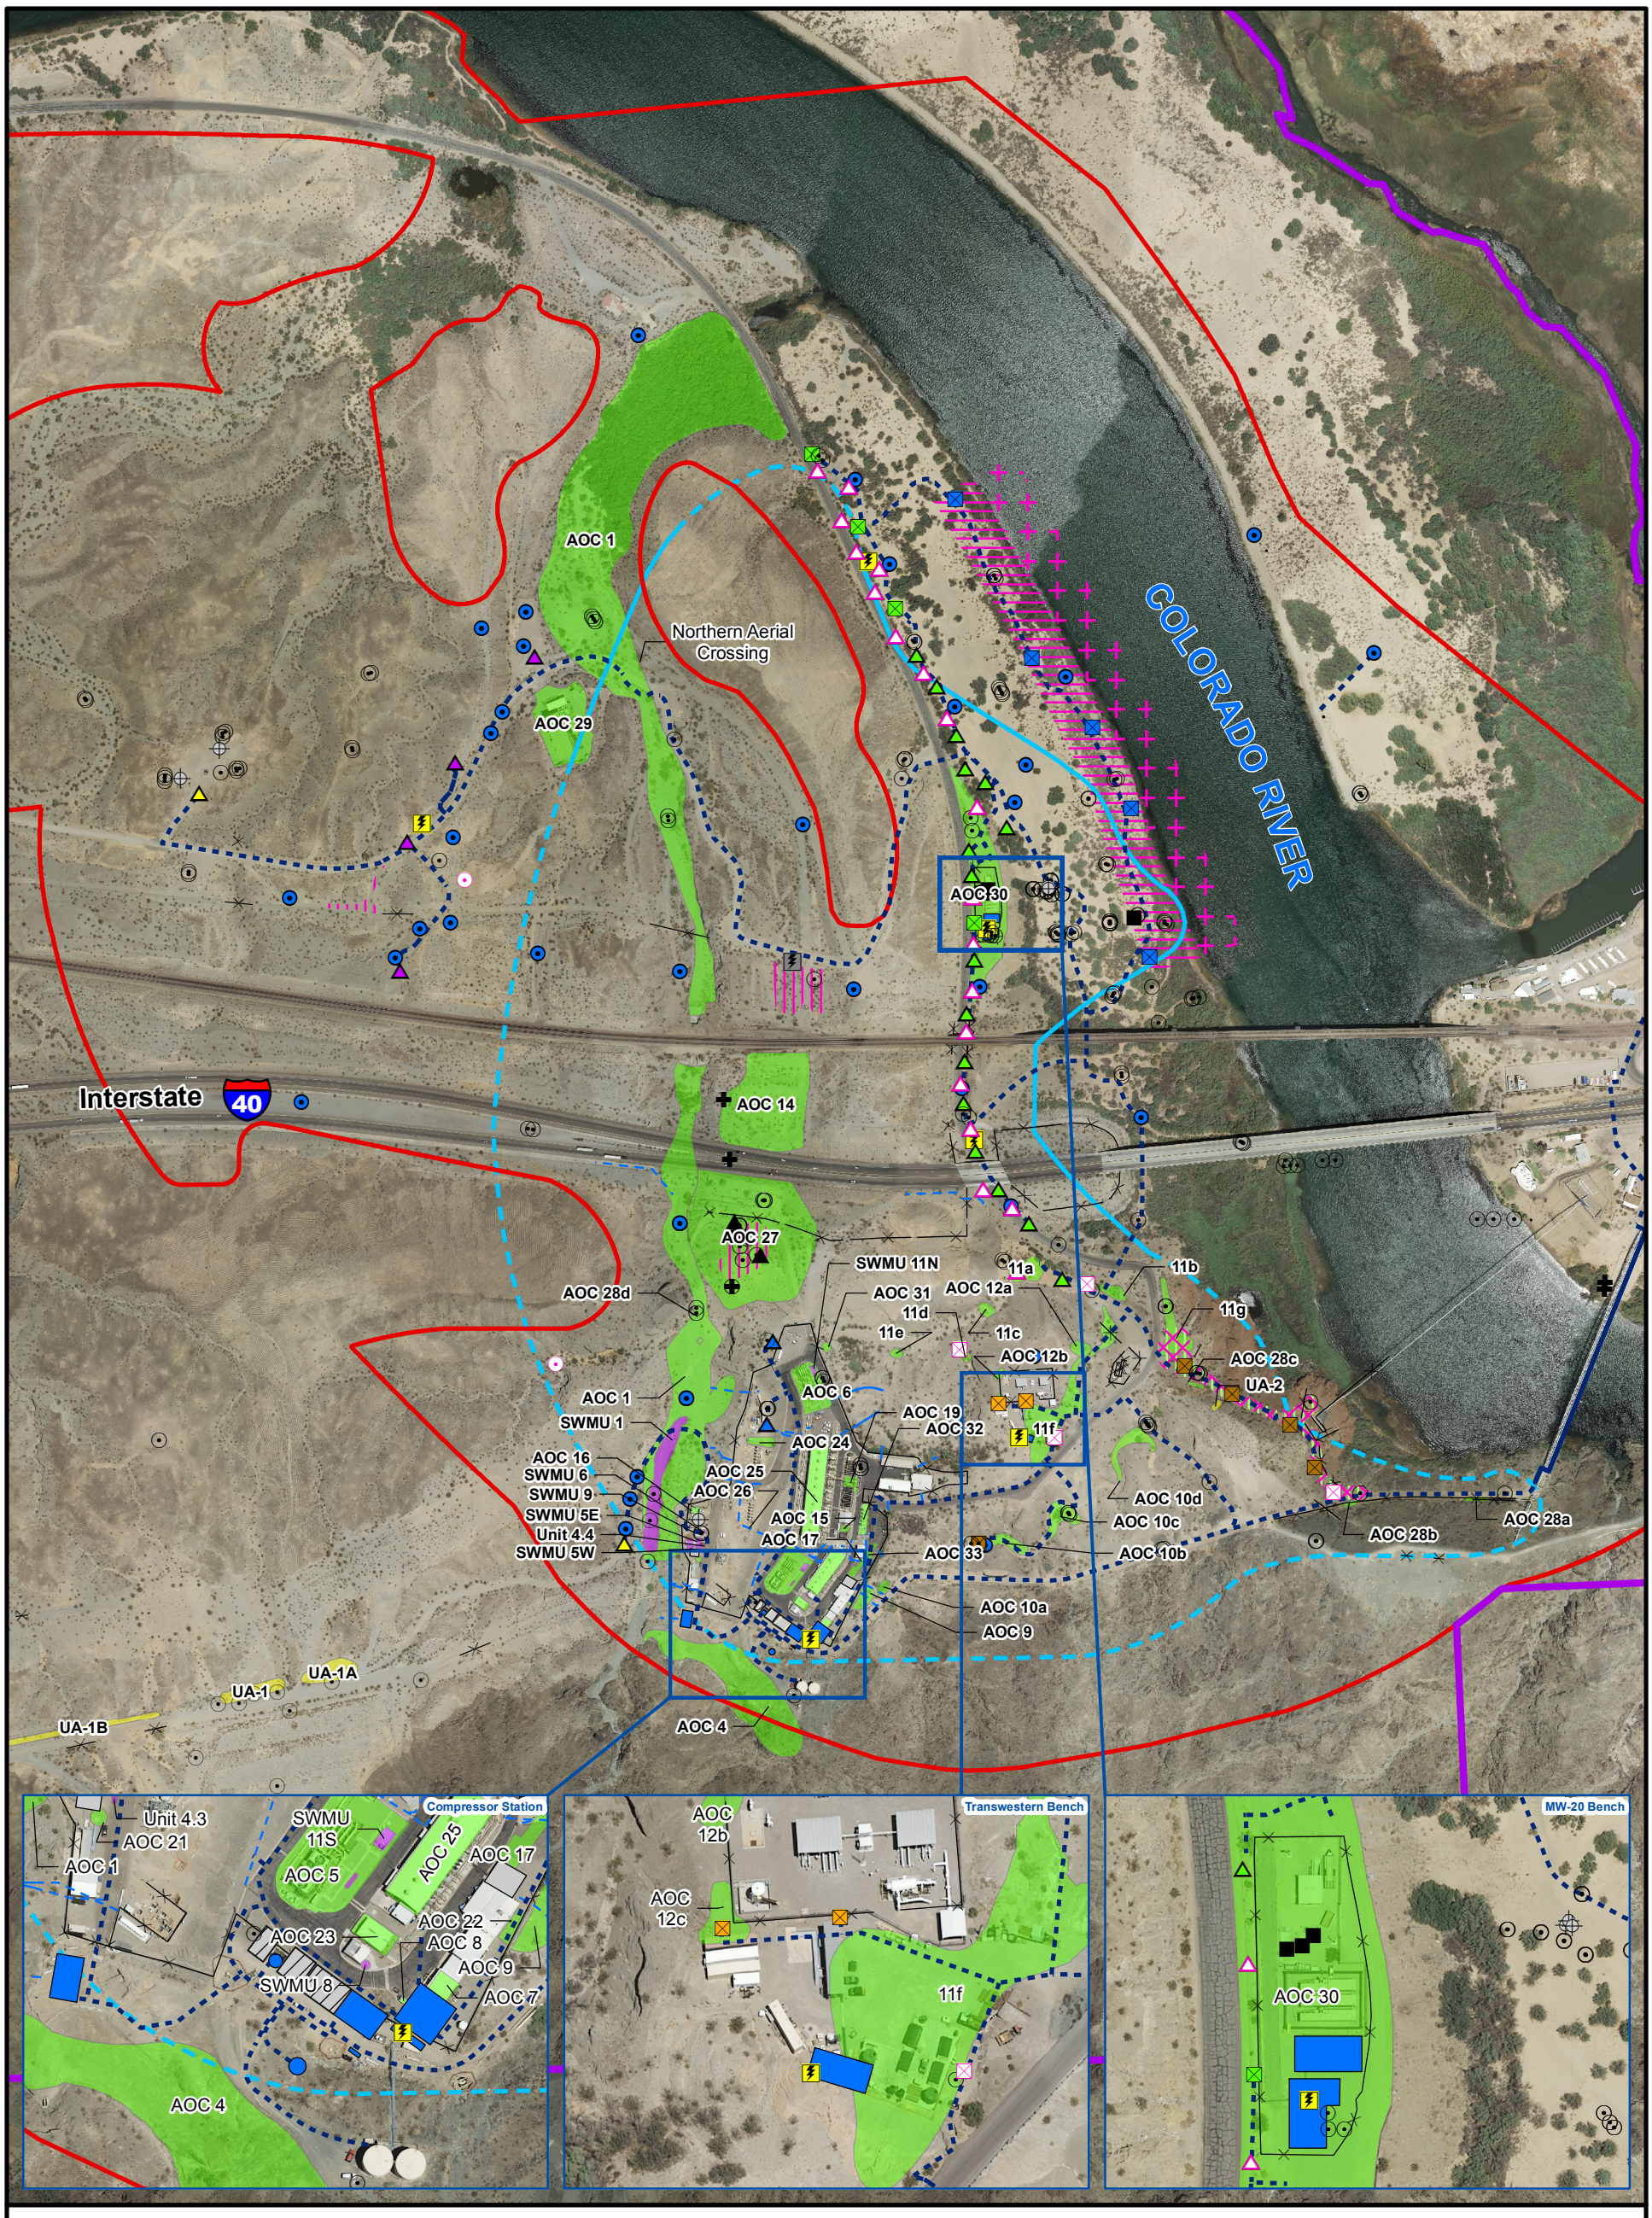
Notes:

[1] Analytical suites as presented in the Revised Final Soil RFI/RI Work Plan (CH2M HILL 2013).

Metals: Antimony (An); Arsenic (As); Barium (Ba); Beryllium (Be), Cadmium (Cd); Hexavalent Chromium (Cr^{+6}); Total Chromium (Total Cr); Cobalt (Co); Copper (Cu); Lead (Pb); Mercury (Hg); Molybdenum (Mo); Nickel (Ni); Selenium (Se); Silver (Hg); Thallium (Tl); Vanadium (V); Zinc (Zn)

Inorganics: Aluminum (Al); Calcium (Ca); Iron (Fe); Magnesium (Mg); Manganese (Mn); Potassium (K); Sodium (Na); Cyanide (CN)

Semivolatile Organic Compounds (SVOCs): 4-Methylphenol; Bis (2-ethylhexyl) phthalate; Di-N-butyl phthalate



Volatile Organic Compounds (VOCs): Methyl acetate

Polycyclic Aromatic Hydrocarbons (PAHs): 1-Methyl naphthalene; 2-Methyl naphthalene; Acenaphthene, Anthracene; Benzo (a) anthracene; Benzo (a) pyrene; Benzo (b) fluoranthene; Benzo (ghi) perylene; Benzo (k) fluoranthene; Chrysene; Dibenzo (a,h) anthracene; Fluoranthene; Fluorene; Indeno (1,2,3-cd) pyrene, Naphthalene; Phenanthrene; Pyrene, PAH Low molecular weight; PAH High Molecular weight; B(a)P Equivalent

Polychlorinated biphenyls (PCBs): Aroclor-1016; Aroclor-1254; Aroclor-1260; Total PCBs

Pesticides: 1,1-dichloro-2.2-bis[p-chlorophenyl] ethylene (4,4-DDE); 1,1,1-Trichloro-2,2-bis(4-chlorophenyl)ethane (4,4-DDT)

Total Petroleum Hydrocarbons (TPH): TPH as diesel; TPH as motor oil

SECTION 2

Soil Management

Soil that may be displaced in the vicinity of the groundwater remedy system during drilling, construction, and O&M activities that are part of the groundwater remediation project or decommissioning and removal of the IM-3 system will be managed according to the processes described in this SMP. This section identifies Soil RFI/RI Investigation Areas in the vicinity of the groundwater remedy system and IM-3 system, and describes the processes for soil characterization, soil screening and classification, handling, short-term storage, and longer storage of displaced soil.

The process presented herein for determining whether displaced soil (including drill cuttings) is hazardous waste, is in compliance with California action-specific ARAR #74 (22 CCR Section 66262.11), Requirements for Waste Determination (DOI 2010). Once determined to be a hazardous waste, the waste will be managed in compliance with California action-specific ARARs #75 through #80, and #84 through #86 (DOI 2010):

- ARAR #75 (22 CCR 66262.12): USEPA identification number
- ARAR #76 (22 CCR, Div 4.5, Ch 14, Article 2): General requirements for hazardous waste facilities
- ARAR #77 (22 CCR 66262.20 and 66262.22): Use of hazardous waste manifest
- ARAR #78 (22 CCR 66262.30, 66262.31, 66262.32 and 66262.33): Packaging, marking, labeling, and placarding hazardous waste shipments
- ARAR #79 (22 CCR 66262.34): Accumulation requirements for hazardous waste
- ARAR #80 (22 CCR 66262.40 and 66262.41): Recordkeeping
- ARAR #84 (22 CCR, Div 4.5, Ch 14, Article 9): Use and management of containers
- ARAR #85 (22 CCR, Div 4.5, Ch 14, Article 10): Tank systems
- ARAR #86 (22 CCR, Div 4.5, Ch 14, Article 12): Waste piles for RCRA hazardous waste

In addition, to maximize onsite reuse of displaced soil and minimize offsite transportation and disposal of site soil, characterization, screening, handling, and storage processes were developed following guidelines in the *Revised Management Protocol for Handling and Disposition of Displaced Site Material, Topock Remediation Project, Needles, California* (Appendix B).

2.1 Soil RFI/RI Investigation Areas Intersected by the Groundwater Remedy Project

At the final design stage, proposed remedy pipeline/conduit alignments (includes direct burial pipelines/conduits, pipeline trenches, and remediation wells [i.e., injection and extraction wells] that are connected to those pipelines), remedy structures, and new monitoring well will intersect twenty-four Soil RFI/RI Investigation Areas. These areas are listed below and shown on Figure 1.0-1:

- SWMU 1 – Former Percolation Bed
- SWMU 5 – Sludge-Drying Beds
- SWMU 6 – Chromium Reduction Tank
- SWMU 9 – Transfer Sump
- AOC 1 – Area Around Former Percolation Bed
- AOC 4 – Debris Ravine
- AOC 7 – Hazardous Materials Storage Area
- AOC 8 – Paint Locker

- AOC 9 – Southeast Fence Line (Outside Visitor Parking Area)
- AOC 10 – East Ravine
- AOC 11 – Topographic Low Areas
- AOC 12 – Fill Areas
- AOC 13 – Unpaved Areas within the Compressor Station
- AOC 17 – Onsite Septic System
- AOC 18 – Combined Hazardous Waste Transference Pipelines
- AOC-21 – Round Area by Sludge Drying Beds
- AOC 22 – Unidentified Three-sided Structure
- AOC 27 – MW-24 Bench
- AOC 28 – Pipeline Drip Legs
- AOC 30 – MW 20 Bench
- AOC 33 – Potential Former Burn Area near AOC 17
- Unit 4.3 – Oil/Water Holding Tank
- Perimeter Area outside of but adjacent to the Compressor Station fence line
- Storm Drain System

The decommissioning and removal of the IM-3 system will affect two AOCs – AOC 29 (IM-3 Treatment Plant) and AOC 30 (MW 20 Bench).

These Soil RFI/RI Investigation Areas are currently being investigated under the Soil RFI/RI program. Tables 1.2-1 and 1.2-2 provide a summary of historical activities at each of these investigation areas, a list of constituents that exceeded interim screening levels, and the proposed analytical suites as presented in the revised Soil FRI/RI Work Plan. Existing soil data collected from within AOCs will be used to assess required protection of workers for health and safety purposes. Personnel engaged in field activities within known AOC areas will have completed the Occupational Safety Health Administration 40-hour health and safety training that meet the requirements of Title 29 CFR Section 1910.120 and Title 8 CCR Section 5192. All personnel will read applicable project-specific health and safety plans.

2.2 Soil and Waste Characterization Process

Soil in the vicinity of the groundwater remedy system expected to be displaced will be pre-characterized following the Groundwater Remedy Implementation—Baseline Soil Sampling and Analysis Plan (Baseline SAP), included as Appendix A of this document. The baseline soil sampling results will be screened following the process described below in Section 2.3 to classify the displaced soil for handling, storage, and/or disposal purposes. Soil generated during 1) post-construction O&M in or near Soil RFI/RI Investigation Areas that has not been pre-characterized and 2) the decommissioning and removal of the IM-3 system infrastructure used for the groundwater remedy, will be stockpiled or placed in lined roll-off bins at the work site, if practicable, or onsite in a temporary storage area designated by PG&E until they have been characterized.

Field segregation of soil will be a key step in the process of management of displaced soil for any ground disturbance activities that occur during remedy construction. As soil is displaced, any soil with odors or visual evidence of contamination will be segregated, characterized, and handled following procedures outlined in this SMP.

Representative sample profile results, existing soil sample results, and knowledge of the area history will be used to assess waste classification for displaced soil that has not been pre-characterized. Additional characterization of displaced soil from or near Soil RFI/RI Investigation Areas will be performed as needed. In general, characterization will entail collection of composite samples from roll-off bins and stockpiles. One four-point composite sample will be taken from each roll-off bin. For stockpiles, one four-point composite sample will be collected per 250 cubic yards.

The waste characterization soil samples collected within or near Soil RFI/RI Investigation Areas will be analyzed for the applicable Soil RFI/RI Investigation Area analytical suite presented in Tables 1.2-1 and 1.2-2. The samples

collected outside areas of known or suspected contamination will be analyzed for PAHs and lead. Analytical results will be screened according to the procedure listed in Section 2.3 to classify the soil for handling, storage, and disposal purposes. It is imperative to coordinate with the waste hauler and disposal facility to ensure proper completion of the profile.

Soil at 1 foot below ground surface (bgs) from each new monitoring, extraction, and injection well locations will be characterized per Section 2.3 as part of the Baseline SAP. Drill cuttings from installation of new monitoring, extraction, and injection wells will be containerized in 55-gallon U.S. Department of Transportation (DOT) drums or lined roll-off bins and characterized as described below. Drill cuttings from RFI/RI Investigation Areas will be segregated from those not within Investigation Areas to prevent comingling. The drill cuttings drums/bins will be stored onsite in a temporary storage area designated by PG&E until they have been characterized. Drum and roll-off bin storage are described in Section 3.1.

Characterization of drilling cuttings will be performed by collection of samples as follows:

- For one drum, one discrete sample will be collected from the drum. The sample will be collected from the center of the drum from at least 12-inches below the surface of the soil.
- For 2 to 10 drums, one discrete sample will be collected from each drum and composited into a single composite sample.
- For more than 10 drums, one composite sample will be collected for every 10 drums.
- For each roll-off bin, one four-point composite sample will be taken from the roll-off bin.

The samples will be analyzed for applicable Soil RFI/RI Investigation Area analytical suite presented in Tables 1.2-1 and 1.2-2. Analytical results will be screened according to the procedure listed in Section 2.3 to classify the soil for handling, storage, and disposal purposes.

2.3 Screening and Classification of Soil

The following process for screening and classification of displaced soil in compliance with California action-specific ARAR #74 (22 CCR 66262.11) is based on the *Revised Management Protocol for Handling and Disposition of Displaced Site Material, Topock Remediation Project, Needles, California* (PG&E 2015) (see Appendix B).

Analytical results from the baseline soil sampling or other characterization of soil samples (i.e., drum or roll-off bins, or areas not pre-characterized) will be used to assess whether displaced soil is suitable for retention onsite for eventual return, reuse, or replacement, or if the soil must be removed from the site for disposal in accordance with applicable state and federal laws and regulations. Analytes detected in the baseline soil sampling or other characterization of soil samples above laboratory detection limits will be screened against the screening values included on Tables 2.4-1 and 2.4-2. These screening values include the following:

- **Interim Screening Levels (Table 2.4-1)** – The screening levels for metals are predominantly Topock-specific soil background values. However, if a background value is not available then the lesser of the DTSC Residential Screening Level (*Human Health Risk Assessment Note 3 – DTSC-Modified Screening Levels* [HERO 2015]) or the ecological comparison value is used. If a DTSC Residential Screening Level is not available, then the lesser of the USEPA residential regional screening level or the ecological comparison value is used (the source document for the ecological comparison values is included in Appendix D of this SMP). These levels are the most conservative, and it is assumed that the project-specific soil cleanup goal will be equal to or greater than these levels. Once established, the project-specific cleanup goals will replace the interim screening levels.
- **Hazardous Waste Toxicity Characteristic Levels (Table 2.4-2)** – These values will be used to assess if the soil should be classified as a non-hazardous waste, a state (non-RCRA California) hazardous waste, or a federal (RCRA) hazardous waste. Specifically, total constituent concentrations expressed in milligrams per kilogram (mg/kg) will be compared to the hazardous waste characteristic levels in Table 2.4-2, and will be evaluated as follows:

- Step 1 – If the total constituent concentration exceeds the total threshold limit concentration (TTLC), the soil represented by the sample will be classified as a non-RCRA hazardous waste. Additional evaluation of the soluble threshold limit concentration (STLC), as described in Step 3 below, will not be performed.
- Step 2 – If the total constituent concentration exceeds the numeric value of the RCRA toxicity characteristic (TC) level by about 20 times or more, the toxicity characteristic leaching procedure (TCLP) will be performed. If the constituent concentration in the TCLP leachate exceeds the TC level, the soil represented by the sample will be classified as a RCRA hazardous waste. Additional evaluation of the STLC, as described in Step 3 below, will not be performed.
- Step 3 – If the sample has not been classified as hazardous waste in Steps 1 or 2, the total constituent concentration will be compared to the STLC. If the total constituent concentration exceeds the numeric value of the STLC by 10 times or more, the California Waste Extraction Test (WET) will be performed. If the constituent concentration in the WET exceeds the STLC, the soil represented by the sample will be classified as a non-RCRA hazardous waste.
- Step 4 – If the sample has not been classified as a hazardous waste in Steps 1, 2, or 3, the soil represented by the sample will be not be classified or managed as hazardous waste.

Subsequent to screening, soil that may be displaced in the vicinity of the groundwater remedy system will be classified into four categories and will be managed as follows:

- RCRA hazardous waste—The waste will be removed from the site within 90 days of generation and disposed of offsite in accordance with applicable laws and regulations (California action-specific ARARs #78 and #79) and the Remedial Design/Remedial Action Consent Decree (CD) (DOI 2013). It is imperative to coordinate with the waste hauler and disposal facility to ensure proper completion of the waste profile and to avoid unnecessary delays in acceptance of a waste to a specific facility (as discussed in Section 4.0).
- Non-RCRA hazardous waste – Same as management of the RCRA hazardous waste.
- Non-hazardous soil for offsite disposal — Soil that is not classified as a hazardous waste, and is greater than the interim screening level or project-specific cleanup goal (once established), will be disposed of offsite (as discussed in Section 2.5).
- Clean soil—Soil that is not classified as a hazardous waste, and is equal to or below the interim screening level, is suitable for immediate return, reuse, or replacement onsite (as discussed in Section 2.4).

2.4 Handling and Storage of Clean Soil

Non-hazardous clean displaced soil (i.e., soil below interim screening levels or project-specific cleanup goals [once established]) will be stockpiled at the work site, if practicable, and recorded in an inventory as described in Section 5.0. Clean soil that was removed from trenches or excavations will be reused as backfill into the same trench or excavation area, if practicable. Clean soil that cannot be immediately used as backfill may be reused in other areas within the APE, or stockpiled for future reuse within the APE. Displaced soil that is stockpiled for future use will be managed following the BMPs described in Section 3.1.2 below, the BMPs Plan presented in Appendix C, the Construction/Remedial Action Work Plan, and the Groundwater Remedy Industrial SWPPP (Appendix E of Volume 1 of this O&M Manual).

Consistent with the special handling procedures requested by the Hualapai Department of Cultural Resources for displaced material generated from clay beds (this does not include clay-containing sediment mixtures, only clay beds), if clay bed(s) are encountered during construction, the clay material will be set aside on 100% cotton muslin (dye free) for future disposition following discussions with the Tribes. For the purposes of this project the identification of a “clay bed,” and therefore the application of this special handling procedure, will be based on the practicability for the clay material to be separated from other excavated soils or drill cuttings. For example, when trenching with a backhoe it may be possible to identify relatively thin beds of clay material (e.g., less than a foot) and separate it from the rest of the excavated soil, but when drilling with a method that doesn’t retrieve

cores that can be closely observed and precisely separated (e.g., hollow-stem auger), a relatively thin clay bed might not be identified or the clay material might become mixed with the rest of the cuttings to the point where it cannot be practicably separated. PG&E will notify the Agencies and Tribes in the event clay material is encountered and separated for storage. Further, salvage of topsoil during installation of trenches will be done where the proposed excavation will occur in areas where undisturbed topsoil may be present. In such areas, the upper 4 inches of soil will be carefully removed and placed near the excavation. The remaining subsurface-soil will then be excavated and stored separately from the topsoil. Following the installation of piping/conduits and backfilling of the trench, the topsoil will be replaced over the trench. Therefore, there will be no need for long-term storage of undisturbed topsoil. The rest of the excavated soil that is not undisturbed topsoil consists of desert soils that are generally low in nutrients and organic matter. Desert soil that has been subject to disturbance typically loses a large percentage of the available nutrient supply and important soil biota. Therefore, salvage of soil from disturbed areas will not occur and there will be no specific actions related to protecting biological integrity while these soils are being stored.

Additional segregation or sorting of material by size may occur, e.g., separating oversize rocks and gravel that are excavated during trenching but are not considered suitable for backfill. Oversize rocks may be used as erosion control (riprap) or processed (crushed) to provide aggregates in concrete, pavements or road surfacing. An onsite segregation unit for screening/crushing may be used to process material for onsite use.

The estimated volume of clean soil (generated from construction of the groundwater remedy) needing storage is approximately 11,000 cubic yards. This volume is based on the total net volume of soil excavated from trenches and building foundations located outside of Soil RFI/RI Investigation Areas that cannot be immediately used as backfill. During the 60% design comment resolution process (September 2013 through March 2014), potential locations for soil storage were evaluated by PG&E and Tribes and discussed with Agencies and landowners/managers (BLM/BOR). As a result of these discussions, PG&E proposed to use an area (located on federal land) in Moabi Regional Park for storage of non-hazardous clean soil (see Figure 2.4-1 at the end of this section). The estimated storage capacity in the identified area is 11,700 cubic yards. It is anticipated that clean soil will be stored in stockpiles and managed per the BMPs presented in the BMPs Plan (Appendix C) and summarized in Section 3.1.2 below, the Construction/Remedial Action Work Plan, and the Groundwater Remedy Industrial SWPPP (Appendix E of Volume 1 of this O&M Manual).

The volume and classification of clean displaced soil from the decommissioning and removal of the IM-3 system requiring storage will not be known until after the system has been decommissioned and removed, which will not occur until after the start of implementation of the groundwater remedy. Since the amount of displaced soil from the decommissioning and removal of the IM-3 system is expected to be minimal and characterization of this displaced soil will not occur until after the SMP has been revised to include the baseline soil sampling results, this displaced soil will be stored and managed following the same process as the soil displaced during the groundwater remedy installation and O&M provided in the revised SMP.

2.5 Handling and Off-site Disposal of Non-Hazardous Soil

The SMP and the revised management protocol for handling and disposition of displaced site material (Appendix B) exclude storage of soil that is non-hazardous but unsuitable for final disposition onsite because contaminants are present above the interim screening level or project-specific cleanup goal (once established).

The estimated volume of non-hazardous soil (from construction of the groundwater remedy) (i.e., soil above interim screening levels) needing disposal is approximately 4,000 cubic yards. This volume is based on the total net volume of soil excavated from trenches and building foundations located within Soil RFI/RI investigation areas. It is anticipated that this soil will be stored initially in roll-off bins and managed per the BMPs described in Section 3.1.3.

It is anticipated that project-specific cleanup goals will be established by the time of the decommissioning and removal of the IM-3 system. Displaced soils (from the decommissioning activities) that are above the clean-up goals will be disposed of offsite as described in the Revised Management Protocol (Appendix B). The volume and

classification of this soil will not be known until after the system has been decommissioned and removed, which will be after the start of implementation of the groundwater remedy. The amount of displaced soil from the decommissioning and removal of the IM-3 system is expected to be minimal.

Notes:

This table presents a reference list of analytes and associated screening levels that may be applicable for making decisions related to disposition of displaced site materials. The specific analytes and screening levels applicable for characterization of displaced material will be determined based on the origin of the material and potential disposition locations.

Interim screening level is background value. If background value is not available then the lesser of the DTSC HHRA Note 3 Residential Screening Levels (DTSC Residential SL) or the ecological comparison value is used. If a DTSC Residential SL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

Background	"Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California" (CH2M HIll 2009c)
DTSC-Residential SLs	Human Health Risk Assessment Note 3 – DTSC-Modified Screening Levels, May 2015.
EPA Residential RSL	United States Environmental Protection Agency Residential Soil Regional Screening Level (THQ=1.0), June 2015.
ECV	Ecological Comparison Values; ECV were calculated as needed for constituents detected during the Part A Phase I sampling (Arcadis 2008)
HHRA Note 2	DTSC Human Health Risk Assessment (HHRA) Note 2: Remedial Goals for Dioxins and Dioxin-like Compounds for Consideration at California Hazardous Waste Sites – Interim (May 2009).
SF RWQCB ESL	San Francisco Bay Regional Water Quality Control Board Environmental Screening Levels for residential direct exposure (2013)
*	One or more screening levels (EPA Residential RSL, DTSC-Residential SLs, ECV, or Soil SL) have values lower than the background level.

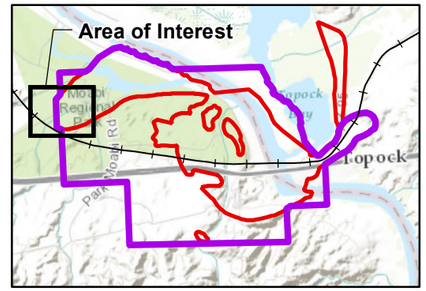
Notes:



NE	not established
mg/kg	milligrams per kilogram
mg/L	milligrams per liter
EPA HW	Environmental Protection Agency Hazardous Waste Code
TC	Toxicity Characteristic
TTLC	Total Threshold Limit Concentration
STLC	Soluble Threshold Limit Concentration
RCRA	Resource Conservation and Recovery Act
TCLP	Toxicity Characteristic Leaching Procedure
WET	California Waste Extraction Test

Hazardous waste critiera exist for kepone, 2,4-D, mirex, pyridine, and 2,45-TP (Silvex); however, since they are not contaminants of potential concern at the Topock site, they are excluded from this table.

a	Total Threshold Limit Concentration (TTLC) from 22 CCR 66261.24(a)(2). Calculated based on the concentration of the elements, not the compounds.
b	Screening level is 10x Soluble Threshold Limit Concentraction (STLC). If screening level is exceeded in total analysis, California Waste Extraction Test (WET) should be run to evaluate whether STLC is exceeded.
c	Screening level is 20x RCRA Toxicity Characteristic (TC). If screening level is exceeded in total analysis, Toxicity Characteristic Leaching Procedure (TCLP) should be run to evaluate whether RCRA TC is exceeded.
d	Soluble threshold limit concentration from 22 CCR 66261.24(a)(2), measured using the WET. Calculated based on the concentration of the elements, not the compounds.
e	RCRA TC level from 22 CCR 66261.24(a)(1), measured using the TCLP.
f	A waste is assigned a RCRA waste code for each constituent where the results of the TCLP equal or exceed the RCRA TC level.
g	If o-, m- and p-Cresol concentrations cannot be differentiated, the total cresol (D026) concentration is used. The regulatory level of total cresol is 200 mg/L.
i	In the case of asbestos and elemental metals, the specified concentration limits apply only if the substances are in a friable, powdered or finely divided state. Asbestos includes chrysotile, amosite, crocidolite, tremolite, anthophyllite, and actinolite.
j	TTLC and STLC exclude barite. TTLC excludes barium sulfate.
k	For STLC, if the waste does not exceed the RCRA TC or exhibit another RCRA hazardous characteristic, the STLC is 560 mg/L, not 5 mg/L.
l	For TTLC, excludes molybdenum disulfide.
h	Quantitation limit is greater than the calculated regulatory level. The quantitation limit therefore becomes the regulatory level.

FIGURE 2.4-1
CLEAN SOIL STORAGE AREA
GROUNDWATER REMEDY IMPLEMENTATION - SOIL MANAGEMENT PLAN
PG&E TOPOCK COMPRESSOR STATION, NEEDLES, CALIFORNIA

CH2MHILL

SECTION 3

Soil Storage

This section describes the storage procedures for soil displaced in the vicinity of the groundwater remedy system during drilling, construction, decommissioning, removal, and O&M activities at the site. Displaced soil will be segregated into the following streams:

- RCRA hazardous waste
- Non-RCRA hazardous waste
- Non-hazardous soil above interim screening levels or project-specific cleanup goals (once established)
- Clean soil

Soil that is classified as clean soil that is suitable for final deposition onsite will be managed following the BMPs described in Section 3.1.2 below, the PG&E Program Quality Assurance Project Plan (Appendix C of the Construction/Remedial Action Work Plan), and the Groundwater Remedy Industrial SWPPP (Appendix E of Volume 1 of this O&M Manual).

The procedures for accumulation of hazardous waste onsite will be in compliance with California action-specific ARAR #79 (22 CCR 66262.34). In addition, containerization of hazardous waste will be in compliance with ARAR #84 (22 CCR, Div 4.5, Ch 14, Article 9), ARAR #85 (22 CCR, Div 4.5, Ch 14, Article 10) and for RCRA hazardous waste, ARAR #86 (22 CCR Div 4.5, Ch 14, Article 12).

3.1 Methods to Store Soil

Soil will be stored in 55-gallon drums/small containers, roll-off bins, and/or stockpiles. Soil that is classified as hazardous waste and placed in containers must comply with Title 22 CCR Div. 4.5, Chapter 15, Article 9 (container management), Article 27, Article 28 and Article 28.5 (air emission standards) as required by ARAR #79, and with 22 CCR Div. 4.5, Chapter 14, Article 9 (container management) as required by ARAR #84. A BMPs Plan for soil storage is included in Appendix C of this SMP, and is summarized in the subsections below. PG&E does not anticipate utilizing any remote locations for storage of hazardous waste. If hazardous waste is encountered, it will likely be stored at the Compressor Station and/or the Transwestern Bench.

3.1.1 Drums/Small Containers

Drums containing soils which are hazardous waste will be stored in a hazardous waste storage area at the Compressor Station and/or Transwestern Bench and disposed of within 90 days of generation. If needed, drums/small containers that contain soil that may be displaced in the vicinity of the groundwater remedy system that is non-hazardous, but unsuitable for final disposition onsite because contaminants are present above the interim screening level, will be staged for offsite transportation following these BMPs:

- Only DOT-specification containers will be used for soil accumulation.
- Empty drums will be inspected and inventoried upon arrival onsite for signs of contamination and/or deterioration.
- Drums and small containers will be transported to the temporary accumulation areas on wood pallets and will be secured together with non-metallic banding.
- Drums will be placed within a bermed and lined area or otherwise will be provided with secondary containment.
- Adequate aisle space (e.g., 36 inches) will be provided for containers such as 55-gallon drums to allow the unobstructed movement of personnel and equipment for inspection purposes. Drums will be placed with no more than two drums per row. The column length must fit within the lined, bermed area.
- Each drum will be provided with its own label, and labels will be visible for inspection purposes.

- Drums will remain closed except when removing or adding soil to the drum. Closed means that the lid and securing ring must be on and securely tightened.
- Drums containing hazardous waste will not be reused.

3.1.2 Stockpiles

Stockpile management procedures and practices will be implemented to reduce or eliminate pollution to the air and stormwater from materials that are stockpiled. Stockpile protection is required year-round. Any stockpiles will be stored in the staging area and outside of the roadway right-of-way. Stockpiles will be located a minimum of 50 feet away from any concentrated flow of stormwater, drainage courses, and inlets. During the rainy season, stockpiles will be covered and anchored down with gravel bags and/or sand bags.

RCRA and non-RCRA Hazardous Soil. Stockpiling of RCRA and non-RCRA hazardous waste/soil is not planned. It is anticipated that all soil that is above soil screening levels or project-specific cleanup goals (once established) will be placed in roll-off bins or similar containers.

If it is necessary to temporarily stockpile soil classified as RCRA or non-RCRA hazardous waste for up to 90 days to facilitate characterization or staging for offsite transportation, the liner will consist of a single sheet of material, or multiple sheets with seams that are sealed together. Hazardous waste stockpiles will use a minimum 20-mil liner if constructed on a foundation (e.g., pavement or compacted soil) or a 60-mil liner if constructed in a location without a foundation (e.g., unpaved, uncompacted soil). Stockpiled soil will not contain free liquids.

Stockpiles will be inspected by a California-registered professional engineer to verify conformance with these requirements. Temporary staging for up to 90 days prior to offsite transportation will not trigger compliance with ARAR #86 (requirements for waste piles that are applicable to RCRA hazardous waste). The contents of the stockpile, including the words “Hazardous Waste” and the accumulation start date, will be posted on a sign next to the stockpile, and the contents and accumulation start date will be entered in the field logbook. Stockpiles will be inspected on a weekly basis to verify that controls to prevent run-on, runoff, and windblown dispersal of soil are in place and effective. Security and emergency response equipment will be provided as described in Section 3.5. After the final volume of stockpiled soil has been removed, the area will be inspected for visual contamination due to stockpiling activities, and any remaining residual contaminated material will be removed.

Non-Hazardous Soil Above Interim Screening Levels or Project-Specific Cleanup Goals (once established). It is anticipated that all soil that is above soil screening levels or project-specific cleanup goals will not be stockpiled and will be placed in roll-off bins or similar containers. If it is necessary to temporarily stockpile displaced soil that is non-hazardous, but unsuitable for final disposition onsite because contaminants are present above the interim screening level, the following BMPs will be implemented:

- Stockpiles will be constructed with liner and perimeter berm to prevent release or infiltration of liquids. Minimum 20-mil polyethylene sheeting or equivalent will be used for liners.
- Wind erosion will be prevented by use of a cover, applying Soiltac® or a similar soil stabilization product, or other suitable means. If a cover is employed it will be minimum 6-mil polyethylene sheeting or equivalent.
- The perimeter berm will be constructed of clean materials (such as hay bales or straw wattle under the liner).
- If a cover is employed, it will extend over the outer edges of the perimeter berm and liner so that rainfall is prevented from entering the stockpile.
- Covers and perimeter berms will be secured in place when not in use and at the end of each workday and as necessary to prevent wind dispersion or run-off from precipitation events.
- Liquids that accumulate inside the berm will be pumped from the stockpile to a container or tank for characterization and disposal.
- If the stockpile is outside of a secured area, the stockpile will be demarcated with barricades, orange cones, and/or caution tape until the stockpiles are removed from the site.

- Erosion control measures will be employed to prevent stockpiled soil from contributing to surface runoff and wind-generated particulate matter as shown on Figure C-1.
- After the final volume of stockpiled soil has been removed, the area will be inspected for visual contamination due to stockpiling activities, and any remaining residual contaminated material will be removed.

Clean Soil. Stockpiles of displaced soil outside of Soil RFI/RI Investigation Areas that is non-hazardous, clean, and suitable for immediate reuse will be stored following these BMPs:

- Stockpiles will be constructed with liner and perimeter berm to prevent release or infiltration of liquids. Minimum 20-mil polyethylene sheeting or equivalent will be used for liners.
- Wind erosion will be prevented by use of a cover, applying Soiltac® or a similar soil stabilization product, or other suitable means. If a cover is employed it will be minimum 6-mil polyethylene sheeting or equivalent.
- The perimeter berm will be constructed of clean materials (such as hay bales or straw wattle under the liner).
- If a cover is employed, it will extend over the outer edges of the perimeter berm and liner so that rainfall is prevented from entering the stockpile.
- Covers and perimeter berms will be secured in place when not in use and at the end of each workday and as necessary to prevent wind dispersion or run-off from precipitation events.
- If the stockpile is outside of a secured area, the stockpile will be demarcated with barricades, orange cones, and/or caution tape until it is removed from the site.
- Erosion control measures will be employed to prevent stockpiled soil from contributing to surface runoff and wind-generated particulate matter as shown on Figure C-1.
- After the stockpile has been removed, all residual material will be removed from the underlying and surrounding areas.

3.1.3 Roll-off Bins

- All empty roll-off bins will be inspected upon arrival onsite. Any roll-off containers arriving with contents, residual contamination, or deterioration will be rejected. Existing damage (dings, significant paint scratches, broken wheels, etc.), if not significant enough to result in rejection, will be documented upon arrival of the bin using photos and written documentation.
- Roll-off bins will be provided with covers and disposable liners.
- Covers will be properly secured, except when adding or removing soil.
- Old labels will be removed, and each bin will be provided with its own label. Labels will be visible.
- Roll-off bins containing soils that are hazardous waste will be stored in a hazardous waste storage area and disposed of within 90 days of generation.
- Roll-off bins containing clean soil can be stored anywhere on PG&E property or at other properties that have granted permission to PG&E.
- Roll-off bins that contain displaced soil that is non-hazardous, but unsuitable for final disposition onsite because contaminants are present above the interim screening level will be stored at designated locations. The bins will be covered and inspected at a specified frequency (see Section 3.4 for inspection frequencies).

3.2 Hazardous Waste Soil Storage Time Limit

In compliance with 22 CCR 66262.34 (California action-specific ARAR #79), non-RCRA and RCRA hazardous wastes will be removed from the site within 90 days from date of generation. The date of generation is the day that a waste is first placed in a container (drum or roll-off bin) or stockpile. Accumulation start date for containers is

documented on the hazardous waste label. A log or other record will be used to document the accumulation start date for stockpiles.

3.3 Labeling

This section describes the labeling of waste containers.

3.3.1 Hazardous Waste Soil

Labeling for hazardous waste soil and soil pending characterization that could potentially be classified as hazardous will be in accordance with 22 CCR, Division 4.5, Chapter 12 (California action-specific ARAR #78) and 49 Code of Federal Regulations (CFR) 172, 173, and 178. Labels will include the type of waste, location from which the waste was generated, and accumulation start date. "Remediation Waste" will be written on the container with a paint pen, or on a blank label on the side of the container. Containers and roll-off bins used to store/accumulate hazardous waste will be labeled with a pre-printed "Hazardous Waste" label specific to California, with the following information:

- Accumulation start date
- Generator name, address, and phone number
- USEPA ID number
- Waste codes
- Description of waste, including hazardous properties and physical state
- DOT shipping description

Prior to transport, the manifest number will be added to each label. Soil pending characterization that could potentially be classified as hazardous will be labeled with the hazardous waste label described above, except that the waste codes and DOT shipping description will not be entered until the analytical results are received. An "Analysis Pending" or "Waste Material" label, which is a temporary or handwritten label, will be placed next to the hazardous waste label until analytical results are received and reviewed. This label will include generator information, type and location of waste, and the accumulation start date. The waste codes and DOT shipping description must be entered on the Hazardous Waste label, and the Analysis Pending label must be removed, within 10 days of receipt of the analytical results.

The appropriate DOT hazard class label will also be placed on the container prior to loading onto the transport vehicle.

3.3.2 Clean Soil/Non-Hazardous Soil

Containers and roll-off bins used to store/accumulate non-hazardous soil will be labeled as follows:

- Place a "Clean Soil" label on containers/roll-off bins containing soil determined to be suitable for onsite reuse. This is a handwritten label with the following information:
  - Material origin – Specific location of the site
  - Material description (e.g., soil, rock, etc.)
  - Date(s) of displacement or accumulation
  - Generating activity (e.g., drilling, excavation, etc.)
- Place a "Non-hazardous Soil for Offsite Disposal" label on containers/roll-off bins containing soil identified for off-site disposal. This is a handwritten label with the following information:
  - Material origin – Specific location of the site
  - Material description (e.g., soil, rock, etc.)
  - Date(s) of displacement or accumulation
  - Generating activity (e.g., drilling, excavation, etc.)
- Different color labels will be used to distinguish between "Non-Hazardous Clean Soil" and "Non-Hazardous Soil for Offsite Disposal."

3.4 Inspections

In compliance with 22 CCR 66264.15 (California action-specific ARAR #76), soil accumulation or storage areas for hazardous waste will be inspected at a frequency specified in the BMPs Plan (Appendix C) for malfunctions, deterioration, discharges, and leaks that could result in a release.

- Containers and roll-off containers will be inspected for proper closure, leaks, signs of corrosion, or signs of general deterioration, proper labeling, and accumulation time.
- Stockpiles will be inspected for liner, cover, and berm integrity and to check that controls for windborne dispersion and run-on and run-off control are functioning properly.
- Secondary containment structures will be inspected for integrity and accumulation of liquids.
- All areas will be inspected to ensure that good housekeeping practices are maintained.

Any deficiencies observed during inspection will be corrected upon discovery, and corrective measures will be documented. The employee inspecting the storage areas will be responsible for documenting the deficiency and implementing its remedy.

Appropriate measures may include transfer of waste from leaking container to new container, replacement of liner or cover, or repair of containment berm. Copies of inspection reports and corrective measures will be maintained onsite and will be available for review.

As part of BMPs, soil storage areas for displaced soil that has been classified as non-hazardous clean soil will be inspected on a monthly basis as specified in the BMPs Plan (Appendix C).

3.5 Security/Emergency Response

In compliance with 22 CCR 66264.14 (California action-specific ARAR #76), a barrier, such as temporary fencing, will be provided for hazardous waste accumulation areas. PG&E does not anticipate utilizing any remote locations for storage of hazardous waste. If hazardous waste is encountered, it will likely be stored at the Compressor Station and/or the Transwestern Bench.

Hazardous waste soil accumulation areas will also have signs that provide 24-hour emergency contacts and telephone numbers. Hazardous waste accumulation areas will contain emergency response equipment appropriate to applicable waste hazards. The project-specific HSPs will identify the project emergency response procedures and equipment, including emergency response contacts and phone numbers.

In addition to the project-specific HSP procedures, hazardous waste accumulation areas will be provided with fire extinguishers, decontamination equipment including an eye wash station, and an alarm system (if radio equipment is not available to all staff working in accumulation area).

SECTION 4

Waste Training, Profiling, Transportation, and Disposal

This section describes guidelines for waste management training, waste profiling, transportation for offsite disposal, and disposal of displaced soil that is classified as a hazardous or non-hazardous waste soil. The previously established practice at the site is that transportation within the plume boundary is considered to be onsite transportation. Consistent with this practice, transportation of soil within the project's APE is considered to be onsite transportation for purposes of complying with hazardous waste requirements.

4.1 Employee Training for Waste Soil Management

In compliance with 22 CCR 66264.16 (California action-specific ARAR #76), field personnel that will manage hazardous or potentially hazardous waste will obtain:

- Hazardous waste management training that meets the requirements of 22 CCR 66265.16, and that will address how to implement applicable provisions of the hazardous waste contingency plan and how to perform job duties related to hazardous waste management in a manner that complies with hazardous waste regulatory requirements. Each employer working at the site is responsible for providing this training to their employees. The specific content of this training will vary by employer and by job function.
- On-the-job training (as applicable to the job description), including:
  - Project-specific HSP review that requires each site worker and guests to review and sign the plan
  - Activity hazard analysis and daily "tailgate" meetings
  - Project-specific Work Plan review (e.g., this SMP)
  - DOT hazardous material training (49 CFR 172.704)

Training documentation will be maintained and will include the job title for each position involving hazardous waste soil management and the name of the person filling the job, written job description including skills and required qualifications, description of type and amount of continuing training given, and records that document training or job experience.

4.2 Hazardous Waste Profiling

As discussed in Section 2, displaced soil from in and near Soil RFI/RI Investigation Areas will be screened to assess whether it is hazardous using prior knowledge of the soil and sample analytical results. However, in some cases, offsite disposal facilities may require additional analyses to evaluate the soil waste stream prior to acceptance. The purpose of pre-disposal profiling of the hazardous waste soil identified for offsite disposal is to characterize the appropriate disposal method and location.

Ultimately, the profile of the waste must meet the acceptance criteria of the disposal facility and be in compliance with all pertinent federal, state, and local regulations. Characterization will be documented on a waste profile form provided by the offsite treatment or disposal facility as part of the waste acceptance process. An approved copy of the waste profile will be received prior to offsite transportation of the material.

4.3 Manifests/Shipping Documentation

In compliance with 22 CCR 66262.20 and 66262.22 (California action-specific ARAR #77), each load of soil classified as hazardous waste will be manifested prior to leaving the site. The hazardous waste manifest (USEPA Form 8700-22) is the shipping document for tracking shipments of hazardous waste from the site to the final disposal facility. Note that each load of non-hazardous waste will be accompanied by a properly completed non-hazardous waste manifest form or bill of lading.

Additionally, each shipment of waste soil will also have a haul ticket. If the signed hazardous waste manifest from the designated offsite facility is not received within 35 days, PG&E will contact the transporter or the designated facility to determine the status of the waste. All communications will be documented. If the signed hazardous waste manifest has not been received within 45 days, PG&E will prepare an Exception Report and submit it to the State of California, as required under 22 CCR 66262.42.

4.4 Department of Transportation (DOT) Requirements

Requirements under 49 CFR 171-178 (DOT) and 22 CCR 66262.30 through 66262.33 (California action-specific ARAR #78) and the CD (DOI 2013) will apply to all offsite shipments of soil that is classified as hazardous waste. These requirements do not apply to shipments of non-hazardous waste. The information contained in this section is provided as a general guide. Requirements specific to each hazardous waste will be determined in the field. It is the responsibility of a DOT-trained individual to ensure that the requirements of 49 CFR 171-178 are met.

4.4.1 Shipping Name

Each shipment will be properly classified using the Hazardous Materials Table in 49 CFR 172.101. All determinations will be made by DOT-trained personnel.

4.4.2 Packaging, Marking, and Labeling

The shipping name, hazard class, identification number, technical names (if applicable), USEPA markings and waste code numbers, and consignee/consignor designations will be marked on packages for shipment (49 CFR 172.301). Once a waste is characterized, reference will be made to the Hazardous Materials Table in 49 CFR 172.101 to determine the appropriate label.

4.4.3 Placards

Appropriate placards will be determined by DOT-trained personnel. Specific placard descriptions are found starting at 49 CFR 172.521. If a placard is required, it will be affixed on each side and each end of the vehicle. It is the shipper's responsibility to provide the proper placards for their shipment if the transporter does not have them.

4.5 California and Arizona Transportation Requirements

California hazardous waste regulations (22 CCR Division 4.5, Chapter 13) require that anyone engaged in the transportation of hazardous waste within California must possess a valid hazardous waste hauler registration issued by DTSC. Transporters operating in Arizona must also be registered with the Arizona Department of Environmental Quality. Transporters operating in Nevada must also hold a permit and certificate of registration issued by the Nevada Department of Environmental Protection.

4.6 Transporter Requirements

Each transportation vehicle and load of hazardous waste will be inspected before leaving the site and will be documented. A PG&E representative will verify that the driver has the appropriate class of driver's license with appropriate endorsements for the class of vehicle being driven before loading hazardous waste onto the vehicle. The quantities of hazardous waste leaving the site will be recorded on a transportation and disposal log. The transporter must be registered with DTSC as a hazardous waste hauler, have a USEPA Identification number, and must comply with transportation requirements outlined in 49 CFR 171-179 (DOT) and 22 CCR 66262.33 (California action-specific ARAR #78).

The transporter will be responsible for ensuring that loaded trucks comply with all applicable weight limits. For each load of material, weight measurements will be obtained for each full and empty container and dump truck. Disposal quantities will be based on the difference of weight measurements between the full and empty container or dump truck. Weights will be recorded on the waste manifest and weight ticket by the disposal facility.

The transporter will observe the following practices when hauling and transporting hazardous waste (and non-hazardous waste) offsite:

- Minimize impacts to general public traffic.
- Trucks/trailers and roll-off bins used for hauling hazardous or regulated waste will be lined and covered with a tarp or ridged closure before transport to comply with EIR mitigation measure HAZ-2f and to prevent spills or releases.
- Decontaminate exterior of vehicle using dry methods as necessary prior to leaving the site.
- Wastes or materials from other projects may not be combined with wastes generated during this project.
- All personnel involved in offsite disposal activities will follow safety and spill response procedures outlined in project-specific HSPs.

4.7 Spill Reporting

In the event of a spill or release of hazardous (or non-hazardous) waste, the transporter must immediately notify a PG&E representative**.** The following information about the spill will be reported and recorded:

- Type of material (for example, soil) and contaminant
- Location
- Estimated volume
- Media affected (for example, spilled on concrete pad or soil)
- Time of spill/release
- Final disposition of spilled material

The transporter will also report any spill or release of hazardous waste, as required by 49 CFR 171.15, to the National Response Center at 800/424-8802 or 202/426-2675. The transporter will also report, in writing, as required by 49 CFR 171.16, to the Director, Office of Hazardous Materials Regulations, Materials Transportation Bureau, Department of Transportation, Washington D.C. 20590.

4.8 Spill Response

The transporter will clean up any spill or release of hazardous (or non-hazardous) waste (including soil) that occurs during transportation or will take such action as may be required or approved by federal, state, or local officials. Spilled waste will be immediately cleaned up, including soils on the outside of the trucks, the truck and/or container, or road surface. Where appropriate, the spilled material will be returned to the original waste container. Regardless, the spilled material will be properly contained and disposed.

4.9 Waste Disposal

Soil classified as RCRA or non-RCRA hazardous waste, and non-hazardous soil will be disposed of at an appropriately permitted facility. In accordance with the requirements of the CD (DOI 2013), prior to the first shipment of waste material offsite, and annually thereafter, PG&E will demonstrate to DOI's satisfaction that USEPA has determined that the proposed receiving facility is operating in compliance with 42 U.S.C. § 9621(d)(3) and 40 CFR § 300.440. If PG&E knows or has reason to know the facility no longer meets the criteria of 40 CFR § 300.440(b), PG&E will inform DOI, propose an alternate receiving facility prior to any subsequent shipments, and demonstrate to DOI's satisfaction that USEPA has determined that the alternate receiving facility is operating in compliance with 42 U.S.C. § 9621(d)(3) and 40 CFR § 300.440. The waste material will be stored onsite in accordance with this waste management plan until approval is received and the waste material is transported offsite. If the waste management facility is out-of-state, prior to the first shipment of waste material, PG&E will provide written notice for disposal of waste material at the listed facilities to the appropriate state environmental official in each receiving facility's state and the DOI Project Manager, and will comply with state law with regard to providing any further notifications. Additionally, PG&E will notify the state environmental official referenced

above and the DOI Project Manager of any major changes in the shipment plan, such as a decision to ship the waste material to a different out-of-state facility.

SECTION 5

Recordkeeping

California action-specific ARAR #80 (22 CCR 66262.40) requires that hazardous waste manifests, biennial reports, exception reports, and waste analysis and waste determination records be retained for three years. Further, 22 CCR 66262.41 requires large quantity generators of RCRA hazardous waste to submit a biennial report to USEPA by March 1 of each even-numbered year that describes hazardous waste generated in the previous odd-numbered year. In addition, the CD (DOI 2013) requires that project-related records be retained until 10 years after receipt of the Certificate of Completion. The following records and documents will be maintained for the hazardous waste:

- Transportation and offsite disposal records, including:
  - Profiles and associated characterization data
  - Manifests, Land Disposal Restriction (LDR) notifications/certifications, bills of lading, and weight tickets
  - Offsite facility waste receipts, certificates of disposal/destruction/recycle
  - Trucking logs
- Training records
- Inspection records

In addition, in accordance with the *Revised Management Protocol for Handling and Disposition of Displaced Site Material* (Appendix B), PG&E will maintain a Displaced Material Inventory for all displaced soil, which will include:

- Material origin – Specific location of the site.
- Material description (e.g., soil, rock, etc.).
- Date(s) of displacement or accumulation.
- Generating activity (e.g., drilling, excavation, etc.).
- Approximate volume of material stored.
- Short-term storage mode and location – Type of storage (including container identification number, as applicable) and location of short-term storage pending soil characterization. In some cases, this information may need to be updated as containers are moved between areas of the site.
- Characterization status – Characterization sample information (e.g., date of submittal and laboratory used), date of receipt of results, and the contamination assessment based on comparison to screening criteria (as discussed in Section 2.3).
- Storage mode and location – Type of storage (including container identification number, as applicable) and location of storage pending decision regarding final disposition. This information may need to be updated as containers are moved between areas of the site.
- Final disposition information – Indication of the onsite or offsite final disposition action identified through discussion with the Tribe(s), Agencies, and the affected land owner(s), as appropriate, based on review of material type and the contamination assessment.

SECTION 6

Soil Management Plan Updates

PG&E developed this SMP based on the final design for the groundwater remedy, current understanding of historical site activities, and available soil data. This final SMP is submitted with the final design documents. An addendum to the SMP will be prepared to update the screening levels for non-hazardous soil after the project specific cleanup goals are established and during future O&M activities, as warranted. A data report will be prepared after the implementation of the baseline soil sampling to document sampling results and refine soil classification volumes.

In addition, as the soil RFI/RI program advances through the RCRA/CERCLA processes, PG&E will also obtain a better understanding of existing soil conditions across the site by collecting additional analytical data, performing a risk assessment, and (if necessary) developing a Corrective Measures Study/Feasibility Study (CMS/FS) for soil. The CMS/FS will develop project-specific goals and propose appropriate soil remedy(ies). In addition, screening levels included in Tables 2.4-1 and 2.4-2 will be updated as regulations change and project-specific decisions are made. PG&E will review all such new relevant information as it becomes available, incorporate it into future addendum to this SMP as appropriate, and submit the addendum to the regulatory agencies for review and approval.

Groundwater Remedy Implementation—
Baseline Soil Sampling and Analysis Plan

Groundwater Remedy Implementation—Baseline Soil Sampling and Analysis Plan, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

1.0 Introduction

Pacific Gas and Electric Company (PG&E) is implementing the selected groundwater remedy of chromium at the Topock Compressor Station (Compressor Station) in Needles, San Bernardino County, California. The selected remedy consists of the following five primary components:

- In-Situ Reactive Zone (IRZ)
- Inner Recirculation Loop
- Freshwater Injection System
- Institutional Controls (ICs)
- Monitored Natural Attenuation (MNA)

Three components for the groundwater remedy system—IRZ, Inner Recirculation Loop, and Freshwater Injection System—involve construction and installation of infrastructure such as pipelines, pipe trenches, buildings, tanks, electrical equipment, and remediation/monitoring wells, and are the focus of this Sampling and Analysis Plan (SAP).

To document baseline soil conditions prior to groundwater remedy implementation, this SAP has been developed to provide the approach and methods to collect and analyze soil samples in the areas used by the groundwater remedy. In addition, the SAP also includes the collection of data to assist with the management of materials displaced during construction activities, in accordance with the *Revised Management Protocol for Handling and Disposition of Displaced Site Material, Topock Remediation Project, Needles, California* (PG&E 2015) (Appendix B of the Soil Management Plan [SMP]) that was developed by a subgroup consisting of representatives from PG&E, Agencies, Interested Tribes, and other stakeholders. As discussed in Section 2.5 of the Soil Management Plan, the management protocol excludes the provision for long-term storage of soil above the interim screening levels. The process for assessing the baseline data for management of displaced materials is described in the main text of the SMP.

In areas where groundwater remedy infrastructure is within 20 feet of or overlaps with Soil Investigation Areas, the approach presented in this SAP has been fully coordinated with the current RCRA Facility Investigation/ Remedial Investigation (RFI/RI) (CH2M HILL 2013) planning activities to minimize the total number of soil samples to be collected and associated ground disturbances, as well as to ensure consistency between the groundwater and soil programs at Topock. Figures A-1, A-1A, A-2, and A-3 show these overlapping areas (or areas within 20 feet) (tables and figures are presented at the end of this appendix). As shown, remedy infrastructure proposed at the final design stage (i.e., excluding future provisional wells) is within 20 feet of or overlaps with the following twenty-four Soil Investigation Areas:

- SWMU 1 – Former Percolation Bed
- SWMU 5 – Sludge Drying Beds
- SWMU 6 – Chromium Reduction Tank
- SWMU 9 – Transfer Sump
- AOC 1 – Area Around Former Percolation Bed
- AOC 4 - Debris Ravine
- AOC 7 – Hazardous Materials Storage Area
- AOC 8 – Paint Locker
- AOC 9 – Southeast Fence Line (Outside Visitor Parking Area)
- AOC 10 – East Ravine

- AOC 11 – Topographic Low Areas
- AOC 12 – Fill Areas
- AOC 13 – Unpaved Areas within the Compressor Station
- AOC 17 – Onsite Septic System
- AOC 18 – Combined Hazardous Waste Transference Pipelines
- AOC 21 – Round Area by Sludge Drying Beds
- AOC 22 – Unidentified Three-sided Structure
- AOC 27 – MW-24 Bench
- AOC 28 – Pipeline Drip Legs
- AOC 30 – MW 20 Bench
- AOC 33 – Potential Former Burn Area near AOC 17
- Unit 4.3 – Oil/Water Holding Tank
- Perimeter Area outside of but adjacent to the Compressor Station fence line
- Storm Drain System

The following sections discuss the sampling and analytical approach (Section 2); sampling methods, sample management, and shipping (Section 3); procedures for waste management and decontamination (Section 4); data management and reporting (Section 5); references (Section 6); and certification (Section 7). The final SAP has a professional stamp by Keith Sheets, CH2M HILL's supervising California-registered Professional Geologist.

2.0 Sampling and Analytical Approach

Baseline soil samples will be collected along the remedy pipelines/conduits alignments, which include direct burial pipelines/conduits, pipeline trenches, and the remediation wells (i.e., injection and extraction wells) that are connected to those pipelines, as well as at the new remedy monitoring well locations. The exception is that baseline soil sampling will not occur along the alignment of the freshwater pipeline in Arizona, and on the California side, leading to the Compressor Station. The freshwater pipeline will contain groundwater pumped from water supply well(s) installed on the Havasu National Wildlife Refuge (HNWR) in Arizona, near the Topock Marsh. Because inorganic compounds are present in the fresh water at such low concentrations, soil underlying the pipeline would not be adversely impacted by inorganic compounds from incidental releases, spills or leaks from the pipeline. All other remedy pipeline alignments will be part of the baseline sampling plan and will follow the sampling guidelines provided below and presented in Figure A-4 .

Baseline soil samples will also be collected at locations of remedy structures/buildings following the sampling guidelines below and presented in Figure A-5.

Where practicable, proposed sample locations are located near existing roads or in other disturbed areas to minimize the potential for impacts to sensitive resources (cultural, historical, and/or biological). Access routes used to collect baseline soil samples are expected to be the same routes used to construct and install the remedy infrastructure. Qualified biologists and cultural resource consultants will be consulted during the selection of final sampling locations.

2.1 Pipeline Alignment (including Connecting Remediation Wells)

The remedy pipeline/conduit alignments will be installed both above and below ground. To assess baseline conditions along the pipeline/conduit alignments, soil samples will be collected approximately every 500 linear feet along the proposed pipeline/conduit runs. If pipelines/conduits are aboveground, baseline soil samples will be collected at 0.5 foot below ground surface (bgs). If pipelines/conduits alignments are underground, then soil samples will be collected at the bottom of the trench if the pipelines/conduit alignments are outside Soil RFI/RI Investigation areas. Except as noted below, if the pipelines/conduit alignments are in or within 20 feet of Soil RFI/RI Investigation Areas, a soil sample will be collected at 1 foot bgs and at the bottom of the trench to assess conditions for management of disturbed soil.

Proposed remedy pipelines/conduits alignments intersect twenty-four Soil RFI/RI Investigation Areas as shown on Figures A-1 and A-1A. These investigation areas are currently undergoing investigations under the Soil RFI/RI program:

- SWMU 1 – Former Percolation Bed
- SWMU 5 – Sludge Drying Beds
- SWMU 6 – Chromium Reduction Tank
- SWMU 9 – Transfer Sump
- AOC 1 – Area Around Former Percolation Bed
- AOC 4 – Debris Ravine
- AOC 7 – Hazardous Materials Storage Area
- AOC 8 – Paint Locker
- AOC 9 – Southeast Fence Line (Outside Visitor Parking Area)
- AOC 10 – East Ravine
- AOC 11 – Topographic Low Areas, including the two new areas
- AOC 12 – Fill Areas
- AOC 13 – Unpaved Areas within the Compressor Station
- AOC 17 – Onsite Septic System
- AOC 18 – Combined Hazardous Waste Transference Pipelines
- AOC 21 – Round Area by Sludge Drying Beds
- AOC 22 – Unidentified Three-sided Structure (in upper yard)
- AOC 27 – MW-24 Bench
- AOC 28 –Pipeline Drip Legs
- AOC 30 – MW 20 Bench
- AOC 33 – Burn Area near AOC 17
- Unit 4.3 – Oil/Water Holding Tank
- Perimeter Area
- Storm Drain System

As part of the Soil RFI/RI, soil samples will be collected from several samples locations within these seventeen areas. To minimize disturbance and potential impacts to sensitive resources, baseline soil samples will not be collected along a pipeline segment if soil RFI/RI Investigation proposed sample locations and/or existing soil data locations are located within 20 feet of the pipeline/conduit run and meet the criteria of the baseline sample program. Proposed Soil RFI/RI sample locations and existing soil data locations pertinent to this baseline sampling plan are shown in Figures A-1 and A-1A. Figure A-4 shows the decision process that will be used to collect baseline soil samples along the pipelines/conduits.

Baseline soil samples will be analyzed for PAHs, sodium, and Title 22 metals in order to assess potential affects to soil associated with the operation of the groundwater remedy and to provide pre-characterization information prior to remedy construction. Title 22 metals is standard testing methodology for assessment of metals, and includes certain metals that are generally of concern at the Topock Compressor Station. If a baseline soil sample location is within 20 feet of a Soil RFI/RI Investigation Area, the sample will also be analyzed for the Soil RFI/RI Investigation Area analytical suite as presented in Table A-1.

2.2 Remedy Structures

A number of remedy structures are proposed to be constructed to support the groundwater remedy system. A majority of the proposed structures will be within the Compressor Station fence line, the Transwestern Bench, and the MW-20 Bench as shown in Figures A-1 and A-1A. There are a few miscellaneous structures that will also require baseline sampling, including well vaults and soil storage areas as well as the satellite maintenance and storage yard at Moabi Regional Park. The following is a list of key remedy structures; these structures are also shown in Figures A-1, A-1A, and A-2:

- **Structures Located Inside the Compressor Station**
  - Remedy-Produced Water Conditioning Plant
  - Conditioned Water Storage Tanks and Secondary Containment
  - Influent Water Storage Tanks and Secondary Containment
  - Freshwater Storage Tank
  - Decontamination Pad (occupies the same footprint as the Contingent Freshwater Pre-injection Treatment Building)
  - Contingent Storage Tanks associated with the Contingent Freshwater Pre-injection Treatment System
- **Structures Located at the Transwestern Bench**
  - Operation Building
- **Structures Located at the MW-20 Bench**
  - Carbon Amendment Building
  - Carbon Storage Tank
- **Other Remedy Structures**
  - Well Vaults
  - Soil Storage/Processing at Moabi Regional Park
  - Long term remedy support area at Moabi Regional Park (this area will also be used as the main construction yard during remedy construction)

To assess baseline conditions in areas where remedy structures will be constructed, soil samples will be collected on a 50-foot grid, or a minimum of one sample location within each remedy structure footprint. Soil samples will be collected at 0.5 foot below the proposed remedy structure. If the remedy structure is being constructed over an existing structure footprint, baseline soil samples will be collected only if the former structure's foundation is being removed and exposing underlying soil. Surface soil samples (0.5 foot below the ground surface) will be collected on a 100-foot grid in the soil storage areas and the satellite maintenance and storage yard at Moabi Regional Park.

The currently proposed remedy structures are located within 20 feet of or overlap six Soil RFI/RI Investigation Areas. These Soil RFI/RI Investigation Areas and their associated analytical suites are included in Table A-1 and are currently undergoing investigations under the Soil RFI/RI program:

- AOC 7 – Hazardous Materials Storage Area
- AOC 8 – Paint Locker
- AOC 11 – Topographic Low Areas, including the two new areas
- AOC 13 – Unpaved Areas within the Compressor Station
- AOC 17 – Onsite Septic System
- AOC 30 – MW 20 Bench

As part of the Soil RFI/RI, soil samples will be collected from several sample locations within these six Soil RFI/RI areas. To minimize disturbance and impacts to sensitive resources, baseline soil samples will not be collected within the remedy structure footprint if soil RFI/RI Investigation proposed sample locations and/or existing soil data points are located within the proposed structure footprint or within 20 feet of the footprint and meet the criteria of the baseline sample program. Figure A-5 shows the decision process that will be used to collect baseline soil samples within remedy structure footprints.

Baseline soil samples will be analyzed for Title 22 metals, PAHs, and sodium. Except as noted below, if the baseline soil sample location is within 20 feet of or overlaps a Soil RFI/RI Investigation Area, the sample will also be analyzed for the same analytical suite for that Soil RFI/RI Investigation Area as presented in Table A-1.

In addition, select baseline sample locations will be used to collect geotechnical data to support the groundwater remedy design. The areas where geotechnical samples will be collected have been identified and are included in the Final Basis of Design Report, Appendix C.

2.3 New Monitoring Well Locations

A number of new monitoring wells are proposed to be installed to support the groundwater remedy system. To assess baseline conditions in areas where the monitoring wells will be installed, one soil sample will be collected at each new monitoring well location at 1.0 feet bgs. Baseline soil samples will be analyzed for Title 22 metals and sodium. If the baseline soil sample location is within 20 feet of or overlaps a Soil RFI/RI Investigation Area, the sample will also be analyzed for the same analytical suite for that Soil RFI/RI Investigation Area as presented in Table A-1.

The new monitoring well locations intersect nine Soil RFI/RI Investigation Areas:

- AOC 1 – Area Around Former Percolation Bed
- AOC 10 – East Ravine
- AOC 11 – Topographic Low Areas, including the two new areas
- AOC 12 – Fill Areas
- AOC 13 – Unpaved Areas within the Compressor Station
- AOC 27 – MW-24 Bench
- AOC 28 – Pipeline Drip Legs
- AOC 30 – MW 20 Bench
- Perimeter Area

3.0 Sampling Methods, Sample Management, and Shipping

For consistency between the groundwater remedy and the Soil RFI/RI program, soil sample collection and handling activities will follow the standard operating procedures (SOPs) included in the Revised Final Soil RFI/RI Work Plan. Those SOPs are also included in Attachment 1 of this SAP. Sample containers, preservation, and hold times are summarized in Table A-1A.

3.1 Sample Management and Storage

Samples will be placed immediately into field coolers with ice; VOC and TPH-gasoline containers will be arranged in the sample cooler standing upright. The field coolers will be taken to the sample management area, where the samples will be transferred into a refrigerator and/or freezer. If transport of a sample to the laboratory is scheduled for a pickup more than 24 hours after sampling, samples will be stored in the freezer.

3.2 Shipping

Samples collected for chemical analysis will be transported to the laboratory via courier, generally daily. Chains-of-custody will accompany all samples to the laboratory.

4.0 Waste Management and Decontamination

The approach for investigation-derived waste (IDW) management and equipment decontamination is presented in the following subsections.

4.1 Equipment Decontamination

If used for sample collected, the downhole drilling tools, tracks on track rigs, and the back ends of the drilling rigs will be decontaminated prior to arrival at the site and will be cleaned between investigation areas as determined necessary by the field team leader. In addition, a visual inspection will be conducted between boring locations to determine if decontamination is necessary. Decontamination will be accomplished by steam-cleaning or pressure washing the core barrel, drill stem, drive casing, and back of the drilling rig. Equipment may also be cleaned using dry methods prior to leaving an excavation area to prevent the tracking of material out of the area. The backs of drill rigs and down-hole drilling tools will be decontaminated before arrival at the site.

Steam-cleaning or pressure washing will be conducted on the decontamination pad located at the Transwestern Bench. Rinseate from the decontamination operation will be collected on the containment pad and will be transferred to the cuttings bin/drum or portable storage tank. Rinseate will be processed at the IM-3 treatment

plant, the new remedy-produced water conditioning plant, or transported to a PG&E-contracted offsite disposal facility.

4.2 Investigation-derived Waste Management

Several types of waste materials will be generated during the drilling and sampling of soil borings, excavation of potholes, and hand excavation for utility clearance. IDW materials that will be generated include drill cuttings, incidental trash, equipment decontamination water, and possibly small quantities of soil from pothole or hand excavation areas. The IDW will be handled in accordance with the *Revised Management Protocol for Handling and Disposition of Displaced Site Material, Topock Remediation Project, Needles, California* (Soil Management Plan Appendix B).

Drill cuttings include fragments of rock and soil that are removed to create the borehole. The cuttings will be contained in drums or lined roll-off bins at staging areas during drilling and sampling activities. After sampling and characterization, drums and bins will be removed from the staging areas. If cuttings or soil are free from contaminants (below interim screening levels presented in Table A-2), material will be designated appropriate for reuse on site. Cuttings and any soil from excavation areas that exceed the hazardous waste characteristic levels presented in Table A-3 will be considered contaminated and transported to a permitted offsite disposal facility. Cuttings and any soil from excavation areas that are below hazardous waste characteristic levels, but above interim screening levels, will be managed following protocols prescribed in this Soil Management Plan.

Water generated during equipment decontamination will be collected in bins or portable storage tanks temporarily located in staging areas near the drilling sites or at the Compressor Station as needed. Secondary containment will be set up at the drilling area for the portable storage tanks or bins. Rinseate will be processed at the IM No. 3 treatment plant, the new remedy-produced water conditioning plant, or transported to a PG&E-contracted offsite disposal facility.

Incidental trash will be collected at the end of each drilling shift and will be disposed of properly.

5.0 Data Management and Reporting

The electronic data will be used to generate validation reports, data summary tables, and figures. Management of data generated from baseline soil sampling will be conducted in a manner that is consistent with the Soil RFI/RI program.

5.1 Data Validation

Data validation will be carried out when the data packages are received from the laboratory. It will be performed on an analytical batch basis using the summary results of calibration and laboratory quality control, as well as those of the associated field samples. Data packages will be reviewed for all analytes. Raw data will be reviewed when deemed necessary. Data validation procedures will include:

- Review of the data package for completeness.
- Review of chain-of-custody records for discrepancies that might degrade data quality.
- Review for compliance with holding time and quality control frequency requirements.
- Evaluation of all calibration and quality control summary results against the project requirements.
- Verification of analyte identification and calculations for at least 10 percent of the data.
- Qualification of the data using appropriate qualifier flags, as necessary, to reflect data usability limitations.
- Initiation of corrective actions, as necessary, based on the data review findings.

Data validation procedures follow the United States Environmental Protection Agency (USEPA) *Contract Laboratory National Functional Guidelines for Inorganic Data Review* (USEPA 2002) and *Contract Laboratory National Functional Guidelines for Organic Data Review* (USEPA 1999), substituting the qualifiers, the calibration and quality control requirements specified in the *PG&E Program Quality Assurance Project Plan, Revision 2* (CH2M HILL 2012), the Addendum to the QAPP, Revision 2 (CH2M HILL 2015), and the *PG&E Program Quality Assurance Project Plan for Dioxins and Furans* (CH2M HILL 2010).

5.2 Reporting

PG&E will present the results of the baseline soil sampling in a data report, summarizing the sampling event and analysis results. The data report will consist of a discussion of the sampling, laboratory analytical results, a discussion of uncertainties in the data, and a discussion of the implications on management of displaced soil, especially storage of soil. Field documentation, summary tables of laboratory results, and laboratory analytical data sheets will be included as attachments or appendices to the report.

TABLE A-1

List of RFI/RI Investigation Areas within 20 feet of or that Overlap with Groundwater Remedy Infrastructure and Proposed Analyte Suite

Groundwater Remedy Implementation - Baseline Soil Sampling and Analysis Plan
Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Soil RFI/RI Investigation Area	Analytical Suite[1]
SWMU 1 – Former Percolation Bed	Title 22 metals, hexavalent chromium, VOCs. SVOCs, PAHs, TPH, pH, pesticides, PCBs[2]
SWMU 5 – Sludge Drying Beds	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs
SWMU 6 – Chromium Reduction Tank	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs
SWMU 9 – Transfer Sump	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs
AOC 1 - Area Around Former Percolation Bed	Title 22 metals, hexavalent chromium, PAHs, pH, PCBs[2], and dioxins and furans
AOC 4 – Debris Ravine	Title 22 metals, PAHs, PCBs, and dioxins/furans
AOC 7 - Hazardous Materials Storage Area	Title 22 metals, hexavalent chromium, VOCs, SVOCs, PAHs, PCBs, TPH, and pH
AOC 8 – Paint Locker	Title 22 metals, VOCs, and TPH
AOC 10 – East Ravine	Title 22 metals, hexavalent chromium, PAHs, Asbestos, dioxins and furans
AOC 9 – Southeast Fence Line (Outside Visitor Parking Area)	Hexavalent chromium, Title 22, PAHs, PCBs, and pesticides
AOC 11 - Topographic Low Areas	Title 22 metals, hexavalent chromium, TPH, SVOCs, PAHs, and PCBs
AOC 12 - Fill Areas	Title 22 metals, hexavalent chromium, VOCs, TPH, PAHs, pH, asbestos, pesticides, and PCBs
AOC 13 - Unpaved Areas within the Compressor Station	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, and asbestos
AOC 17 - Onsite Septic System	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, and PAHs
AOC 18 – Combined Hazardous Waste Transference Pipelines	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, PCBs, and PAHs
AOC 21 – Round Area by Sludge Drying Beds	Title 22 metals, hexavalent chromium, calcium, sodium, and pH
AOC 22 - Unidentified Three-sided Structure	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, PCBs, and PAHs
AOC 27 – MW-24 Bench	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, PCBs, pesticides, PAHs, and dioxins and furans
AOC 28 - Pipeline Drip Leg	TPH, PAHs, and PCBs
AOC 30 - MW 20 Bench	Title 22 metals, hexavalent chromium, sodium, and chloride
AOC 33 – Former Potential Burn Area Near AOC 17	Title 22 metals, hexavalent chromium, VOCs, TPH, SVOCs, PAHs, PCBs, asbestos, and dioxin and furans
Unit 4.3 – Oil/Water Holding Tank	Title 22 metals, hexavalent chromium, pH, VOCs, TPH, SVOCs, and PAHs
Perimeter Area	Title 22 metals, hexavalent chromium, TPH, SVOCs, PAHs, and PCBs
Storm Drain System	Title 22 metals, hexavalent chromium, TPH, PAHs, and PCBs

Notes:

[1] Analytical suites as presented in the Revised Final Soil RFI/RI Work Plan.(CH2M HILL 2013)
[2] PCB analysis only on soil collected between 0 and 2 feet below ground surface
AOC - Area of Concern
PAHs - polynuclear aromatic hydrocarbons
PCBs - polychlorinated biphenyls
SVOCs - semivolatile organic compounds
TPH - total petroleum hydrocarbons
VOCs - volatile organic compounds

Analyte	Method	Container and Minimum Quantity		Preservation	Holding Time
		Water	Soil/Sediment		
Asbestos	Water – EPA 100.1/100.2-TEM Soil- PLM/BULK (present/absent); CARB435/PLM; TEM	1-liter sonicated P	4-oz G	Chill to 4°C (±2°C)	Water: 48 hour holding time Soil: 1 year
Multiple (California WET)	STLC Extraction Analysis by methods listed above	See specific method above for container	8-oz G	Chill to 4°C (±2°C)	See specific matrix and method above for holding time
Multiple (RCRA TCLP)	TCLP Extraction Analysis by methods listed above	See specific method above for container	8-oz G	Chill to 4°C (±2°C)	See specific matrix and method above for holding time

Notes:

< = less than
≤ = less than or equal to
°C = degrees centigrade
G = glass
HCl = hydrochloric acid
HNO_3 = nitric acid
mL = milliliters
NH_4OH = ammonium hydroxide
$(NH_4)_2SO_4$ = ammonium sulfate
oz = ounce
P = polyethylene
PCBs = polychlorinated biphenyls
PAHs = polynuclear aromatic hydrocarbons
RCRA = Resource Conservation and Recovery Act
SIM = selected ion monitoring
SVOCs = semivolatile organic compounds
T = brass sleeves in the sample barrel (sometimes called California brass)
TCLP = Toxicity Characteristic Leaching Procedure
TLC = Teflon lined closure
TPH = total petroleum hydrocarbons
VOCs = volatile organic compounds
WET = Waste Extraction Test

	trans-1,3-Dichloropropene	1,800	EPA Residential RSL	NE
	Trichloroethene	940	EPA Residential RSL	See Table A-3
	Trichlorofluoromethane (Freon 11)	730,000	EPA Residential RSL	NE
	Vinyl chloride	59	EPA Residential RSL	See Table A-3
	Xylenes, total	650,000	EPA Residential RSL	NE

Notes:

This table presents a reference list of analytes and associated screening levels that may be applicable for making decisions related to disposition of displaced site materials. The specific analytes and screening levels applicable for characterization of displaced material will be determined based on the origin of the material and potential disposition locations.

Interim screening level is background value. If background value is not available then the lesser of the DTSC HHRA Note 3 Residential Screening Levels (DTSC Residential SL) or the ecological comparison value is used. If a DTSC Residential SL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

Background	"Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California" (CH2M HIll 2009c)
DTSC-Residential SLs	Human Health Risk Assessment Note 3 – DTSC-Modified Screening Levels, May 2015.
EPA Residential RSL	United States Environmental Protection Agency Residential Soil Regional Screening Level (THQ=1.0), June 2015.
ECV	Ecological Comparison Values; ECV were calculated as needed for constituents detected during the Part A Phase I sampling (Arcadis 2008)
HHRA Note 2	DTSC Human Health Risk Assessment (HHRA) Note 2: Remedial Goals for Dioxins and Dioxin-like Compounds for Consideration at California Hazardous Waste Sites – Interim (May 2009).
SF RWQCB ESL	San Francisco Bay Regional Water Quality Control Board Environmental Screening Levels for residential direct exposure (2013)
*	One or more screening levels (EPA Residential RSL, DTSC-Residential SLs, ECV, or Soil SL) have values lower than the background level.
NE	not established
mg/kg	milligrams per kilogram
ng/kg	nanograms per kilogram
µg/kg	micrograms per kilogram

Notes:

NE	not established
mg/kg	milligrams per kilogram
mg/L	milligrams per liter
EPA HW	Environmental Protection Agency Hazardous Waste Code
TC	Toxicity Characteristic
TTLC	Total Threshold Limit Concentration
STLC	Soluble Threshold Limit Concentration
RCRA	Resource Conservation and Recovery Act
TCLP	Toxicity Characteristic Leaching Procedure
WET	California Waste Extraction Test

Hazardous waste critiera exist for kepone, 2,4-D, mirex, pyridine, and 2,45-TP (Silvex); however, since they are not contaminants of potential concern at the Topock site, they are excluded from this table.

a	Total Threshold Limit Concentration (TTLC) from 22 CCR 66261.24(a)(2). Calculated based on the concentration of the elements, not the compounds.
b	Screening level is 10x Soluble Threshold Limit Concentraction (STLC). If screening level is exceeded in total analysis, California Waste Extraction Test (WET) should be run to evaluate whether STLC is exceeded.
c	Screening level is 20x RCRA Toxicity Characteristic (TC). If screening level is exceeded in total analysis, Toxicity Characteristic Leaching Procedure (TCLP) should be run to evaluate whether RCRA TC is exceeded.
d	Soluble threshold limit concentration from 22 CCR 66261.24(a)(2), measured using the WET. Calculated based on the concentration of the elements, not the compounds.
e	RCRA TC level from 22 CCR 66261.24(a)(1), measured using the TCLP.
f	A waste is assigned a RCRA waste code for each constituent where the results of the TCLP equal or exceed the RCRA TC level.
g	If o-, m- and p-Cresol concentrations cannot be differentiated, the total cresol (D026) concentration is used. The regulatory level of total cresol is 200 mg/L.
i	In the case of asbestos and elemental metals, the specified concentration limits apply only if the substances are in a friable, powdered or finely divided state. Asbestos includes chrysotile, amosite, crocidolite, tremolite, anthophyllite, and actinolite.
j	TTLC and STLC exclude barite. TTLC excludes barium sulfate.
k	For STLC, if the waste does not exceed the RCRA TC or exhibit another RCRA hazardous characteristic, the STLC is 560 mg/L, not 5 mg/L.
l	For TTLC, excludes molybdenum disulfide.
h	Quantitation limit is greater than the calculated regulatory level. The quantitation limit therefore becomes the regulatory level.

Well-SOP-01 Rev. 0

Standard Operating Procedure for Well and Borehole Permanent Decommissioning

PREPARED FOR:	Topock Groundwater Remediation Project
COPY TO:	Project File
PREPARED BY:	Pacific Gas & Electric Company
DATE:	August 27, 2014

This document defines the standard operating procedures (SOP) for decommissioning groundwater wells and boreholes associated with the Pacific Gas and Electric Company (PG&E) Topock Remediation Project, Needles, California (Site). This document was developed, in part, as a direct result of Tribal concerns that included dialog regarding future decommissioning activities at the site between PG&E, agencies, and Native American Indian Tribes (Tribes). PG&E acknowledges that the Topock Remediation Project is an area that is culturally important to the Tribes and that the activities, materials, and procedures used in this process are of specific interest. Tribes have raised concerns with drilling intrusions, well and borehole decommissioning, emplacement of foreign materials into the earth, and retention of soils displaced as a result of drilling. Based on Tribal input, the potential for use of displaced site material in the decommissioning process, which may require a variance with the applicable permitting agency, is included in this document (Section 2.2.3).

An initial draft of this SOP was submitted for review and comment by the agencies and Tribes. The comments received, PG&E responses to these comments, as well as the conclusions of discussion during a June 6, 2014 conference call regarding the PG&E responses to comments are documented in Attachment A.

This SOP will be used as a reference to guide the development of future work plans required for agency, Tribal, and stakeholder review prior to conducting all well and borehole decommissioning tasks associated with the groundwater remedy. For the purpose of this SOP, an exploratory borehole (borehole) is defined as a drilled borehole in which no casings have been installed, regardless of whether or not the borehole was drilled to the water table. However, California boreholes drilled to the water table must be decommissioned per water well standards. The technical procedures included in this SOP are based on applicable regulatory and project-specific guidance information; however, specific work plans for well decommissioning tasks are necessary to evaluate task-specific details and ensure overall compliance. The structure of the SOP has been developed to provide adequate flexibility such that it can be applied to different well types and sizes in a variety of environmental settings. Specifically, this SOP provides a summary of the following key criteria that must be considered when developing a scope of work to decommission a well or exploratory borehole:

- Regulatory information and project-specific resources
- General technical specifications and procedures used for well or borehole decommissioning
- Evaluation of the well or borehole decommissioning scenarios

1.0 Summary of Guidance Information

Multiple sources of guidance information must be considered prior to conducting well or borehole decommissioning activities. Groundwater wells at the Site are located in the states of California and Arizona. Both states regulate the minimum specifications and procedures for the decommissioning of groundwater monitoring and supply wells to protect the quality of groundwater. Further, project-specific documents provide additional guidance related to sensitive cultural and biological resources. A summary of key regulatory information (project-specific applicable or relevant and appropriate [ARAR] numbers are provided) and project-specific resource documents associated with conducting groundwater well or borehole decommissioning activities is provided in the following subsections.

1.1 Regulatory Information – California (ARAR #98)

Statewide minimum standards for decommissioning a groundwater well in the State of California were established by the California Department of Water Resources (DWR) in the California Well Standards. The California Well Standards were originally established in Bulletin 74 (February 1968), later re-written as Bulletin 74-81 (December 1981), and later supplemented by Bulletin 74-90 (June 1991). The DWR states that the California Well Standards may not be sufficient for local conditions and local permitting agencies may need to adopt more stringent standards to ensure groundwater quality protection. However, The County of San Bernardino is the local permitting agency for Site wells located in California and have adopted the DWR standards.

The California Well Standards identify well destruction (or decommissioning for this SOP) requirements for both water supply wells (Part III of Bulletin 74-81), and monitoring wells and exploratory boreholes[1] (Part III of Bulletin 74-90). Although San Bernardino County does not require permits for the decommissioning of boreholes that do not reach the water table, DTSC has stated that they may request that some exploratory boreholes that do not reach the water table be decommissioned as wells under certain circumstances. For example, a borehole that terminates within 10 to 20 feet the water table and is located in an area where the potential for infiltration (e.g., wash channels) or future spills (e.g., an area of active industrial operations) is greater. The general requirements for both well types are similar; however, special considerations for monitoring wells and exploratory boreholes address the potential for these well types to be in areas of known or potential pollution or contamination.

1.2 Regulatory Information – Arizona (ARARs #48 and #49)

Development of rules for adopting standards for the construction and abandonment (or decommissioning for this SOP) of a groundwater well in the State of Arizona are required under Arizona Revised Statute 45-594(A). In response to the statute, the Arizona Department of Water Resources (ADWR), adopted the Well Abandonment Rule. The Well Abandonment Rule as Arizona Administrative Code (A.A.C) R12-15-816 was originally established on March 5, 1984. An amendment to the rule was effected on June 18, 1990. The Well Abandonment Rule requires that the abandonment (decommissioning) of a well be accomplished through filling or sealing the well so as to prevent the well from allowing the vertical movement of water. The rule contained general guidance for the decommissioning process, but lacked specific information regarding applicable aquifer conditions, and for the depths, types of materials and methods for the well decommissioning. ADWR provided additional written guidance for well abandonment to comply with A.A.C. R12-15-816(G) in the Well Abandonment Handbook on October 3, 2008.

The Well Abandonment Handbook (WAH) provides a standard well decommissioning method to be used for the post-installation of any well or borehole, regardless of the aquifer or vadose zone conditions applicable to the well (Section IV A). In addition, the WAH details five alternative abandonment methods. The five alternatives are for specific vadose zone and aquifer conditions which may include contamination, single or multiple aquifers, or dry wells (Section IV B). For example, Alternative 4, which applies to wells that only penetrate a single aquifer without vertical flow components and no water quality contamination issues, might be applicable to wells in the Topock area that are 8-inches or greater in diameter. A variance option to Alternative 4 permits the use of clean fine sand to fill the well being decommissioned.

Legal authorization from the ADWR is required to decommission most types of wells in the State of Arizona. ADWR requires a statewide decommissioning form to be filed and reviewed prior to decommissioning. The notice of intention to abandon a well (NOIA) can be obtained from the ADWR Groundwater Management Support Section in Phoenix or other local offices. In addition, all forms are available online at http://www.azwater.gov/azdwr/WaterManagement/NOI/documents/PermitsFormsApplicationsNOI.htm. The permit must be signed and filed by the well owner. The information on the NOIA must include a well construction diagram with proposed decommissioning specifications; casing type, description of the proposed method of decommissioning (over-drilling, jacking, perforation, etc.); a description of the method of emplacing sealing or fill materials; and the specific type and estimated amount of grout material to be used (water-cement ratio, water-

[1] San Bernardino County does not require permits for the installation or decommissioning of boreholes that do not reach the water table.

bentonite ratio and/or other materials or additives used). ADWR performs a completeness and substantive review of the NOIA to determine whether the proposed abandonment methods and materials meet the requirements of the ADWR abandonment rule in R12-15-816(G). If an alternative method of decommissioning is proposed in lieu of the standard method, further substantive review is performed by ADWR to verify that the proposed methods apply, and whether appropriate fill materials were chosen. A proposal to use an alternative decommissioning method requires an application to ADWR for a variance from the well decommissioning rule (a deviation from the standard decommissioning method). Following ADWR confirmation that the proposed well decommissioning methods and materials meet the requirements of the rule, a well decommissioning authorization card is mailed to the designated well drilling contractor and well decommissioning operations may begin.

1.3 Project-specific Resources

In addition to regulatory guidance, project specific requirements or information must be considered prior to initiating well decommissioning activities. The following is a list of documents that may be applicable:

- **Topock Well Inventory Data Package** – Inventory of wells related to the Topock Remediation Project for reference when developing specific plans for well decommissioning. This data package includes a technical memorandum, well location map, and a searchable spreadsheet of well details. As requested by DTSC, the well inventory spreadsheet (electronic file) and available well logs associated with the Topock Project will be archived on the DTSC website. This archive will be updated periodically as additional wells and boreholes are installed.
- **Environmental Impact Report (EIR) Mitigation Measures Reporting Program (MMRP)** – This document details specific compliance criteria that must be considered before, during, and after implementation of well decommissioning activities.
- **Management Protocol for Handling and Disposition of Displaced Site Material** – This document identifies the general approach and management protocols required for the handling and disposition of soil and/or rock that is displaced as a result of activities associated with the Pacific Gas and Electric Company (PG&E) Topock Remediation Project. The use of displaced site material for use in the well decommissioning process is discussed in Section 2.2.3.
- **Special Handling for Clay Material Encountered During Drilling** – As requested by the Hualapai Department of Cultural Resources, special handling procedures for drill cuttings generated from clay beds will be used in the field (this does not include clay-containing sediment mixtures, only clay beds). If clay bed(s) are encountered during drilling, then the cutting from those interval(s) will be set aside on 100% cotton muslin (dye free) for future disposition, following discussions with the Tribes. PG&E will notify the agencies and Tribes in the event clay material is encountered and separated for storage.
- **Previous Well Decommissioning Work Plans** –
  - Well PGE-6 Revised Decommissioning Work Plan (November 10, 2006).
  - Final Revised Implementation Plan for Repair of Monitoring Wells MW-38S and MW-38D and Old Well/Pipe Reconnaissance (February 11, 2011).
- **Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Permit Exemption –** Per the November 16, 2007 Memorandum from the United States Department of the Interior, remedial actions including well decommissioning are exempt from the federal, state, and local permitting process. Since the issuance of this memorandum, the applicability of this exemption has been confirmed with the County of San Bernardino, California in February 2008 and January 2011. However, the County of San Bernardino will need to be consulted in the event a variance to the California Well Standards is required. The applicability of this exemption has not been confirmed with the State of Arizona. Regardless of the permit exemption, all work plans for decommissioning activities will be reviewed and approved by the appropriate state and federal agencies prior to implementation.

1.4 General Technical Resources

In addition to regulatory guidance and project specific information various technical resources should be considered during the development of a work plan for well or borehole decommissioning. The following is a list of documents that may be useful:

- Monitoring Well Design and Construction for Hydrogeologic Characterization. Guidance Manual for Ground Water Investigations. July 1995. State of California, Environmental Protection Agency.
- ASTM Standard D5299-99 (2005), "Standard Guidance for Decommissioning of Groundwater Wells, Vadose Zone Monitoring Devices, Boreholes, and Other Devices for Environmental Activities", ASTM International, West Conshohocken, PA, 2005, www.astm.org.
- ASTM Standard C150/C150M-12, "Standard Specification for Portland Cement", ASTM International, West Conshohocken, PA, 2012, www.astm.org.
- ASTM Standard D4380-84 (2006), "Standard Test Method for Density of Bentonitic Slurries", ASTM International, West Conshohocken, PA, 2012, www.astm.org.

2.0 General Technical Specifications and Procedures for Decommissioning Wells and Exploratory Boreholes

Monitoring wells or exploratory boreholes that are no longer useful must be properly decommissioned to ensure the quality of groundwater is protected and eliminate a possible physical hazard to humans and animals. Notification or permitting requirements should be evaluated prior to the initiation of well decommissioning activities in the field. Involved oversight agencies will be notified in advance of any decommissioning activities to ensure concurrence with decommissioning of a particular well(s). The general process for decommissioning a well at the Topock site is presented on Figure 1, Well Decommissioning Decision Protocol. The information provided in this section is intended to be applicable for wells or boreholes located in either California or Arizona; however, it is assumed that the details included in the specific work plan(s) will be designed in compliance with the appropriate state regulations, and reviewed by the appropriate permitting agency. In addition, depending on the condition of the aquifer and well(s) subject to decommissioning, potentially applicable variance options that include the minimization of the placement of sealing material should be evaluated with the lead agencies during well decommission work plan development (e.g., Arizona Alternative 4 – variance option). A discussion of the primary steps identified in this protocol, including the potential materials and methods required for each, is presented in the following subsections.

2.1 Evaluation of Well or Borehole

Key well or borehole information should be assembled and reviewed prior to initiating decommissioning activities to determine lithologic and well construction details, the current condition of the well or borehole, soil and water quality information, applicable regulatory criteria, and identification of the procedures and materials that should be used. The majority of this information will be available through review of drilling and well installation information, the Topock Well Inventory, groundwater sample collection logs, or other related documents. The Topock Well Inventory can be found online at: http://dtsc-topock.com/sites/default/files/Topock-Well-Inventory_Tech-Memo.pdf. However, it is possible that additional survey of the given well or borehole will be required to obtain all key information. The following is a list of survey techniques that may be utilized to evaluate the condition of well or borehole (list is not intended to be all-inclusive):

- Well measurement – Evaluation of the depth to the bottom of, or the depth to water within, a well or borehole. This is typically accomplished using a graduated measuring tape with a water sensor or blunt weight at the end.
- Video survey – An in-well video camera can be used to evaluate the condition of the well casing and screen, and identify obstructions. In-well cameras are typically calibrated for depth and orientation (i.e. north, south, east and west), and deployed on a cable using a winch.

- Geophysical survey – Depending on the well casing type, depth to water, potential presence of metallic centralizers or other well construction components, and other variables, select geophysical survey tools may be useful. Similar to an in-well camera, in-well geophysical tools are deployed on a cable using a winch. While not a complete list, examples of geophysical tools that may be useful include:
  - Acoustic (Cement Bond Log) – Used to determine the quality of cement bonding in cased or sealed wells.
  - Gamma – Used to determine intervals of bentonite seals and gravel pack.
  - Caliper – Used to verify diameter of the well or borehole, which is used to calculate borehole and well casing volumes, and identifies obstructions or areas of borehole washout or constriction.
  - Casing Inspection Thickness Measurement (CITM) – An in well survey that uses electromagnetic waves to measure well casing wall thickness in carbon based steels. Survey can be used to understand or measure the integrity of the well casing.

2.2 Identification of Materials and Placement Requirements

Different types of materials are required for different well or borehole decommissioning scenarios depending on above-ground, and subsurface environment. Sealing materials are required when the potential for flow of water through the material must be kept to an absolute minimum such that the volume of water and possible pollutants and contaminants passing through them will be of minimal consequence (no material is completely impervious). Filler material is permitted for use under some circumstances when the flow of water through the material is not of critical concern. Potential materials suitable for use during well and borehole decommissioning at the Topock site and associated placement requirements are listed in the following subsections.

2.2.1 Sealing Material

Conventional sealing activities are performed with the objective of completely filling the borehole or well casing, voids in the formation in the vicinity of the borehole, and if not over-drilled, the gravel pack and annular spaces. Sealing materials are required for use when decommissioning wells and boreholes regardless of whether they are located in an area of known or potential pollution or contamination. In uncontaminated areas where the well is wholly situated in unconsolidated material in an unconfined groundwater zone, the sealing material is focused in the upper 20 feet of the well or borehole to prevent the infiltration of potential surface contamination. In areas of known or potential soil or groundwater contamination, sealing material is required throughout the entirety of the well or borehole. The following is a list of sealing materials that may be used at the Topock site:

- Neat cement – Compose entirely of Type II/V Portland cement grout with up to 6% bentonite powder.
- Sand-cement grout – Composed of Portland cement with no more than two parts sand to one part cement by weight of sand.
- Concrete – Composed of Portland cement and aggregated mixed at a ratio of at least 564 lbs. of cement per cubic yard of aggregate. Aggregate used must be smaller than 1/5 of the radial thickness of the annular seal and is typically reserved for large volume/diameter borehole or well decommissioning.
- Bentonite clay – Composed of commercially prepared, powdered, granulated, pelletized, or chipped/crushed sodium montmorillonite clay with the largest dimension of pellet or chip being less than 1/5 the radial thickness of the annular seal. Bentonite cannot be used as a sealing material opposite zones of fractured rock, unless otherwise approved by lead agencies. As bentonite seals may have a tendency to dry, shrink and crack in arid and semi-arid areas where subsurface moisture levels can be low, they are not recommended for sealing the vadose zone at the Topock site. In addition, bentonite is not recommended for application in high TDS environments (e.g., >5,000 parts per million) due to the adverse effects on its ability to properly swell and seal in these conditions.

According to Arizona and California Well Standards, drilling mud or cuttings are not acceptable sealing materials.

Water used for the preparation of sealing materials should be potable, compatible with the type of sealing material used and free of contaminants and suspended matter. All manufacturers' specifications for mixture

volumes and curing times must be strictly followed (typically, ASTM C150, Standard Specification for Portland cement). Further, the use of any additives must comply with the requirements of ASTM C494 (Standard Specification for Chemical Admixtures for Concrete).

Sealing material must be placed into a well or borehole at the required interval(s) in one continuous decommissioning operation, which may include multiple lifts of sealant, using methods that prevent the free-fall, dilution, and/or separation of aggregates from the cementing materials. Typically, fluid sealing material is placed using a tremie pipe with positive displacement pumping (pumped under pressure), beginning at the bottom of the sealed interval with the end of the tremie pipe submerged two feet or more below the surface of the grout during placement. When using a tremie pipe, if sealing material is placed throughout the well or borehole, static water is either displaced out of the top by the injected column of sealing material, or into the formation (applicable SOPs for waste management/spill containment will followed). Alternatively, fluid sealing material may need to be pumped into the well under pressure, using the well casing as the conduit. In this case the static water and the sealing material are forced into the voids of the well/borehole and formation. When fluid sealing material is placed under pressure, the pressure must be maintained long enough for the sealing material to cure, as applicable. Dry sealing material, such as bentonite chips or pellets, are typically placed by using a tremie pipe or the well casing as a conduit. Dry sealing materials require water for hydration and proper sealing. Regardless of sealing material type or placement method, verification shall be made that the volume of the material placed in the well or borehole is at least equal to the calculated volume of void space to be sealed.

2.2.2 Filler Material

Filler materials are permitted for use in select portions of the decommissioned well or borehole when located in uncontaminated areas. Suitable filler materials include clay, silt, sand, gravel, crushed stone, native soils, mixtures of the aforementioned types, as well as sealing materials defined above. However, materials containing organic matter are not acceptable.

Filler material must be placed into the well or borehole from the bottom up, such that bridging does not occur and the entire void space is filled. To assure that bridging has not occurred during placement, verification shall be made that the volume of the material placed in the well or borehole (with appropriate porosity assumptions) is at least equal to the calculated volume of void space to be filled (i.e., empty hole).

2.2.3 Displaced Site Material

As discussed in Section 1.3 (Management Protocol for Handling and Disposition of Displaced Site Material), soil and rock that are displaced as a result of the Topock Remediation Project may be retained on site for future use. One of the potential reuses for this material identified in the management protocol is replacement into borings. If the material was generated as drill cuttings, then lead agencies must agree that the material can be used as a component of either sealing or filler material for the purpose of well or borehole decommissioning (a variance may be required).

The requirements for placement of displaced site material, should it be deemed appropriate for use based on physical and chemical composition, are the same as that for filler material. Additional processing of the displaced material may be required to ensure that grain size requirements are met, that the material is free of organic matter, and that the material can be practicably placed into the well or borehole (i.e., prevent bridging). This processing may require the use of heavy equipment for grading or crushing the material so that it is suitable for use in the decommissioning process. An appropriate onsite location would need to be identified if such processing were required.

2.3 Well or Borehole Decommissioning Scenarios

Following evaluation of the well or borehole and in coordination with lead agencies, it must be determined if the well can be decommissioned in place (with or without modification) or if the well materials must be removed. The following subsections define the decommissioning scenarios that may apply pending completion of the well evaluation and coordination with lead agencies, responsible agencies (San Bernardino County or Arizona

Department of Water Resources), affected land owner, Tribes, and other stakeholders. Artesian groundwater conditions have not been observed at the Topock site, and therefore, are not considered in this SOP.

All wells associated with the Topock Remediation Project are considered to be in non-urban areas. When developing work plans that include well or borehole decommissioning, lead and responsible agencies (San Bernardino County) in California will be consulted to confirm this assumption. For the purpose of this SOP, well or borehole decommissioning scenarios are presented for two types of well site environments. These environments, Type 1 and Type 2, are defined as:

- Type 1 Well Environment – A well classified as Type 1 is located outside the area of known or potential soil or groundwater contamination (e.g., as determined by the soil and/or groundwater quality data available for the location or the likelihood of a future release in the area) and is not located in an area that is subject to increased surface water infiltration relative to nearby upland areas (e.g., channel of Bat Cave Wash).
- Type 2 Well Environment – A well classified as Type 2 is located in an area of known or potential soil or groundwater contamination (e.g., as determined by the soil and/or groundwater quality data available for the location or the likelihood of a future release in the area) and/or in an area that is subject to increased surface water infiltration relative to nearby upland areas (e.g., channel of Bat Cave Wash). Any wells located on the Topock Compressor Station, within wash channels, within areas of concern (AOCs), or within/adjacent to roads are in a Type 2 environment.

Three approaches to well and borehole decommissioning, including one approach that would require the approval of a variance to the California Well Standards, were presented by DTSC as draft concepts for discussion during the January 19, 2012 TWG Meeting. This information is provided as Attachment B to this SOP for consideration when developing future work plans that involve borehole or well decommissioning. The overriding consideration for the variance scenario presented in Attachment B was that the decommissioning method would provide seals that had a net permeability equal to or less than the naturally occurring geologic materials encountered along the borehole.

2.3.1 Exploratory Borehole

Typically, exploratory boreholes at the Topock site are installed as part of a data collection effort (i.e., lithologic, soil or groundwater sample collection) and are immediately decommissioned once the data collection objectives for that borehole have been achieved. Therefore, the borehole is typically decommissioned while the drilling tools or casing is still in place, prior to demobilization from that borehole. The following general procedure should be followed for decommissioning an exploratory borehole:

1. Evaluate the borehole for obstructions immediately prior to conducting decommissioning activities. If an obstruction is encountered that will prevent successful sealing of the borehole, attempts must be made to remove it prior to placement of the sealing material.
2. Place sealing material from total depth to ground surface. Typically, sealing material will be placed using a tremie pipe with positive displacement pumping. Industry practice is to place sealing material from total depth to the ground surface. However, if the boring is not within an area of known or potential pollution or contamination as determined by the soil and/or groundwater quality data available for the borehole, evaluate using displaced site material, or filler material if displaced site material is not available or appropriate, in lieu of sealing material in the upper 5 to 10 feet of the borehole. The use of displaced site material or filler material may require a permit variance if the borehole reached the water table.
3. Verify that the resulting condition of the borehole opening at the surface does not present a physical hazard to humans or animals. If voids are present fill voids created with displaced site material, or filler material if displaced site material is not available or appropriate.

2.3.2 Decommissioning a Well in Place

Wells determined to have been constructed in conformance with applicable standards without indication of compromise since the time of installation may be decommissioned in place. This decommissioning option should be utilized whenever acceptable to the regulatory agencies as it represents the field procedures that are least intrusive and create the least amount of disturbance. Further, this decommissioning method is appropriate if the well is in good repair but cannot be removed (e.g., wells constructed with large diameter steel casing), or if removal would negatively influence sealing of the well (e.g., a collapse during removal). In this case the monitoring well casing and any other significant voids (i.e., pore spaces in the gravel pack), at a minimum, should be completely filled with sealing material. The following general procedure should be followed for decommissioning a well in place:

1. Conduct evaluation of the well as detailed in Section 2.1 and verify with lead agencies, responsible agencies (San Bernardino County or Arizona Department of Water Resources), affected land owner, Tribes, and other stakeholders that the well should be decommissioned in place, and whether it is in a location considered to be Type 2.
2. Evaluate well for obstructions immediately prior to conducting decommissioning activities. If an obstruction is encountered that will prevent successful sealing of the well, attempts must be made to remove it prior to placement of the sealing and/or filler material.
3. Place sealing material. Typically, if fluid sealing material is used, this will be conducted using a tremie pipe with positive displacement pumping.
    a. Type 1 Well – Evaluate using filler material in lieu of sealing material in portions of the well casing. Place sealing material from total depth to near ground surface.
    b. Type 2 Well – Place sealing material from total depth to within 5 feet of the ground surface (bgs).
4. Decommission well head.
    a. Type 1 Well – Remove all well head protection and excavate around the well casing to a depth of approximately 1 to 5 feet bgs, or as practicable. Remove all well materials to a depth of approximately 1 to 5 feet bgs, or as practicable, cap casing with sealing material such that it extends beyond the diameter of the borehole and will drain fluids away from the borehole. Backfill the void created with displaced site material, or filler material if displaced site material is not available or appropriate.
    b. Type 2 Well – Remove all well head protection and excavate around the well casing to a depth of 5 feet bgs. Remove all well materials to a depth of 5 feet bgs, cap casing with sealing material such that it extends beyond the diameter of the borehole and will drain fluids away from the borehole. Backfill the void created with displaced site material, or filler material if displaced site material is not available or appropriate.

Note that the Type 1 and Type 2 well scenarios are subtly different. While the Type 2 scenario requires the removal of all well materials to a depth of 5 feet bgs (per CA well standards), Type 1 wells do not require the removal of any well materials. The removal of well materials to a depth of approximately 1 to 5 feet bgs, or as practicable, is not required by CA well standards, but included per stakeholder comments.

2.3.3 Decommissioning a Well in Place with Modification

It may be determined that a well should be decommissioned in place, but requires modification prior to sealing. This method may be appropriate in the event well materials or an obstruction cannot be removed, clogged screen cannot be removed, or if removal would negatively influence sealing of the well. In this scenario it may be required to remove a portion of the well casing, perforate sections of the well screen or casing, or conduct other well modifications to facilitate proper sealing. The following general procedure should be followed for decommissioning a well in place when a modification is required:

1. Conduct evaluation of the well as detailed in Section 2.1 and verify with lead agencies, responsible agencies (San Bernardino County or Arizona Department of Water Resources), affected land owner, Tribes, and other stakeholders that the well should be decommissioned in place, what modification work is required, and whether it is considered to be Type 2.
2. Implement required well modification.
3. Place sealing material. The condition that warrants well modification must be evaluated to determine the method use to place the sealing material. For example, if casing perforations above the water table are required, sealing under pressure may be appropriate.
    a. Type 1 Well – Evaluate using filler material in lieu of sealing material in portions of the borehole. Place sealing material from total depth to near ground surface, or in the event casing is removed, the new top of casing depth. If a portion of the casing is removed, sealing or filler material requirements for the interval above the top of casing must be determined through discussion with lead agencies, responsible agencies (San Bernardino County or Arizona Department of Water Resources), affected land owner, Tribes, and other stakeholders.
    b. Type 2 Well – Place sealing material from total depth to within 5 feet of the ground surface (bgs). If a portion of the casing is removed, sealing or filler material requirements for the interval above the top of casing must be determined through discussion with lead agencies, responsible agencies (San Bernardino County or Arizona Department of Water Resources), affected land owner, Tribes, and other stakeholders.
5. Decommission well head.
    a. Type 1 Well –Remove all well head protection and excavate around the well casing to a depth of approximately 1 to 5 bgs, or as practicable. Removal all well materials to a depth of approximately 1 to 5 feet bgs, or as practicable, cap casing with sealing material such that it extends beyond the diameter of the borehole and will drain fluids away from the borehole. Backfill the void created with displaced site material, or filler material if displaced site material is not available or appropriate.
    b. Type 2 Well – Remove all well head protection and excavate around the well casing to a depth of 5 bgs. Removal all well materials to a depth of 5 feet bgs, cap casing with sealing material such that it extends beyond the diameter of the borehole and will drain fluids away from the borehole. Backfill the void created with displaced site material, or filler material if displaced site material is not available or appropriate.

2.3.4 Decommissioning a Well by Removing Well Materials

In some cases a well may be decommissioned by complete removal of the well materials. This method may be appropriate in the event a well was not constructed in accordance with applicable standards and the deficiencies may prevent the proper sealing of the well, even with modification. Further, when removal is practicable, lead agencies, responsible agencies (San Bernardino County or Arizona Department of Water Resources), affected land owner, or other stakeholders may determine this method preferable to others. Removal is typically conducted by over-drilling the existing well materials with larger diameter drilling tools. Typically, this method is only applied to wells constructed with polyvinyl chloride (PVC) casing or limited lengths of smaller diameter steel casing. Other methods of casing removal (e.g., hydraulic casing jacks) may be useful to remove limited lengths of larger diameter steel casing. The following general procedure should be followed for decommissioning a well by removing the well materials:

1. Conduct evaluation of the well as detailed in Section 2.1 and verify with lead agencies, responsible agencies (San Bernardino County or Arizona Department of Water Resources), affected land owner, Tribes, and other stakeholders that the well should be decommissioned by removal.
2. Remove well materials. Typically, this is conducted by over-drilling or in some cases by combination of the use of hydraulic casing jacks combined with over-drilling.

3. Evaluate borehole for obstructions immediately prior to conducting decommissioning activities. If an obstruction is encountered that will prevent successful sealing of the borehole, it must be removed prior to placement of the sealing material.
4. Place sealing/filler material from total depth to ground surface. Typically, this will be conducted using a tremie pipe with positive displacement pumping. Industry practice is to place sealing material from total depth to the ground surface. However, if the boring is not within an area of known or potential pollution or contamination, evaluate using filler material in lieu of sealing material in portions of the borehole.
5. Decommission remaining elements of the well head protection and fill voids created with displaced site material, or filler material if displaced site material is not available or appropriate.

Other methods may be employed for removal of the well, particularly for steel well materials and steel conductor casings used to seal off upper lithologic zones. Specifically, the well string (or conductor casing) may be pulled by jacking with external equipment, or with the drill rig. Once the well string is removed from the borehole, the remaining materials in the original borehole should be over-drilled to remove them from the formation.

2.4 Well Decommissioning Reporting

Following completion of well decommissioning tasks, reporting of field activities must be completed in compliance with the lead agencies requirements. In addition, project-specific reporting must be completed (as required) and the Topock Well Inventory must be updated to reflect the results of decommissioning activities. The timeline for reporting requirements will be specified in the project-specific work plan. The Well Decommissioning Report will be submitted to lead agencies no later than 90 days after completion of well decommissioning activities and will include, at a minimum:

- A summary of the approval process completed prior to well decommissioning, including reference to submitted work plans, subsequent communication and modifications (as applicable) and documentation of approval to proceed;
- Discussion regarding application of the Well Decommissioning Decision Protocol;
- Details of the work performed, including explanation of the applicable well decommissioning scenario and materials utilized;
- Documentation of compliance with applicable permitting requirements, and;
- Signature and seal of an appropriately licensed professional geologist or engineer.

Well Decommission Decision Protocol
Standard Operating Procedure for
Well and Borehole Decommissioning
PG&E Topock Compressor Station
Needles, California

Attachment A
Responses to Comments on Draft *Standard Operating Procedure for Well and Borehole Decommissioning*

Responses to Comments on *Standard Operating Procedure for Well and Borehole Decommissioning*, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California

Absolute Comment No.	Comment Source/Number	Section	Reference Text	Comment	Response	Summary of June 6, 2014 RTC Discussion
1	Arizona Department of Water Resources (ADWR) February 28, 2013 Letter ADWR-1			The text in the Standard Operation Procedure (SOP), section 1.2 states that all required forms can be obtained from the Phoenix ADWR offices. All forms are available online at: http://www.azwater.gov/iazdwr/WaterManagement/NOI/documents/PermitsFormsApplicationsNOI.htm	The text in **bold** will be added to the following statement. The notice of intention to abandon a well (NOIA) can be obtained from the ADWR Groundwater Management Support Section in Phoenix or other local offices. **In addition, all forms are available online at:** http://www.azwater.gov/iazdwr/WaterManagement/NOI/documents/PermitsFormsApplicationsNOI.htm	No additional comments.
2	ADWR-2			The SOP document describes requirements for abandoning (decommissioning) wells in Arizona and California and technical specifications and procedures for abandoning wells at the Topock Compressor Station remediation site. The proposed methods are thorough, protective of the aquifer, and consistent with minimum well construction and abandonment requirements in Arizona Administrative Code (A.A.C.) R12-15-816 and substantive policy described in the ADWR "Well Abandonment Handbook" (2008).	PG&E appreciates the review and input from ADEQ and ADWR on this SOP.	No additional comments.
3	ADWR-3			The proposed methods suggested for abandoning exploratory boreholes in Arizona utilizing "granulated material" are satisfactory. The methods are consistent with the variance option of Alternative 4 in the "Well Abandonment Handbook". Notices of Intent to Abandon a Well must be accompanied with a written request for a variance from the provisions of the minimum well construction and abandonment standards and in accordance with A.A.C. R12-15-820.	This comment is specific to the *Revised Implementation Plan for Evaluation of Alternative Freshwater Sources in the Topock Remediation Project Area, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California* (January 28, 2013). However, as noted by the Fort Mojave Indian Tribe in comment FMIT-6, this represents an example of successful application of a variance to the standard well decommissioning procedure in Arizona. This variance was approved by ADWR based on project-specific information about the condition of the aquifer and planned boreholes (not a well in this example). PG&E anticipates similar discourse with the regulatory agencies based on future project-specific information in the development of future well decommissioning work plans.	No additional comments.
4	Department of Toxics Substances Control (DTSC) Document edits in redline strikeout DTSC-1	2nd paragraph	However, California boreholes drilled to the water table must be decommissioned per water well standards.	[DTSC Comment CG1]: Revise text. Clarify that an exploratory borehole drilled to the water table in California must comply with well decommissioning standards. Underlined text indicates new text inserted into document.	The text in **bold** will be added to the following statement. For the purpose of this SOP, an exploratory borehole (borehole) is defined as a drilled borehole in which no casings have been installed, regardless of whether or not the borehole was drilled to the water table. **However, California boreholes drilled to the water table must be decommissioned per water well standards.**	No additional comments.
5	DTSC-2	1.1	[1.] San Bernardino County does not require permits for the installation or decommissioning of boreholes that do not reach the water table.	[DTSC Comment CG2]: Please note that DTSC may request that some exploratory boreholes that do not reach the water table be decommissioned as wells under certain circumstances (e.g., deep boreholes that almost reach the water table). Please incorporate this concept into the SOP.	The text in **bold** will be added to the following statement. The California Well Standards identify well destruction (or decommissioning for this SOP) requirements for both water supply wells (Part III of Bulletin 74-81), and monitoring wells and exploratory boreholes[1]. **Although San Bernardino County does not require permits for the decommissioning of boreholes that do not reach the water table, DTSC has stated that they may request that some exploratory boreholes that do not reach the water table be decommissioned as wells under certain circumstances. For example, a borehole that terminates within 10 to 20 feet the water table and is located in an area where the potential for infiltration (e.g., wash channels) or future spills (e.g., an area of active industrial operations) is greater.**	No additional comments.

Absolute Comment No.	Comment Source/Number	Section	Reference Text	Comment	Response	Summary of June 6, 2014 RTC Discussion
6	DTSC-3	1.3	However, the County of San Bernardino will need to be consulted in the event a variance to the California Well Standards is required.	[DTSC Comment CG3]: As the SOP is now sufficiently developed, it is important to have San Bernardino review the next version and provide input as they are a key decision maker regarding well decommissioning.	After PG&E response to comments from ADWR, DTSC, Fort Mojave Indian Tribe and the Hualapai Dept of Cultural Resources included in this table have been addressed and discussed by the Well Decommissioning Subgroup, a draft of this SOP will be submitted to the County San Bernardino for their review and input.	No additional comments.
7	DTSC-4	2.0	Involved oversight agencies will be notified in advance of any decommissioning activities to ensure concurrence with decommissioning of a particular well(s).	Underlined text indicates new text inserted into document.	The proposed text has been added to the document.	No additional comments.
8	DTSC-5	2.1	drilling and well installation information	[DTSC Comment YA4]: A repository of drilling logs and installation notes should be put into a central archive for access by involved stakeholders.	Drilling logs and installation notes, where available, have been included in various documents submitted to the agencies following field work. As specific well decommissioning work plans are developed, this information will be included in those plans. **Further, as requested by DTSC, the well inventory spreadsheet (electronic file) and available well logs associated with the Topock Project will be archived on the DTSC website. This archive will be updated periodically as additional wells and boreholes are installed.** The text above in **bold** will be added to Section 1.3, first bullet (Topock Well Inventory Data Package).	No additional comments.
9	DTSC-6	2.1	Topock Well Inventory	[DTSC Comment CG5]; Include the current Topock Well Inventory as an electronic attachment to this SOP.	The text in **bold** will be added to the following statement. The majority of this information will be available through review of drilling and well installation information, the Topock Well Inventory, groundwater sample collection logs, or other related documents**. An electronic copy of the Topock Well Inventory has been included in this SOP under Attachment A.**	No additional comments.
10	DTSC-7	2.1	Geophysical survey – Depending on the well casing type, depth to water, presence or absence of centralizers, and other variables, select geophysical survey tools may be useful.	Underlined text indicates new text inserted into document.	The modified text in **bold** will be added to the statement. Geophysical survey – Depending on the well casing type, depth to water, **potential presence of metallic centralizers or other well construction components**, and other variables, select geophysical survey tools may be useful.	No additional comments.
11	DTSC-8	2.2.1	Bentonite cannot be used as a sealing material opposite zones of fractured rock, unless otherwise approved by lead agencies (DTSC/DOI).	Underlined text indicates new text inserted into document. Deleted text includes "the permitting" agency. Subsequent comment from DTSC regarding when bentonite is appropriate as a sealing material…	The proposed edit has been incorporated into the document. In addition, based on subsequent discussion with DTSC, the following text in **bold** has been added to Section 2.2.1, fourth bullet (bentonite clay): **In addition, bentonite is not recommended for application in high TDS environments (e.g., >5,000 parts per million) due to the adverse effects on its ability to properly swell and seal in these conditions.**	No additional comments.
12	DTSC-9	2.2.3	If the material was generated as drill cuttings, then lead agencies must agree that the material can be used as a component of either sealing or filler material for the purpose of well or borehole decommissioning (a variance may be required).	[DTSC Comment CG6]: Change text as a permit exemption may be used and since DOI and DTSC will, at a minimum, be approving agencies. Underlined text indicates new text inserted into document. Deleted text includes "the permitting" agency.	The proposed edit has been incorporated into the document.	No additional comments.

Absolute Comment No.	Comment Source/Number	Section	Reference Text	Comment	Response	Summary of June 6, 2014 RTC Discussion
13	DTSC-10	2.3	Following evaluation of the well or borehole and in coordination with the lead agencies, it must be determined if the well can be decommissioned in place (with or without modification) or if the well materials must be removed.	Underlined text indicates new text inserted into document. Deleted text includes "the permitting" agency.	The proposed edit has been incorporated into the document.	No additional comments.
14	DTSC-11	2.3	The following subsections define the decommissioning scenarios that may apply pending completion of the well evaluation and coordination with lead agencies, responsible agencies **(San Bernardino County or Arizona Department of Water Resources)**, affected land owner, **Tribes,** and other stakeholders.	Underlined text indicates new text inserted into document. Deleted text includes "the permitting" agency.	The proposed edit has been incorporated into the document.	Tech in **bold and underlined** in the "Reference Text" column has been added globally as requested during the call.
15	DTSC-12	2.3.2	1. Conduct evaluation of the well as detailed in Section 2.1 and verify with lead agencies, responsible agencies, affected land owner, and other stakeholders that the well should be decommissioned in place.	[DTSC Comment CG7]: The urban versus non-urban terms created concern to some tribes and distracted from the technical issues at hand. It is recommended that explicit reference to the term be minimized (see highlights in text and Figure 1). Perhaps just referencing the standards will suffice. Underlined text indicates new text inserted into document. Deleted text includes "the permitting" agency.	The proposed edit has been incorporated into the document. See response to comment DTSC-16 regarding the urban and non-urban topic. Reference June 6, 2014 RTC Discussion and what changes result (e.g. Type 1 and Type 2).	As a result of the June 6, 2014 RTC Discussion the terms "urban" and "non-urban" have been removed from the SOP. These terms have been replaced throughout with "Type 1" and "Type 2". A definition for these terms has been added to the beginning of Section 2.3. In addition, Figure 1 has been revised to include the new terminology.
16	DTSC-13	2.3.2	a. Non-urban Area – Place sealing material from total depth to near ground surface.	Yellow highlight added.	See response to comment DTSC-16.	See summary for comment DTSC-12.
17	DTSC-14	2.3.2	b. Urban Area – Place sealing material from total depth to within 5 feet of the ground surface (bgs).	Yellow highlight added.	See response to comment DTSC-16.	See summary for comment DTSC-12.
18	DTSC-15	2.3.2	c. For urban or non-urban area wells located outside an area of known or potential pollution or contamination as determined by the soil and/or groundwater quality data available for the location, evaluate using filler material in lieu of sealing material in portions of the well casing.	[DTSC Comment CG8]: Made edit assuming that well is left in place and could only fill well casing with filler or sealing material. Yellow highlight added. Underlined text indicates new text inserted into document. Deleted text includes "borehole".	The proposed edits have been incorporated into the document. See response to comment DTSC-16 regarding highlighted text.	See summary for comment DTSC-12.

Absolute Comment No.	Comment Source/Number	Section	Reference Text	Comment	Response	Summary of June 6, 2014 RTC Discussion
19	DTSC-16	2.3.2	a. Non-urban Area – Remove all well head protection and excavate around the well casing to a depth of approximately 5 feet bgs, or as practicable. Remove all well materials to a depth of approximately 5 feet bgs, or as practicable, cap casing with sealing material such that it extends beyond the diameter of the borehole and will drain fluids away from the borehole. Backfill the void created with displaced site material, or filler material if displaced site material is not available or appropriate. b. Urban Area – Remove all well head protection and excavate around the well casing to a depth of 5 <u>feet</u> bgs. <u>Remove</u> all well materials to a depth of 5 feet bgs, cap casing with sealing material <u>such that it extends beyond the diameter of the borehole and will drain fluids away from the borehole</u>. Backfill the void created with displaced site material, or filler material if displaced site material is not available or appropriate.	[DTSC Comment YA9]: Urban and non-urban decommissioning scenarios appear to be the same. If that the case, let's not differentiate between the two. Yellow highlight added. Underlined text indicates new text inserted into document.	The proposed edits have been incorporated into the document. The following text in **bold** has been added at the end of Section 2.3.2 to address the comment regarding the urban and non-urban topic: **Note that the urban and non-urban scenarios are only subtly different. While the urban scenario requires the removal of all well materials to a depth of 5 feet bgs (per CA well standards), non-urban areas do not require the removal of any well materials. The removal of well materials to a depth of approximately 5 feet bgs, or as practicable, is not required by CA well standards, but included per stakeholder comments.** To further clarify this difference in the text, bullet 4a (decommission well head, non-urban area) has been revised to indicate a range of 1 to 5 feet bgs. The same revision has been made to Section 2.3.3, bullet 4a, and Figure 1.	See summary for comment DTSC-12.
20	DTSC-17	2.3.3	1. Conduct evaluation of the well as detailed in Section 2.1 and verify with <u>lead agencies</u>, <u>responsible agencies</u>, affected land owner, and other stakeholders that the well should be decommissioned in place, what modification work is required, and whether it is in a location considered to be urban.	Underlined text indicates new text inserted into document. Deleted text includes "the permitting".	The proposed edit has been incorporated into the document.	See summary for comment DTSC-11.
21	DTSC-18	2.3.3	a. Non-urban Area – Place sealing material from total depth to near ground surface, or in the event casing is removed, the new top of casing depth. If a portion of the casing is removed, sealing or filler material requirements for the interval above the top of casing must be determined through discussion with <u>lead agencies, responsible agencies</u>, affected land owner, and other stakeholders.	Yellow highlight added. Underlined text indicates new text inserted into document. Deleted text includes "the permitting".	The proposed edit has been incorporated into the document. See response to comment DTSC-16 regarding highlighted text.	See summary for comment DTSC-12.
22	DTSC-19	2.3.3	b. Urban Area – Place sealing material from total depth to within 5 feet of the ground surface (bgs). If a portion of the casing is removed, sealing or filler material requirements for the interval above the top of casing must be determined through discussion with <u>lead agencies, responsible agencies</u>, affected land owner, and other stakeholders.	Yellow highlight added. Underlined text indicates new text inserted into document. Deleted text includes "the permitting".	The proposed edit has been incorporated into the document. See response to comment DTSC-16 regarding highlighted text.	See summary for comment DTSC-12.

Absolute Comment No.	Comment Source/Number	Section	Reference Text	Comment	Response	Summary of June 6, 2014 RTC Discussion
23	DTSC-20	2.3.3	c. For urban or non-urban area wells located outside an area of known or potential pollution or contamination, evaluate using filler material in lieu of sealing material in portions of the borehole.	Yellow highlight added.	See response to comment DTSC-16.	See summary for comment DTSC-12.
24	DTSC-21	2.3.3	a. Non-urban Area –Remove all well head protection and excavate around the well casing to a depth of approximately 5 bgs, or as practicable. Remove all well materials to a depth of approximately 5 feet bgs, or as practicable, cap casing with sealing material such that it extends beyond the diameter of the borehole and will drain fluids away from the borehole. Backfill the void created with displaced site material, or filler material if displaced site material is not available or appropriate. b. Urban Area – Remove all well head protection and excavate around the well casing to a depth of 5 bgs. Removal all well materials to a depth of 5 feet bgs, cap casing with sealing material such that it extends beyond the diameter of the borehole and will drain fluids away from the borehole. Backfill the void created with displaced site material, or filler material if displaced site material is not available or appropriate.	[DTSC Comment CG10]: See Comment YA9 above. Urban and non-urban decommissioning scenarios appear to be the same. If that the case, let's not differentiate between the two. Yellow highlight added.	See response to comment DTSC-16.	See summary for comment DTSC-12.
25	DTSC-22	2.3.4	Further, when removal is practicable, lead agencies, responsible agencies, affected land owner, or other stakeholders may determine this method preferable to others. Removal is typically conducted by over-drilling the existing well materials with larger diameter drilling tools.	Underlined text indicates new text inserted into document. Deleted text includes "the permitting".	The proposed edit has been incorporated into the document.	See summary for comment DTSC-11.
26	DTSC-23	2.3.4	1. Conduct evaluation of the well as detailed in Section 2.1 and verify with lead agencies, responsible agencies, affected land owner, and other stakeholders that the well should be decommissioned by removal.	Underlined text indicates new text inserted into document. Deleted text includes "the permitting".	The proposed edit has been incorporated into the document.	See summary for comment DTSC-11.
27	DTSC-24	2.4	Following completion of well decommissioning tasks, reporting of field activities must be completed in compliance with the lead agencies requirements.	Underlined text indicates new text inserted into document.	The proposed edit has been incorporated into the document.	No additional comments.
28	DTSC-25	2.4	The Well Decommissioning Report will be submitted to lead agencies no later than 90 days after completion of well decommissioning activities.	Underlined text indicates new text inserted into document.	The proposed text and text deletions have been incorporated into the document.	No additional comments.
29	DTSC-26	Figure 1	Between steps 3 and 4	Insert step: "Obtain approval to proceed from lead agencies"	The proposed revision to Figure 1 has been incorporated.

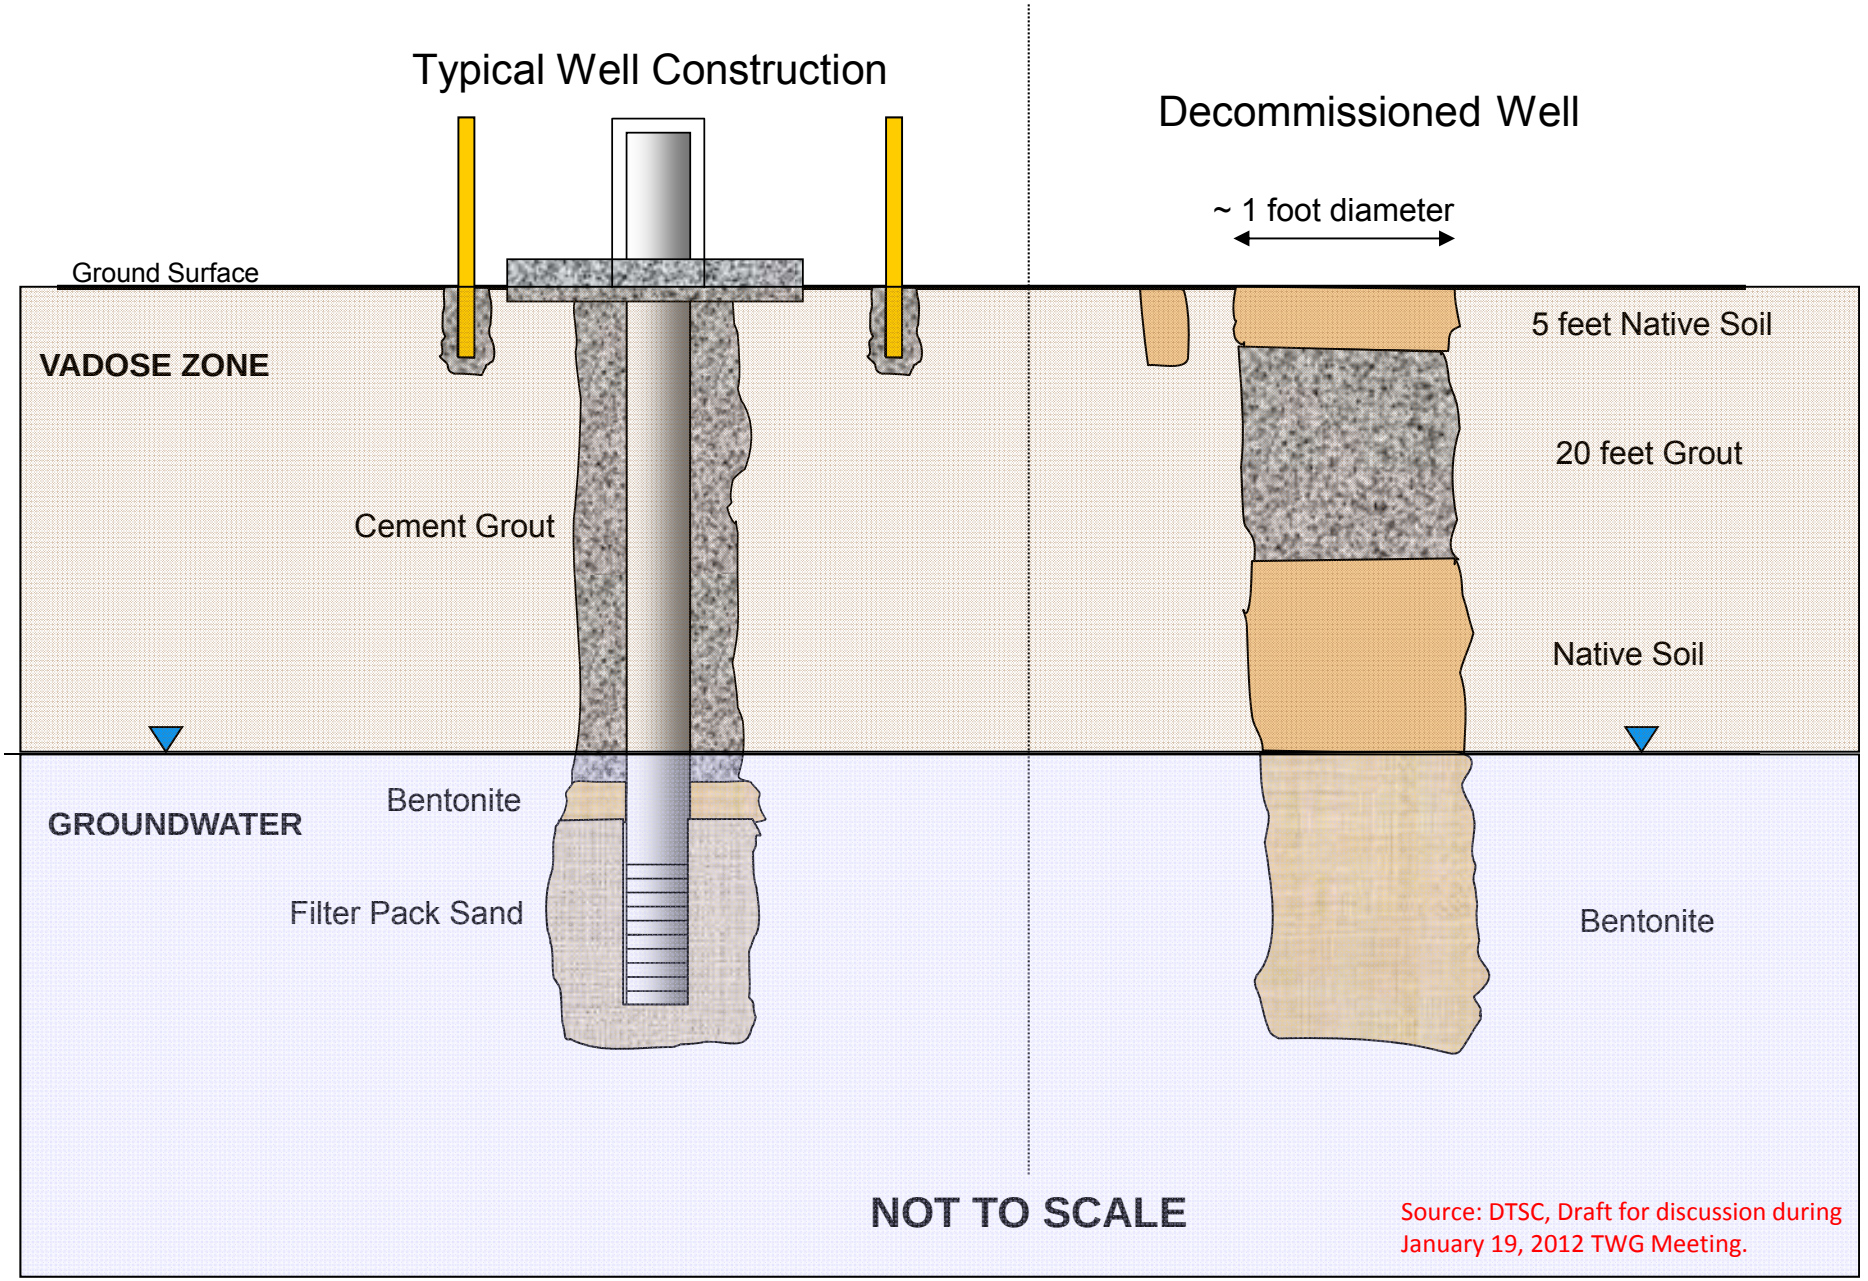
30	DTSC-27	Figure 1	After step 13	Insert step: "Document all activities in a Well Decommissioning Report to be submitted no later than 90 days after the decommissioning event.	The proposed revision to Figure 1 has been incorporated.	
31	DTSC-28	Figure 1	Step 12	Delete "e.g., urban area vs. non-urban area" within the brackets.	The proposed revision to Figure 1 has been incorporated.	
32	Hargis + Associates, Inc. Fort Mojave Indian Tribe (FMIT) April 19, 2013 Letter FMIT-1	General	No specific text.	The Tribe has asked for and supported this effort to proceduralize the decommissioning of the physical intrusions into the landscape created by the drilling of wells and boreholes. Nevertheless, the alternatives available for the decommissioning procedure remain hurtful as they represent a permanent disfiguration of the hallowed landscape across which the project will be constructed. Basically, once a well/borehole is in place, the options for decommissioning involve either the emplacement of foreign, unnatural materials in place of the materials emplaced for during well construction/operation, or attempting to destroy the original downhole materials. In the process of well destruction, however, an even greater disturbance results. Neither option is attractive to the Tribe. Avoiding further disturbances by not constructing additional wells/boreholes of course is the Tribe's preference, particularly recognizing that the cumulative number of anticipated intrusions will perhaps be 350 or more before the project is over. Nevertheless, considering the reality that more disturbances will be created as a result of the remedy, the Tribe emphasizes that flexibility must be maintained. The decision as to how to proceed with decommissioning will necessarily be case-specific and requires advance discussions and consultations with the Tribes.	Comment noted. PG&E has drafted this SOP in coordination with the agencies and Tribes to meet regulatory requirements and minimize both disturbance and the placement of foreign materials. PG&E anticipates further discussions with and input from the Tribes on future work plans, as well as consultation with Tribes in accordance with the consultation protocol detailed in the Programmatic Agreement.	
33	FMIT-2	Preface	"This document was developed as a direct result of Tribal concerns …	The preface claims that "This document was developed as a direct result of Tribal concerns …" While this is in part true, it should be acknowledged that it would have been necessary to develop and SOP for this purpose for overall project purposes anyway. The Tribal request is consistent with the ARARs identified for this action.	Comment noted. The second sentence of the first paragraph has been edited to read as follows (new text in **bold**): This document was developed**, in part,** as a direct result of Tribal concerns that included dialog regarding future decommissioning activities at the site between PG&E, agencies, and Native American Indian Tribes (Tribes).	No additional comments.
34	FMIT-3	Preface	"… use of displaced site material in the decommissioning process …"	The preface also asserts that the "… use of displaced site material in the decommissioning process …" is based on Tribal input. This again is not a possibility related to Tribal input or preference. Provisions for backfilling certain boreholes with drill cuttings is an option that is commonly exercised, such as for exploratory borings. Nevertheless, the Tribe generally regards the earth materials removed from their natural place as a disturbance and potentially a desecration of the land. This section should probably also reference the preparation of an SOP for the handling and disposition of soils displaced as a result of project activities.	While permits are not required for the decommissioning of exploratory boreholes that do not reach the water table, based on the regulations~~, it is not best industry practice to backfill boreholes with drill cuttings~~. The SOP for the handling of disposition of soils displaced as a result of project activities (Management Protocol for Handling and Disposition of Displaced Site Material) is referenced in Section 1.3. A reference to the use of displaced site material (Section 2.2.3) is already included in the first paragraph of the document.	The response has been revised per the discussion. Changes shown in ~~strikeout~~.
35	FMIT-4	Preface	"exploratory borehole."	The preface offers a definition of an "exploratory borehole." Considering that the shelf life of this document is anticipated to be in excess of three decades, there should be a definition section for this term as well as others used throughout the text, such as "decommissioning," "displaced site material," "sealing material," "filler material," "monitor well," "production or extraction well," "injection well," etc. It is understood that some of these terms do not presently appear in the text, but it is necessary to establish the types of wells/boreholes to which this SOP applies. Perhaps a section further explaining the applicability and scope of this SOP is needed.	The first sentence of the second paragraph of the SOP has been revised as follows (new text in **bold**): This SOP will be used as a reference to guide the development of future work plans required for agency, Tribal, and stakeholder review prior to conducting **all** well and borehole decommissioning tasks **associated with the groundwater remedy**. Based on the revised text definition of well types would only add complexity to the SOP. The definition of "sealing material", "filler material", and "displaced site material" is provided in detail in Sections 2.2.1, 2.2.2, and 2.2.3, respectively.	No additional comments.



Absolute Comment No.	Comment Source/Number	Section	Reference Text	Comment	Response	Summary of June 6, 2014 RTC Discussion
36	FMIT-5	Section 1.0		Both California and Arizona regulatory requirements are outlined in Section 1.0, however, the respective subsections fail to mention provisions for variances within the regulations and guidance documents cited. Additionally, are there any conflicts between the rules promulgated by the two states?	Section 1.2 (Regulatory Information – Arizona [ARARs #48 and #49]) states: *If an alternative method of decommissioning is proposed in lieu of the standard method, further substantive review is performed by ADWR to verify that the proposed methods apply, and whether appropriate fill materials were chosen. A proposal to use an alternative decommissioning method requires an application to ADWR for a variance from the well decommissioning rule (a deviation from the standard decommissioning method).* The technical specifications and procedures for decommissioning well and exploratory boreholes presented in Section 2 of the SOP were developed to be in compliance with both California and Arizona regulations.	No additional comments.
37	FMIT-6	Section 1.3		Section 1.3 discusses CERCLA exemptions for permitting proposed well abandonment. It refers to various discussions with San Bernardino County authorities in this regard and further indicates that, to date, no discussions have been scheduled. It is strongly recommended that PG&E initiate the further discussions with the respective regulatory authorities in both California and Arizona. In fact, it may be advisable to familiarize the regulatory personnel with the context of this particular procedure. The Tribe notes that a preliminary exchange has been made with the Arizona Department of Water Resources (ADWR) through the Arizona Department of Environmental Quality (ADEQ) in regard to the decommissioning of borings proposed in support of exploration for a freshwater source in Arizona. The February 28, 2013, letter from ADWR addresses a proposed variance for this purpose. This seems to indicate ADWR's willingness to work with PG&E in regard to such requests. Accordingly, further liaison with these agencies may be helpful in future situations. If the Tribe can do anything to facilitate such discussions in the interest of its preferences, it stands ready to support such an effort.	PG&E appreciates the Tribe's willingness to assist with discussions with state permitting agencies related to well decommissioning variance options. PG&E anticipates holding these discussions with the agencies when future work plans that involves well decommissioning are being developed so that specific aquifer and well conditions can be contemplated in the context of potential variance options. Further, given that the groundwater remediation project is estimated to last for tens of years, the evaluation of variance options at the time each well decommissioning plan is developed will allow for potential changes in well decommissioning regulations to also be considered.	No additional comments.

Absolute Comment No.	Comment Source/Number	Section	Reference Text	Comment	Response	Summary of June 6, 2014 RTC Discussion
38	FMIT-7	Section 2.0		Section 2.0 discusses general procedures for decommissioning. Considering the subsections that follow, it appears that PG&E is targeting a specific recommendation for the well/borehole decommissioning procedure under consideration. As discussed earlier, the Tribe requires discussion and consultation on a case-by-case basis because of the variation in construction characteristics, location, and other factors that enter into the decision. Accordingly, at the outset of such discussions, the Tribe would need information in regard to the alternative procedures available for each case. This information would facilitate the Tribes' decisions on the long-term fate of the intrusions.	As stated at the beginning Section 2.0, *The information provided in this section is intended to be applicable for wells or boreholes located in either California or Arizona; however, it is assumed that the details included in the specific work plan(s) will be designed in compliance with the appropriate state regulations, and reviewed by the appropriate permitting agency.* To more clearly acknowledge that potential for well decommissioning procedures that would require a variance to the applicable state regulations, the following statement in **bold** has been added to the document after the text referenced above: **In addition, depending on the condition of the aquifer and well(s) subject to decommissioning, potentially applicable variance options that include the minimization of the placement of sealing material should be evaluated with the lead agencies during well decommission work plan development (e.g., Arizona Alternative 4 – variance option).** In addition, the following text has been added to the end of the second paragraph in Section 1.2 (new text in **bold**): *The Well Abandonment Handbook (WAH) provides a standard well decommissioning method to be used for the post-installation of any well or borehole, regardless of the aquifer or vadose zone conditions applicable to the well (Section IV A). In addition, the WAH details five alternative abandonment methods. The five alternatives are for specific vadose zone and aquifer conditions which may include contamination, single or multiple aquifers, or dry wells (Section IV B).* ***For example, Alternative 4, which applies to wells that only penetrate a single aquifer without vertical flow components and no water quality contamination issues, might be applicable to wells in the Topock area that are 8-inches or greater in diameter. A variance option to Alternative 4 permits the use of clean fine sand to fill the well being decommissioned.*** Further, the text included in box number 13 on the decision flow chart presented in Figure 1 has been revised as follows (including text strikeout per comment DTSC-28 and with new text in **bold**): Place sealing/filler material within the borehole or well casing in accordance with regulatory and project-specific guidance**, and any permitting agency-approved variance conditions**.	During the June 6, 2014 subgroup discussion, the Tribes requested that additional information on potential variance conditions that had been previously developed by DTSC be added to this SOP. Please advise if the three schematics included in new Attachment A to this SOP are appropriate and meet the intent of this comment. Thank you.
39	FMIT-8	Section 2.2		The subsections under Section 2.2 do not appear to recognize provisions for variances as discussed earlier. Indeed such scenarios need to be developed and discussions held with the respective regulatory authorities as to the acceptability, need and justifications, and technical rationale for such requests. To this point, the subcommittee has spent time on alternative conceptual designs. This SOP does not include or acknowledge this work.	The subsections under Section 2.2 simply present the different types of materials that can be used for various well or borehole decommissioning scenarios, and not is not intended to evaluate or disqualify variance well decommissioning options. See the response to FMIT-7, which adds text to more clearly acknowledge the potential for variance options.	During the June 6, 2014 subgroup discussion, the Tribes requested that additional information on potential variance conditions that had been previously developed by DTSC be added to this SOP. Please advise if the three schematics included in new Attachment A to this SOP are appropriate and meet the intent of this comment. Thank you.

Absolute Comment No.	Comment Source/Number	Section	Reference Text	Comment	Response	Summary of June 6, 2014 RTC Discussion
40	FMIT-9	Section 2.3		Section 2.3 develops different scenarios. However, these scenarios only relate to standard situations and again do not consider the possibilities of variances. The situations in which variances are appropriate and applicable for consideration need to be developed in this procedure, otherwise those following the procedure will simply adhere strictly to the content. Additionally, this section appears to only consider the California rules, which distinguish between "urban" and "non-urban" areas. This, for example, is not a relevant consideration for the Site and is not referenced in the Arizona guidelines. The design for well decommissioning should not have to be a choice between these two options.	The evaluation of scenarios in Section 2.3 were developed in consideration of both California and Arizona regulations. The distinction between urban and non-urban is subtle and has been clarified as detailed in the response to comment DTSC-16. Both California and Arizona regulations detail specific procedures depending on aquifer and well conditions. California regulations do not reference any variance conditions, while the Arizona regulations reference alternatives to the recommended standard decommissioning procedure and some variance options associated with those alternatives. Variance conditions or potential scenarios that may or may not be approved by regulatory agencies should not be included in an SOP. Also, see comment FMIT-7.	During the June 6, 2014 subgroup discussion, the Tribes requested that additional information on potential variance conditions that had been previously developed by DTSC be added to this SOP. Please advise if the three schematics included in new Attachment A to this SOP are appropriate and meet the intent of this comment. Thank you.
41	FMIT-10	Section 2.4		Section 2.4 discusses "Well Decommissioning Reporting," and specifies that the information be reported in the Topock Well Inventory. Is this information also reported in the Well Registry for the respective states?	Yes, well decommissioning reports are filed with ADWR and California DWR in accordance with the respective well standards for each state. As noted in the first sentence of Section 2.4 (including edit made in accordance with comment DTSC-24): Following completion of well decommissioning tasks, reporting of field activities must be completed in compliance with the lead agencies requirements.	No additional comments.
42	FMIT-11	Figure 1		Figure 1 needs to be changed to reflect the above comments.	See response to comment FMIT-7.	No additional comments.
43	Hualapai Department of Cultural Resources (HDCR) April 24, 2013 Letter HDCR-1			On behalf of the Hualapai Tribe, we feel that is very important to have minimal disturbance in an area that has been under constant environmental change due to the operations of the Topock Compressor Station. As wells and well materials are intrusive, we feel that it is best that all well casings be left in-situ when and if wells are to be decommissioned. This will be the least intrusive and create the least amount of disturbance.	PG&E agrees that the decommissioning procedure which involves the least amount of disturbance that is acceptable to the regulatory agencies should be implemented. The following text in **bold** has been added to Section 2.3.2 (Decommissioning a Well in Place): **This decommissioning option should be utilized whenever acceptable to the regulatory agencies as it represents the field procedures that are least intrusive and create the least amount of disturbance.**	No additional comments.
44	HDCR-2			In the process of decommissioning, Hualapai prefer that natural materials from the immediate vicinity be placed inside the well-casings, and that wells be capped with the least amount of invasive materials, i.e. concrete, steel bolts, etc. As wells come under the decommissioning process, Hualapai would like to be informed about each well that is going to be subject to decommissioning.	See response to comment FMIT-1 regarding consultation with the Tribes on future work plans, and FMIT-7 regarding clarifying information that is being added to the document to acknowledge the potential for variance conditions.	No additional comments.

SOP-B2

Soil Classification and Logging Procedures
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) provides guidance to obtain accurate and consistent descriptions of soil characteristics during soil-sampling operations. The characterization is based on visual examination and manual tests not on laboratory determinations.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan, work plan or event-specific field instructions. Planned borehole depth, proposed well construction/specifications, and field sampling summary table, if available.

2) Applicable project work plan or monitoring plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project* Plan (Procedures Manual), as required.

3) Topock Program Health and Safety Plan (HSP).

4) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available.

5) Blank field notebook.

6) Blank CH2M HILL soil boring log Form D1586.

PREPARATION AND SETUP

1) Review event-specific work plan or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.

2) Initiate field logbook for sampling activity.

3) Review sampling procedures and equipment, and planned sample depths with drilling contractor and field crew.

EQUIPMENT LIST

- Indelible pens
- Tape measure or ruler
- Field logbook
- Spatula
- HCl, 10-percent solution
- Squirt bottle/Spray bottle with water

- Rock- or soil-color chart (e.g., Munsell)
- Grain-size chart
- Hand lens
- Unified Soil Classification System index charts and tables to help with soil classification

PROCEDURES

This section covers several aspects of the soil characterization: instructions for completing the CH2M HILL soil boring log (see Form D1586, Attachment A) and the field logging of soil using the "Unified Soil Classification System and Logging Criteria" (Attachment B).

Instructions for Completing Soil Boring Logs

- Soil boring logs will be completed on field boring log forms. Information collected will be consistent with that required for Form D1586 (attached), a standard CH2M HILL form, or an equivalent form that supplies the same information.
- The information collected in the field to perform the soil characterization is described below.
- Field personnel should review completed logs for accuracy, clarity, and thoroughness of detail. Samples also should be checked to see that information is correctly recorded on both jar lids and labels and on the log sheets.

Heading Information

1) **Boring/Well Number.** Enter the boring/well number. A numbering system should be chosen that does not conflict with information recorded for previous exploratory work done at the site. Number the sheets consecutively for each boring.
2) **Location.** If stationing, coordinates, mileposts, or similar project layout information is available, indicate the position of the boring to that system using modifiers such as "approximate" or "estimated," as appropriate.
3) **Elevation.** Elevation will be determined at the conclusion of field activities.
4) **Drilling Contractor.** Enter the name of the drilling company and the city and state where the company is based.
5) **Drilling Method and Equipment.** Identify the bit size and type, drilling fluid (if used), and method of drilling (e.g., rotary, hollow-stem auger, sonic). Information on the drilling equipment (e.g., CME 55, Mobile B61) should be noted.
6) **Water Level and Date.** Enter the depth below ground surface to the apparent water level in the borehole. The information should be recorded as a comment. If free water is not encountered during drilling or cannot be detected because of the drilling method, this information should be noted. Record date and time of day (for tides, river stage) of each water level measurement.

7) **Date of Start and Finish.** Enter the dates the boring was started and completed. Time of day should be added if several borings are performed on the same day.

8) **Logger.** Enter the first initial and full last name of the logger.

Technical Data

1) **Depth Below Surface.** Use a depth scale that is appropriate for the sample spacing and for the complexity of subsurface conditions.

2) **Sample Interval.** Note the depth at the top and bottom of the sample interval.

3) **Sample Type and Number.** Enter the sample type and number. SS-1 = split spoon, first sample. Number samples consecutively regardless of type. Enter a sample number even if no material was recovered in the sampler.

4) **Sample Recovery.** Enter the length to the nearest 0.1 foot of soil sample recovered from the sampler. Often, there will be some wash or caved material above the sample; do not include the wash material in the measurement. Record recovery in feet.

5) **Soil Description.** The soil classification should follow the format described in the "Field Classification of Soil" subsection below.

6) **Comments.** Include all pertinent observations (changes in drilling fluid color, rod drops, drilling chatter, rod bounce as in driving on a cobble, damaged Shelby tubes, and equipment malfunctions). In addition, note if casing was used, the sizes and depths installed, and if drilling fluid was added or changed. You should instruct the driller to alert you to any significant changes in drilling (changes in material, occurrence of boulders, and loss of drilling fluid). Such information should be attributed to the driller and recorded in this column. Specific information might include:

   - The date and the time drilling began and ended each day.
   - The depth and size of casing and the method of installation.
   - The date, time, and depth of water level measurements.
   - Depth of rod chatter.
   - Depth and percentage of drilling fluid loss.
   - Depth of hole caving or heaving.
   - Depth of change in material.
   - Health and safety monitoring data.
   - Drilling interval through a boulder.

Field Classification of Soil

This section presents the format for the field classification of soil. In general, the approach and format for classifying soils should conform to the "United Soils Classification System and Logging Criteria" (see charts and criteria, Attachment B).

- The Unified Soil Classification System (USCS) is based on numerical values of certain soil properties that are measured by laboratory tests (ASTM D 2487). It is possible, however, to estimate these values in the field with reasonable accuracy using visual-manual procedures (ASTM D 2488). In addition, some elements of a complete soil description, such as the presence of cobbles or boulders, changes in strata, and the relative proportions of soil types in a bedded deposit can be obtained only in the field.
- Soil descriptions should be precise and comprehensive without being verbose. The correct overall impression of the soil should not be distorted by excessive emphasis on insignificant details. In general, similarities rather than differences between consecutive samples should be stressed.

Soil Descriptions

Soil descriptions must be recorded for every soil sample collected. The format and order for soil descriptions should be:

1) Soil name (synonymous with ASTM D 2488 Group Name) with appropriate modifiers. Soil name should be in all capitals in the log, for example "POORLY-GRADED SAND."
2) Group symbol, in parentheses, for example, "(SP)."
3) Color, using Munsell color designation.
4) Particle size distribution (i.e., sand, silt, clay).
5) Moisture content.
6) Relative density or consistency.
7) Soil structure, mineralogy, or other descriptors.

This order follows, in general, the format described in ASTM D 2488.

(1) Soil Name

The basic name of a soil should be the ASTM D 2488 Group Name on the basis of visual estimates of gradation and plasticity. The soil name should be capitalized.

Examples of acceptable soil names are illustrated by the following descriptions:

- A soil sample is visually estimated to contain 15-percent gravel, 55-percent sand, and 30-percent fines (passing No. 200 sieve). The fines are estimated as either low- or highly-plastic silt. This visual classification is SILTY SAND WITH GRAVEL with a Group Symbol of (SM).
- Another soil sample has the following visual estimate: 10-percent gravel, 30-percent sand, and 60-percent fines (passing the No. 200 sieve). The fines are estimated as low-plastic silt. This visual classification is SANDY SILT. The gravel portion is not included in the soil name because the gravel portion was estimated as less than 15 percent. The Group Symbol is (ML).

The gradation of coarse-grained soil (more than 50 percent retained on No. 200 sieve) is included in the specific soil name in accordance with ASTM D 2488.

- There is no need to further document the gradation.
- However, the maximum size and angularity or roundness of gravel and sand-sized particles should be recorded.
- For fine-grained soil (50 percent or more passing the No. 200 sieve), the name is modified by the appropriate plasticity/elasticity term in accordance with ASTM D 2488.

Interlayered soil should each be described starting with the predominant type.

- An introductory name, such as "Interlayered Sand and Silt," should be used.
- In addition, the relative proportion of each soil type should be indicated (see Table 1 for example).

Where helpful, the evaluation of plasticity/elasticity can be justified by describing results from any of the visual-manual procedures for identifying fine-grained soils, such as reaction to shaking, toughness of a soil thread, or dry strength as described in ASTM D 2488.

(2) Group Symbol

The appropriate group symbol from ASTM D 2488 must be given after each soil name.

1) The group symbol should be placed in parentheses to indicate that the classification has been estimated.
2) In accordance with ASTM D 2488, dual symbols (e.g., GP-GM or SW-SC) can be used to indicate that a soil is estimated to have about 10-percent fines.
3) Borderline symbols (e.g., GM/SM or SW/SP) can be used to indicate that a soil sample has been identified as having properties that do not distinctly place the soil into a specific group. Generally, the group name assigned to a soil with a borderline symbol should be the group name for the first symbol. The use of a borderline symbol should not be used indiscriminately. Every effort should be made to first place the soil into a single group.

(3) Color

Soil color is described by comparing the sample with the Munsell Soil Color Charts. The Munsell colors should be used unless directed otherwise by project sampling plans. Instructions for their proper use are in the color charts. The color name shall precede the Munsell color notation (e.g., "yellowish brown, 10 YR 5/4"), with color hue and chroma number parenthetically entered in the borelog description. If no color chip is available, the color should be simply described as primary color (i.e., green, brown, gray, yellow, tan, etc.).

(4) Particle Size Distribution

Within the gravel sizes and the sand sizes, there are further divisions based on particle sizes. Gravel is divided into fine and coarse gravel. Fine-gravel particles (pebbles) are those that would pass through 3/4-inch opening but not a 1/4-inch opening. The fine gravel ranges from pea- to marble-sized. Coarse-gravel particles are those that would pass through a 3-inch opening but not a 3/4-in opening. Common objects of this size are grapes and tennis balls. Cobbles range from 3 inches to 12 inches in size; boulders are larger than 12 inches.

Sand is divided into three sizes: fine, medium, and coarse. Sand passes a No. 4 sieve (approximately 1/4 inch) and is retained in a No. 200 sieve (0.003 inch). Fine-sand particles pass a No. 40 sieve (approximately 1/64 inch) and are retained in the No. 200 (0.003 inch) sieve. These particles are sugar- or table salt-sized. Medium sand passes the No. 10 sieve (approximately 1/2 inch) and retained on the No. 40 sieve. These particles are about the same size as the openings in window screening. Coarse-sand particles would pass a No. 4 sieve (approximately 1/4 inch) and be retained on a No. 10 sieve. Rock salt granules fall in this size range. Sand and gravel particle sizes are illustrated in ASTM D2488 along with percentage estimating charts. The percentages of different grain size fractions are important in the soil type determination.

(5) Moisture Content

Soil moisture content shall be estimated using only the terminology described below:

- Dry - Absence of moisture, dusty, dry to the touch
- Moist - Damp but no visible water
- Wet - Visibly free water, usually sampled from below the water table

(6) Relative Density or Consistency

An estimate of the consistency shall accompany descriptions of all fine-grained soil (silt and clay where more than 50 percent of the material would pass the No. 200 sieve). A pocket penetrometer is the most accurate method for estimating the consistency of fine-grained soils. The table below lists characteristics for soil consistency identification.

Consistency	Unconfined Compressive Strength (tons/ft)[a]	Blows/foot (SPT) [b]	Manual Procedure
Very soft	<0.25	0 – 4	Thumb will penetrate soil more than 1 inch (25 mm).
Soft	0.25 - 0.50	4 – 8	Thumb will penetrate soil about 1 inch (25 mm).
Firm (formerly stiff)	-1.50	8 – 15	Thumb will indent soil about 1/4 inch (6 mm).
Hard	-2.00	15 – 30	Thumb will not indent soil but readily indented with thumbnail.
Very hard	>4.0	> 30	Thumbnail will not indent soil.

Notes:

[a] Pocket penetrometer

[b] Blows/foot is defined as the total number of blows required to drive the second and third 6 inches of penetration (blow counts for the first 6 inches are also noted) while driving an 18-inch SPT sampler with a 140-pound hammer falling a free height of 30 inches. Conversion factors may be applied when the field log information is transferred to the final log when using a sampler other than an SPT (Standard penetrometer) (e.g., S&H or Modified California), or when using different hammer weights and drop. The conversion factor is approximately 0.5 for an S&H sampler with a hammer weight of 140 pounds falling 30 inches.

Descriptions of all coarse-grained soil (sand and gravel where less than 50 percent of the material would pass the No. 200 sieve and 100 percent would pass the 3-inch sieve) shall be

accompanied by an estimate of the density based upon standard penetrometer (SPT) blow counts. The following terminology should be used:

Density	Blows/foot (SPT)
Very loose	< 4
Loose	4-10
Medium dense	10-30
Dense	30-50
Very dense	> 50

(7) Soil Structure, Mineralogy, and Other Descriptors

Discontinuities and inclusions are important and should be described. Such features include joints or fissures, slickensides, bedding or laminations, veins, root holes, and wood debris.

Significant mineralogical information such as cementation, abundant mica, or unusual mineralogy should be described.

Other descriptors may include particle angularity or shape, maximum particle size, hardness of large particles, plasticity of fines, dry strength, dilatancy, toughness, reaction to HCl, and staining, as well as other information such as organic debris, odor, or presence of free product. Criteria for the use of these other descriptions include:

- Structure:
  - Stratified - Alternating layers of varying material or color with layers at least 1/4-inch thick; note thickness.
  - Laminated - Alternating layers of varying material or color with the layers less than 1/4-inch thick; note thickness.
  - Fissured - Breaks along definite planes of fracture with little resistance.
  - Slickensides - Fracture planes appear polished or glossy, often striated.
  - Blocky - Cohesive soil that can be broken down into small angular lumps that resist further breakdown.
  - Lensed - Inclusion of small pockets of different soils, such as lenses of sand within clay; note thickness.
  - Homogeneous - Same color and appearance throughout.
  - Grading - Whether the particles increase or decrease in size toward the top of logged interval.
- Particle Shape:
  - Flat - Particles with width/thickness ratio > 3.
  - Elongated - Particles with length/width ratio > 3.

  - Elongated and flat - Particles meet criteria for both flat and elongated.

- Particle Angularity:
  - Angular - Particles have sharp edges and relatively planar sides with unpolished surfaces.
  - Subangular - Particles are similar to angular description but have rounded edges.
  - Subrounded - Particles have nearly planar sides but have well-rounded corners and edges.
  - Rounded - Particles have smoothly-curved sides and no edges.
- Cementation:
  - Weak - rumbles or breaks with handling or little finger pressure.
  - Moderate - Crumbles or breaks with considerable finger pressure.
  - Strong - Will not crumble or break with finger pressure.
- Reaction with HCl:
  - None - No visible reaction.
  - Weak - Some reaction, bubbles forming slowly.
  - Strong - Vigorous reaction, bubbles forming immediately.

Comments

This section should be reserved for information not pertaining to lithologic description. Sample information including sample identifier, analysis, matrix, and depth interval should be included in the boring log comments. Information related to drilling, such as drilling rate, chatter, and equipment malfunctions should also be well documented in the comments section of the boring log. Additionally interpretations of the lithologic data may also be presented in the comments section. Examples of this include "transition between Older Alluvium and Fanglomerate," "paleosol horizon B," or "conductive zone."

Recovery

Recovery data are entered along the left side of the boring log. Enter the length of retrieved core to the nearest 0.1 foot of sample recovered and record the value in feet. Do not count slough or caved material as part of the total recovered length of core. Record total length and percent of sample recovered. If using a 5-foot sample barrel, multiply the total length by 2 and 100 to get a percentage number. Similarly, if using a 2.5-foot sampler, multiply by 4 and 100 to get the percent recovery.

Backfilling

When a boring is completed and the water level measured, the boring shall be backfilled to ground surface according to applicable regulations. The destruction of the hole shall be noted on the log. Borehole destruction should follow SOP 28 *Soil Boring Abandonment*

Attachments

- Unified Soil Classification System and Logging Criteria

Key Checks and Preventive Maintenance

Check entries to the soil boring log and field logbook in the field; because the samples will be disposed of, confirmation and corrections cannot be made later. Check that sample numbers and intervals are properly specified. Check that drilling and sampling equipment is decontaminated using the procedures defined in SOP *Decontamination of Drilling Rigs and Equipment*.

NOTE:
Percentages are based on estimating amounts of fines, sand, and gravel to the nearest 5%
(After ASTM Designation D2488 Standard Test Method for Classification of Soils for Engineering Purposes)

Flow Chart for Classifying Fine-grained Soil
(50% or more passing No. 200 sieve)
Field Guide for Soil Classification and Logging Procedures

similar, the material is classified as poorly graded or well sorted. If fines represent less than 5 percent of the total mass, the symbol SP is used for a poorly-graded sand and SW for a well graded sand. If silts and/or clays exceed 12 percent, the symbols GC, SC, GM, and SM are used, respectively.

If the silts and clays are between 5 to 12 percent of the total sample weight, a dual classification with two group symbols is used. The first symbol is GW, GP, SW, or, SP, and the second is GC, GM, SC, or SM. The group name corresponds to the first group symbol plus the modifying words "with clay" or "with silt" to indicate the plasticity characteristics. If the fines plot on the CL-ML range on the plasticity chart (Figure 2-2), possible dual classification group names are:

GW-GM	well graded gravel with silt
GW-GC	well graded gravel with clay
GP-GM	poorly graded gravel with silt
GP-GC	poorly graded gravel with clay
SW-SM	well graded sand with silt
SW-SC	well graded sand with clay
SP-SM	poorly graded sand with silt
SP-SC	poorly graded sand with clay

If silts and clays exceed 12 percent of the total weight of sample, the modifiers "M" and "C" are used, respectively. If a sand or gravel has more than 15 percent of the other coarse-grained constituent, the words "with gravel" or "with sand" are added to the group name. A flow chart for classifying coarse-grained soils is presented in Figure 2-3.

2.2 Fine-grained Soils

Particles passing the No. 200 sieve are silts (M) and clays (C). These soils must undergo testing in order to differentiate between them. Typical tests used are: dry strength, dilatancy, toughness, and plasticity. These terms are further discussed in Tables 2-2 through Table 2-6. Silts have little or no dry strength when dry, while clays have considerable dry strength. Dry strength, dilatancy, and toughness are also used to identify the fine-grained fraction of coarse-grained soils.

TABLE 2-2
Criteria for Describing Dry Strength

Description	Criteria
None	The dry specimen crumbles into powder with the mere pressure of handling.
Low	The dry specimen crumbles into powder with some finger pressure.
Medium	The dry specimen breaks into pieces or crumbles with considerable finger pressure.
High	The dry specimen cannot be broken with finger pressure. The specimen will break into pieces between the thumb and a hard surface.
Very high	The dry specimen cannot be broken between the thumb and a hard surface.

TABLE 2-3
Criteria for Describing Dilatancy

Description	Criteria
None	There is no visible change in the specimen.
Slow	Water appears slowly on the surface of the specimen during shaking, and does not disappear, or disappears slowly upon squeezing.
Rapid	Water appears quickly on the surface of the specimen during shaking, and disappears quickly upon squeezing.

TABLE 2-4
Criteria for Describing Toughness

Description	Criteria
Low	Only slight pressure is required to roll the thread near the plastic limit. The thread and the lump are weak and soft.
Medium	Medium pressure is required to roll the thread to near the plastic limit. The thread and the lump have medium stiffness.
High	Considerable pressure is required to roll the thread to near the plastic limit. The thread and the lump have very high stiffness.

TABLE 2-5
Identification of Inorganic Fine-grained Soils from Manual Tests

Soil Symbol	Dry Strength	Dilatancy	Toughness
ML	None to low	Slow to rapid	Low or thread cannot form
CL	Medium to high	None to slow	Medium
MH	Low to medium	None to slow	Low to medium
CH	High to very high	None	High

TABLE 2-6
Criteria for Describing Plasticity

Description	Criteria
Nonplastic	A 1/8-inch (3-mm) thread cannot be rolled at any water content.
Low	The thread can barely be rolled, and the lump cannot be formed when drier than the plastic limit.
Medium	The thread is easy to roll, and not much time is required to read the plastic limit. The thread cannot be re-rolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit.
High	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be re-rolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier that the plastic limit.

Fine-grained soils are accurately determined in the laboratory using the Atterberg Limits test. This test include liquid limit, plastic limit, and plasticity index measurements. The liquid limit is the water content of a soil at the point of transition from a plastic to a liquid state. The plastic limit is the water content of a soil at the point of transition from a semisolid to a plastic state. The plasticity index is the difference between the liquid limit and the plastic limit.

As shown in the Figure 2-2, five fields have been identified. These include:

- Silty Clays (CL), Organic Silts (OL) or Organic Silty Clays (OL) of low plasticity
- Fat Clays (CH) and Organic Clays (OH)
- Inorganic Silts (ML) and Organic Silty Clays (OL) of low plasticity
- Silts (MH) and Organic Clays (OH) of a high plasticity
- Silty Clays to Clayey Silt (CL-ML) of low plasticity

Fine-grained soils with a liquid limit > 50 are modified by the symbol H (MH or CH), and those with a liquid limit < 50 are modified by the symbol L (ML or CL). Fine-grained soils containing 30 percent or more coarse-grained fraction should be modified by descriptive terms, such as "gravelly" or "sandy." If the coarse fraction is between 15 and 30 percent, the words" with sand and/or gravel" should be added to the group name. A flow chart for classifying fine-grained soils is presented in Figure 2-4.

2.3 Organic Soils

To classify organic soils, the percentage organic material present in the soil as well as the non-organic fines must be estimated. When the organic content ranges from 18 to 36 percent, the material is an organic clay or an organic silt, depending on the nature of the fine-grained constituents. When the organic content is between 36 and 90 percent, the material is designated a muck or peaty muck (OL or OH). A flow chart for classifying organic soil is presented in Figure 2-4. The term "peaty" is added if the organic remains are

SOP-B3

Borehole Sampling and Logging of Soil Borings
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) provides guidance for sample collection from soil borings during the drilling process, and proper documentation necessary. Detailed guidance for sample collection, preservation and handling is provided in Section 4.0 of the site Quality Assurance Project Plan (QAPP) and in the Topock Program *Sampling, Analysis, and Field Procedures Manual* (Procedures Manual). SOP-B2 provides detailed guidance for soil characterization and logging.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP), work plan or event-specific field instructions. Planned borehole depth, proposed well construction/specifications, and field sampling summary table, if available.

2) Applicable project work plan or monitoring plan. Refer to the Procedures Manual and QAPP, as required.

3) Topock Program Health and Safety Plan (HSP).

4) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available.

5) Blank sampling log and field notebook.

PREPARATION AND SETUP

1) Review event-specific work plan or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.

2) Initiate field logbook for sampling activity.

3) Review sampling procedures and equipment, and planned sample depths with drilling contractor and field crew.

Equipment List

- Field logbook
- Borehole log
- Blue or black waterproof or permanent ink pens
- Trash bags
- Plastic sandwich bags
- Paper towels

- Stainless steel sampling equipment (provided by driller)
- Decontamination equipment (Alconox® solution in spray bottle, brushes, buckets, rinse water spray bottle)
- Soil sample containers appropriate for sample analysis and preservation as called for in SAP and QAPP (glass jars, brass sleeves, Encore® containers, sandwich bags, etc.)
- Soil sampling equipment not provided by driller (spatula or putty knife, stainless steel compositing bowl, hand auger, etc.)
- Groundwater sample containers appropriate for sample analysis and preservation as called for in SAP and QAPP (glass jars, VOA vials, plastic jars, etc.)
- Groundwater sample equipment not provided by driller (pump, filters, tubing, power supply, etc.)
- Water quality meters
- Water level indicator
- Distilled water
- Coolers with ice
- Protective waterproof gloves (nitrile or latex)

GUIDELINES

Soil Boring Logs Documentation

Soil boring logs will be completed on the soil boring log forms during the drilling activities at the time of the logging and soil descriptions. Information collected will be consistent with the standard CH2M HILL form (See SOP-B2 attachment A). Sample data may also be documented in the comments section of the boring log.

Items documented on the borehole log include:

1) **Sample Interval:** The top and bottom depth of each sample run should be recorded on the borelog. Sampling includes samples collected for analysis as well as core retrieved for logging purposes.

2) **Sample Type and Number:** Enter the sample type and number consistent with the sampling and analysis plan at the correct depth intervals. An "x" should be placed across the vertical interval where the environmental soil, grab groundwater, or geotechnical sample was collected.

3) **Sample Recovery:** Enter the length of retrieved core to the nearest 0.1 foot of sample recovered, and record the value in feet. Do not count slough or caved material as part of the total recovered length of core. Record total length and percent of sample recovered. If using a 5-foot sample barrel, multiply the total length by 2 and 100 to get a percentage number. Similarly, if using a 2.5-foot sampler, multiply by 4 and 100 to get the percent recovery.

4) **Sampling:** Sampling difficulties shall be noted. Disturbed samples shall be noted on the log as well as the sample recovery. The top of the sample shall be marked on the container.

5) **Water Levels:** Water-level measurements, where groundwater is encountered, are required for each boring. Changes in soil moisture shall be noted and, if there is no water encountered, a note to that effect shall be included on the borehole log. The date and time of water-level measurements shall be documented.

At a minimum, sample identifiers (IDs) should be noted on boring logs at the depth collected. When time and space allows, a summary of analytical sample information can be included. When inclusion of these data prevents documentation of drilling information, sample data should be omitted in order to document drilling.

Borehole Sampling by Drilling—General Procedure

Split-spoon sampling procedures shall be executed in accordance with American Society for Testing and Materials (ASTM) D1586, "Standard Method for Penetration Test and Split-barrel Sampling of Soils" (ASTM 1984). California (2-inch) or Modified California (2.5-inch) split-barrel samplers may also be used.

1) The split-spoon or split-barrel sampler shall be advanced to the top of the sampling interval using a wire-line or sample rods such as A or AW. The larger-diameter samplers may be fitted with three 6-inch-long stainless-steel sleeves. The sampler shall be driven 18 inches or to refusal, with a 140-pound hammer dropping repeatedly 30 inches. Refusal shall be defined as requiring 50 blows with the hammer to advance the sampler less than 6 inches.

2) The number of blows required to drive the sampler each 6 inches shall be recorded on the borelog.

3) As the sample tubes are disassembled, an organic vapor monitor probe shall be inserted into the gap between two sample liners, and the liner exhibiting the highest reading shall be selected for analysis.

4) In general, the middle liner is collected for laboratory analysis, and 10 percent of the bottom liners are collected for quality assurance testing. A sample of the soil in the top liner typically is placed in a re-sealable plastic bag or 8-ounce clear glass jar and left in the sun for approximately 15 minutes to allow any volatile organic compounds (VOC) to volatilize.

5) After the 15 minute volatilization period, the soil vapor in the plastic bag is then measured for VOCs by taking a reading of the headspace. Background VOCs for the bag are determined by monitoring the air in an empty bag.

6) Results of the organic vapor monitoring are recorded on the boring log.

7) Small portions of soil at the ends of the sleeve are scraped off for classification.

Borehole Sampling by Drilling—Split Spoon Sampling

1) Samples collected for laboratory analysis using split spoon sampling device will be separated and transferred from the split-spoon halves into sample jars by clean stainless-steel utensils.

2) Samples for VOCs will be separated and collected first, followed by semivolatile organic compounds samples.

3) For VOC samples, avoid mixing the soil before sampling and sample directly from the split spoon. See SOPs for guidance on homogenizing soil samples and for VOC sampling using EnCore samplers, respectively.

Borehole Sampling by Drilling—Direct-push Sampling

1) Samples collected for laboratory analysis using a direct-push sampling drill rig will be handled by either opening the tube and placing the soil in sample jars or cutting the acetate tube and submitting it the laboratory directly.

2) For samples that will be removed from the acetate tube, the tube will be cut open longitudinally using a double-bladed razor knife.

   - Soil will be inspected and logged prior to removal of soil samples.
   - A short section of soil will be removed from the acetate sleeve using a stainless-steel utensil, homogenized in a clean stainless-steel bowl, and placed in sample jars.
   - Soil collected for VOC analysis will be sampled directly from the split acetate sleeve using EnCore samplers.

3) Alternatively, a short (6-inch) length of liner will be cut from the acetate sleeve and collected directly for laboratory analysis.

   - The section of acetate liner will be removed, capped with Teflon sheeting and plastic end caps at both ends, and taped with clear label or packing tape.
   - Labels shall be affixed to the liners with job designation, time, boring number, sample depth interval, sample number, date sampled, and the initials of the sampler clearly marked.
   - The samples shall then be enclosed in a plastic bag and stored in a cooler maintained at 4°C.
   - Sample information shall be placed on the chain-of-custody, the borelog, and the field logbook. All samples shall be handled in accordance with *Chain of Custody Procedures*.

Borehole Sampling by Drilling—Split-barrel Sampling

Soil samples can also be collected using a 3-foot-long or 5-foot-long split-barrel sampler. The split-barrel sampler is similar to the split-spoon sampler that is used to hold steel or brass sampling sleeves, but the split-barrel sampler typically is not used to hold sample sleeves.

1) The sampler is lowered to the base of the drill bit and is advanced slightly ahead of the drill bit and augers (or conductor casing). The weight of the drill string and sample barrel along with the drilling and cutting action of the drill bit advances the face of the split-barrel sampler into the formation.

2) Once the desired depth interval is reached, the split-barrel sampler is retrieved using a cable or tool steel sections.

3) The retrieved sampler is unscrewed, and one or both halves are laid on the sample table. The soil typically will form a continuous column of soil in one of the split-barrel halves.

4) The soil column is split longitudinally for soil descriptions using a putty knife or spatula.

5) Samples for VOC analysis are collected immediately directly from the soil column.

6) Other soil samples are collected after the core section has been described and logged. The soil is described following the procedures in the following sections.

Groundwater Sampling

1) Groundwater samples can be collected by hydropunch by bailer or by pumping from an isolated zone. Collection of groundwater by bailing is not an accurate method of collection depth discrete groundwater samples, as the zone sampled is poorly isolated.

2) Hydropunch samples are collected below the bit of the drill stem, in relatively undisturbed soil zone. This method of sample collection may be difficult in fine-textured soils and in very rocky soils. To collect these samples, a point is driven below the depth of the drill bit, then a screen zone is opened within this point and water allowed to flow in. The hydropunch tool must be decontaminated between samples.

Groundwater can also be collected from the open or cased borehole with a bailer. A disposable or decontaminated stainless-steel bailer is lowered into the boring, and water is collected. This method is preferable for collection of groundwater from the water table. Attempts can be made to collect discrete groundwater samples beneath the water table; however, the boring must be cased with watertight, stainless-steel pipe, and the boring must be evacuated prior to collection of samples.

Alternatively, discrete groundwater samples can be collected by isolating a zone with casing and packers. To collect these samples, the borehole is first advanced to the depth at which a sample is required. Then casing is advanced to within 20 feet of the sample zone. Next, a pump and packers are lowered into the hole. The zone from which samples are to be collected is isolated with a packer, and water is pumped directly from the target zone.

Sample Handling

Sample preservation and sampling procedures are detailed in Section 4.0 of the QAPP. Additional information is provided in the Procedures Manual and in the appropriate SAP.

KEY CHECKS AND ITEMS

- Check entries to the soil boring log and field logbook in the field during sampling activities because the samples will be disposed at the end of the fieldwork, confirmation and corrections cannot be made later.

- Check that the sample numbers and intervals are properly specified.
- Ensure that drilling equipment is decontaminated prior to the beginning of work and between each borehole.
- All materials generated during sampling (debris, PPE, decontamination liquids, etc.) will be placed in 55-gallon drums or roll-off bins for storage pending analysis and disposal off site, as outlined in SOP 39, Standard of Practice H-83, and Appendix D of the project *Soil and Groundwater Management Plan*.

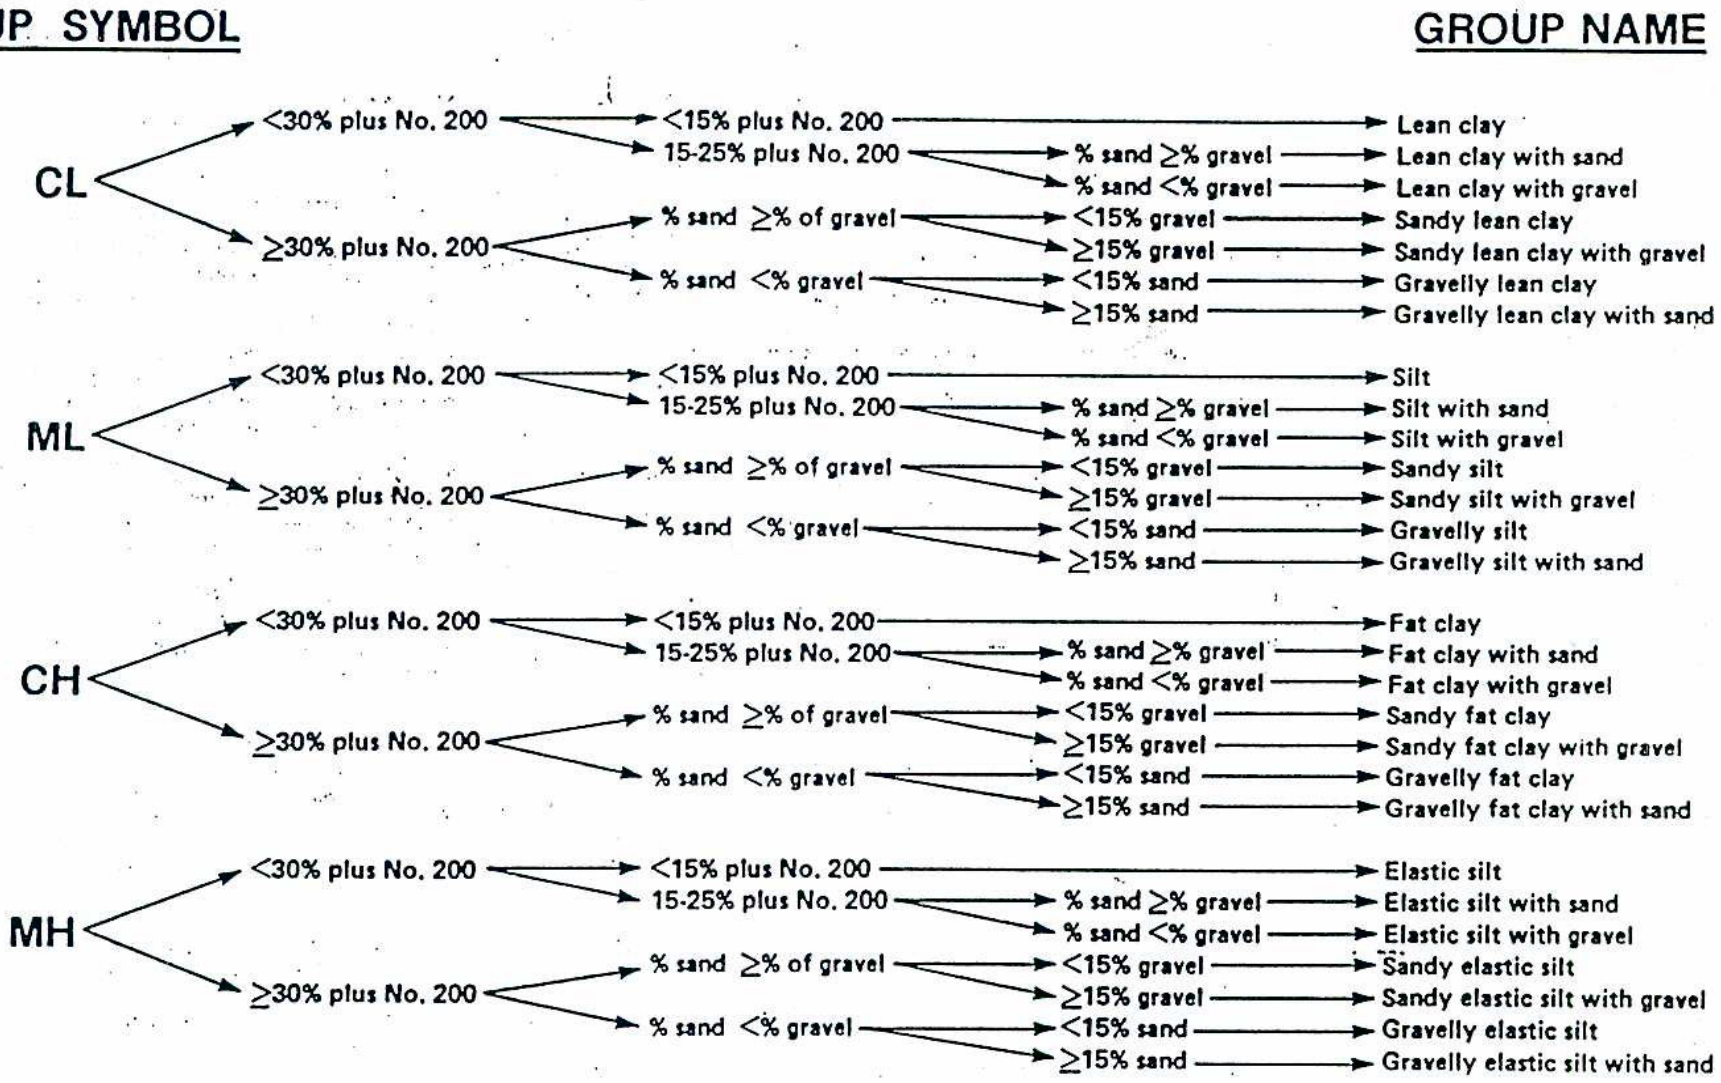
Unified Soil Classification System and Logging Criteria

GENERAL SOIL CATEGORIES			SYMBOLS		TYPICAL SOIL TYPES
COARSE GRAINED SOILS More than half is larger than No. 200 sieve	GRAVEL More than half coarse fraction is larger than No. 4 sieve size	Clean Gravel with little or no fines	GW		Well Graded Gravel, Gravel-Sand Mixtures
			GP		Poorly Graded Gravel, Gravel-Sand Mixtures
		Gravel with more than 12% fines	GM		Silty Gravel, Poorly Graded Gravel-Sand-Silt Mixtures
			GC		Clayey Gravel, Poorly Graded Gravel-Sand-Clay Mixtures
	SAND More than half coarse fraction is smaller than No. 4 sieve size	Clean sand with little or no fines	SW		Well Graded Sand, Gravelly Sand
			SP		Poorly Graded Sand, Gravelly Sand
		Sand with more than 12% fines	SM		Silty Sand, Poorly Graded Sand-Silt Mixtures
			SC		Clayey Sand, Poorly Graded Sand-Clay Mixtures
FINE GRAINED SOILS More than half is smaller than No. 200 sieve	SILT AND CLAY Liquid Limit Less than 50%		ML		Inorganic Silt and Very Fine Sand, Rock Flour, Silty or Clayey Fine Sand, or Clayey Silt with Slight Plasticity
			CL		Inorganic Clay of Low to Medium Plasticity, Gravelly Clay, Sandy Clay, Silty Clay, Lean Clay
			OL		Organic Clay and Organic Silty Clay of Low Plasticity
	SILT AND CLAY Liquid Limit Greater than 50%		MH		Inorganic Silt, Micaceous or Diatomaceous Fine Sandy or Silty Soils, Elastic Silt
			CH		Inorganic Clay of High Plasticity, Fat Clay
			OH		Organic Clay of Medium to High Plasticity, Organic Silt
HIGHLY ORGANIC SOILS			PT		Peat and Other Highly Organic Soils



UNIFIED SOIL CLASSIFICATION SYSTEM

NOTE:
Percentages are based on estimating amounts of fines, sand, and gravel to the nearest 5%
(After ASTM Designation D2488 Standard Test Method for Classification of Soils for Engineering Purposes)

Flow Chart for Classifying Fine-grained Soil
(50% or more passing No. 200 sieve)
Field Guide for Soil Classification and Logging Procedures

similar, the material is classified as poorly graded or well sorted. If fines represent less than 5 percent of the total mass, the symbol SP is used for a poorly-graded sand and SW for a well graded sand. If silts and/or clays exceed 12 percent, the symbols GC, SC, GM, and SM are used, respectively.

If the silts and clays are between 5 to 12 percent of the total sample weight, a dual classification with two group symbols is used. The first symbol is GW, GP, SW, or, SP, and the second is GC, GM, SC, or SM. The group name corresponds to the first group symbol plus the modifying words "with clay" or "with silt" to indicate the plasticity characteristics. If the fines plot on the CL-ML range on the plasticity chart (Figure 2-2), possible dual classification group names are:

GW-GM	well graded gravel with silt
GW-GC	well graded gravel with clay
GP-GM	poorly graded gravel with silt
GP-GC	poorly graded gravel with clay
SW-SM	well graded sand with silt
SW-SC	well graded sand with clay
SP-SM	poorly graded sand with silt
SP-SC	poorly graded sand with clay

If silts and clays exceed 12 percent of the total weight of sample, the modifiers "M" and "C" are used, respectively. If a sand or gravel has more than 15 percent of the other coarse-grained constituent, the words "with gravel" or "with sand" are added to the group name. A flow chart for classifying coarse-grained soils is presented in Figure 2-3.

2.2 Fine-grained Soils

Particles passing the No. 200 sieve are silts (M) and clays (C). These soils must undergo testing in order to differentiate between them. Typical tests used are: dry strength, dilatancy, toughness, and plasticity. These terms are further discussed in Tables 2-2 through Table 2-6. Silts have little or no dry strength when dry, while clays have considerable dry strength. Dry strength, dilatancy, and toughness are also used to identify the fine-grained fraction of coarse-grained soils.

TABLE 2-2
Criteria for Describing Dry Strength

Description	Criteria
None	The dry specimen crumbles into powder with the mere pressure of handling.
Low	The dry specimen crumbles into powder with some finger pressure.
Medium	The dry specimen breaks into pieces or crumbles with considerable finger pressure.
High	The dry specimen cannot be broken with finger pressure. The specimen will break into pieces between the thumb and a hard surface.
Very high	The dry specimen cannot be broken between the thumb and a hard surface.

TABLE 2-3
Criteria for Describing Dilatancy

Description	Criteria
None	There is no visible change in the specimen.
Slow	Water appears slowly on the surface of the specimen during shaking, and does not disappear, or disappears slowly upon squeezing.
Rapid	Water appears quickly on the surface of the specimen during shaking, and disappears quickly upon squeezing.

TABLE 2-4
Criteria for Describing Toughness

Description	Criteria
Low	Only slight pressure is required to roll the thread near the plastic limit. The thread and the lump are weak and soft.
Medium	Medium pressure is required to roll the thread to near the plastic limit. The thread and the lump have medium stiffness.
High	Considerable pressure is required to roll the thread to near the plastic limit. The thread and the lump have very high stiffness.

TABLE 2-5
Identification of Inorganic Fine-grained Soils from Manual Tests

Soil Symbol	Dry Strength	Dilatancy	Toughness
ML	None to low	Slow to rapid	Low or thread cannot form
CL	Medium to high	None to slow	Medium
MH	Low to medium	None to slow	Low to medium
CH	High to very high	None	High

TABLE 2-6
Criteria for Describing Plasticity

Description	Criteria
Nonplastic	A 1/8-inch (3-mm) thread cannot be rolled at any water content.
Low	The thread can barely be rolled, and the lump cannot be formed when drier than the plastic limit.
Medium	The thread is easy to roll, and not much time is required to read the plastic limit. The thread cannot be re-rolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit.
High	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be re-rolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier that the plastic limit.

Fine-grained soils are accurately determined in the laboratory using the Atterberg Limits test. This test include liquid limit, plastic limit, and plasticity index measurements. The liquid limit is the water content of a soil at the point of transition from a plastic to a liquid state. The plastic limit is the water content of a soil at the point of transition from a semisolid to a plastic state. The plasticity index is the difference between the liquid limit and the plastic limit.

As shown in the Figure 2-2, five fields have been identified. These include:

- Silty Clays (CL), Organic Silts (OL) or Organic Silty Clays (OL) of low plasticity
- Fat Clays (CH) and Organic Clays (OH)
- Inorganic Silts (ML) and Organic Silty Clays (OL) of low plasticity
- Silts (MH) and Organic Clays (OH) of a high plasticity
- Silty Clays to Clayey Silt (CL-ML) of low plasticity

Fine-grained soils with a liquid limit > 50 are modified by the symbol H (MH or CH), and those with a liquid limit < 50 are modified by the symbol L (ML or CL). Fine-grained soils containing 30 percent or more coarse-grained fraction should be modified by descriptive terms, such as "gravelly" or "sandy." If the coarse fraction is between 15 and 30 percent, the words" with sand and/or gravel" should be added to the group name. A flow chart for classifying fine-grained soils is presented in Figure 2-4.

2.3 Organic Soils

To classify organic soils, the percentage organic material present in the soil as well as the non-organic fines must be estimated. When the organic content ranges from 18 to 36 percent, the material is an organic clay or an organic silt, depending on the nature of the fine-grained constituents. When the organic content is between 36 and 90 percent, the material is designated a muck or peaty muck (OL or OH). A flow chart for classifying organic soil is presented in Figure 2-4. The term "peaty" is added if the organic remains are

SOP-B5

Decontamination of Personnel and Equipment, Well Drilling, and Subsurface Sampling and Investigations
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure provides general guidelines for the decontamination of personnel, sampling equipment, and monitoring equipment used in potentially-contaminated areas.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP).
2) Applicable project work plan or monitoring plan, which includes a health and safety plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project Plan*, as required.

PREPARATION AND SETUP

1) Initiate field log sampling book for activity.
2) Inspect all equipment necessary to carry out activities detailed in event-specific SAP.
3) Review decontamination guidelines for equipment necessary to carry out activities.

Equipment List

- Demonstrated analyte-free, deionized water (specifically, ASTM Type II water)
- Distilled water
- Potable water; must be from a municipal water supplier, otherwise an analysis must be run for appropriate volatile and semivolatile organic compounds and inorganic chemicals (e.g., Target Compound List and Target Analyte List chemicals)
- 2.5% (W/W) Liquinox® and water solution
- Large plastic pails or tubs for Liquinox® and water, scrub brushes, spray or squirt bottles for Liquinox® solution, and distilled or deionized water, plastic bags, and sheets
- Department of Transportation (DOT)-approved 55-gallon drum for disposal of waste
- Nitrile or latex gloves
- Decontamination pad and steam cleaner/high pressure cleaner for large equipment

GUIDELINES

Personnel Decontamination

Decontamination should be performed after completion of tasks whenever personnel come in contact with contaminated (or potentially-contaminated) soils or fluids. Full or emergency decontamination should be performed when contaminant concentrations are not known and when potentially-contaminated fluids come into contact with skin beneath clothing, eyes, nose, or ears.

Procedures for full/emergency decontamination are to:

1) Remove contaminated clothing.

2) Step into containment area (decontamination pad or large pail).

3) Rinse away fluids and soil.

4) Wash skin with Liquinox® solution in such a way as to not abrade skin. (Liquinox® solution should be made with potable water and sufficient detergent to create foamy suds.) Eyes and mucus membranes in contact with contaminants must be washed with eye wash or drinking water continuously for at least 15 minutes.

5) Rinse with potable water.

6) If no other clothes are available, wash affected clothes in Liquinox® solution prior to donning. If other clothes are available, contaminated clothes may be isolated for later wash or disposed of along with personal protective equipment (PPE).

7) Any PPE worn (including disposable latex booties, gloves, and disposable coveralls) should be discarded into DOT-approved 55-gallon drum located at the MW-20 bench.

8) Dispose of wash and rinseate water in an appropriate container with other chromium contaminated fluids. These fluids may be taken to the MW-20 bench for treatment or to a Baker® tank within the PG&E facility for containerization.

9) Replace all appropriate clothing and PPE before resuming work or departing site.

Moist soil or water containing known concentrations of hexavalent chromium less than 50 parts per billion that comes into contact with hands need not require full decontamination. Dry soil containing chromium that comes into contact with clothing can also be decontaminated in an abbreviated manner.

Daily decontamination and minor exposure contact decontamination procedures are to:

1) Wash hands and skin that comes in contact with soils or water that may contain small concentrations of chromium as soon as possible after contact. Wash with Liquinox® solution and rinse with potable water.

2) If contaminated soil or water contacts hands through hole or over lip of gloves, remove gloves and wash hands thoroughly before donning new gloves.

3) Discard gloves into DOT-approved 55-gallon drum located on the MW-20 bench at the end of the day or event.

4) Remove coveralls or dry soils from clothing before leaving site. Clothing contaminated by moist soil or water containing hexavalent chromium should be removed and promptly washed.

5) At the end of the work day, shower entire body, including hair, either at the work site or at hotel.

Sampling Equipment Decontamination—Groundwater Sampling Pumps

Sampling pumps are decontaminated after each use as follows:

1) Don waterproof (nitrile or latex) gloves.

2) Run pump and reusable tubing through with Liquinox® solution (made with potable water) so that the pump and all portions or the tubing have been flushed with the solution for at least 30 to 60 seconds. More time is required if water is present in the tubing. If unsure, run for 2.5 minutes. Outside of the tubing should also be submerged and washed in the solution.

3) Run pump and reusable tubing through first rinse (with potable or distilled water) so that the pump and all portions or the tubing have been flushed with the solution for at least 60 seconds. More time is required if any suds are present in the pump or tubing.

4) Run pump and reusable tubing through second rinse (with distilled water) so that the pump and all portions or the tubing have been flushed with the solution for at least 30 seconds. More time is required if water from first rinse is present in tubing.

5) Equipment blank samples may be taken at this point using ASTM Type II water or distilled water as required by laboratory.

Sampling Equipment Decontamination—Other Equipment

Reusable sampling equipment is decontaminated after each use as follows:

1) Don nitrile or latex gloves.

2) Wash all equipment surfaces that contacted the potentially contaminated soil/water with Liquinox® solution (made from potable water). Water quality meters that are not placed within wells should not be washed with detergent, as this will degrade sensors; these meters should be double-rinsed. Any portion of equipment that is placed inside wells (including cables and pipe) and that comes in contact with moisture should be washed with detergent.

3) Rinse equipment and supplies with potable water, if the equipment is not used to collect groundwater or soil samples. Equipment used to collect samples or take water quality parameters should be rinsed with distilled water.

4) Air dry or towel dry with paper towels.

5) Collect all rinseate and dispose of in Baker® tank within the PG&E facility or Denbeste® tank at the MW-20 bench.

6) Decontamination materials (e.g., plastic sheeting, tubing, etc.) that have come in contact with used decontamination fluids or sampling equipment will be disposed of in DOT-approved 55-gallon drums if highly contaminated. If not contaminated, equipment can be washed and disposed of in trash.

7) Preserved bottles may need to be washed before being packed or handed without gloves. The outsides of filled bottles should be rinsed and toweled dry to prevent contact with strong acids or based.

Heavy Equipment and Tools

Heavy equipment such as drilling rigs, drilling rods/tools, and the backhoe will be decontaminated upon arrival at the site and between locations as follows:

1) Set up a decontamination pad in designated area.

2) Steam clean heavy equipment until no visible signs of dirt are observed. This may require wire or stiff brushes to dislodge dirt from some areas.

KEY CHECKS AND ITEMS

- Clean with solutions of Liquinox® and potable water. Rinse with distilled or deionized water if equipment is used to collect samples or water readings; otherwise, rinse with potable water.
- Equipment placed within wells should be thoroughly decontaminated and before being placed in a well. All potions of this equipment that come into contact with moisture should be decontaminated.
- Decontaminate filled sample bottles before relinquishing them to anyone.

SOP-B7

Homogenization of Soil and Sediment Samples
Standard Operating Procedures for PG&E Topock Program

The homogenization of soil and sediment samples is performed to minimize any bias of sample representativeness introduced by the natural stratification of constituents within the sample. Standard techniques for soil and sediment homogenization and equipment are provided in this SOP. These procedures do not apply to aliquots collected for volatile organic compounds (VOCs) or field gas chromography screening; samples for these analyses should NOT be homogenized.

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP).
2) Applicable project work plan or monitoring plan. Refer to Topock Program *Sampling, Analysis, and Field Procedures Manual* and *Quality Assurance Project Plan,* as required.
3) Topock Program Health and Safety Plan (HSP).
4) Previous sampling logs.
5) Blank sampling logs and field notebook.

PREPARATION AND SETUP

1) Review event-specific SAP or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Initiate field logbook for sampling activity.

EQUIPMENT LIST

- Sample containers
- Stainless-steel spoons or spatulas
- Stainless-steel pans
- Phthalate-free gloves

PROCEDURES

Sample Homogenization

1) Soil and sediment samples to be analyzed for semivolatiles, pesticides, polychlorinated biphenyls, metals, cyanide, or field x-ray fluorescence screening should be homogenized in the field.
2) After a sample is taken, a stainless-steel spatula should be used to remove the sample from the split spoon or other sampling device. The sampler should not use fingers to do this, as gloves may introduce organic interferences into the sample.

3) Samples for VOCs should be taken immediately upon opening the spoon and should not be homogenized.

4) Prior to homogenizing the soil or sediment sample, any rocks, twigs, leaves, or other debris should be removed from the sample.

5) The sample should be placed in a decontaminated stainless-steel pan and thoroughly mixed using a stainless-steel spoon. The soil or sediment material in the pan should be scraped from the sides, corners, and bottom, rolled into the middle of the pan, and initially mixed.

6) The sample should then be quartered and moved to the four corners of the pan. Each quarter of the sample should be mixed individually, then rolled to the center of the pan and mixed with the entire sample again.

Equipment Decontamination

1) All stainless-steel spoons, spatulas, and pans must be decontaminated following procedures specified in SOP *Decontamination of Personnel and Equipment* prior to homogenizing the sample.

2) A composite equipment rinse blank of homogenization equipment should be taken each day it is used.

SOP-B9

Drilling--Sonic Method
Standard Operating Procedures for PG&E Topock Program

REQUIRED DOCUMENTS

1) Event-specific sampling and analysis plan (SAP), Work Plan or event-specific field instructions. Planned borehole depth, proposed well construction/specifications, and field sampling summary table, if available.

2) Applicable project work plan or monitoring plan. Refer to Topock Program Sampling, Analysis, and Field Procedures Manual and QAPP (Procedures Manual), as required.

3) Topock Program Health and Safety Plan (HSP)

4) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available

5) Blank sampling log and field notebook

Equipment List:

- Drilling rig (Sonic)
- Drill rods and core barrel

GUIDELINES

PRIOR TO INTRUSIVE ACTIVITIES AT ANY DRILLING LOCATION THE AREA WILL HAVE BEEN CLEARED OF ALL UTILITIES AND THE CLEARANCE RECORDED IN THE FIELD LOGBOOK. It is also the field team leader's responsibility to confirm that all required access permits are in place.

Prior to the start of drilling, the area of site activity will be identified and delineated using stakes and/or flagging. The extent of impact will be mineralized at all times and the delineated area of activity decreased when possible. All sensitive vegetation or habitats will be delineated with stakes and/or flagging and no impact will occur in these areas.

Sampling depths and total depths of holes shall be determined by temporary marking of drill equipment, by reference to standard equipment dimensions (for example, 5-foot hollow-stem auger flights), or by measurement using a fiberglass tape. Final total depth measurements will be confirmed using a weighted fiberglass tape. Observations by the field geologist or engineer shall be recorded directly in the borehole log.

The field borehole log is the standard form used to document subsurface geologic conditions. The borehole log is divided into two areas. One portion contains spaces for noting information on the drilling and sampling methods. The second portion contains space for noting lithologic descriptions. All sheets shall be filled out completely, legibly, and in ink. The borehole log will be filled out in the field at the time of the drilling and sampling. The original logs shall be permanent records, and information on the logs may not be

erased. If corrections are needed, information shall be crossed out with a single line and the correction shall be initialed and dated.

The use of water and drilling fluid to assist in sonic drilling for monitoring well installation will be avoided, unless required for such conditions as running sands or drilling bedrock formations.

Temporary outer casing, drill rods, core barrels, and other downhole drilling tools will be properly decontaminated prior to the initiation of drilling activities and between each borehole location. Core barrels and other downhole soil sampling equipment will also be properly decontaminated before and after each use.

Sonic inner casing (sample tube) will have an inside diameter of at least 3.25 inches. Samples may be collected for chemical analysis. For sonic drilling, these samples are collected in a metal trough. A continuous core is collected and the sample interval is selected from the length of core run.

Surface casing may be installed where soil borings will penetrate a confining layer or when there is risk of eroding soil during the drilling process if water is used.

PROCEDURES

Instructions for Completing Soil Boring Logs

Soil boring logs will be completed in the field log books. Information collected will be consistent with that required for Form D1586 (attached), a standard CH2M HILL form or an equivalent form that supplies the same information. Procedures will follow the SOP "*Soil*

Non-Core Collection Drilling

At locations or depths from which core collection is not required, drilling may proceed without the recovery of soil cores. The drilling will include advancing the larger outer casing and the use of water to facilitate cuttings removal from the boring. The inner casing drill rods may or may not be used, depending on the cuttings recovery when drilling with the larger outer casing.

Continuous Core Drilling

At locations or depths when core collection is required, drilling will proceed using an outer casing and an inner core sample tube. The inner core sampling tube will be advanced first without the use of water. Before removal of the sampling tube, the outer casing will be advanced, using water only as needed for cuttings removal, to the same total depth as the inner casing. The outer casing will stabilize the boring when the sampling tube is removed. The process is repeated in 10 to 20 foot intervals, as the lithology of the boring permits.

The length of each drilling interval should be adjusted depending on the lithology and the quality and recovery percentage of the sample cores retrieved. At locations with very hard drilling (i.e. with large cobbles or hard materials) or when percent recovery decreases, the drilling interval should be decreased until such time that the conditions change.

After retrieval of the inner sampling core tube, the minimally disturbed sample cores will be collected into plastic liner sleeves in intervals of 2 to 3 feet. The plastic sleeves will be

immediately sealed on both ends. The cores will be used for visual descriptions and may be used for analysis for geochemical and geotechnical parameters.

KEY CHECKS AND ITEMS

- Check entries to the soil boring log and field logbook in the field during sampling activities because the cores will be disposed at the end of the fieldwork, confirmation and corrections cannot be made later.
- Check that the sample numbers and intervals are properly specified.
- Ensure that drilling equipment is decontaminated prior to the beginning of work and between each borehole.
- All materials generated during sampling (debris, PPE, decontamination liquids, etc.) will be placed in approved IDW storage containers pending analysis and disposal off site as outlined in SOP-B6, *Disposal of Waste Fluids and Solids (IDW)*.

SOP-B11

Site Clearance and Permitting
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) addresses the procedures for site clearance and permitting at the Topock site. This SOP should be used to obtain proper site clearance and permits before any work is performed at a site.

REQUIRED DOCUMENTS

1) Applicable project work plan, event-specific sampling and analysis plan (SAP), and/or Procedures Manual, if applicable.

2) Topock Program Health and Safety Plan (HSP).

3) Site map with work locations identified.

PREPARATION AND SETUP

1) Review applicable project work plan, event-specific SAP, Procedures Manual, and HSP.

2) Identify locations where work will be performed, determine if any subsurface work will be needed.

3) Before the start of any work obtain approval by the appropriate land agencies (such as BLM, USFWS, County of San Bernardino). Activities located on PG&E property fall under the jurisdiction of the County; however, approval may also be required from BLM and/or USFWS for activities such as access, waste management, etc. Work in Topock, Arizona falls under the jurisdiction of the Arizona Department of Water Resources.

4) Before the start of any work obtain appropriate approval by the regulatory agencies. These include at a minimum the DTSC if in California, and ADEQ is in Arizona. Other regulatory approvals that may be required include, but are not limited to CDFG, USFWS, USACE and RWQCB. Approval from the Arizona Land Department may also be required for wells drilled in Arizona.

If subsurface work will be involved, follow the following steps:

1) Follow the guidelines of the Southern California Underground Service Alert (USA) agency to mark the edges of the work location as outlined on their web page (http://www.digalert.org). If in Arizona, the Arizona Blue Stake should be contacted for location of buried facilities (www.azbluestake.com). Make sure to:

   - Identify delineated areas with white markings with the requesters company name or logo within the pre-marked zones

   - Delineate the exact area of excavation with white paint through the use of dots or dashes, or a continuous solid line. Limit the size of each dash to approximately 6" in length and 1" width with interval spacing not less that approximately 4 feet. Dots of

approximately 1" diameter are typically used to define arcs or radii and may be placed at closer intervals in lieu of dashes. Limit width of lines to 1".

- For point locations (such as a soil boring or well) mark the exact location in the USA or Blue Stake box with a stake. Make sure the delineated area around the stake is of adequate radius (50 to 100 feet is appropriate for drilling).

2) Call USA at 1-800-227-2600 or Arizona Blue Stake at 1-800-782-5348 at least three working days before the start of work at the identified location and provide them with the information requested on the location request form. Be ready to give the location in terms of feet relative to I-40 and to Park Moabi Road when calling. You will be assigned a Dig Alert Number, file this number until work at the delineated area is complete. (The number does expire after two weeks and a new number may need to be obtained if work has been delayed.)

3) Mark the Dig Alert Number in the delineated area using white paint as soon as possible after calling USA or Arizona Blue Stake.

4) If the location is in a developed area, contact a private utility locator and have them perform a sweep of the delineated work area. Util-Locate at (866) 421-5325 is typically used for this service.

5) In some cases the utility companies may need to be contacted directly by CH2M HILL. If the following companies do not respond to the USA or Blue Stake ticket or if we are working in their easements, use the following contact information and procedures:

Southwest Gas: Main contact is Jim Default/702-365-2097 (The required minimum clearance distance from gas pipelines is 18-inches**.** Potholing may need to be performed in advance of design completion Southwest Gas should be called prior to construction activities). If Southwest Gas does not come to the site after the USA call, contact them at their Bullhead City office at (928) 763-7766

Southern California Gas Co.: Main contact is Frank Castro/818-701-4566; secondary contact is Martin Woodsworth/818-701-4543. If we need to work in their easement, we must provide a letter from BLM giving us permission to be on the property. Southern California Gas Co. also requires advance notification of construction activities. They may also require a copy of the design drawing, potholing activities, and the issuance of a "Non-Interference" letter, if applicable, before work can proceed. One of their representatives may need to be in the field when digging is occurring near their pipeline.

TransWestern Pipeline Co.: Main contacts are Ron Westbrook (ROW Department)/713-345-3067 and Mike Baxter (Operations)/928-757-3620. They may require potholing if proposed construction activities are near their pipelines. Crossing pipeline requires filling out a simple form.

Burlington Northern Santa Fe Railroad: Main contact is Greg Rousseau (BNSF)/909-386-4079. Prior to work in their easements submit the proper application with the $250 fee to the Staubach Company.

City of Needles Utility Dept: Main contact is Ron Myers/760-326-5700 (ext. 7 for the utilities department). Work activities may need to be a minimum of 10 to 15 feet from their utility poles.

6) Do not start subsurface work at the site until the delineated area has been marked or cleared by the appropriate utility agencies.

If the work includes a performing a well installation or abandonment, or drilling a boring in California:

1) Apply for a San Bernardino County well permit two to three weeks before the start of drilling (one permit per well; cost is /$212.00 per well). Obtain a permit application by calling the Environmental Health Services Department at 1-909-387-4666 (open Monday through Friday, 8:00 a.m. to 5:00 p.m. The fee schedule for permits is located at http://www.sbcounty.gov/ dehs/FEESCHEDULE/feeschedule.htm#wateranchor. Fill out the appropriate permit form and provide it to the California-licensed driller contracted to perform the well installation. The driller is expected to review and file the permit with the San Bernardino County Department of Environmental Health Services (Steve Sesler), address below.

Environmental Health Services
385 N. Arrowhead, 2nd Floor
San Bernardino, CA 92415-0160

2) A well permit needs to be obtained from San Bernardino County for well abandonment by the same procedure described in #11. Check the 'destruction' box on the same permit form used for well installation.

3) A permit also needs to be obtained from San Bernardino County for any boring that reaches to or below the water table, even if a well is not actually installed. The permit process is the same as described in #11.

If the work includes a performing a well installation or abandonment, or drilling a boring in Arizona:

1) Apply for an Arizona Department of Water Resources (DWR) well permit two to three weeks before the start of drilling (one permit per well; cost is /$150.00 per well). Obtain a permit application by calling the DWR at 1-(602) 771-8500 (open Monday through Friday, 8:00 a.m. to 5:00 p.m. MST). All ADW permits and instructions can be found at http://www.azwater.gov/dwr/Content/Find_by_Category/Permits_Forms_Applications/default.htm
Fill out the appropriate permit form (55-44A) and provide it to the Arizona-licensed driller contracted to perform the well installation. The driller is expected to review and file the permit with the Arizona Department of Water Resources address below.

Arizona Department of Water Resources
3550 N. Central Avenue
Phoenix, AZ 85012

Upon completion of the well, the driller must submit a Driller Report and Well Log (Form 55-55) to the DWR within 30 days. The form and instructions can be found on the DWR webpage.

2) A well abandonment permit needs to be obtained from the Arizona Department of Water Resources prior to well abandonment (form 55-38). Exploratory wells that are abandoned before the drill rig leaves the site are exempt from the well abandonment permit requirements. The well abandonment form and instructions are included as Attachment 4 and can be found at the ADW webpage . No fee is required for filing this form.

   Within 30 days of well abandonment a Well Abandonment Completion Report (Form 55-58) must be filed with the DWR.

SOP-B15

Volatile Organic Compound (VOC) Soil Sampling
Standard Operating Procedures for PG&E Topock Program

This standard operating procedure (SOP) provides guidance for Volatile Organic Compound (VOC) sample collection from soil. Additional guidance for sample collection, preservation and handling is provided in Section 4.0 of the PG&E Quality Assurance Project Plan (QAPP). SOP-B2 and SOP-B3 *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL, 2005) provides additional guidance for soil characterization and logging.

Required Documents

1) Event-specific planned sample table (PST).
2) Applicable project work plan or monitoring plan. Refer to the Procedures Manual and QAPP as required.
3) Topock Program Health and Safety Plan (HSP).
4) Previous sampling, drilling, or well construction logs from other boreholes or wells in the vicinity, if available.
5) Field notebook.
6) Database generated sampling logs.

Preparation and Setup

1) Review event-specific PST or event-specific field instructions, previous sampling logs, Procedures Manual, and HSP.
2) Coordinate with the Project Chemist for coolers, sample containers, and courier pickup of the samples.
3) Initiate field logbook for sampling activity.
4) Review sampling procedures and planned sample depths with field crew.
5) Field-check and set up equipment for sampling, decontamination, spill prevention, and health and safety.

Equipment List

- Pre-labeled soil sample containers appropriate for sample analysis and preservation as called for in PST and QAPP (Pre-weighed Vials, glass jars, auger sleeves, etc.)
- Soil sampling equipment (stainless steel trowel, spatula, EnCore™ Sampler, EasyDraw Syringe®, or a disposable plastic syringe with a barrel smaller than the neck of the soil vial with the cap removed from the plunger, etc.)
- Field notebook

- Sediment sampling logs generated from database
- Blue or black waterproof or permanent ink pens
- Trash bags
- Paper towels
- Decontamination equipment (Alconox® solution in spray bottle, brushes, buckets, rinse water spray bottle)
- Water level indicator
- Distilled water
- Coolers with ice
- Protective waterproof gloves (nitrile or latex)

SOIL SAMPLING LOGS DOCUMENTATION

Soil sampling logs or boring logs (SOP-B2 and SOP-B3 *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* [CH2M HILL, 2005]) will be completed at the time of sample collection. Items to be documented on the sampling log include:

6) **Sample Interval:** The top and bottom depth of each sample run should be recorded on the log. Sampling includes samples collected for analysis as well as retrieved for logging purposes.

7) **Sample Type and Number:** Enter the sample type and number consistent with the sampling and analysis plan at the correct depth intervals. An "x" should be placed across the vertical interval where the environmental soil, grab groundwater, or geotechnical sample was collected.

8) **Sample Recovery:** Enter the length of retrieved sample to the nearest inch of sample recovered. Record total length and percent of sample recovered.

9) **Sampling:** Sampling difficulties shall be noted. The top of the sample shall be marked on the container.

10) **Water Levels:** Water-level measurements, where groundwater is encountered, are required for each boring. Changes in soil moisture shall be noted and, if there is no water encountered, a note to that effect shall be included on the sediment sampling log. The date and time of water-level measurements shall be documented.

At a minimum, sample identifiers (IDs) should be noted on sampling logs at the depth collected. When time and space allows, a summary of analytical sample information can be included.

VOLATILE ORGANIC COMPOUNDS (VOC) SOIL SAMPLING - COLLECTION OF SAMPLES FOR ANALYSIS

It is recommended (EPA Method 5035A) that VOC soil samples be collected in a coring device to minimize volatilization and soil disturbance to prevent constituent losses. After

collection, the sample shall be immediately transferred to the sample vial (to be used for analysis) and stored for no longer than 48 hours at 4 C ± 2° C prior to analysis. Freezing the samples between -7 and -20° C within 48 hours and maintaining them frozen until analysis allows a 14 day holding time. Chemical preservation techniques are also available as options.

Use either a commercially available sampler (such as the EnCore™ Sampler or EasyDraw Syringe®) or a disposable plastic syringe to collect VOC soil samples. To use a syringe, cut the syringe end of the barrel off and removed the rubber 'cap' from the plunger, prior to sampling (barrel of the syringe needs to be smaller than the neck of the soil vial). One sampler is needed for each sample aliquot to be collected (typically the laboratory will supply the sampler along with the sample vials, but arrangements must be made prior to sampling).

11) Weigh 3 empty samplers and note the weight. Using the same 3 samplers collect several trial samples (try to collect 5.0 ± 0.2g). Weigh each trial sample (total weight – syringe weight = sample weight) and note the length of the soil column in the syringe. Use the data to determine the length of soil in the syringe that corresponds to 5.0 grams. The length of the soil column equal to 5 grams becomes the volume for the project location. Discard each trial sample.

12) The VOC sample collection process should be completed in the least amount of time as possible in order to minimize the loss of VOCs. Sample collection should be done with the least amount of disturbance/disruption as possible. Additional, exposure of the sampling location's surface layers should be considered if the material may have already lost VOCs or if it may have been contaminated by other means. Removal of surface layers can be accomplished by scraping the surface using a clean spatula, scoop, knife, or shovel.

13) Insert a clean coring tool into a freshly exposed surface; do not trap air between the sample and the plunger. For greater ease in pushing into the solid matrix, the front edge of these tools can be sharpened. The optimum diameter of the coring tool depends on the size of the opening of the collection vial (tool should fit inside mouth), the sample characteristics (e.g., particles size, cohesion), and volume of sample required for analysis. After an undisturbed sample has been obtained by pushing the barrel of the coring tool into a freshly exposed surface, quickly wipe the exterior of the barrel with a clean disposable towel. Transfer the sample into a pre-weighted vial by gently pushing the plunger, (use extreme care to ensure none of the preservative is lost if the sample is collected into a pre-preserved vial – water, methanol or NaHSO4), verify the sealing surfaces are clean, and secure the cap (the transfer should take less than 10 seconds). **Note: Samples are collected in pre-weighed and pre-labeled vials provided by the laboratory; no additional labels are to be added to the vials!** Complete the label attached by the laboratory (fill in sample ID-only). All vials from one sample location will be placed into a zip-lock bag and the sample information shall be recorded on a label attached to the bag.

14) As a last resort non-cohesive granular samples (sand, gravel, or a mixture of gravel and fines) that can not be easily obtained or transferred using coring tools, can be quickly sampled using a decontaminated stainless steel spatula or scoop. Decontamination is

covered in section 3.3 of the PG&E Program QAPP and in SOP-B5 *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (CH2M HILL, 2005).

15) As with the collection of aqueous samples for volatiles, collect at least 3 replicate samples. This will allow the laboratory an additional sample for reanalysis, if needed. The replicate samples should be taken from the same soil stratum or the same section of the solid waste being sampled, and within close proximity to the location from which the original sample was collected.

16) In addition, if a VOC sample is the only sample to be collected at a given location, collect at least one additional aliquot for the determination of percent moisture. Trip blanks and equipment blanks should be collected per the PG&E Program QAPP. However, trip blanks do not apply to samples that have been frozen upon collection.

17) Transport the sample at 4^{o} C, to the lab in less than 48 hours or freeze (reagent water preserved samples to between -7 and -20^{o} C) within 48 hours and transport frozen.

18) Complete Soil Sampling Logs and Chain of Custody Logs.

SOP-B16

Field-portable X-Ray Fluorescence Soil Sampling
Standard Operating Procedures for PG&E Topock Program

This Standard Operating Procedure (SOP) describes the analysis of in situ and ex situ soil and debris samples using a field portable x-ray fluorescence (XRF) instrument. SOP-B2 and SOP-B3 in the *Sampling, Analysis, and Field Procedures Manual, PG&E Topock Program* (SAFPM) (CH2M HILL, 2005) provides additional guidance for soil characterization and logging.

Required Documents

1. Event-specific planned sample table (PST).
2. Applicable project work plan or monitoring plan. Refer to the SAFPM and the *PG&E Program Quality Assurance Project Plan, Revision 2, Topock Compressor Station, Needles, California* (CH2M HILL, 2012) as required.
1. Topock Program Health and Safety Plan.
3. Field notebook.
4. Database generated chain-of-custody.
5. XRF Functional Check Log

Preparation and Setup

1. Review event-specific PST or event-specific field instructions, previous sampling logs, SAFPM, and health and safety plan.
2. Coordinate with the project chemist for coolers, sample containers, and courier pickup of the samples.
3. Initiate field logbook for sampling activity.
4. Initiate electronic file for XRF instrument download.
5. Review sampling procedures and planned sample depths with field crew.
6. Field-check and set up equipment for functional checks, sampling, decontamination, spill prevention, and health and safety.

Equipment List

- Niton XRF meter and stand
- Spare battery chargers
- Field notebook
- Trowel for smoothing soil surfaces

- Reusable plastic bags or stainless steel tray
- Disposable sample cups with x-ray film and lids
- X-ray window film (Mylar, Kapton, Spectrolene, polypropylene, or equivalent; 2.5 to 6.0 micrometers thick)
- Disposable scoops, stainless-steel spoons, or other appropriate mixing tools
- Appropriate quality assurance/quality control (QA/QC) standards and blank sand
- Chemwipes
- Decontamination equipment (Alconox solution [or equivalent] in spray bottle, brushes, buckets, rinse water spray bottle) for mixing tools and trowels
- Protective waterproof gloves (nitrile or latex)

XRF Analysis Documentation

The XRF sample results will be recorded by the associated software in an Excel format. The files will be downloaded at the end of each day and emailed to the project chemist for review. Any additional sample logging and sample collection should follow the protocol and procedures found in the appropriate SOP. Detailed notes should be recorded in the sampler's field notebook or in a log generated from the field database. Items to be documented on the sampling log include (include as much of the following information in the XRF software as possible):

1. Record type of boring or excavation equipment and the total boring or excavation depth.
2. If multiple samples are being collected at one location at a variety of depths, record all sample depths.
3. Record date and time of sample collection in addition to the full sample ID that is listed in the PST.
4. Sampling difficulties shall be noted (that is, difficult slope or abnormal debris in sample location).
5. Analysis start time and the source count time (that is, 60, 90, or 120 seconds, etc.) will be documented on sample collection sheet. Analysis and count time are automatically recorded in the XRF software.

Field-portable XRF Soil Sampling, Collection of Samples for Analysis

In Situ Sample Preparation

When the soil moisture is less than 20 percent, the error associated with moisture may be minimal. If areas are encountered where the moisture content is greater than 20 percent (moisture is visible), consult with the project chemist for options available for proceeding with field analysis.

For in situ analysis of soil:

1. Remove large or nonrepresentative debris from the selected location. This debris includes rocks, gravel, vegetation, and concrete.
2. Homogenize the location chosen for analysis by mixing in place an area approximately 4 inches by 4 inches by 3 inches deep using a clean (or decontaminated) stainless-steel or disposable spoon. Smooth and firmly tamp the location to provide as flat and smooth an area as possible.
3. Stretch a section of x-ray window film over the area to be tested to maintain a dust-free environment for the nose of the instrument. (Use in situ analysis for metals-only samples.)
4. To initiate a reading, position the nose of the XRF against the x-ray film, squeeze the shutter release, and firmly press the instrument flat against the surface. Source count times for in situ analysis usually range from 3 to 5 minutes, varying among instruments and depending on requirement detection limits.
5. After the in situ field screening is performed, inspect the nose of the instrument for contamination, which may affect future analysis. If necessary, clean it with a soft cloth or tissue.

For confirmation samples, or where samples for organic analysis are to be collected, the soil samples should be treated as ex situ samples, below.

For in situ analysis of debris:

1. In some cases, the large or nonrepresentative debris removed in Step 1 above may need analysis. The debris for analysis can include rocks, wood, concrete, etc.
2. Analyze debris that is too large or difficult to homogenize by locating multiple locations on the surface of the debris that are as flat and smooth as possible. Scan a minimum of three locations or approximately 10 percent of the surface area (whichever is greater).
3. Stretch a section of x-ray window film over the area to be tested to maintain a dust-free environment for the nose of the instrument. (Use in situ analysis for metals only samples.)
4. To initiate a reading, position the nose of the XRF against the x-ray film, squeeze the shutter release, and firmly press the instrument flat against the surface. Source count times for in situ analysis usually range from 3 to 5 minutes, varying among instruments and depending on requirement detection limits.

After the in situ field screening is performed, inspect the nose of the instrument for contamination, which may affect future analysis. If necessary, clean it with a soft cloth or tissue.

Ex Situ Sample Preparation

For ex situ analysis:

There are several possible correct methods for the ex situ analysis of samples. The area that previously would have been homogenized for the in situ analysis should be scooped out and placed into a clean (or decontaminated) stainless-steel or disposable pan (do not use

plastic if organic analysis will be performed on any of this homogenized sample) using a stainless-steel or disposable spoon or spatula (do not use plastic if organic analysis are associated with the homogenized sample). The sample should then be thoroughly mixed (homogenized) using the same spoon or spatula.

1. The preferred method is to setup the portable field stand in an area where the XRF can be stationed and left in place for the day. Use the Niton software and a laptop computer to setup the method criteria and control the XRF instrument during the soil analysis.

    a. Starting with the previously homogenized sample, use the supplied soil sieves, bowl, and mortar to generate a finely ground well homogenized sample. (Note: This step is not required if the soil sample was passed through a sieve during the homogenization step.)

    b. Transfer the prepared sample into a new sample cup (order replacement supplies from Niton), place the X-ray film over the cup, and snap the lid in place. Place the sample cup in the portable field test stand. The XRF points upward, the sample rests on top of the XRF with the X-ray film directly in contact with the nose of the XRF cup lid facing down.

    c. Using the computer, start the analysis. The source count time should be at least 2 minutes for chromium. Consult previous analysis to determine if multiple scan frequencies are required (or contact the project chemist).

    d. Prepare the next sample while the XRF is analyzing the current sample.

2. An alternative method to using the portable field stand is to identify the sample for XRF analysis and homogenize the sample (as described above).

    a. Transfer the sample to a re-sealable plastic bag and firmly molded into a flat smooth surface.

    b. Use the Niton software and a laptop computer or the included PDA to setup the method criteria.

    c. To start the analysis, position the nose of the XRF against the flat smooth surface of the sample and squeeze the shutter release (or press the start button on the laptop or PDA). Be sure to maintain constant pressure against the sample. If contact is broken, the analysis will need to be restarted. The source count time for ex situ analysis usually range from one to two minutes, depending on the required detection limits (see 1c above for count times).

    d. After the ex situ field screening is performed, inspect the nose of the instrument for contamination, which may affect future analysis. If necessary, clean it with a soft cloth or tissue.

3. Transfer the sample to a labeled glass jar for shipment to the confirmation laboratory (if applicable).

Sample Analysis

In today's modern XRF models:

1. An X-ray source is used for detection. Expose the sample to the X-ray source for a minimum of 1 minute. Longer exposure times may be needed depending on the media that is being analyzed and the required detection levels. The time needed for analysis will be determined in the field by analyzing standards that have concentrations of the metals of concern near the required detection levels. Better detection limits can usually be obtained by homogenizing the sample, increasing the exposure time, and using two or more scan frequencies. Use a minimum of a 2-minute exposure for chromium analysis.
2. When the XRF instrument displays the results they include the analyte, the result, and a percent confidence (displayed as a ± value). The result is displayed as nondetect for analytes that do not meet the percent confidence established in the instrument. The lower the required detection levels, the longer the analysis time required to meet the percent confidence.
3. Download saved data from XRF instrument daily (if data are collected in PDA). Foreword the data files to the project chemist daily.
4. All samples collected for offsite confirmation will also be analyzed using the XRF and will be treated as ex situ samples.

Using older models:

1. Expose the sample to the energy source for a minimum of 1 minute. Longer exposure times may be needed depending on the media that is being analyzed as well as the age of the detector (non X-ray detectors). The time needed for analysis will be determined in the field by analyzing standards that have concentrations of the metals of concern near the required detection levels. Better detection limits can usually be obtained by homogenizing the sample, increasing the exposure time. Use a minimum of a 2-minute exposure for chromium).
2. When the XRF instrument indicates the results for the suite of analyzed elements and their concentrations, it includes a standard deviation for the reported concentrations. An analyte concentration is considered **not detected** if the result value is **less than two times the standard deviation**. The lower the required detection levels, the longer the analysis time required to reduce the result's standard deviation.
3. Record the readings (electronically or documented on the sampling log). Review the standard deviations for the elements of interest and determine if a longer analysis time is needed to reduce the standard deviations, thereby allowing the desired accuracy and precision for the concentrations. The standards will be analyzed using increasingly longer times until the required detection level is achieved.
4. Record values in field notebooks.
5. Download saved data from XRF instrument daily.
6. Samples collected for offsite confirmation will also be analyzed using the XRF and will be treated as ex situ samples.

Calibration

Two forms of calibration are important with XRF testing: an energy calibration and a sample matrix calibration.

Energy Calibration

The Niton XLi 702 automatically re-calibrates the energy scale when powered on. The energy scale can also be re-calibrated by pressing "Reset" on the instrument. The energy calibration should be performed every two hours.

Sample Matrix Calibration

Modern XRF instruments, such as the Niton Xli 702, do not require site specific calibrations to account for sample matrix effects. United States Environmental Protection Agency Method 6200 allows both fundamental parameters and Compton normalization as two techniques to eliminate site specific calibrations. Niton uses the Compton normalization method to automatically correct for sample specific matrix effects. The XRF is calibrated internally at the factory on NIST standard reference soil samples. Ensure the annual factory calibration certification is on file. This internal calibration is used for subsequent field work, without need for adjustment or recalibration at other sites.

Quality Assurance and Quality Control (Functional Checks)

Even though no onsite calibration will be performed, the method does require QA/QC functional check-testing protocols. The QA/QC that will be used to document that the XRF is operating properly will have the following steps:

- A startup operations check
- Analysis of a blank sample (clean sand)
- Analysis of standard sample(s)
- Analysis of duplicate samples
- QA/QC procedures will be compliant with manufacturer's instructions.

1. At the beginning of each day perform QA/QC functional check procedure or when the instrument is turned on after more than 2 hours of down time or if the operating environment changes, such as a temperature change of more than 20 degrees Fahrenheit.

2. Two types of blanks should be analyzed, an instrument blank and a method blank. An instrument blank sample (silicon dioxide, provided by Niton) will be analyzed at the start and end of each day and once every 20 samples, to confirm proper zero calibration of the XRF. The blank will be analyzed following the procedure for the ex situ sample analysis. A method blank is used to monitor for any field induced contamination. The method blank should follow any preparation procedures performed on the samples, such as mixing or ex situ analysis. **A method blank will be analyzed each day**.

3. A set of three to ten QC samples will be collected from the site during the initial field activities. These samples will be well homogenized, and a portion sent to the offsite laboratory for characterization. The remaining sample will be collected in re-sealable bags, labeled, and stored with the XRF for use as standards. Three to five of the on-site standards will be analyzed at the start of each day. The results of the standards will be plotted against the original XRF results and a correlation value will be calculated. A

correlation coefficient of 0.90 or greater must be achieved to meet the project objectives. A running log of all onsite standards analyzed will be maintained. One of the standards will be analyzed after every 20 samples. The readout from the XRF **must be within 20 percent relative percent difference of the known QC sample concentration**.

4. The last QA/QC step will be to analyze duplicate samples (two separate aliquots) at a rate of 1 in 10. These duplicate measurements must be within 35 percent of each other for the analysis to continue. If the sample results are not in agreement, then the reason for this discrepancy must be determined.

5. The Niton XL3t 600 displays both concentration and precision for each sample analyte measurement. The precision displayed by the Niton's 95 percent (2-sigma level) confidence intervals; whereas the precision calculated in EPA method 6200 is at a 68 percent (1-sigma) level. The Niton also calculates and displays detection limits for analytes if the concentration is below three standard deviations. This bypasses the need for replicate measurements on low-level standards.

Note: Volatile organic compounds, semivolatile organic compounds, and other organic samples cannot be collected from the homogenized soil if plastic is used for homogenizing or after XRF analysis, if contacted by plastic.

SOP-B17

Standard Operating Procedure for the Installation of Permanent Soil Gas Sampling Implants

This procedure is recommended as a practical approach for installation of permanent soil gas implants using a hand auger or hydrovac where the intent is to collect shallow soil vapor samples, and continuing with hydrovac and/or hollow-stem auger to collect deeper soil vapor samples. This SOP should be used where its application is consistent with the project's data quality objectives and in conjunction with SOP B18 *Standard Operating Procedure for the Collection of Soil Gas Samples from Soil Gas Probes Using Summa™ Canisters.* Only persons trained in the collection of soil gas samples should attempt this procedure.

1. Implant/Probe System Set-up

1.1 Obtain all necessary equipment for hand auguring or hydrovac to 5 feet below ground surface (BGS), and for hydrovac or hollow stem augering to depth greater than 5 feet BGS.

1.2 This technique can only be used in the vadose zone, not below the water table.

1.3 Several screen lengths are available (3", 6", 14", 21") but for discrete intervals required in Vapor Intrusion investigations, a 6" screen is recommended.

1.4 It is necessary to coordinate the hardware (i.e. size of tubing, fittings, sampling interface assembly, etc.) that mates the soil gas probe sampling line to the sampling system (i.e. Tedlar bags, Summa canisters, etc.). This step is critical to achieve a leak free system. All connections should be inert gas tight compression fittings (i.e. Swagelok® or equal) and all sample transfer lines should be made of Teflon® tubing.

1.5 Prior to installation of implants at a given location a utility survey must be completed, the necessary permits acquired, and in the case of private property - permission granted.

1.6 The drilling system must be decontaminated prior to use. Steam cleaning is the preferred method of decontamination. Once decontaminated, the auger/drill rod must be shown to be free of contaminates. As a minimum, a suitably sensitive organic vapor meter should be used for this purpose. Any probe that does not pass decontamination should not be used.

1.7 Handle and store decontaminated hand augers and drill rods in a manner that prevents contamination.

2. Implant Installation

2.1 Assemble the hand auger and/or other coring device. Auger/hydrovac/drill to the desired depth. Be sure that the final depth of the hole includes extra depth to include length of the screen. (i.e. for 5' BGS with a 6" screen, push the probe to 5'6", for 15' BGS with a 6" screen, push the probe to 15'6").

2.2 Attach the ¼" Teflon tubing to the implant. Use sufficient tubing so that at least 2' will be left above ground. Plug the exposed end of the tubing with a cap.

2.3 Remove the auger/drill rod and put a section of PVC pipe down the hole. The PVC pipe is helpful to help center the implant in the middle of the hole and to be sure that the filter

pack material makes it to the bottom of the hole. Thread the implant and tubing down the inside of the PVC pipe until it reaches the bottom.

2.4 Determine the volume of glass beads or sand (#2/12 or #2/16) needed to fill the space around the implant plus an additional 6″ space above the implant. Pour the sand/beads into the hole as the PVC pipe is slowly removed. Do not pull on the tubing. Remove the PVC pipe from the hole completely once the filter pack material has been set in place.

2.5 Determine the volume of dry bentonite needed to fill the next 1 foot of hole. Pour dry bentonite into the hole until it measures 1 foot above the sand pack.

2.6 Determine the volume of hydrated bentonite needed to fill the hole to 6″ below the upper nested probe. Place hydrated bentonite to the point 6″ below the upper nested probe. Measure the depth to make sure the upper probe will be installed at 5′6″ BGS.

2.7 Follow steps 2.2 through 2.4 for the installation of the upper nested probe.

2.8 Determine the volume of dry bentonite needed to fill the next 1 foot of hole. Pour dry bentonite into the hole until it measures 1 foot above the upper sand pack.

2.9 Determine the amount of hydrated bentonite needed to complete the hole. Pour in granular bentonite and hydrate. Repeat the procedure in 6″ increments to ground level.

2.10 Optional: Enlarge the hole and install the flushmount so that it is flush with the ground surface. Label probe tubing with location and depth. Coil the extra tubing inside the enclosure and cover.

2.11 Wait at least 48 hours before sampling.

2.12 When calculating dead volume, use the internal volume of the Teflon tubing, the internal volume of the implant, and the volume of the glass bead pack (assume 30% porosity).

2.13 The ground surface shall be replaced and repaired to original condition.

SOP-B18

Collection of Soil Gas Samples from Temporary and Permanent Soil Gas Probes using SUMMA Canisters and a Helium Leak Check

---

1. Scope and Application

This procedure offers a practical approach for the collection of soil gas samples from soil gas probes from permanently installed vapor points into SUMMA canisters. Soil gas sample integrity is verified by using a real time helium leak checking procedure before taking each sample. This must be done after probe installation and before sampling as well as before each subsequent sample for permanent probes. This standard operating procedure (SOP) should be used in conjunction with CH2M HILL's SOPs: "Soil Gas Probe Installation SOP" or "Soil Gas Implant Installation SOP," and when its application is consistent with the project's data quality objectives. Only persons trained in the collection of soil gas samples should attempt this procedure.

2. Site-Specific Considerations

2.1. Prior to attempting soil gas sampling there should be an understanding of subsurface conditions at the site.

2.1.1. Depth to Groundwater – soil gas samples should be collected in the vadose zone (and above the capillary fringe). Generally, soil gas samples should not be collected at a depth above 5 feet below ground surface (bgs). Sampling at multiple depths should be considered.

2.1.2. Soil permeability **-** It may not be feasible to collect soil gas from tighter grain soils with little pore volume, such as clays; if there are clay layers present in the subsurface, these intervals should be avoided. For sampling in these soils, it is recommended to uses soil gas implants with a wider bore hole. Care should be taken during purging and sampling so that the vacuum in the sampling system never exceeds 7 "Hg (100 "water).

3. Other Considerations

3.1. A utility clearance should be performed prior to mobilization, as with all intrusive site work.

3.2. Soil gas sampling should not be performed until 48 hours after a significant rain event (>1 inch of rainfall).

4. Apparatus and Materials

4.1. The soil gas probes should be installed by a licensed driller.

4.2. Teflon tubing, ¼-inch outer diameter sample tubing.

4.3. Swagelok® ¼-inch nut and ferrule sets for connecting the probe tubing to the sampling manifold.

4.4. The helium leak check equipment, including the enclosure, helium cylinder (high purity helium), and helium detector (Dialectric MGD is preferred). The enclosure may be provided by the driller or can be constructed from polyvinyl chloride (PVC) pipe. The helium detector can be rented from an equipment rental company.

4.5. MultiRae five gas meter. (Optional if onsite atmospheric gas analysis is required)

4.6. Air pump for purging and electric supply for the pump (either generator or power inverter with adapter for car battery). Must be capable of a flow of 200 mls/min and a vacuum of 20 "Hg.

4.7. Sampling manifold consisting of Swagelok® gas tight fittings with three valves and one pressure gauge to attach the probe to the air pump and the sample canister. This manifold must be clean, free of oils, and flushed free of volatile organic compounds (VOCs) prior to use.

4.8. Canister, SUMMA polished, certified clean and evacuated. (Canisters are typically provided by the laboratory.)

4.9. Flow controller or critical orifice, certified clean and set at desired sampling rate. These are typically provided and set by the laboratory.

4.10. Negative pressure gauge, oil-free and clean, to check canister pressure. The pressure gauges are typically provided by the laboratory. The laboratory may either provide one pressure gauge to be used with all of the canisters, or a pressure gauge for each canister to be left on during sample collection. Sometimes the canisters are fitted with built-in pressure gauges that are not removable.

4.11. Shipping container, suitable for protection of canister during shipping. Typically, strong cardboard boxes are used for canister shipment. The canisters should be shipped back to the laboratory in the same shipping container in which they were received.

4.12. Wrenches and screw driver (clean and free of contaminants), various sizes as needed for connecting fittings and making adjustment to the flow controller A 9/16-inch wrench fits the ¼-inch Swagelok® fittings, which most canisters and flow controllers have.

5. System Set-up

5.1. Acquire all the necessary hardware and sampling equipment shown in Figure 1. Be sure to use ¼-inch outside diameter Teflon sample tubing. ***Do not connect the canister at this time***.

5.2. Assemble or obtain the necessary fittings and vacuum gauge to create a soil gas probe and sampling manifold as shown in Figure 1. This manifold must be clean, free of oils, and flushed free of VOCs prior to use. Note: use only gas tight fittings such as Swagelok® or equivalent. Be sure to place the helium leak check enclosure over the probe, and push the sample tubing through the hole in the cap before attaching the sampling manifold.

5.3. Adjust the purge system evacuation pump sampling rate to achieve the desired flow rate of 200 milliliters/min. This should be performed at the outlet of the vacuum pump prior to purging, either by using a suitable flow meter, or determining the amount of time required to fill a 1- liter Tedlar bag.

5.4. Summa canisters are pre-evacuated by the laboratory. The vacuum will need to be verified in the field prior to use with a pressure gauge.

5.5. Flow controllers (if used) should come pre-set by the laboratory to sample at a pre-determined rate based on specific project requirements (see Table 1 for the most common options). In some cases [that is, project-specific quality assurance (QA)], the flow rate will need to be verified in the field prior to use. This is accomplished with a bubble meter, vacuum source, and instructions supplied by the laboratory.

6. System Leak Checking and Purging

6.1. ***Physical Leak Check*** - Perform a leak check of the sample manifold system by:

6.1.1. Make sure the gas probe valve (valve #1) is closed and the sample valve (valve #2) is open.

6.1.2. Open the purge valve (valve #3) and start the purge pump. Verify that the flow is set to 200 milliliters per minute (ml/min).

6.1.3. Close the sample valve (valve #2) and achieve a vacuum gauge reading of approx. 15 inches of mercury ("Hg).

6.1.4. A leak-free system will be evident by closing off the purge valve (valve #3), turning off the purge pump, and observing no loss of vacuum within the sampling manifold system for a period of 30 seconds. Repair any leaks prior to use.

6.1.5. Record the leak check date and time on the field sampling log.

6.2. ***System Purge and Helium Leak Check*** -A purge of the soil gas probe and sampling manifold system is required before taking each sample. The helium leak check procedure is also performed during this step. This leak check will verify the integrity of the implant as well as the probe and ground interface. This is accomplished by:

6.2.1. Where the ground surface is soft, the helium leak check enclosure is pressed down slightly into the ground surface. In situations where the ground surface is hard (for example, asphalt), apply a slight downward pressure to achieve a buildup of helium in the leak check enclosure.

6.2.2. Start the flow of helium under the leak check enclosure at 200 ml/min. Try and position the tube so the helium is directed at the interface of the probe and the ground. Let the helium fill the enclosure for a couple of minutes.

6.2.3. Turn the helium leak detector on and make sure that the detector is not reading any helium before proceeding. Verify that the helium concentration inside the leak check enclosure is >10% by placing the probe of the helium detector into the hole where the sample tubing comes out or under the enclosure wall. It is not necessary to verify that the helium concentration is 100% as this is bad for the detector. Safety factors will be incorporated into measured purge gas helium concentration to verify the probe seal integrity.

6.2.4. Purging is carried out by pulling soil gas through the system at a rate of 200 ml /min for a time period sufficient to achieve a purge volume that equals at 3 dead volumes (internal volume of the in-ground annular space, sample line, and sampling manifold system). When calculating the dead volume, be sure to take into account the inside diameter and length of the Teflon sample tubing, as well as the probe outside diameter and retract distance for the annular space for temporary probes. For permanent probes, calculate the volume of the annular space using a nominal 30% porosity for the sand or glass bead pack. If during the purge (or sampling) the vacuum exceeds 7 "Hg, then reduce the pump flow rate. The system vacuum must stay below this level at all times.

6.2.5. Open the sample valve (valve #2) and the purge valve (valve #3) and start the purge pump. Verify that the flow rate is still 200 ml/min.

6.2.6. To start the soil gas probe purge, open the gas probe valve (valve #1) and close the sample valve (valve #2) at the same time, and start timing.

6.2.7. During the last 5 minutes of the purge (or the entire purge time if less than 5 minutes), attach a Tedlar bag to the purge pump exhaust on open the bag's valve.

6.2.8. If the vacuum gauge reads >7 "Hg during the purge, then close the purge valve (valve #3) and monitor the vacuum in the manifold and probe. If there is no significant change after a minute, then there is an insignificant amount of soil gas and the vacuum is too great to take

a soil gas sample. Several things can cause this. Consult with the project manager and take corrective action.

6.2.8.1. The soil formation is too 'tight' (that is, high clay or moisture content). Try using a lower flow rate. (temporary or permanent probe)

6.2.8.2. The soil formation is too 'tight'. Try a different depth or location. (temporary probe)

6.2.8.3. With a temporary probe system, the expendable tip may not have released when the probe was retracted. Try retracting the probe a little further, or use a long thin rod to poke the tip loose.

6.2.8.4. If water is visible in the flexible soil gas tubing, stop the purging immediately. It is not possible to take a soil gas sample at that depth or location.

6.2.9. At the end of the pre-determined purge time and after the system is verified to be leak free, close the purge valve (valve #3), close the valve to the Tedlar bag, and turn off the pump. Do not open the purge valve again. Doing so will result in loss of the purge integrity and will require re-purging.

6.2.10. Attach the Tedlar bag to the helium detector using a piece of flexible rubber tubing and open the valve. If a helium reading of >0.1%, or 1000 ppmv, is observed, then the probe leak check has failed and corrective action should be taken. This includes first checking the fittings and connections and trying another purge and leak check. It may also be necessary to remove the soil gas probe and re-install it in a nearby location. Using a limit of 0.1 % allows for a 10x safety margin to verify that the leak check was <1% (verify that this limit is consistent with appropriate project-specific agency guidance).

6.2.11. Remove Tedlar bag and turn off the helium leak detector.

6.2.12. Record the purge date, time, purge rate, leak check result, and purge volume on the field sampling log.

6.2.13. Immediately move on to the sampling phase. Little to no delay should occur between purging and sampling.

7. Sample Collection

7.1. 'Clean' sampling protocols must be followed when handling and collecting samples. This requires care in the shipping, storage, and use of sampling equipment. Cleanliness of personnel who come in contact with the sampling equipment is also important: no smoking, no eating, no drinking, no perfumes, no deodorants, no dry cleaned clothing, etc. Canisters should not be transported in vehicles with gas-powered equipment or gasoline cans. Sharpie markers should not be used for labeling or note-taking during sampling.

7.2. The SUMMA canisters are certified clean and evacuated by the laboratory to near absolute zero pressure. Care should be used at all times to prevent inadvertent loss of canister vacuum. ***Never open the canister's valve unless the intent is to collect a sample or check the canister pressure.***

7.3. Verify that the vacuum pressure of the canister is between 28 – 30 inches Hg. Do not use a canister that has an initial pressure less than 28 inches Hg because that canister likely leaked during shipment.

7.3.1. Remove the protective cap from the valve on the canister.

7.3.2. If using an external gauge, attach the gauge to the canister and open the valve. If the pressure gauge has two openings, make sure that the other opening is closed; the canister cap can be used for this. After taking the reading, close the canister and remove the gauge.

7.3.3. If using assigned pressure gauges, attach the pressure gauge to the canister, then attach the flow controller. When sample collection begins, record the initial pressure.

7.4. Attach the canister to the flow controller and then connect the flow controller to the sample valve (valve #2) on the sampling manifold. Open the sample valve (valve #2)

7.5. Before taking the sample, confirm that the sampling system valves are set as follows: 1) the purge valve (valve #3) is confirmed to be closed, gas probe valve (valve #1) is open, and 2) the sample valve is (valve #2) is open.

7.6. Slowly open the canister's valve approximately one full turn.

7.7. After sampling for the appropriate amount of time (determined from project instructions, see Table 1), close the sample valve (valve #2) and the canister's valve. If the canister has a built-in or assigned pressure gauge, allow the canister to fill until the vacuum pressure reaches 0 – 10 inches Hg. Remove the canister from the sampling manifold.

7.8. If using an external vacuum gauge, re-attach it, open the canister valve, and record the final pressure. Close the valve, remove the gauge, and replace and tighten the cap on the canister. Ideal pressure in the canister is between 0-10 inches Hg. More than 10 inches Hg can greatly increase reporting limits. Consult with the project team if this condition is encountered.

7.9. Record the sampling date, time, canister identification (ID), flow controller ID, and any other observation pertinent to the sampling event on the field sampling log. The temperature and barometric pressure should be recorded.

7.10. Fill out all appropriate documentation (sampling forms, sample labels, chain of custody, sample tags, etc.).

7.11. Disassemble the sampling system.

8. Sample Handling and Shipping

8.1. Fill out all appropriate documentation (chain of custody, sample tags) and return canisters and equipment to the laboratory

8.2. The canisters should be shipped back to the laboratory in the same shipping container in which they were received. The samples do not need to be cooled during shipment. DO NOT put ice in the shipping container.

8.3. When packing the canisters for shipment, verify that the valve (just past finger tight) and valve caps are snug (1/4 turn past finger tight), and use sufficient clean packing to prevent the valves from rubbing against any hard surfaces. Never pack the cans with other objects or materials that could cause them to be punctured or damaged.

8.4. Do not place sticky labels or tape on any surface of the canister!

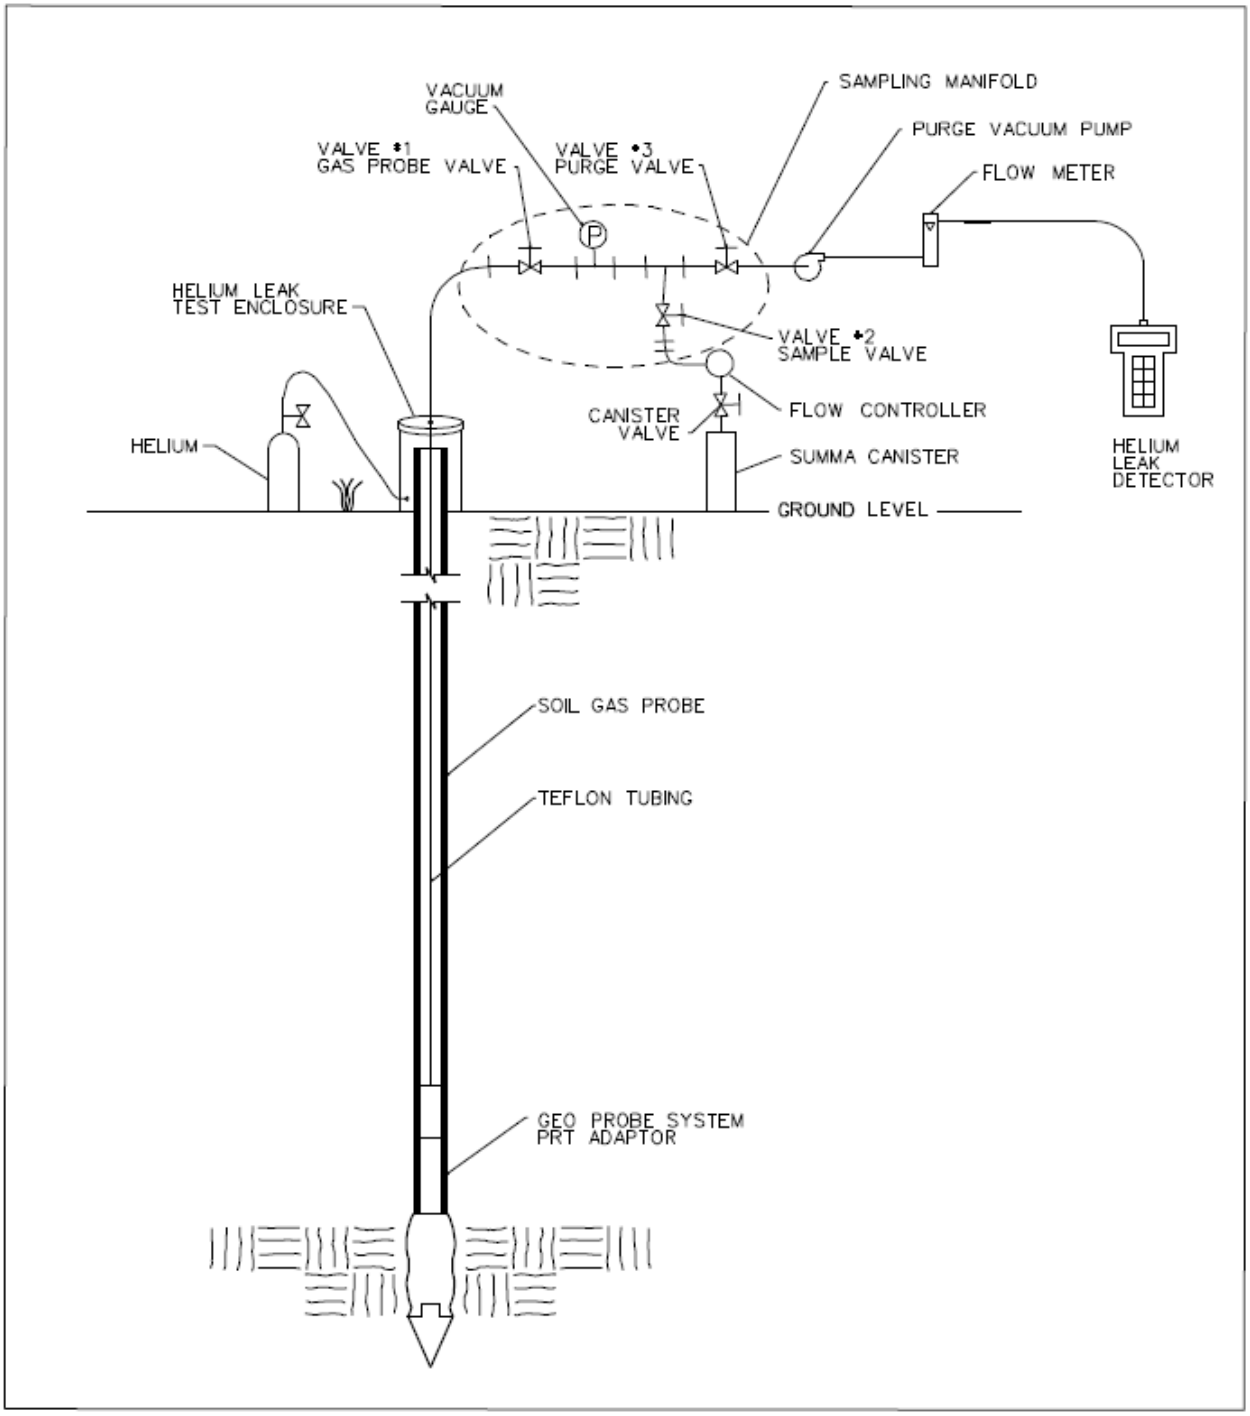
8.5. Place a custody seal over the openings to the shipping container.

8.6. Make sure to insure the package for the value of the sample containers and flow controllers.

8.7. Ship canisters for overnight delivery.

9. Quality Control

9.1. Canister supplied by the laboratory must follow the performance criteria and quality assurance prescribed in U.S. Environmental Protection Agency (EPA) Method TO-14/15 for canister cleaning, certification of cleanliness, and leak checking. SOPs are required.



9.2. Flow controllers supplied by the laboratory must follow the performance criteria and QA prescribed in EPA Method TO-14/15 for flow controller cleaning and adjustment. SOPs are required.

Table 1 – Common Sampling Rates for Soil Gas Sampling

Can Size	Length of sampling time	Sampling Flow Rate (ml/min)
6 Liter	1 hour	90
6 Liter	8 hours	11.25
6 Liter	24 hours	3.75
1 Liter	5 minutes	180
1 Liter	1 hour	15
850 ml	5 minutes	150
850 ml	1 hour	12

Revised Management Protocol for Handling and Disposition of Displaced Site Material

Revised Management Protocol for Handling and Disposition of Displaced Site Material, Topock Remediation Project, Needles, California

PREPARED FOR:	Topock Remediation Project Files
PREPARED BY:	Pacific Gas and Electric Company
DATE:	October 3, 2012 (submitted with 90% Design); rev. 1 July 2015 (submitted as part of 90% Responses to Comments); rev. 2 November 2015 (submitted with Final Design)

This document presents the general approach and management protocol required for the handling and disposition of soil and/or rock (referred to as "material" throughout the document) that is displaced as a result of past (as practical), present, and future activities associated with the Pacific Gas and Electric Company (PG&E) Topock Remediation Project, Needles, California. Specifically, this includes material removed from the Earth (i.e., displaced) as a result of drilling, excavation, sampling, testing, construction, grading, and other remedial activities. The management of material that may be disturbed as a result of remedial activities but not displaced from its natural location, such as soil disturbed by foot or vehicle traffic along a pathway, is not within the scope of this protocol. This protocol is applicable to the handling and disposition of displaced materials only. Further, materials that were not part of the natural site condition (e.g., building materials, equipment, waste, debris, or imported fill[1]) are not included in this protocol.

A draft of this protocol (dated October 3, 2012[2]) was included in the Soil Management Plan associated with the Basis of Design Report/Pre-Final (90%) Design Submittal and Construction/Remediation Action Work Plan (September 8, 2014). Subsequent to agency review of the design submittal, this protocol has been revised per comment from the U.S. Department of the Interior (DOI) (Comment #803, DOI-333 [see Attachment 1]). The October 3, 2012 draft of this protocol included a provision for the long-term storage of material that is determined to be non-hazardous waste but unsuitable for a final disposition decision on-site because contaminants are present above the interim screening level. The 90% design submittal identified an area (located on federal land) for the long-term storage of material that is generated during construction of the final groundwater remedy and is characterized to meet this profile; however, the DOI comment indicates that based on discussions with San Bernardino County, the adjacent lessee of Moabi Regional Park, and internal discussions between the U.S. Bureau of Land Management (BLM) and the DOI, PG&E must find an alternate location for storage. Based on further clarifications from DOI and BLM, PG&E understood that storage of waste soil above screening levels would not be allowed anywhere on federal lands within the project area. The remaining potential storage locations are private properties owned by the Fort Mojave Indian Tribe (FMIT) and PG&E. Given the groundwater remedy facilities already planned to be located on the Topock Compressor Station (TCS) and the TCS's operational needs for the property for natural gas compressor operations, there is space on PG&E property only to temporarily store a small number of soil bins at a time while awaiting analysis prior to final disposition. There is no available space on PG&E property to store waste soil on a longer-term basis. The FMIT did not identify any locations on the Tribe's property within the project area for this purpose. PG&E also contacted treatment storage and disposal facilities (TSDFs) and was told that the TSDFs would accept the waste soil for disposal, but not storage.

[1] For the purpose of this protocol, imported fill is defined as unconsolidated mixtures of sand, silt, and gravel (engineered gradations, or otherwise) that were not originally derived from inside the defined project boundary. Specific examples of imported fill material may include road base material, shading material used in pipeline trenches, or crushed rock used for railroad ballast.

[2] Responses to comments on the May 14, 2012 draft of this protocol (see Attachment 1) were incorporated in the October 2, 2012 draft of the protocol.

Given the above, PG&E determined that there was no available alternate location for the long-term storage of material with concentrations above the interim screening levels. Therefore, this protocol has been revised to exclude this provision.

1.0 Introduction

PG&E carefully plans Topock Remediation Project activities to minimize both the disturbance and displacement of site material. The land and soils are to be handled and managed with care and respect. Therefore, the protocol established in this plan is intended to minimize the amount of displaced material that leaves the site and instead, provide for eventual return, reuse, or restoration of the material onto the lands from which it was displaced. Through the application of this protocol and its incorporation into future work plans involving material displacement, it is anticipated that the goal of careful and respectful handling of soil material will be fulfilled.

In addition to addressing Tribal requests, this protocol was developed to comply with Mitigation Measure CUL-1a-8 as set forth in the certified Environmental Impact Report (EIR) and Mitigation Monitoring and Reporting Plan (MMRP) adopted by the California Department of Toxic Substances Control (DTSC). This measure requires PG&E to develop a Cultural Impact Mitigation Program (CIMP) as part of the final design of the approved groundwater remedy, and specifically subparagraph (g) requires the CIMP to include protocols for handling soil cuttings[3]. DTSC adopted this measure following its determination that the project area is a significant historical resource for California Environmental Quality Act (CEQA) purposes (Final EIR, p. 4.4-57). Similarly, as part of the consultation process for the Programmatic Agreement (PA) under Section 106 of the National Historic Preservation Act (NHPA), BLM determined that a traditional cultural property (TCP) eligible for inclusion on the National Register of Historic Places exists within the Area of Potential Effect (APE). Throughout this document, the term “site” refers to the project area.

2.0 Statement from Fort Mojave Indian Tribe

The following statement was made by the Fort Mojave Indian Tribe regarding the site background and cultural significance:

> *The Topock site and adjacent lands are part of a larger geographical area referred to as a Traditional Cultural Landscape (TCL). The TCL is the ancestral home of the Fort Mojave Indian Tribe and other Native American Tribes including the Hualapai Nation, Colorado River Indian Tribes, Quechan Nation, Cocopah Tribe, and Yavapai-Prescott Nation. This entire TCL is of tribal religious significance. In some areas and at certain times, tribal members carry out various cultural activities and religious ceremonies.*
>
> *The very nature of the remedial activities being performed at the Topock Compressor Station involve disturbance to the TCL. Such activities as drilling, soil sampling, excavation, construction, monitoring, testing, vehicle movement, foot traffic, geophysical and other surveys, emplacement of markers, and discharge of water, solids, and other material disturb the sanctity of the land that is held in the hearts of Native Americans.*
>
> *In particular, the removal and disturbance of soils, both surficially and from the subsurface, is of concern to the Tribes because such actions are regarded as profound disruptions of the sacred landscape. While the nature and significance of this concern is not easily understood by non-Native Americans, perhaps the following excerpt, attributed to the Duwamish Chief Sealth, begins to aid in the understanding:*
>
> > *Every part of this country is sacred to my people. Every hillside, every valley, every plain and grove has been hallowed by some fond memory or some sad experience of my tribe. Even the*

[3] Mitigation Measure CUL-1a-8(g) states the following: Protocols for the repatriation of clean soil cuttings generated during construction activities and during drilling associated with repair/replacement activities during operations and maintenance phases. The soil cuttings shall be managed in compliance with applicable laws and regulations on site.

rocks that seem to lie dumb as they swelter in the sun along the silent seashore in solemn grandeur thrill with memories of past events connected with the fate of my people, and the very dust under your feet responds more lovingly to our footsteps than to yours, because it is the ashes of our ancestors, and our bare feet are conscious of the sympathetic touch, for the soil is rich with the life of our kindred. (Chief Sealth, 1854)

The Pacific Gas & Electric Company (PG&E), in its implementation of the remedial actions required by the United States Department of the Interior (DOI) and the California Department of Toxic Substances Control (DTSC) must commit to performing these actions in a manner that is respectful of Native American values.

3.0 General Protocol for Management of Displaced Material (Mitigation Measure: CUL-1a-8[g])

This section presents each element of the protocol for the management of displaced material, including work planning, handling and short-term storage, contamination assessment, and final disposition. A graphical presentation of key elements of this process, and associated decision points, is presented on Figure 1 at the end of this document.

3.1 Work Planning

PG&E is required to prepare a work plan whenever a field activity is performed at the Topock site in support of a regulatory requirement or action. Through the established federal regulatory review process, these work plans are made available for review by process stakeholders and by the governments of affected Native American Indian Tribes (referred to as "Tribes" throughout this document) via the consultation process set forth in the PA's Consultation Protocol, consistent with Section 106 of the NHPA. In addition to the information describing the scope of work, field logistics and other implementation details, work plans that involve activities that displace site material also describe the process for the management and disposition of the materials. Work plans finalized subsequent to the development of this protocol will include specific description of the process for involving the input of Tribe(s) regarding the management of the material that will be displaced as a result of the work. Key procedural information to be included in the work plan will include, but not be limited to, the following:

- Summary of measures planned to minimize the amount of disturbance that will be incurred.
- Notification procedures to inform the Tribe(s), involved regulatory agencies, and affected land owner(s) regarding the proposed activities that will disturb/displace soil or other materials.
- The location of proposed disturbance activities (e.g. access pathways) and displacement activities (e.g. drilling or sampling locations), including maps.
- Estimation of the volume and type(s) of material that will be displaced.
- The location and methodology for short-term storage of displaced material (see Section 3.2).
- Methods that will be used to assess whether contaminants are present (see Section 3.3).
- Methods that will be used to minimize the volume of material that may be displaced during work including specific measures, such as field screening and material segregation strategies, to try and minimize the volume of material that requires disposal. .
- The anticipated location and methodology for final on- or off-site disposition (see Section 3.5).

3.2 Handling and Short-term Storage

Material that is displaced as a result of Topock Remediation Project activities including drilling, excavation, sample collection, testing, construction, grading, or other activities will be handled on-site in accordance with the project-specific work plan. Displaced material that must be characterized for key chemical properties prior to identifying

the appropriate final disposition method will be stored for the short term. Short-term storage areas and the protocol for handing material in these areas may vary by project. Depending on the type and volume of material displaced, location, land owner considerations, and other pertinent factors, short-term storage methods may include storage devices (e.g. bins) or properly maintained stockpiles that prevent this material from commingling with other areas of the environment. In some cases, short-term storage for characterization may not be necessary. For example, displaced material that is pre-characterized or characterized rapidly as work is conducted will be managed directly for final disposition (see Section 3.4).

Specific material handling and short-term storage details will be defined in the approved work plan for a given activity. Key details to be identified in the work plan include:

- The mode and location of short-term storage.
- The method of transfer from the point of origin to short-term staging area.
- Best management practices/regulatory requirements to prevent releases of the potentially contaminated material during transfer and storage.
- Best management practices to protect the material from weather, erosion, contamination, and vandalism while located in the short-term staging area(s).
- Method for segregation of soils based by location, as practicable and appropriate.

A key element of this handling protocol is the development of an inventory of all material displaced by Topock Remediation Project activities. Key information maintained in this inventory will include:

- Material displacement authorization – Specific work plan under which the work was conducted.
- Material origin – Specific location of the site.
- Material description (e.g., soil, rock, etc.).
- Date(s) of displacement or accumulation.
- Generating activity (e.g., drilling, excavation, etc.).
- Approximate volume of material stored.
- Short-term storage mode and location – Type of storage (including container identification number, as applicable) and location of short-term storage pending material characterization. In some cases, this information may need to be updated as containers are moved between areas of the site.
- Characterization status – Characterization sample information (e.g., date of submittal and laboratory used), date of receipt of results, and the contamination assessment based on comparison to screening criteria (see Section 3.3).
- Final disposition information – Indication of the on-site or off-site final disposition action identified through discussion with Tribe(s), agencies, and the affected land owner(s), as appropriate, based on review of material type and the contamination assessment (see Section 3.4).

Once the displaced material has been managed through final disposition, it will no longer be tracked in the displaced material inventory.

3.3 Contamination Assessment

Key chemical property information will be used to determine the final disposition method, and specifically, whether displaced material is suitable for retention on-site for eventual return, reuse, or replacement, or if the material must be removed from the site for disposal in accordance with applicable State and Federal laws and

regulations. Key information that will be considered to assess whether the material is contaminated, and therefore, whether the material can remain on-site or not, includes:

- Existing information including knowledge of the history of an area, or laboratory analytical results collected during previous phases of work. Use of existing information may preclude the need for additional analytical testing. When available, this information will be included in the work plan.
- Results of characterization samples collected for laboratory analysis, and observation of the physical properties of the material (e.g., white powder, burned material, boulders, etc.), as defined in the approved work plan for a given activity.
- Screening values for various analytes identified for the purpose of determining the appropriate material disposition method. Tables 1 and 2 at the end of this document present a reference list of analytes and associated screening levels that may be applicable for making decisions related to disposition of displaced site materials. The specific analytes applicable for characterization of displaced material will be determined based on the origin of the material and potential disposition locations. Screening values included on Tables 1 and 2 are defined in the following bullets, which will be modified as screening levels are added to these tables:
  - **Interim Screening Levels (Table 1)** – This is predominantly the background value. However, if the background value is not available then the lesser of the DTSC residential Screening Level (HERO's *Human Health Risk Assessment Note 3 – DTSC-modified Screening Levels*)[4] or the ecological comparison value is used. If a DTSC residential screening level is not available, it is the lesser of the United States Environmental Protection Agency (USEPA) residential regional screening level or the ecological comparison value. This value is the most conservative, and it is assumed that the project-specific cleanup goal and/or Tribal screening level will be equal to or greater than this value.
  - **Hazardous Waste Toxicity Characteristic Levels (Table 2) –** These values are used to determine if the material should be classified as a State or Federal hazardous waste. Specifically, total constituent concentrations expressed in milligrams per kilogram (mg/kg) will be compared to the hazardous waste characteristic levels in Table 2, and will be evaluated as follows:
    1. If the total constituent concentration exceeds the total threshold limit concentration (TTLC), the soil represented by the sample will be classified as a non-RCRA California hazardous waste. Additional evaluation of the soluble threshold limit concentration (STLC), as described in step 3 below, will not be performed.
    2. If the total constituent concentration exceeds the numeric value of the RCRA toxicity characteristic (TC) level by about 20 times or more, the toxicity characteristic leaching procedure (TCLP) will be performed. If the constituent concentration in the TCLP leachate exceeds the TC level, the soil represented by the sample will be classified as a RCRA hazardous waste. Additional evaluation of the STLC, as described in step 3 below, will not be performed.
    3. If the sample has not been classified as hazardous waste in steps 1 or 2, the total constituent concentration will be compared to the STLC. If the total constituent concentration exceeds the numeric value of the STLC by about 10 times or more, the California Waste Extraction Test (WET) will be performed. If the constituent concentration in the WET exceeds the STLC, the soil represented by the sample will be classified as a non-RCRA California hazardous waste.
    4. If the sample has not been classified as a hazardous waste in steps 1, 2, or 3, or by other applicable hazardous waste standards, the soil represented by the sample will not be classified or managed as hazardous waste.

[4] California Department of Toxic Substances Control's Human and Ecological Office (HERO). 2015. *Human Health Risk Note 3–DTSC-Modified Screening Levels*. May 3.

These values will be used to determine the final disposition of displaced material by comparing the representative concentration of a given volume of material to the screening values. The methodology for determining the representative concentration will be established in the project-specific work plan and should not be limited to a concentration-by-concentration comparison, but could include statistical estimates or averages based on multiple samples. Material that has a representative concentration that is equal to or below the interim screening level or project-specific cleanup goal (once established) is suitable for return, reuse, or replacement on-site. Material that has a representative concentration that is greater than the interim screening level or project-specific cleanup goal (once established), or is characterized as hazardous waste will be disposed of off-site in accordance with applicable laws and regulations.

The screening levels included in Tables 1 and 2 must be updated as applicable regulations and project-specific decisions are made. PG&E will review this information as remediation work plans are developed and implemented. As changes are determined appropriate, PG&E will submit revisions to the regulatory agencies and Tribe(s) for review and comment. Only agency approved values will be utilized.

3.4 Final Disposition

Final disposition refers to the final action taken on behalf of the Topock Remediation Project as it relates to the management of material displaced during associated activities. This protocol has been designed with the purpose of minimizing the volume of material that is disposed of off-site. Material determined to have a representative concentration that is equal to or less than the interim screening level or project-specific cleanup goal (once established) will be retained on site for return, reuse, and/or restoration. Material determined to have a representative concentration that is greater than this value will be transported off site for disposal in accordance with applicable laws and regulations or treated on site if appropriate based on the selection of the final soil remedy. Material return, reuse, and/or restoration options associated with final disposition on site are discussed in Section 4.

4.0 Return, Reuse, and/or Restoration of Displaced Material

Final on-site disposition alternatives include the return, reuse, and/or restoration of the displaced material. The preferred disposition alternative(s) will be considered on a case-by-case basis with the regulatory agencies, Tribe(s), and affected land owner(s), as suitable material is identified. Material types may differ by physical or chemical properties, and therefore the preferred on-site disposition alternative may also vary. Alternatives that have been preliminarily identified include, but are not limited to:

- Replacement of material into original borings, trenches, or excavations, from which they were removed.
- Replacement of material into borings, trenches, or excavations other than those from which they were removed.
- Creation of topographical or landscape barriers to protect sensitive areas.
- Creation of berms or other structures (e.g., gabions) to prevent erosion.
- On-site road maintenance (this alternative may require sorting the material for different physical sizes).
- Stockpiling in designated areas.

The above list of final on-site disposition alternatives is preliminary, and should not be considered complete. Further, if material is found to contain concentrations of volatile organic compounds it may not be suitable for return, reuse, and/or restoration near buildings where vapor intrusion would be of concern. Coordination with agencies, Tribe(s), and affected land owners is critical in design of the work plan to identify the preferred on-site disposition alternative(s) and communication milestones, so the material can be efficiently managed.

Material displaced as part of past remediation project activities was managed in accordance with project-specific work plans. As a result, some material has been retained at the site because contaminant concentrations were

below the Interim Screening Level. Therefore, previously displaced material is available for the return, reuse, and/or restoration alternatives included in the bullets above, or as additional uses are developed. As of June 2012, the estimated volume of material that has been retained and stockpiled through past remediation project activities is approximately 30 to 35 cubic yards.

	Vinyl chloride	59	EPA Residential RSL	See Table 2
	Xylenes, total	650,000	EPA Residential RSL	NE

Notes:

This table presents a reference list of analytes and associated screening levels that may be applicable for making decisions related to disposition of displaced site materials. The specific analytes and screening levels applicable for characterization of displaced material will be determined based on the origin of the material and potential disposition locations.

Interim screening level is background value. If background value is not available then the lesser of the DTSC HHRA Note 3 Residential Screening Levels (DTSC Residential SL) or the ecological comparison value is used. If a DTSC Residential SL is not available, it is the lesser of the USEPA residential regional screening level or the ecological comparison value.

Background	"Final Soil Background Investigation at Pacific Gas and Electric Company Topock Compressor Station, Needles, California" (CH2M HIll 2009c)
DTSC-Residential SLs	Human Health Risk Assessment Note 3 – DTSC-Modified Screening Levels, May 2015.
EPA Residential RSL	United States Environmental Protection Agency Residential Soil Regional Screening Level (THQ=1.0), June 2015.
ECV	Ecological Comparison Values; ECV were calculated as needed for constituents detected during the Part A Phase I sampling (Arcadis 2008)
HHRA Note 2	DTSC Human Health Risk Assessment (HHRA) Note 2: Remedial Goals for Dioxins and Dioxin-like Compounds for Consideration at California Hazardous Waste Sites – Interim (May 2009).
SF RWQCB ESL	San Francisco Bay Regional Water Quality Control Board Environmental Screening Levels for residential direct exposure (2013)
*	One or more screening levels (EPA Residential RSL, DTSC-Residential SLs, ECV, or Soil SL) have values lower than the background level.
NE	not established
mg/kg	milligrams per kilogram
ng/kg	nanograms per kilogram

Notes:

NE	not established
mg/kg	milligrams per kilogram
mg/L	milligrams per liter
EPA HW	Environmental Protection Agency Hazardous Waste Code
TC	Toxicity Characteristic
TTLC	Total Threshold Limit Concentration
STLC	Soluble Threshold Limit Concentration
RCRA	Resource Conservation and Recovery Act
TCLP	Toxicity Characteristic Leaching Procedure
WET	California Waste Extraction Test

Hazardous waste critiera exist for kepone, 2,4-D, mirex, pyridine, and 2,45-TP (Silvex); however, since they are not contaminants of potential concern at the Topock site, they are excluded from this table.

a	Total Threshold Limit Concentration (TTLC) from 22 CCR 66261.24(a)(2). Calculated based on the concentration of the elements, not the compounds.
b	Screening level is 10x Soluble Threshold Limit Concentraction (STLC). If screening level is exceeded in total analysis, California Waste Extraction Test (WET) should be run to evaluate whether STLC is exceeded.
c	Screening level is 20x RCRA Toxicity Characteristic (TC). If screening level is exceeded in total analysis, Toxicity Characteristic Leaching Procedure (TCLP) should be run to evaluate whether RCRA TC is exceeded.
d	Soluble threshold limit concentration from 22 CCR 66261.24(a)(2), measured using the WET. Calculated based on the concentration of the elements, not the compounds.
e	RCRA TC level from 22 CCR 66261.24(a)(1), measured using the TCLP.
f	A waste is assigned a RCRA waste code for each constituent where the results of the TCLP equal or exceed the RCRA TC level.
g	If o-, m- and p-Cresol concentrations cannot be differentiated, the total cresol (D026) concentration is used. The regulatory level of total cresol is 200 mg/L.
h	This footnote letter skipped intentionally.
i	In the case of asbestos and elemental metals, the specified concentration limits apply only if the substances are in a friable, powdered or finely divided state. Asbestos includes chrysotile, amosite, crocidolite, tremolite, anthophyllite, and actinolite.
j	TTLC and STLC exclude barite. TTLC excludes barium sulfate.
k	For STLC, if the waste does not exceed the RCRA TC or exhibit another RCRA hazardous characteristic, the STLC is 560 mg/L, not 5 mg/L.
l	For TTLC, excludes molybdenum disulfide.

Notes:

* Throughout this figure the term "material" is defined as soil and rock that may be displaced (i.e., removed from the Earth) as a result of work activities including drilling, excavation, sample collection, testing, construction, grading, or other activities. This does not include materials that were not part of the natural site condition (e.g. building materials, equipment, or imported fill).

Throughout this figure, the term “site” refers to the area within the Area of Potential Effect (APE).

General Management Protocol for Handling and Disposition of Displaced Site Material
PG&E Topock Remediation Project
Needles, California

Pacific Gas and Electric Company®

Attachment 1:
Responses to Comments

PG&E TOPOCK COMPRESSOR STATION
COMBINED COMMENTS RECEVIED FROM: DOI, DTSC, FMIT, AND THE TRC
ON THE DRAFT (MAY 14, 2012) "MANAGEMENT PROTOCOL FOR HANDLING AND DISPOSITION OF DISPLACED SITE MATERIAL, TOPOCK REMEDIATION PROJECT, NEEDLES, CALIFORNIA" AND ASSOCIATED PG&E RESPONSES, FOR DISCUSSION

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
1	In redline	Page 3, Handling and Short Term Storage First paragraph	DTSC	In some cases, short-term storage for characterization may not be necessary.	List some examples for clarity.	In situations where characterization data is available prior to disturbance, or is made available during disturbance (e.g. field screening or expedited laboratory analysis), short-term storage may not be necessary. Text will be revised to read as follows (changes in bold): "In some cases, short-term storage for characterization may not be necessary. **For example,** displaced material that is pre-characterized **or characterized rapidly as work is conducted** will be managed **directly** for long-term storage or final disposition, as appropriate (see Sections 3.4 and 3.5, respectively).	Resolved.
2	In redline	Page 3, Handling and Short Term Storage First paragraph	DTSC	Displaced material that is pre-characterized **per an agency approved work plan** will be managed for long-term storage or final disposition, as appropriate (see Sections 3.4 and 3.5, respectively)	Strike "per an agency approved work plan". Comment: Data may come from other sources (e.g., opportunistic samples). No need to limit available data.	Text will be deleted. See revised text in response to comment 1.	Resolved.
3	In redline	Page 4, Handling and Short Term Storage Final bullet	DTSC	Final disposition information – Indication of the **on-site** or off-site final disposition action identified through discussion with Tribe(s), agencies, and the affected land owner(s), as appropriate, based on review of material type and the contamination assessment (see Section 3.5).	Comment: Need to define "on-site/site/on site" used throughout the document to clearly understand where soil may end up.	The following statement has been added to the end of the second paragraph in Section 1.0: "Throughout this document, the term "site" refers to the area within the APE."	Resolved.
4	In redline	Page 4, Contamination Assessment First bullet	DTSC	Existing information including knowledge of the history of an area, or laboratory analytical results collected during previous phases of work. Use of existing information may preclude the need for additional analytical testing. When available, this information **should** be included in the work plan.	Replace "should" with "will".	Concur. The change has been incorporated.	Resolved.
5	In redline	Page 5, Contamination Assessment – (bullet) Hazardous Waste Toxicity Characteristic Levels Bullet 2	DTSC	If the total constituent concentration exceeds the numeric value of the RCRA toxicity characteristic (TC) level by **about** 20 times or more, the toxicity characteristic leaching procedure (TCLP) will be performed. If the constituent concentration in the TCLP leachate exceeds the TC level, the soil represented by the sample will be classified as a RCRA hazardous waste. Additional evaluation of the STLC, as described in step 3 below, will not be performed.	Add word "about". Comment: Adding flexibility to conduct leach tests if the dry values are in the neighborhood. Do this due to potential for soil to be heterogeneous.	Concur. The change has been incorporated.	Resolved.

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
6	In redline	Page 5, Contamination Assessment – (bullet) Hazardous Waste Toxicity Characteristic Levels Bullet 3	DTSC	If the sample has not been classified as hazardous waste in steps 1 or 2, the total constituent concentration will be compared to the STLC. If the total constituent concentration exceeds the numeric value of the STLC by **about** 10 times or more, the California Waste Extraction Test (WET) will be performed. If the constituent concentration in the WET exceeds the STLC, the soil represented by the sample will be classified as a non-RCRA California hazardous waste.	Add word "about".	Concur. The change has been incorporated.	Resolved.
7	In redline	Page 5, Contamination Assessment Last paragraph, last sentence	DTSC	As changes are determined appropriate, PG&E will submit revisions to the regulatory agencies and Tribe(s) for review **and acceptance. Only agency approved values will be utilized.**	Add text in bold.	Concur. Final text based on discussion with DTSC: As changes are determined appropriate, PG&E will submit revisions to the regulatory agencies and Tribe(s) for review and comment. Only agency approved values will be utilized.	Resolved.
8	1	End of document Table 2	DTSC	None.	The document does not speak to inside the fence line versus outside the fence line. If we use the Interim Screening Levels identified in this document for displaced soils originating from inside the fence line, there is a potential that more soil will be stored unnecessarily as inside the fence line soils would probably exceed background levels.	The management protocol currently addresses all material, regardless of area of origin, in the same way. A screening level specific to material inside the fence line may be established at a later date. As discussed at the end of Section 3.3, this management protocol will be updated as applicable regulations and project-specific decisions are made.	Resolved.
9	2	End of document	DTSC	None.	Will inside the fence line soils versus outside the fence line soils be allowed to move back and forth? How does this tie into the on-site soil management plan (SMP) being developed by PG&E? Discuss components of the SMP in this protocol.	This management protocol will be applied to material displaced as a result of remediation project activities regardless of whether the material originated inside or outside the fence line. Therefore soils may move outside from inside, or potentially vice-versa depending on designated storage areas or reuse options. The SMP will mirror the concepts in this protocol. Because this document is the standard protocol and the SMP will be a standalone document as part of the operations and maintenance manual for the groundwater remedy, the SMP will reference this document and include additional detail, but we do not see a reason to reference the SMP in this protocol. Further, this management protocol will be updated as is determined necessary based on additional details included in the finalized SMP.	**Subsequent DTSC Comment:** The comment should be revised to clarify that the SMP is not limited to groundwater and is intended to ensure potentially contaminated soils are adequately identified and handled at the compressor station (inside the fence line). See absolute comment 154 from the RTC table (June 29, 2012) for the soils work plan. **PG&E Response:** The SMP is part of the final groundwater remedy design document, and therefore, is specific to groundwater. However, details regarding the management of potentially contaminated soils on the compressor station (inside the fence line) will be addressed in the Soil RFI/RI Work Plan (Appendix J – Displaced Soil and Hazardous Waste Management Procedures). Resolved.

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
10	3	End of document Table 1	DTSC	None.	Interim Screening Level Source: Include soils screening levels for groundwater protection as screening criteria.	The Interim Screening Level represents the most conservative value, and are lower than the soil screening level for groundwater protection, with the exception of hexavalent chromium and molybdenum. The soil screening level for protection to groundwater for hexavalent chromium and molybdenum is below the background concentration for these metals. Final reuse decisions will be based on the more conservative Interim Screening Level or the project-specific clean up goal (or hazardous waste criteria), and therefore inclusion of soil screening levels for groundwater protection would not add a meaningful decision criteria to the protocol.	**Subsequent DTSC Comment:** Table 1 will need to be modified to identify that the soil screening level for molybdenum is below background. **PG&E Response:** Concur. The edit has been made. Resolved.
11	4	End of document Table 1	DTSC	None.	Interim Screening Level: The protocol should address screening criteria for vapor intrusion to indoor air, to ensure that vapor intrusion pathways will not be potentially created (e.g., do not place VOC impacted soil in areas that have, or likely to have enclosed structures such as MW-20 bench).	VOCs have not been detected in soils to date. Therefore there is no need to develop screening levels that are protective of indoor air from vapor intrusion pathways. However, the following statement will be added to second paragraph of Section 4.0: "Further, if material is found to contain concentrations of volatile organic compounds it may not be suitable for return, reuse, and/or restoration near buildings where vapor intrusion would be of concern."	Resolved.
12	5	End of document Table 1 - Notes	DTSC	None.	Include fluoride salts as they are COPC.	The note in Table 2 has been revised as discussed with DTSC.	Resolved.
13	6	End of document Table 2	DTSC	None.	Any listed wastes to be concerned with?	At this time we are not aware of any listed wastes that need to be considered for this management protocol. Additional soil data is pending collection as part of the soil investigation. As discussed at the end of Section 3.3, this management protocol will be updated as applicable regulations and project-specific decisions are made.	Resolved.
14	In redline	Figure 1	DTSC	**Agencies direct** PG&E to develop work plan based on regulatory requirement or action.	Revised text: PG&E to develop work plan based on regulatory requirement/action **or PG&E initiative**.	Concur. The change will be incorporated.	Resolved.
15	In redline	Figure 1	DTSC	PG&E begins work and generates material.	Revised text: PG&E begins work and generates material **and characterization data**.	To clarify, the word "additional" will be deleted from the decision box two levels below the box commented on, and the original box will not be edited.	**Subsequent DTSC Comment:** Edits were not completed as stated in text. Box 10: Add "characterization" in front of "data". Box 12: Delete "additional" as proposed. **PG&E Response:** Concur. The edits have been made. Resolved.
16	In redline	Figure 1	DTSC	Material is suitable for **on-site** return, reuse, and/or restoration alternatives.	Define "on-site".	The following note has been added to the figure: "Throughout this figure, the term "site" refers to the area within the Area of Potential Effect (APE)."	Resolved.

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
17	In redline	Page 5, Contamination Assessment Last paragraph, last sentence	DOI	As changes are determined appropriate, PG&E will submit revisions to the regulatory agencies and Tribe(s) for review **and acceptance. Only agency approved values will be utilized.**	It is unclear what is meant by acceptance. (See also comment 7 [DTSC])	See response to comment 7 (DTSC).	Resolved.
18	In redline	Page 6, Long-term Storage First paragraph, second sentence	DOI	Per DOI comment on this protocol (received in February 2012), this material must remain on-site until project-specific cleanup goals are finalized.	For clarification, DOI stated that the material could not be returned to the land until cleanup criteria are finalized in the ROD and may be stored until that time.	To clarify, the text has been revised as follows: "Per DOI comment on this protocol (received in February 2012), this material cannot be returned to the land until cleanup criteria are finalized in the Record of Decision (ROD) and may be stored until that time."	Resolved.
19	1		FMIT	None.	The 5-14-12 draft protocol still does not address the matter of the existing inventory of displaced soils. It only looks forward to activities that will involve soil disturbance as part of future work plans. This comment has been made previously by FMIT, but the issue remains unaddressed. The existing inventory of displaced soils must be addressed in this protocol. It is not anticipated that the handling and disposition of the existing soil inventory would be different from procedures and policies for addressing future displaced soils. A section of this protocol must address disposition of the existing displaced soils inventory.	As stated in the first sentence of the document, the intent is for this management protocol to apply to material that is displaced as a result of past (as practical), present, and future activities associated with the Topock Remediation Project. To speak specifically to the inventory of previously displaced soils at the site, the following text has been added to the end of Section 4.0 (Return, Reuse, and/or Restoration of Displaced Site Material): "Material displaced as part of past remediation project activities was managed in accordance with project-specific work plans. As a result, some material has been retained at the site because contaminant concentrations were below the Interim Screening Level (previously displaced material that has exceeded these levels was disposed off-site in accordance with the work plans). Therefore, previously displaced material is available for the return, reuse, and/or restoration alternatives included in the bullets above, or as additional uses are developed. As of June 2012, the estimated volume of material that has been retained and stockpiled through past remediation project activities is approximately 30 to 35 cubic yards."	
20	2		FMIT	None.	The draft does not address soil disturbances associated with the soils investigation. It appears that only soils displaced as a result of the groundwater remedy activities are explicitly covered. Again, this point has been raised by FMIT but remains largely unaddressed. FMIT realizes the necessity and importance of PG&E's addressing the respective mitigation measure (CUL-1a-8[g]) but that measure does not exclude applying these procedures to all displaced soils. The issue of soil handling was initially raised by FMIT years ago, and was not intended to be limited to the fulfillment of a mitigation measure for, or the implementation of, the groundwater remedy. PG&E has apparently reframed the issue to limit the scope of the protocol, however, the FMIT is concerned with the disturbance and displacement of soils, regardless of the	Based on clarification received from FMIT during the June 15, 2012 call, the tribes want this protocol to be inclusive of all activities at the Topock Compressor Station. This topic has been tabled for future discussion with PG&E, and the protocol will not be modified at this time. DTSC comment from September 18, 2012 letter to FMIT in response to September 7, 2012 letter from FMIT: As indicated in the first paragraph of the Protocol, "*This document presents the general approach and management protocol required for the handling and disposition of soil and/or rock (referred to as "material" throughout the document) that is displaced as a result of past (as practical), present, and future activities*	The Tribe believes that this item has not yet been adequately addressed. The Tribe's position on this item is documented in the letter attached to the RTCs table. The agency response letter is also attached.

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
					associated activity or remedial action at the Site, and expects the PG&E and the Agencies to examine and find solutions for the whole of the issue.	*associated with the Pacific Gas and Electric Company (PG&E) Topock Remediation Project, Needles, California. Specifically, this includes material removed from the Earth (i.e., displaced) as a result of drilling, excavation, sampling, testing, construction, grading, and other remedial activities*". As cited, DTSC does not interpret the Protocol to be limited only to soil displaced as a result of groundwater remedy implementation. On the contrary, the scope appears to be sufficiently broad to cover all aspects of the environmental project conducted under the oversight of DTSC and the US Department of the Interior. DTSC is aware, however, that this protocol, once developed, could be submitted by PG&E to comply with a portion of Mitigation Measure CUL-1a-8 of the certified Final Environmental Impact Report where PG&E is to develop a protocol for handling soil cuttings to be included in the Cultural Impact Mitigation Program as part of the final design of the approved groundwater remedy. Currently, DTSC is in the process of conducting a California Environmental Quality Act (CEQA) evaluation for the soil investigation work plan. Based on the results of the soil CEQA evaluation, the same mitigation measure may be found to be appropriate for the soil investigation activities. Note that displaced soils from soil investigation activities will not be generated until after the soil CEQA evaluation is completed and the soil investigation work plan is approved.	
21	3		FMIT	None.	There is no commitment to minimize disturbances that are not associated with the listed activities as a result of incidental or associated activities (e.g., vehicles, etc.). PG&E is directing this primarily at CUL-1a-8[g], however, FMIT again requests that these procedures be a broader statement of policy committing to minimization or disturbance for all Site activities. Other soil disturbing activities that PG&E might perform should also 'voluntarily' follow this protocol.	See response to comment 20 (FMIT). Per Aug-6, 2012 discussion, additional detail was added to the bullets in Section 3.1 regarding areas of disturbance and displacement.	
22	4		FMIT	None.	The application of soil criteria for the determination of reuse needs some additional flexibility. Since there will likely be (or should be) several discrete soil samples with chemical concentrations for a given amount of soil, it is the average of these values for that soil accumulation that should be used. This is justified because exposure occurs over an area and the soil will be further mixed when it is placed back on the site.	The specific process for characterization of displaced site material is an example of a detail that would be included in the project-specific work plan. DTSC comment from September 18, 2012 letter to FMIT in response to September 7, 2012 letter from FMIT: In addition to potential concentration-by-concentration comparison between the disturbed soil and screening criteria, DTSC does not object to considering other alternative methods as long as the methods will yield data that are representative of the material in question, are in accordance with waste classification regulations, and standard practice for classifying materials such as	As of the September 7, 2012 letter, the Tribe believes that this item has not yet been adequately addressed. The Tribe's position on this item is documented in the letter attached to the RTCs table. The agency response letter is also attached. The document has been revised per the direction in the September 18, 2012 letter in response to the September 7, 2012 letter (as detailed in the column to the left).

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
						investigation derived soil cuttings for the purposes of determining proper disposal. DTSC concurs with the approach that additional details regarding this issue can be addressed in the individual work plans. PG&E Comment – The sixth paragraph on page 5 has been revised to read as follows (text additions are in **bold**): "These values will be used to determine the final disposition of displaced material **by comparing the representative concentration of a given volume of material to the screening values. The methodology for determining the representative concentration will be established in the project-specific work plan and should not be limited to a concentration-by-concentration comparison, but could include statistical estimates or averages based on multiple samples**. Material that **has a representative concentration that** is equal to or below the interim screening level is suitable for return, reuse, or replacement on-site. Material that is characterized as hazardous waste must be disposed of off-site in accordance with applicable laws and regulations. Material that **has a representative concentration that** is greater than the interim screening level, but not classified as a hazardous waste, will be stored on-site until the project-specific cleanup goals are established. Until these goals are established, material that falls into this intermediate category will be retained on-site for "long-term storage" (see Section 3.4)."	
23	5	Table 1	FMIT		Why is the "Project-specific Cleanup Goal" differentiated from the "Tribal Screening Level"? The Tribal land use scenario is the most appropriate future land use and the calculation of risk-based concentrations is a "Project-specific Cleanup Goal" and not a screening level.	Based on discussion during the June 15, 2012 call, it is premature to have the project-specific cleanup goals and the tribal screening levels included on Table 1 since they have yet to be determined. Therefore, these columns will be deleted from Table 1. As discussed at the end of Section 3.3, this management protocol will be updated as applicable regulations and project-specific decisions are made.	
24	6		FMIT		The overall logic that would set screening criteria according to the location of origin of the soil is flawed. Soil disturbances often involve commingling of soils to various depths, while the potential exposure scenarios usually relate to materials at or near the surface. The depth of soil placement/reuse should be considered in the decision for reuse.	Separation of displaced soil to this level of detail (shallow vs. deeper) greatly increases the level of complexity related to soil testing and management scenarios and could result in a larger storage footprint, but could be accomplished. However, current return, reuse, and/or restoration scenarios are not depth-specific, and deeper reuse scenarios may be limited. Variables like future erosion or change in regulations also complicate two-tier reuse scenarios. The document will be revised as additional screening levels are developed.	The Tribe believes that this item has not yet been adequately addressed. The Tribe's position on this item is documented in the letter attached to the RTCs table. The agency response letter is also attached.

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
						DTSC comment from September 18, 2012 letter to FMIT in response to September 7, 2012 letter from FMIT: DTSC supports PG&E's response in the RTC summary table that separation of displaced soil to this level of detail (shallow vs. deep) greatly increases the level of complexity related to soil testing and management scenarios and could result in a larger storage footprint. The current return, reuse, and/or restoration scenarios are not depth-specific, and deeper reuse scenarios may be limited. Variables like future erosion or change in regulations also complicate two-tier reuse scenarios. More importantly, the decision to reuse soil that is above screening criteria regardless of depth ultimately rests on the respective land owners who own the land where the displaced soil will be reused. If potentially contaminated soils will be reused, the land owner must agree to a land use covenant restricting the use of their land after backfilling. DTSC believes that this issue cannot be managed at a global level since the decision is dependent on location, depth, concentration of material and landowner acceptance, DTSC believes that this issue can be deferred and handled on a case-by-case basis, potentially during the individual work plan, to first determine if there are potential locations that will require deep backfill, and more importantly, the individual land-owners preference on this issue. **PG&E comment – Additional detail regarding potential material reuse scenarios that are specific to a given work plan will be included in the individual work plans, as necessary.**	
25	7	Figure 1	FMIT		We suggest adding a number to each block in the diagram for clarity. In the "second to the last block" it says "Material must be managed offsite." If contaminant concentrations are less than or equal to (<) project-specific cleanup goal, why couldn't they be treated onsite if appropriate and feasible?	Numbers will be added to flow chart boxes. The text in the "second to last block" will be modified to read as follows: "Material will be managed off site, or treated on site if appropriate based on the selection of the final soil remedy." Additional text has also been added to Section 3.5.	
26	1	Page 4, Contamination Assessment	Hualapai / TRC		Key information that will be used in assessing whether the displaced material is contaminated is discussed in Section 3.3 Contamination Assessment. Within this section it is stated that contamination determinations of displaced materials can be based on "existing information including knowledge of the history of an area" and "observation of the physical properties of the material". It is unclear however, how physical observation or historical knowledge of an area can be used in comparisons against the quantitative interim screening values provided in	Examples of key physical properties have been added to the second bullet in Section 3.3, and now reads as follows: "Results of characterization samples collected for laboratory analysis, and observation of the physical properties of the material (e.g., white powder, burned material, boulders, etc.), as defined in the approved work plan for a given activity." Regarding "existing information/history of an area", see response to comment 27 (Hualapai/TRC).	

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
					Tables 1 and 2.		
27	2	Page 4, Contamination Assessment Third bullet.	Hualapai / TRC	The specific analytes and interim screening levels applicable for characterization of displaced material will be determined based on the origin of the material and potential disposition locations.	Section 3.3 Contamination Assessment states that "the specific analytes and interim screening levels applicable for characterization of displaced material will be determined based on the origin of the material and potential disposition locations." This statement appears to suggest that the interim soil screening levels that are provided in Tables 1 and 2 are not to be consistently applied to all displaced soils but rather the origin and fate of the displaced soil will dictate which analyte will be evaluated and what interim threshold value is used. This is unclear and could use additional clarification.	The screening levels included on Tables 1 and 2 will be applied uniformly to all analytes included on the table. To clarify, the text "**and screening levels**" will be deleted from the statement. Regarding specific analytes, the protocol provides flexibility such that a subset of analytes included on Table 1 may be used to characterize displaced material, as determined appropriate. For example, material that is generated from an area not suspected of dioxin/furan contamination may not need to be characterized for dioxin/furan concentrations prior determining the appropriate disposition alternative.	
28	3		Hualapai / TRC		Interim screening values should not be based on background values. The use of background is unnecessarily over-conservative, the background data are based on a small yet variable group of samples, and use of the background threshold value will inevitably result in long term stockpiling of soils with no associated risk. Until a Tribal Screening level is developed it can still be safely assumed that the use of a CHHSL interim screening value will be equal to or greater than the Tribal Screening level and should be used in place of the background screening level.	The use of background is purposefully conservative until project-specific cleanup goals are established. While it is correct that this may result in long term storage of soils that are later determined to have no associated risk, agency input and concurrence is required if less conservative values are to be used.	
29	4		Hualapai / TRC		The use of ecological screening values (ECVs) should only occur in situations were displaced soils would be returned to surface locations. Most of the developed ECVs were developed based on exposures to terrestrial receptors which would not come into contact with subsurface soils. Clearly no significant pathway of exposure for ecological receptors exists for soils removed and replaced into deep boreholes. Therefore if ECVs are to be used it is suggested that there use be limited to the screening of only surface related soils.	See response to comment 24 (FMIT) and 28 (Hualapai/TRC).	

Absolute Comment No.	Agency Comment No.	Comment Location (Page)	Commenter	Reference Text	Comment	PG&E Response and/or Proposed Edits	Comment Status
30	5		Hualapai / TRC		It was clearly stated in the Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil that "the ECVs, while based on information developed during the ecological risk assessment (ERA) scoping, are to be applied only to soil investigation planning in conjunction with background values. Specifically, the ECVs are not intended for use as either cleanup goals or as screening levels to eliminate COPECs." Furthermore within the Revised Addendum to the Revised Human Health and Ecological Risk Assessment Work Plan (August 2008) PG&E states that "ECVs were developed to support the soil investigation data gaps assessment". Therefore it appears that the use of ECVs as interim screening levels for the determination of soil cleanup is outside of the scope of which these values were developed.	ECVs are only included on Table 1 for select analytes as the Interim Screening Level (see notes). However, the Interim Screening Level is not used for the determination of soil clean-up. The Interim Screening Level is used as the most conservative screening level to determine if the material is suitable for on-site return, reuse, and/or restoration alternatives. As presented on Figure 1, if the material contains contaminant concentrations greater than the Interim Screening Level (and below hazardous waste criteria), then it must stored until project-specific clean-up goals are established.	
31	6		Hualapai / TRC		There may be a need for rapid field analyses in order to, for example, place cuttings materials back down a bore hole or to work in very sensitive areas. Selected elements and possible field methods need to be discussed as part of the process to define screening levels.	It is conceivable that rapid field screening or laboratory analytical data may be necessary to make expeditious decisions related to the characterization of displaced material. However, these operational details are deferred to the project-specific work plan, where all details related to the implementation of the scope of work can be fully considered. The reference list of potentially applicable analytes and associated screening levels (Table 1) is being developed based on past operation information available for the Site, and therefore, is inclusive of all analytes of potential concern. However, this list is not dependant on the types of analytical methods (field or fixed-base laboratory) used for characterization of displaced site material.	
32	7		Hualapai / TRC		Other details were not presented in the report. For example, composite samples may be collected and analyzed in order to categorize a batch of soils. A displaced material tracking data base may be necessary in order to catalog the site locations, depths, methods of displacement, etc.	Many operational details, such as the method(s) for characterizing soils that are displaced as a result of Topock Remediation Project activities, are deferred to the project-specific work plan. See also the response to comment 22 (FMIT). Please refer to Section 3.2 (Handling and Short-term Storage) regarding plans to build an inventory of all material displaced by Topock Remediation Project activities.

Re: FMIT Comments on Revised Protocol on Displaced Materials, August 28, 2012

Dear Mr. Marcos:

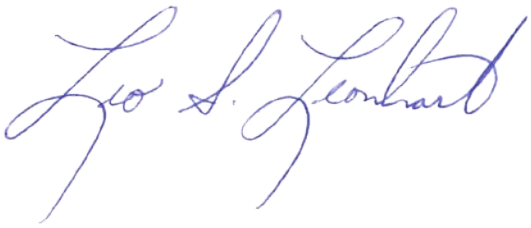
Hargis + Associates, Inc. (H+A) on behalf of our client, the Fort Mojave Indian Tribe ("the Tribe" or "FMIT"), is hereby providing comments on the above-referenced revision to the Displaced Materials Protocol ("the Protocol"), in response to your email of September 4, 2012.

The Tribe is concerned over the suggestion that this Protocol is nearing finalization, yet there does not appear to be full resolution of Tribal comments. The Tribe agrees that this document has been prepared in a collaborative manner with frequent opportunity to exchange ideas and for the parties to provide input. Nevertheless, our review of the "Response to Comments," (RTC) prepared by the Pacific Gas & Electric Company (PG&E), characterizes the status of various tribal comments as "resolved." However, some of the issues that have been consistently raised by the Tribe during the process in fact remain unresolved. As you know from the correspondence of July 23, 2012, referenced below, the Tribe has concerns with the comment resolution process for the project in general.

The Tribe commented previously on the RTC process for the draft *Soil RCRA Facility Investigation/Remedial Investigation Work Plan (Work Plan), PG&E Topock Compressor Station, Needles, California.* Specifically, the last column of the RTC table identifies the resolution status of individual "Absolute Comments," much like the last column in PG&E's RTC for the displaced soils protocol. The Tribe took issue with the fact that the Agencies, the California Department of Toxic Substances Control (DTSC) and U.S. Department of the Interior (DOI), characterized the resolution status as "resolved," when in fact the Tribe had certain residual issues.

While the Tribe understands that the ultimate decisions for project matters remain the Agencies' responsibility, it is important that dissenting views of Tribes and stakeholders be documented in the record whenever the "resolution" overrides the concerns expressed throughout the process. On August 31, 2012, the Tribe received a letter from DOI and DTSC in response to the Tribe's letter of July 23, 2012, expressing concerns over the RTC process. The Agencies' letter recognized that several of the Tribe's issues in fact remain unresolved and indicated that DOI would request that PG&E remove the "resolved" notation from all Tribal comments. DOI further

indicated its willingness to consult with the Tribe on the matter and procedure for issue resolution.



The RTC for the displaced soils protocol is unacceptable to the Tribe for the same reasons: the document seems to state that PG&E, not the Agencies, had made determinations in regard to issue resolution. This function properly belongs to the Agencies and must not be directly or indirectly delegated to a third party. Also, the document does not accurately reflect unresolved issues raised by the Tribe or document why they cannot be accommodated, if that is the case, a key part of meaningful collaboration and consultation. Perhaps finalization of the Protocol can await the Agencies' consideration of this letter and the conclusion any further discussions on this subject with the Tribes.

Accordingly, below, the Tribe hereby is identifying three items where the Tribal issues remain unresolved, and requests that either these issues be resolved jointly with the Tribe(s) or the reasons why these issues cannot be accommodated at this time be identified and documented within the RTC summary. The comments are attached.

Please contact me if you have questions concerning this letter.

Sincerely,

HARGIS + ASSOCIATES, INC.

839.07 Displaced Materials

Fort Mojave Indian Tribe Comments on the Draft Soils Reuse Protocol that Remain Unresolved

Comments on the RTC

1. Comment 20 by FMIT.

   There are two separate issues that have been inappropriately combined. The first issue is the Tribe's position that this Protocol should apply to all aspects (*e.g.,* groundwater and soil) of the Topock Remediation Project. The second issue was the request by the Tribe that the Protocol be applied to all soil-related projects. This second issue was potentially addressed by moving it to discussions between PG&E and the Tribes directly. However, this resolution does not address the first issue. Therefore, the Tribe again requests that this Protocol be applied to all aspects of the Topock Remediation Project.

2. Comment 24 by FMIT and 29 by Hualapai/TRC.

   The comment and the comment's final sentence are two separate, but related issues regarding the application of the soil criteria to decide on the disposition of disturbed soils. One issue is that it should be the final location of disturbed soil replacement that determines the applicable criteria, not the source location of the disturbed soil. And second, when the final location of disturbed soil replacement is selected, if the location has deep (*i.e.,* below 2 feet bgs) backfill areas, and if future erosion is unlikely, then this deeper backfill soil may have less stringent acceptance criteria. While it is understood that the Protocol has criteria that are not depth-related, this issue of backfill depth can be used to decrease the amount of soil that must be removed from the site, thereby lessening the impact of the cleanup on the Site.

Comments on the August 30, 2012, Draft Protocol

1. Page 5, paragraph 6.

   FMIT has commented previously that when the Protocol describes a simple comparison between the material *(i.e.,* the disturbed soil) and the criteria, without further discussion, it gives the impression that concentration-by-concentration comparisons will be used. As discussed in the last teleconference, there may be other estimates of 'material concentration' that could be used (*e.g.,* average). While the RTC specifies that the procedure for this comparison will be addressed in specific work plans, the Tribe requests that this paragraph be edited to include the statement "material concentrations will be established for each soil pile in short-term storage. This concentration may include a statistical estimate for that soil pile." (Note: 'pile' may not be the correct word in this context and a substitute can be discussed.)

RESPONSE TO SEPTEMBER 7, 2012 LETTER ON FMIT COMMENTS REGARDING REVISED PROTOCOL ON DISPLACED MATERIALS, PACIFIC GAS AND ELECTRIC COMPANY (PG&E), TOPOCK COMPRESSOR STATION, NEEDLES, CALIFORNIA

Dear Dr. Leonhart:

The Department of Toxic Substances Control (DTSC) is in receipt of your letter dated September 7, 2012, which was sent on behalf of the Fort Mojave Indian Tribe (FMIT) pertaining to the FMIT concerns over the *"Management Protocol for Handling and Disposition of Displaced Site Material, Topock Remediation Project"* (Protocol). DTSC appreciates the FMIT's input as provided in your letter, and believes that they will help greatly in quickly resolving any potentially unresolved issues related to the Protocol.

As you know, it has been nearly one year since your initial draft of what has evolved into the current version of the Protocol. Its development has been a collaborative effort between the various agencies, Tribes, stakeholders and PG&E as part of the displaced soil committee. The parties involved have met multiple times to discuss the details of the document and its implementation strategy. DTSC believes that these meetings throughout the past year demonstrate the commitment of all parties to completing this task and to provide meaningful input into its development.

After reviewing the August 28, 2012 version of the Protocol, DTSC believes that the document has captured the issues and the resolutions suggested during the yearlong dialogues of the committee. However, in your letter, you expressed, on behalf of the FMIT, concern over DTSC's suggestion that the Protocol is nearing completion, and your letter indicates that the response to comments (RTC) summary table does not accurately reflect unresolved issues raised by the Tribes. You specified three

Printed on Recycled Paper

comments that the FMIT believes remain unresolved and you requested that these issues be resolved jointly with the Tribes or document the reasons why they cannot be accommodated at this time in the RTC summary table.

DTSC notes, however, that the 'resolved' status for comments listed on the RTC table were determined by the committee members during the various meetings after each comment was discussed. Never the less, DTSC will request PG&E to revise the RTC summary table for those three comments to reflect the FMIT's position. DTSC is providing the following discussion to clarify our understanding of the issues raised by the three specific comments. DTSC hopes that the responses adequately address the FMIT's comments so that the Protocol can continue to move forward.

1. Absolute Comment No. 20 by FMIT – According to the FMIT comment, the Protocol does not address soil disturbances associated with the soils investigation, and it appears that only soils displaced as a result of the groundwater remedy activities are explicitly covered. The FMIT requests that the protocol to be applied to all aspects (e.g., groundwater and soil) of the Topock Remediation Project.

As indicated in the first paragraph of the Protocol, *"This document presents the general approach and management protocol required for the handling and disposition of soil and/or rock (referred to as "material" throughout the document) that is displaced as a result of past (as practical), present, and future activities associated with the Pacific Gas and Electric Company (PG&E) Topock Remediation Project, Needles, California. Specifically, this includes material removed from the Earth (i.e., displaced) as a result of drilling, excavation, sampling, testing, construction, grading, and other remedial activities".* As cited, DTSC does not interpret the Protocol to be limited only to soil displaced as a result of groundwater remedy implementation. On the contrary, the scope appears to be sufficiently broad to cover all aspects of the environmental project conducted under the oversight of DTSC and the US Department of the Interior. DTSC is aware, however, that this protocol, once developed, could be submitted by PG&E to comply with a portion of Mitigation Measure CUL-1a-8 of the certified Final Environmental Impact Report where PG&E is to develop a protocol for handling soil cuttings to be included in the Cultural Impact Mitigation Program as part of the final design of the approved groundwater remedy.

Currently, DTSC is in the process of conducting a California Environmental Quality Act (CEQA) evaluation for the soil investigation work plan. Based on the results of the soil CEQA evaluation, the same mitigation measure may be found to be appropriate for the soil investigation activities. Note that displaced soils from soil investigation activities will not be generated until after the soil CEQA evaluation is completed and the soil investigation work plan is approved. DTSC will instruct PG&E to add a statement in the RTC summary table reflecting DTSC's position.

2. Absolute Comments No. 24 by FMIT and 29 by Hualapai/TRC – The Tribes request that the depth of the soil placement/reuse should be considered in the decision for reuse.

DTSC supports PG&E's response in the RTC summary table that separation of displaced soil to this level of detail (shallow vs. deep) greatly increases the level of complexity related to soil testing and management scenarios and could result in a larger storage footprint. The current return, reuse, and/or restoration scenarios are not depth-specific, and deeper reuse scenarios may be limited. Variables like future erosion or change in regulations also complicate two-tier reuse scenarios.

More importantly, the decision to reuse soil that is above screening criteria regardless of depth ultimately rests on the respective land owners who own the land where the displaced soil will be reused. If potentially contaminated soils will be reused, the land owner must agree to a land use covenant restricting the use of their land after backfilling. DTSC believes that this issue cannot be managed at a global level since the decision is dependent on location, depth, concentration of material and landowner acceptance, DTSC believes that this issue can be deferred and handled on a case-by-case basis, potentially during the individual work plan, to first determine if there are potential locations that will require deep backfill, and more importantly, the individual land-owners preference on this issue. DTSC will instruct PG&E to revise the RTC summary table to remove the 'resolved' status for this comment, incorporate DTSC's position, and indicate that additional detail can be included in the individual work plans.

3. FMIT Comment on page 5, paragraph 6 of the August 2012 draft protocol – The FMIT requests the inclusion of the statement, *"material concentrations will be established for each soil pile in short-term storage. This concentration may include a statistical estimate of the soil pile"*. In addition to potential concentration-by-concentration comparison between the disturbed soil and screening criteria, DTSC does not object to considering other alternative methods as long as the methods will yield data that are representative of the material in question, are in accordance with waste classification regulations, and standard practice for classifying materials such as investigation derived soil cuttings for the purposes of determining proper disposal. DTSC concurs with the approach that additional details regarding this issue can be addressed in the individual work plans. DTSC will instruct PG&E to update the Protocol and RTC summary table to incorporate the FMIT's proposed concept as a potential alternative.

Finally, your letter indicated that the FMIT has concerns with the comment resolution process for the project in general. The FMIT expressed similar concerns in a letter dated July 23, 2012. DTSC and the U.S. Department of the Interior provided a response to the FMIT letter on August 31, 2012. If you feel that this letter and the August 31, 2012 letter do not adequately address your general concerns regarding the comment resolution process for the project, we would like to meet with you to discuss any remaining concerns you may have.

DTSC hopes that this letter provided additional clarification and adequately addressed the FMIT's issues related to the Protocol. As always, DTSC appreciates the Tribes and stakeholders continuing involvement on the PG&E Topock project and we look forward to working with you in moving the overall project forward. If you have any questions, please feel free to contact me at (714) 484-5492.

Response to DOI Comment #803 on the 90% Design
Topock Groundwater Remediation Project
PG&E Topock Compressor Station, Needles, California

Comment No.	Unique Comment ID (if applicable)*	Comment Type (Design/ Non-Design)	Comment Category	Section/ Page	Reference Text	90% Design Comment *(Please provide sufficient detail, include specifically what you are looking for)*	PG&E Response	DTSC Response	DOI Response	Tribes Response	Final Resolution
803	DOI-333	Design	Infrastructures	2.1.3/2-6	The soil storage area, also comprising approximately 1.55 acres, will serve as the primary storage area for excavated soils…	Based on discussions with San Bernardino County, the adjacent lessee of Park Moabi Regional Park, and internal discussions between the Bureau of Land Management and the Department of the Interior, PG&E must find an alternate location for storage of waste soil above screening levels.	Based on further clarifications from DOI and BLM, PG&E understands that storage of waste soil above screening levels will not be allowed on federal lands. The remaining potential storage locations are private properties owned by FMIT and PG&E. Given the remedy facilities already planned to be located on the TCS and the Station's own operational needs for the property for its natural gas compressor operations, there is only space on PG&E property to temporarily store soil bins while awaiting analysis prior to final disposition. There is not adequate space on PG&E property to store waste soil on a long term basis. PG&E also contacted local TSDFs and was told that the TSDFs would accept the waste soil for disposal, not for storage. Given the above, at this time, PG&E has not been able to identify an alternate location for storing the waste soil. PG&E defers to the FMIT regarding its views on potential use of the Tribe's property within the project area for this purpose. In the meantime, in response to this comment, PG&E will eliminate the proposed soil storage area at Moabi Regional Park and move the proposed CHQ into that area. Note that displaced soils that are below screening levels may still be stored at the currently proposed soil processing area and the CHQ (subject to space availability). The management protocol for handling and disposition of displaced site materials (Appendix C to the CIMP, Appendix B to the Soil Management Plan) was revised to reflect that the materials above screening levels will be disposed of offsite. The revised protocol was provided in this 90% RTC period and included in **Attachment Q** of the final RTC table.		Resolved.		This RTC was discussed at the July 23, August 19, and August 26 TWG meetings. Comment resolved.

Appendix C
Construction and Operations Best Management Practices (BMPs) Plan for Soil Storage

Construction and Operations Best Management Practices (BMPs) Plan for Soil Storage

This Best Management Practices (BMPs) Plan for soil storage during construction and operations of the final groundwater remedy at the Pacific Gas and Electric Company (PG&E) Topock Compressor Station has been prepared as required by the following Environmental Impact Report (EIR)[1] mitigation measures and Applicable or Relevant and Appropriate Requirements (ARARs):

- Mitigation measure AIR-1 requires the implementation of fugitive dust control measures during construction activities.
- Mitigation measure HYDRO-1 requires the implementation of BMPs to meet the substantive criteria of applicable federal, state, and local permit and regulatory requirements for stormwater discharges associated with construction and land disturbance activities.
- ARAR #34 requires the implementation of BMPs for stormwater runoff which comes in contact with construction activities (>1 acre of ground disturbance).

This BMPs Plan has been prepared to meet the above requirements, and in accordance with the substantive criteria of the NPDES General Permit for Stormwater Discharges Associated with Construction and Land Disturbance Activities Order No. 2009-0009-DWQ, Amended Order No. 2010-014-DWQ, Amended Order No. 2012-0006-DWQ, NPDES No. CAS000002 (California General Permit)[2] for construction activities in San Bernardino County, California, as well as the substantive criteria of the Arizona Pollutant Discharge Elimination System (AZPDES) General Permit AZG2013-001 for Stormwater Discharges associated with Construction Activity to Waters of the United States (General Permit) for construction activities in Mojave County, Arizona.

This BMPs Plan has been prepared by a California Qualified SWPPP Developer (QSD) and will be implemented under the direction of a Qualified SWPPP Practitioner (QSP). A summary of key BMPs identified for soil storage of the project is presented below in Section 1.0; inspection, monitoring, corrective actions, reporting, and recordkeeping information for the BMPs Plan is presented in Section 2.0; and workers training and education in Section 3.0.

The PG&E Topock Site Operations Manager and the Field Team Leader will have control over day-to-day activities, and will implement this BMP Plan under the direction of the QSP (see Section 2.2 for additional details on the BMPs Project Team).

1.0 Project BMPs

This section provides a summary of the Project BMPs. The specific EIR mitigation measures other than HYDRO-1 or project SOPs are referenced for each BMP category where appropriate. Figure C-1 at the end of this appendix shows the site topography and inferred surface water flow for the soil storage area located at Moabi Regional Park. It should be noted that during construction, temporary storage (or staging) of displaced soils will also occur in staging areas near the primary work zones (i.e., construction zones).

1.1 Erosion Control BMPs

Scheduling – In order to reduce the amount and duration of soil exposed by construction activities, a schedule will be established to coordinate construction activities and construction site BMPs while taking local climate into

[1] California Department of Toxic Substances Control (DTSC). 2011. *Final Environmental Impact Report for the Topock Compressor Station Groundwater Remediation Project*. January.

[2] State Water Resources Control Board (SWRCB). 2009. Construction General Permit Fact Sheet. Adopted Order No. 2009-0009-DWQ. Sacramento, CA.

consideration. Construction site BMPs will be installed prior to start of construction and inspected prior to and after anticipated rain or erosion events. Sufficient lag time will be built into the schedule to allow for rain delays.

Preservation of Existing Vegetation – Existing vegetation will be preserved whenever feasible. Preservation of existing vegetation will be incorporated into the schedule prior to the commencement of clearing and grubbing or other soil disturbing activities. In the event that existing vegetation needs to be disturbed, areas that need to be preserved will be identified by a qualified biologist and marked with temporary fencing. All employees and subcontractors will be informed on the limits of disturbance within the construction site and will be instructed to keep clear of delineated areas.

Geotextiles and Mats – A natural (excelsior, straw, coconut, etc.) or synthetic (usually polyethylene) material will be used to reduce soil erosion by wind or water. Stockpiles will be covered and secured.

1.2 Sediment Control BMPs

Silt Fence – Silt fences will be placed below areas where sheet flows discharge from the site. They will also be used as interior controls below disturbed areas where runoff may occur in the form of sheet and rill erosion and around inlets within disturbed areas. Silt fences are most effective when used in combination with erosion controls around temporary spoil areas and stockpiles, and below other small cleared areas.

Fiber Rolls/Sediment Wattles – These consist of aspen wood excelsior, straw, flax, or other similar materials that are rolled and bound into tight tubular rolls and placed on the face of slopes at regular intervals depending on steepness of slopes to intercept runoff and reduce flow velocity. Rolls/wattles will be installed prior to start of construction activities to form a barrier around work areas and stockpiles and will be anchored down with stakes. If the stockpiles are on paved areas, gravel or sand bags are preferred; however, fiber rolls can be used and secured with gravel or sand bags. The fiber rolls/sediment wattles will be inspected prior to forecasted rain events and after rain events to ensure the fiber rolls are working properly. Sediment accumulated by the fiber rolls will be removed periodically to maintain the effectiveness of the fiber rolls.

Gravel Bag Berms – Gravel bag berms can be used as an alternative to fiber rolls and sediment wattles. If used, they will be installed prior to rain events to form a barrier to intercept runoff or reduce its velocity. Gravel bags will also be used, if necessary, during trenching activities when stockpiles are onsite. In the event that gravel bag berms are used as perimeter erosion control, the bags will be placed two bags high. When used to anchor stockpiles, they will be placed one bag high.

Sand Bag Berms – Sand bag berms can also be used as an alternative to fiber rolls and sediment wattles. If used, they will be installed prior to rain events to form a barrier to intercept runoff or reduce its velocity. The purpose is to allow sediment to settle from runoff before water leaves the construction site. Sand bags will also be used, if necessary, during trenching activities when stockpiles are left onsite.

Straw Bale Barriers – Straw bale barriers can also be used as an alternative to fiber rolls, gravel bag berms, and sand bag berms. Straw bale barriers intercept and slow down sheet flow runoff, causing temporary ponding. The temporary ponding provides quiescent conditions allowing sediment to settle. Straw bale barriers also interrupt the slope length and thereby reduce erosion by reducing the tendency of sheet flows to concentrate into rivulets, which erode rills, and ultimately gullies, into disturbed, sloped soils. Straw bale barriers will be placed one bag high.

1.3 Stockpile Management Control BMPs

Stockpile management procedures and practices are implemented to reduce or eliminate pollution to the air and stormwater from materials that are stockpiled. Stockpile protection is required year-round. Any stockpiles will be stored in the staging area and outside of the roadway right-of-way. Stockpiles will be located a minimum of 50 feet away from any concentrated flow of stormwater, drainage courses, and inlets. During the rainy season, stockpiles will be covered and anchored down with fiber rolls/sediment wattles, silt fences, gravel bags, sand bags, and/or straw bales. Additional stockpile management BMPs are presented in the subsections below.

Non-RCRA Hazardous Soil. It is anticipated that non-RCRA hazardous soil will be placed in roll-off bins or similar containers. If it is necessary to temporarily stockpile non-RCRA hazardous soil the following BMPs will be followed:

- Stockpiles will be constructed with liners and perimeter berms to prevent release or infiltration of liquids. Minimum 20-mil polyethylene sheeting or equivalent will be used for liners if the stockpile is on a foundation, or minimum 60-mil polyethylene sheeting or equivalent will be used if the stockpile is not on a foundation.
- Wind erosion will be prevented by use of a cover, applying Soiltac® or a similar soil stabilization product, or other suitable means. If a cover is employed it will be minimum 6-mil polyethylene sheeting or equivalent.
- The perimeter berm will be constructed of clean materials (such as hay bales or straw wattle under the liner).
- If a cover is employed, it will extend over the outer edges of the perimeter berm and liner so that rainfall is prevented from entering the stockpile.
- Covers and perimeter berms will be secured in place when not in use and at the end of each workday and as necessary to prevent wind dispersion or runoff from precipitation events.
- Only soil that does not contain free liquids will be stockpiled.
- Liquids that accumulate inside the berm will be pumped from the stockpile to a container or tank for characterization and disposal.
- If the stockpile is outside of a secured area, the stockpile will be demarcated with barricades, orange cones, and/or caution tape until it is removed from the site.
- Erosion control measures will be employed to prevent stockpiled soil from contributing to surface runoff and wind-generated particulate matter.
- The stockpile will be inspected weekly and after storms to verify that controls for windblown dispersion and prevention of runoff and run-on are functioning properly.
- After the stockpile has been removed, the area will be inspected and all residual material will be removed from the underlying and surrounding areas.

The stockpile location will be certified by a California-registered professional engineer for compliance with these requirements, consistent with California Health and Safety Code Section 25123.3(b)(4)(B).

Non-Hazardous Soil Above Interim Screening Levels or Project-Specific Cleanup Goals (once established). It is anticipated that all soil that is above soil screening levels or project-specific cleanup goals will not be stockpiled and will be placed in roll-off bins or similar containers. If it is necessary to temporarily stockpile displaced soil that is non-hazardous, but unsuitable for final disposition onsite because contaminants are present above the interim screening level, the following BMPs will be followed:

- Stockpiles will be constructed with liners and perimeter berms to prevent release or infiltration of liquids. Minimum 20-mil polyethylene sheeting or equivalent will be used for liners.
- Wind erosion will be prevented by use of a cover, applying Soiltac® or a similar soil stabilization product, or other suitable means. If a cover is employed it will be minimum 6-mil polyethylene sheeting or equivalent.
- The perimeter berm will be constructed of clean materials (such as hay bales or straw wattle under the liner).
- If a cover is employed, it will extend over the outer edges of the perimeter berm and liner so that rainfall is prevented from entering the stockpile.
- Covers and perimeter berms will be secured in place when not in use and at the end of each workday and as necessary to prevent wind dispersion or run-off from precipitation events.
- Liquids that accumulate inside the berm will be pumped from the stockpile to a container or tank for characterization and disposal.

- If the stockpile is outside of a secured area, the stockpile will be demarcated with barricades, orange cones, and/or caution tape until it is removed from the site.
- Erosion control measures will be employed to prevent stockpiled soil from contributing to surface runoff and wind-generated particulate matter.
- After the final volume of stockpiled soil has been removed, the area will be inspected for visual contamination due to stockpiling activities, and any remaining residual contaminated material will be removed.

Clean Soil. Stockpiles of displaced soil outside of Soil RFI/RI Investigation Areas that is non-hazardous, clean, and suitable for immediate reuse will be stored following these BMPs:

- Stockpiles will be constructed with liner and perimeter berm to prevent release or infiltration of liquids. Minimum 20-mil polyethylene sheeting or equivalent will be used for liners.
- Wind erosion will be prevented by use of a cover, applying Soiltac® or a similar soil stabilization product, or other suitable means. If a cover is employed it will be minimum 6-mil polyethylene sheeting or equivalent.
- The perimeter berm will be constructed of clean materials (such as hay bales or straw wattle under the liner).
- If a cover is employed, it will extend over the outer edges of the perimeter berm and liner so that rainfall is prevented from entering the stockpile.
- Covers and perimeter berms will be secured in place when not in use and at the end of each workday and as necessary to prevent wind dispersion or run-off from precipitation events.
- If the stockpile is outside of a secured area, the stockpile will be demarcated with barricades, orange cones, and/or caution tape until it is removed from the site.
- Erosion control measures will be employed to prevent stockpiled soil from contributing to surface runoff and wind-generated particulate matter.
- After the stockpile has been removed, all residual material will be removed from the underlying and surrounding areas.

1.4 Wind Erosion Control BMPs

To comply with EIR Mitigation Measures AIR-1a, AIR-1b, AIR-1c, and AIR-1e, wind erosion control will be applied as necessary to prevent nuisance dust and minimize the movement of sediment disturbed during construction. Specifically, the project site will be watered periodically with a water truck for short-term stabilization of disturbed surface areas to minimize visible fugitive dust emissions during dust episodes. A water truck also will be used to control dust on disturbed surfaces during visible dusting episodes. Loaded haul vehicles will be covered on publicly maintained roads. Graded sites will be stabilized using soil binders, as necessary, upon completion of grading when subsequent development is delayed or expected to be delayed more than 30 days, except when such delay is caused by precipitation that dampens the disturbed surface area sufficiently to eliminate visible fugitive dust emissions. Non-essential earth-moving activities will also be curtailed under high wind conditions (winds greater than 25 miles per hour).

1.5 Tracking Control BMPs

Stabilized Construction Entrance/Exit – A temporary construction entrance is defined as a stabilized point of entrance/exit to a construction site to reduce the tracking of mud and dirt onto private or public roads by construction vehicles. A temporary construction entrance will be established in the laydown area to minimize sediment tracking. The temporary construction entrance will be inspected routinely. To comply with EIR Mitigation Measure AIR-1d, project-related track out or spills on publicly maintained paved surfaces will be cleaned up within twenty-four hours.

1.6 Good Housekeeping BMPs

Good housekeeping measures are in addition to the above project-specific BMPs, and will be implemented onsite for the duration of the Project.

- Cover and berm loose stockpiled construction materials that are not actively being used.
- Contain and securely protect stockpiled waste materials from wind and rain at all times unless actively being used.

1.7 Drums/Small Containers

Drums containing soils which are hazardous waste will be stored in a hazardous waste storage area at the Compressor Station and/or the Transwestern Bench and disposed of within 90 days of generation. If needed, drums/small containers that contain soil that may be displaced in the vicinity of the groundwater remedy system that is non-hazardous, but unsuitable for final disposition onsite because contaminants are present above the interim screening level or project-specific cleanup goals, will be staged for offsite transportation following these BMPs:

- Only DOT-specification containers will be used for soil accumulation.
- Empty drums will be inspected and inventoried upon arrival onsite for signs of contamination and/or deterioration.
- Drums and small containers will be transported to the temporary accumulation areas on wood pallets and will be secured together with non-metallic banding.
- Drums will be placed within a bermed and lined area or otherwise will be provided with secondary containment.
- Adequate aisle space (e.g., 36 inches) will be provided for containers such as 55-gallon drums to allow the unobstructed movement of personnel and equipment for inspection purposes. Drums will be placed with no more than two drums per row. The column length must fit within the lined, bermed area.
- Each drum will be provided with its own label, and labels will be visible for inspection purposes.
- Drums will remain closed except when removing or adding soil to the drum. Closed means that the lid and securing ring must be on and securely tightened.

1.8 Roll-off Bins

- All empty roll-off bins will be inspected upon arrival onsite. Any roll-off containers arriving with contents, residual contamination, or deterioration will be rejected. Existing damage (dings, significant paint scratches, broken wheels, etc.), if not significant enough to result in rejection, will be documented upon arrival of the bin using photos and written documentation.
- Roll-off bins will be provided with covers and disposable liners.
- Covers will be properly secured, except when adding or removing soil.
- Old labels will be removed, and each bin will be provided with its own label. Labels will be visible.
- Roll-off bins containing soils that are hazardous waste will be stored in a hazardous waste storage area and disposed of within 90 days of generation.
- Roll-off bins containing clean soil can be stored anywhere on PG&E property or at other properties that have granted permission to PG&E.
- Roll-off bins that contain displaced soil that is non-hazardous, but unsuitable for final disposition onsite because contaminants are present above the interim screening level will be stored at designated locations. The bins will be covered and inspected at a specified frequency (see Section 2.0 for inspection frequencies).

2.0 Visual Inspection, Monitoring for Non-Visual Pollutants, Reporting, Training, and Recordkeeping

This section discusses visual inspections, monitoring for non-visual pollutants, reporting, workers training and education, and recordkeeping.

2.1 Visual Inspection after Qualifying Rain Event

In conformance with the substantive requirements of the Arizona General Permit (Order No. AZG2013-001) and California General Permit (Order No. 2009-0009-DWQ), visual inspections will be implemented to assess the effectiveness of BMPs related to soil storage, and to modify those BMPs, if necessary, to continue to reduce pollutants and impacts on receiving waters. Anticipated activities associated with the inspections include the following:

- Visually inspect BMPs and stormwater discharges at discharge locations within two business days (48 hours) after each qualifying rain event (producing precipitation of one-half inch or more of discharge). The objectives are to 1) identify whether BMPs were adequately designed, implemented, and effective, and 2) identify additional BMPs accordingly.
- Visually inspect the discharge of stored or contained storm water that is derived from and discharged subsequent to a qualifying rain event producing precipitation of ½ inch or more at the time of discharge. Stored or contained storm water that will likely discharge after operating hours due to anticipated precipitation will be observed prior to the discharge during operating hours.
- Record the time, date and rain gauge reading of all qualifying rain events.
- Implement corrective actions as appropriate.

Rain event inspections will occur during working hours when it is safe to do so. In the event of rain over a weekend or during a long holiday the inspection can occur prior to or after the weekend. If the inspection day falls on a Sunday, the inspection may be conducted on the following Monday.

Inspections are not required under adverse conditions. The QSP is not required to inspect areas that, at the time of inspection, are considered unsafe for inspection personnel. Inspections may be postponed when conditions exist such as local flooding, high winds, or electrical storms, or situations that otherwise make inspections unsafe. The inspection must resume as soon as conditions are safe. Results of the inspection and any corrective action perform will be documented and kept onsite. An example Inspection and Corrective Action Report Form, which may be used for both Arizona and California inspections and corrective actions is included in Attachment 1.

2.2 Visual Inspection for Non-Stormwater Discharge

In addition, quarterly visual inspections will be conducted for non-stormwater discharge. The objective is to inspect for the presence of (or indications of prior) unauthorized and authorized non-storm water discharges and their sources. Inspection records will include the personnel performing the visual observation (inspections), the dates and approximate time of the inspection, and the response taken to eliminate unauthorized non-storm water discharges and to reduce or prevent pollutants from contacting non-storm water discharges, if any.

2.3 Monitoring for Non-Visual Pollutants

Monitoring for non-visual pollutants will be conducted to determine whether pollutants that are known to occur on the soil storage sites and that cannot be visually observed or detected in storm water discharges, are being conveyed from the site by storm water.

The QSP will develop and implement the sampling and analysis requirements prior to the start of construction, to monitor for non-visual pollutants associated with soil storage activities. These requirements may be modified as needed to meet the monitoring objectives. Sampling and analysis is only required where the QSP believes pollutants associated with construction activities have the potential to be discharged with storm water runoff due to a spill or in the event there was a breach, malfunction, failure and/or leak of any BMP. If sampling is required as

determined by the QSP, samples will be collected down-gradient from potential discharge locations, in areas which can be safely accessed. In addition, a sample of stormwater that has not come into contact with the disturbed soil or the materials stored or used on-site (uncontaminated sample) will be collected for comparison with the discharge sample. These samples will be collected during the first two hours of discharge from rain events that occur during business and daylight hours and which generate runoff.

Samples will be analyzed for parameters indicating the presence of pollutants identified in the pollutant source assessment required in Section J.2.a.i. of the Construction General Permit (SWPPP Appendix A) which states:

> *"Identify the products used and/or expected to be used and the end products that are produced and/or expected to be produced. This does not include materials and equipment that are designed to be outdoors and exposed to environmental conditions (i.e. poles, equipment pads, cabinets, conductors, insulators, bricks, etc.)."*

2.4 Reporting

Annual reports include a summary and evaluation of all sampling and analysis results, original laboratory reports, and chain of custody forms, a summary of all corrective actions taken during the compliance year, and identification of any compliance activities or corrective actions that were not implemented. Annual reporting is a requirement of permitted SWPPP documents and reports are submitted electronically through SMARTs. Because this is not a permitted SWPPP, the annual reports will not be submitted through SMARTs. The annual reports will be submitted to DTSC (in compliance with mitigation measure HYDRO-1) and DOI.

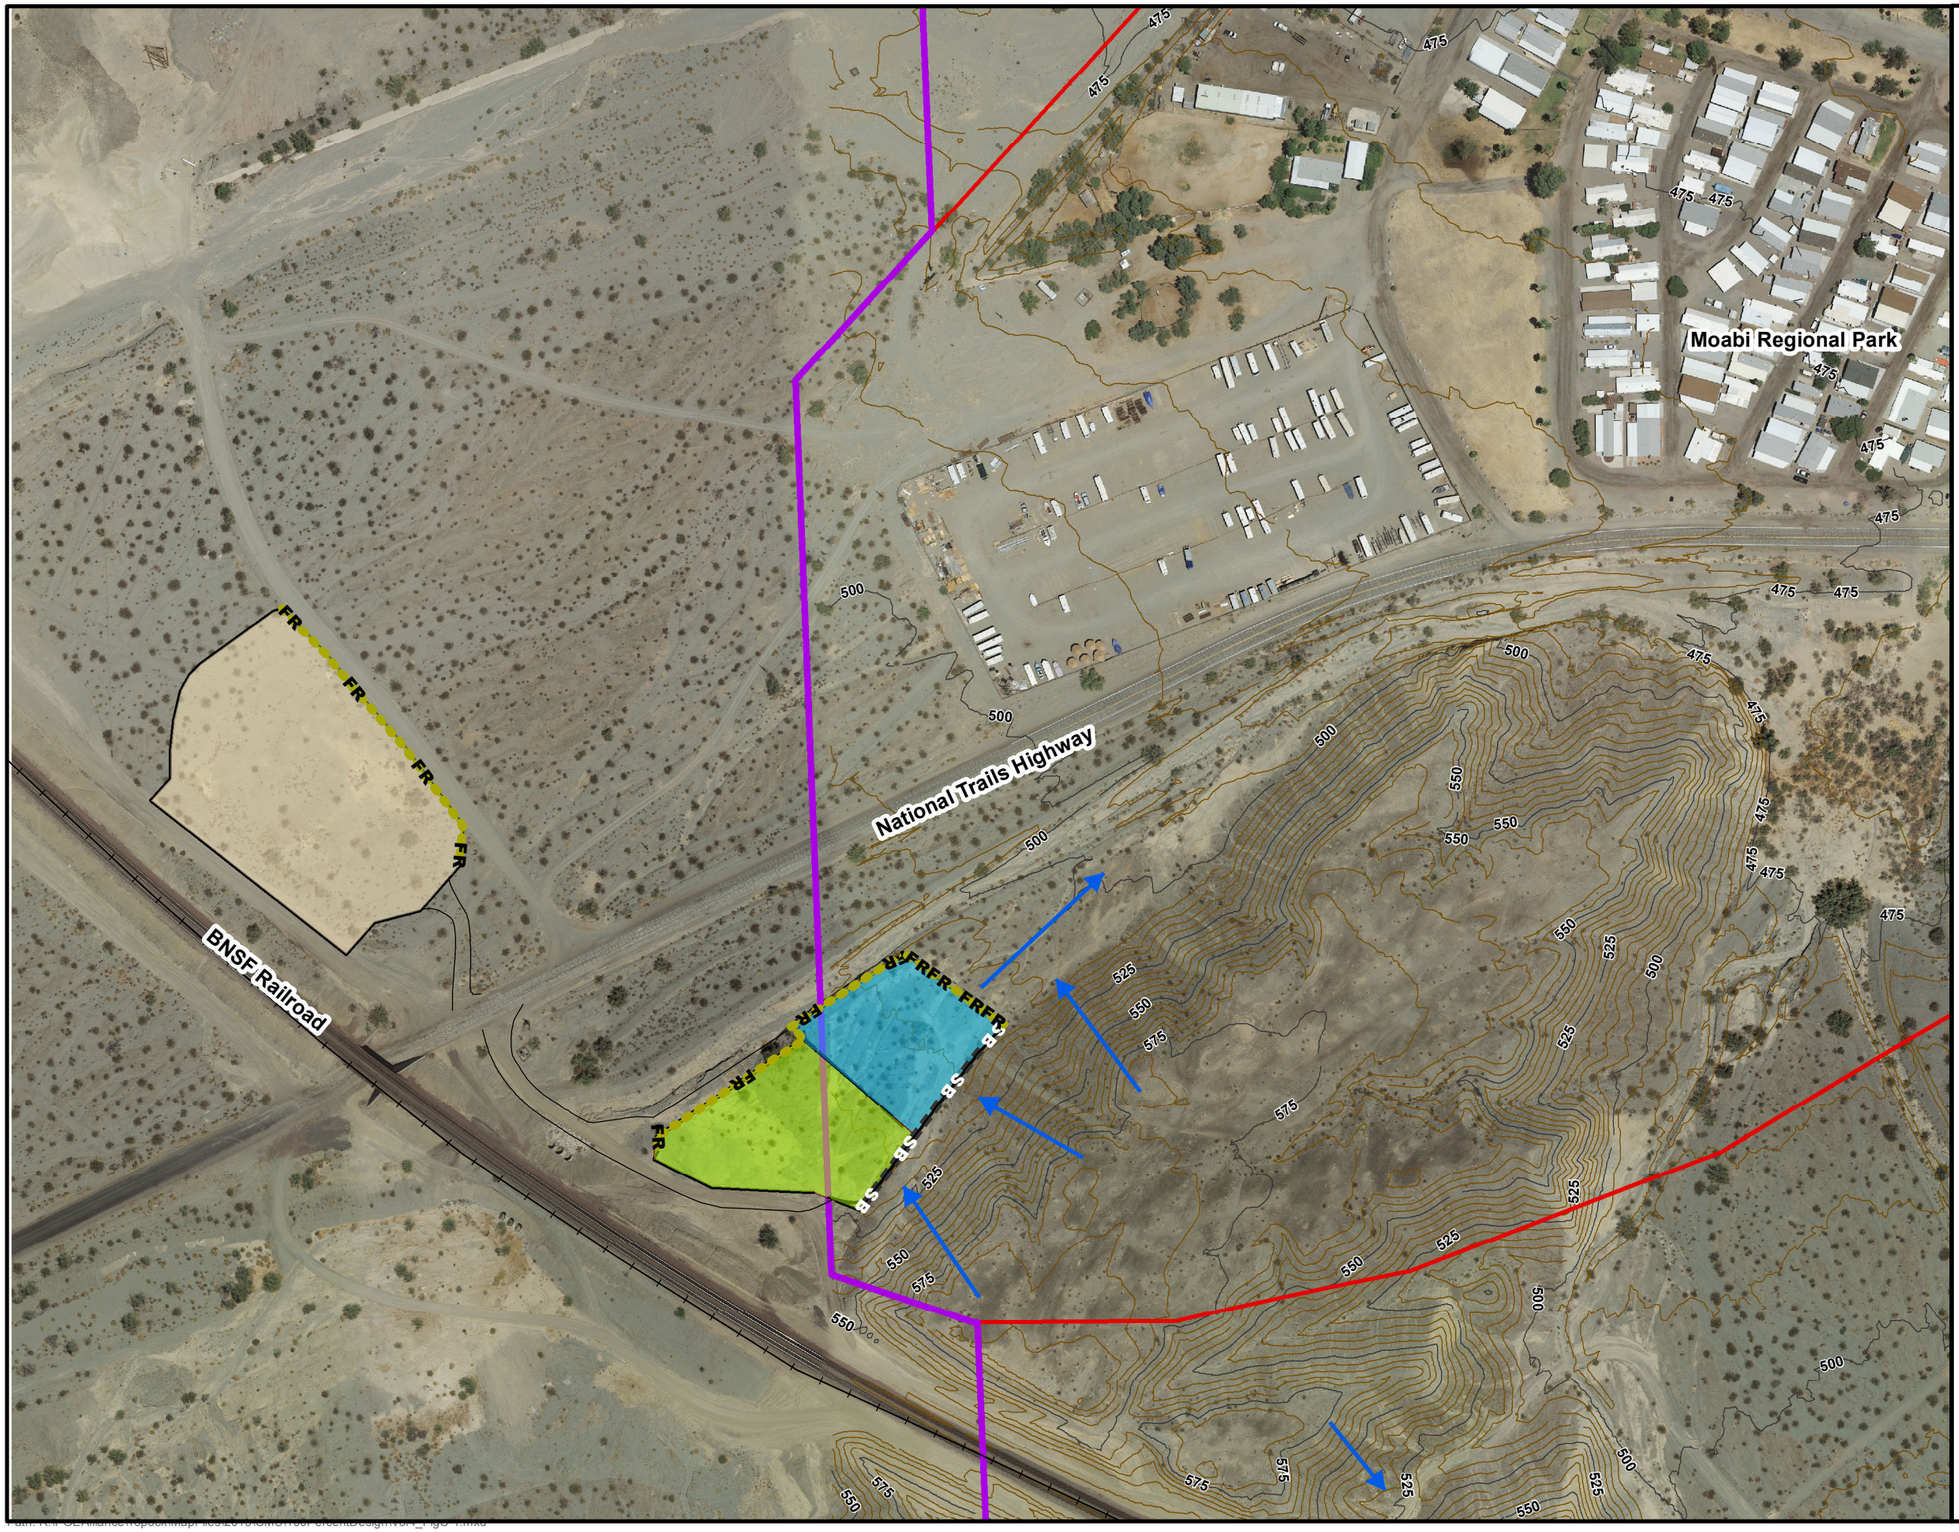
2.5 Workers Training and Education

Prior to the beginning of construction, construction workers will be trained on the overall storm water management program and more specifically, on proper implementation of this BMPs plan. Persons directly responsible for compliance with the plan, such as inspectors, workers installing and maintaining the erosion control devices, and workers collecting stormwater samples, will receive additional training. New personnel that require stormwater management training after the start of construction will be provided training. Documentation of the training will be kept onsite.

In parallel, Operations staff will be trained on overall storm water management program and more specifically, on the proper implementation of this operations BMPs Plan for soil storage, as well as the Industrial SWPPP included as appendix to the O&M Plan (Volume 1 of the O&M Manual).

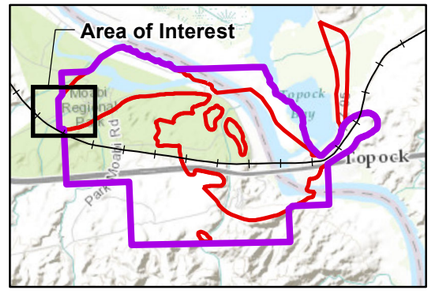
2.6 Record Keeping

The following records will be maintained onsite:



- This BMPs Plan and any updates necessary to reflect current conditions and to maintain accuracy.
- Copies of relevant documents that would affect the provisions or implementation of the BMPs Plan.
- Descriptions and dates of any incidences of significant spills, leaks, or other releases pertaining to soil storage that resulted in discharges of pollutants in stormwater to a regulated municipal separate stormwater systems or to waters of the U.S., the circumstances leading to the release and actions taken in response to the release and measures taken to prevent the recurrence of such releases.
- Documentation of maintenance, including repairs of structural control measures, including the date(s) of discovery of areas in need of repair/replacement, date(s) that the structural control measure(s) returned to full function, and the justification for any extended repair schedules. The maintenance records will include the date(s) of regular maintenance.
- BMP inspection reports and corrective action report forms (see Attachment 1 for an example of a corrective action report form which may be used for both California and Arizona).
- Annual reports.
- Training documentation.

2.7 BMPs Project Team



The BMPs Project Team members include:

- PG&E Site Operations Manager, Curt Russell
- PG&E Environmental Inspector, Chris Smith
- PG&E Construction Project Manager, Danielle Starring – Operational control over construction plans and specifications
- QSD, Gino Nguyen (CH2M HILL) – BMPs Plan development
- QSP, to be appointed – Operational control over construction plans and specifications
- Construction Contractors, to be appointed
- Field Team Leader, to be appointed – Responsible for day-to-day activities
- Field Operators, to be appointed – Responsible for day-to-day activities

The BMPs Project team as defined above represents the current project organization. PG&E may reorganize and/or assign other parties to these roles over the course of the construction and O&M of the groundwater remedy to ensure project success.

VICINITY MAP

LEGEND

- Long-term Remedy Support Area (0.8 Acres Approximate)
- Soil Storage/Processing Area (2.56 Acres)
- Temporary Construction Laydown Area (1.05 Acres Approximate)
- Area of Potential Effects (APE)
- EIR Project Area
- Estimated Flow Direction
- Sand Bags (SB)
- Fiber rolls/sediment wattles/ straw bales/silt fence (FR)

Notes:

1. This is a conceptual layout. Locations are approximate. BMPs are not drawn to scale.
2. Descriptions of activities/functions anticipated for the construction support areas are included in the Construction/Remedial Action Work Plan.
3. Descriptions of activities/functions anticipated for the long-term remedy support areas are included in Section 3.5 of the BOD, and the O&M Manual.

Inspection and Corrective Action Report Form

2013 Construction General Permit
Inspection & Corrective Action Report Form

ADEQ Arizona Department of Environmental Quality

Section I. General Information (see instructions)

Name of Project		CGP Tracking No.	AZCON – _____	Inspection Date	___ / ___ / _____

☐ **Check box when using this form to inspect an inactive/ unstaffed construction site (this option applies to an entire site only).** See Part 4.2(4) of the permit. Inspect the site immediately before becoming inactive/ unstaffed and every 6 months thereafter and within 24 hours of each storm event of 0.5 inch or greater in 24 hours.

Inspector Name, Title & Contact Information	**Name:** _____ **Title:** _____ **Contact information:** _____
Present Phase of Construction	

Inspection Schedule (all days are calendar days) *(Note: you may be subject to different inspection frequencies in different areas of the site. Check all that apply.)*

Routine Schedule: ☐ Every 7 days ☐ Every 14 days and within 24 hours of a 0.5" storm event

☐ Once per month, but not within 14 days of the previous inspection and within 24 hours of a 0.25" storm event

Reduced Schedule: once per month (but not within 14 days of the previous inspection) and before an anticipated storm event and within 24 hours of the end of each storm event of 0.5 inch or greater in 24 hours.

☐ Once per month (in stabilized areas)

☐ Once per month (where discharges are unlikely based on seasonal rainfall patterns)

☐ Once per month (where winter conditions exist and earth-disturbing activities are being conducted)

Discharge points within 1/4 mile of an impaired water or outstanding Arizona water (OAW): ☐ Every 7 days and within 24 hours of a 0.5" storm event

Was this inspection triggered by either a 0.25" or 0.5" storm event? ☐ Yes ☐ No

If yes, duration of storm event: ☐ < 1 hour ☐ < 6 hrs ☐ > 6 hrs

If yes, how was the storm event determined (either 0.25" or 0.5")?

☐ Rain gauge on site ☐ Weather station representative of site. Specify weather station source: _____

Total rainfall amount that triggered the inspection (in inches)**:** _____

Identify all sources of non-stormwater discharges occurring at the site and the associated control measures in place

sources of non-stormwater discharges:	control measures associated with the non-stormwater discharges:
1. _____	1. _____
2. _____	2. _____
3. _____	3. _____
4. _____	4. _____
5. _____	5. _____

Adverse or Unsafe Conditions for Inspection

Did you determine that any portion of the site was unsafe for inspection per CGP Part 4.2(6)? ☐ Yes ☐ No

If "yes", complete the following:

- Describe the conditions that prevented you from conducting the inspection in this location:

- Location(s) where conditions were found:

Note: *Inspections may be postponed when adverse or unsafe conditions exist such as local flooding, high winds, or electrical storms, or situations that otherwise make inspections unsafe. However, the inspection must resume as soon as conditions are safe.*

Section II. Description of Discharges and Condition of the Discharge Locations (CGP Part 4.3(11)) (see instructions)

Discharge Point	Observations *(Note: discharges may not occur at every discharge point on the site after a storm event. Check all that apply.)*
1.	Describe the discharge: ☐ Stormwater ☐ Non-stormwater ☐ None Since the last inspection, do you see any evidence of erosion, sediment accumulation and/ or other pollutants that can be attributed to your discharge? ☐ Yes ☐ No
If yes, describe the characteristics of the discharge (color, odor, clarity, etc.) specify the location(s) of these conditions, and indicate whether modification, maintenance, or corrective action is needed to correct the problem. Also, describe any visible signs of erosion or sediment accumulation.	
2.	Describe the discharge: ☐ Stormwater ☐ Non-stormwater ☐ None Since the last inspection, do you see any evidence of erosion, sediment accumulation and/ or other pollutants that can be attributed to your discharge? ☐ Yes ☐ No
If yes, describe the characteristics of the discharge (color, odor, clarity, etc.) specify the location(s) of these conditions, and indicate whether modification, maintenance, or corrective action is needed to correct the problem. Also, describe any visible signs of erosion or sediment accumulation.	
3.	Describe the discharge: ☐ Stormwater ☐ Non-stormwater ☐ None Since the last inspection, do you see any evidence of erosion, sediment accumulation and/ or other pollutants that can be attributed to your discharge? ☐ Yes ☐ No
If yes, describe the characteristics of the discharge (color, odor, clarity, etc.) specify the location(s) of these conditions, and indicate whether modification, maintenance, or corrective action is needed to correct the problem. Also, describe any visible signs of erosion or sediment accumulation.	

Section II. CONTINUATION SHEET FOR: Description of Discharges and Condition of the Discharge Locations [Print additional sheets as necessary]

Discharge Point	Observations *(Note: discharges may not occur at every discharge point on the site after a storm event. Check all that apply.)*
#___.	Describe the discharge: ☐ Stormwater ☐ Non-stormwater ☐ None Since the last inspection, do you see any evidence of erosion, sediment accumulation and/ or other pollutants that can be attributed to your discharge? ☐ Yes ☐ No
If yes, describe the characteristics of the discharge (color, odor, clarity, etc.) specify the location(s) of these conditions, and indicate whether modification, maintenance, or corrective action is needed to correct the problem. Also, describe any visible signs of erosion or sediment accumulation.	
#___.	Describe the discharge: ☐ Stormwater ☐ Non-stormwater ☐ None Since the last inspection, do you see any evidence of erosion, sediment accumulation and/ or other pollutants that can be attributed to your discharge? ☐ Yes ☐ No
If yes, describe the characteristics of the discharge (color, odor, clarity, etc.) specify the location(s) of these conditions, and indicate whether modification, maintenance, or corrective action is needed to correct the problem. Also, describe any visible signs of erosion or sediment accumulation.	
#___.	Describe the discharge: ☐ Stormwater ☐ Non-stormwater ☐ None Since the last inspection, do you see any evidence of erosion, sediment accumulation and/ or other pollutants that can be attributed to your discharge? ☐ Yes ☐ No

Section IV. Corrective Action Report Form

Section IV.A. – General Information

(Complete this section within 24 hours of discovering the condition that triggered corrective action)

Date/ Time Problem First Discovered	Date: ___ / ___ / _____ Time: _____ ___AM ___PM	Today's Date	___ / ___ / _____

Name and Contact Information of Individual Completing this Form

Name: _____

Contact information: _____

What site conditions triggered the requirement to conduct corrective action? *(Check the box that applies)*

- ☐ A necessary stormwater control was never installed, was installed incorrectly, or not in accordance with the requirements in Part 2 and/or 3
- ☐ A prohibited discharge described in Part 1.4 has occurred or is occurring
- ☐ ADEQ or USEPA has determined that modifications to the control measures are necessary to meet the requirements of Part 3.

Provide a description of the problem: (Provide description of the specific problem that triggered the need for corrective action, and the specific location where it was found. If you have already provided this explanation in an inspection report, you can refer to that report.)

Deadline for completing corrective action:

- ☐ Work will be completed no more than 7 calendar days after the date the problem was discovered (enter date): ____ / ____ / _____
- ☐ It is infeasible to complete work within the first 7 days, therefore, the work will be completed as soon as practicable following the 7th day (enter date): ____ / ____ / _____

If the estimated date of completion falls after the 7-day deadline, document the following: (1) The reason it is infeasible to complete work within 7 days, and (2) The schedule for installing and making the new or modified stormwater control operational in the soonest practicable timeframe.

NOTE: *Any corrective actions that result in changes to any of the stormwater controls or procedures shall be documented in the SWPPP within 7 calendar days of completing the corrective action work.*

Subject: Topock Compressor Station – Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil

Dear Dr. Eichelberger and Ms. Marr:

Enclosed is a technical memorandum prepared as part of the RCRA Facility Investigation/Remedial Investigation (RFI/RI) process to support the soil investigation and site characterization at the Pacific Gas and Electric (PG&E) Topock Compressor Station. This technical memorandum describes the methods used to develop soil ecological comparison values (ECVs) for the currently defined chemicals of potential ecological concern (COPECs) potentially associated with activities at the Topock site. The currently identified COPECs are metals and polycyclic aromatic hydrocarbons (PAHs). The ECVs, while based on information developed during the ecological risk assessment (ERA) scoping, are to be applied only to soil investigation planning in conjunction with background values. Specifically, the ECVs are not intended for use as either cleanup goals or as screening levels to eliminate COPECs. This technical memorandum provides the background and objectives for this effort, the approach used to develop the ECVs, and the recommended ECVs for the current COPECs. Note that the COPEC list may be expanded or contracted based on the results of planned site investigation activities, including the development of soil background levels.

If you have any questions regarding this technical memorandum, please call me at (805) 546-5243.

Sincerely,

Yvonne Meeks
Topock Project Manager

Subject:
Technical Memorandum 3: Ecological Comparison Values for Metals and Polycyclic Aromatic Hydrocarbons in Soil

---

The purpose of this technical memorandum is to describe the methods used to develop soil ecological comparison values (ECVs) for the currently defined chemicals of potential ecological concern (COPECs) potentially associated with activities at the Pacific Gas and Electric (PG&E) Topock Compressor Station, located in San Bernardino County, California, 15 miles southeast of Needles (site). The currently identified COPECs are metals and polycyclic aromatic hydrocarbons (PAHs). The ECVs, while based on information developed during the ecological risk assessment (ERA) scoping, are to be applied only to soil investigation planning in conjunction with background values. Specifically, the ECVs are not intended for use as either cleanup goals or as screening levels to eliminate COPECs. The following sections provide the background and objectives for this effort, the approach used to develop the ECVs, and the recommended ECVs for the current COPECs. Note that the COPEC list may be expanded or contracted based on the results of planned site investigation activities, including the development of soil background levels.

Background and Objectives

The Topock Compressor Station began operations in December 1951, compressing natural gas supplied from the southwest United States for transport through pipelines to PG&E's service territory in central and northern California. This site is currently active and will continue operating into the foreseeable future.

PG&E is currently conducting investigative and remedial activities at the site. Historically, chromium was added to cooling water, and from 1951 to 1964, untreated wastewater was discharged to Bat Cave Wash. In 1996, PG&E entered into a Corrective Action Consent Agreement with the California Department of Toxic Substances Control (DTSC) to govern the investigation and remediation of the site. In July 2005, a Consent Agreement was executed with U.S. Department of Interior agencies that outlined the process by which PG&E would comply with the Comprehensive Environmental Response, Compensation, and Liability Act requirements for remediation of the site.

As part of the remedial investigation, soil data are being collected and analyzed for site characterization. The primary objective of soil ECVs, along with background data and Preliminary Remediation Goals (PRGs), is to assist in evaluating the adequacy of the site characterization. The ECVs, PRGs, and background concentrations will be used to evaluate the data collected for the Part A Phase I soil investigation and assist in identifying data gaps that may require Phase II soil sampling. As explained by CH2M HILL (2006a), developing soil ECVs can provide a tool for (1) confirming data adequacy and quality; and (2) evaluating the need for, and designing the sampling and analysis program for, the Part A Phase 2 soil investigation. Procedures for field sampling, chain of custody, laboratory analysis, reporting, and data validation are designed to provide an accurate measure of site characterization. However, technical issues exist that may impair the sampling and analysis process (e.g., typical laboratory-proposed detection limits may be elevated relative to risk-based comparison values). The soil ECVs developed herein can be used for additional soil data quality assessment such as to evaluate the use of appropriate method detection limits. The soil ECVs can also be used to evaluate the data collected to define the extent of the site-related constituents in soil and assess the need for additional site characterization data. Furthermore, the soil ECVs can also be used to optimize the selection of sampling locations to limit disturbing the existing habitat and evaluate the program for additional sampling, if deemed necessary.

The soil ECVs, which are risk-based values, were developed based on conservative exposure and effects assumptions using the standard hazard quotient (HQ) model for assessing risk to ecological receptors (USEPA,1997). The soil ECVs are not strictly site-specific but are relevant to the site. The approach is generic ecological assessment to the extent that off-the-shelf exposure parameters and toxicity values were used. The exposure assumptions and effect levels or toxicity values used in the model were obtained from guidance documents and widely accepted literature sources. The exposure assumptions were based on representative species likely present at the site based on species observation records, habitat, and feeding guilds. The toxicity values were based on endpoints measuring survival, growth, and reproduction to meet the assessment endpoint such as protection of ecological receptor populations. Details of the model are described below.

Approach

In this technical memorandum, soil ECVs were developed for metals and PAHs identified as preliminary COPECs in the *Human Health and Ecological Risk Assessment Work Plan* (RAWP) (ARCADIS, 2008).

The preliminary COPECs include Title 22 metals, hexavalent chromium, manganese, total petroleum hydrocarbons (TPH), and PAHs. Toxicity values are not available for TPH, and therefore, soil ECVs were not developed for TPH. The Title 22 metals include antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, and zinc. The PAHs include total low molecular weight (LMW) PAHs and total high molecular weight (HMW) PAHs. The National Oceanic and Atmospheric Administration (NOAA) defines LMW PAHs as PAHs with less than or equal to 3 rings and with molecular weight less than or equal to 192 atomic mass units (amu) (NOAA, 2000). Parent LMW PAHs include naphthalene, acenaphthylene, acenaphthene, fluorene, anthracene, and phenanthrene. HMW PAHs are defined as PAHs with greater than or equal to 4 rings and with molecular weight greater than or equal to 202 amu (NOAA, 2000). Parent HMW PAHs include pyrene, fluoranthene, benz(a)anthracene, chrysene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(g,h,i)perylene, indeno(1,2,3-cd)pyrene, and dibenz(a,h)anthracene.

For the objectives of this memorandum, soil ECVs were calculated for metals and PAHs using both lowest observed adverse effect levels or concentrations (LOAELs or LOAECs) and no-adverse effect levels or concentrations (NOAELs or NOAECs). The soil ECVs selected were based on the target toxicity values (i.e., values below which no unacceptable risk is expected; NOAELs or NOAECs) for the protection of the ecological receptors based on the representative receptors selected for the ecological risk assessment (ARCADIS, 2008) and include:

- Plants
- Invertebrates
- Birds
  - Gambel's Quail (granivore)
  - Cactus Wren (insectivore)
  - Red-Tailed Hawk (carnivore)
- Mammals
  - Desert Shrew (insectivore)
  - Merriam's Kangaroo Rat (granivore)
  - Desert Kit Fox (carnivore).

Soil Ecological Comparison Values Based on Plants and Invertebrates

For plants and invertebrates, although more than one exposure pathway is considered complete, generally route-specific doses are not quantified for plants and invertebrates. Exposures to soil are expressed in milligrams per kilogram (mg/kg), rather than doses, and generally encompass all potential exposure pathways for plants and invertebrates. Therefore, the screening values for the protection of plants and invertebrates discussed in the RAWP (ARCADIS, 2008) were used as soil ECVs, as presented in Table 1. The sources of screening values for plants and soil invertebrates used to develop soil ECVs are listed in order of preference:

- *Guidance for Developing Ecological Soil Screening Levels (Eco-SSLs)* (USEPA, 2008b)

- Oak Ridge National Laboratory (ORNL) documents (Efroymson et al., 1997a,b).

Confidence in certain screening values presented in the ORNL documents is low, as indicated in Table 1. Confidence in plant screening values for antimony, barium, beryllium, hexavalent chromium, mercury, molybdenum, thallium, and vanadium is low due to the low number of studies on which the screening values are based or other factors (Efroymson et al., 1997a). The soil type and test species (typically agricultural) may also vary significantly from site-specific conditions, or the toxic effects may be unspecified in the source study. There may be significant variability in the toxic responses noted. Similarly, confidence in the invertebrate screening values is low for arsenic, hexavalent chromium, and mercury because of the low number of studies on which they are based or other factors (Efroymson et al., 1997b).

In the RAWP, screening values were developed only for metals as presented in Table 1. These values were obtained from the sources listed above and are not discussed in this memorandum. To calculate soil ECVs for PAHs, screening values for plants and invertebrates were developed as described below.

Polycyclic Aromatic Hydrocarbon Screening Values for Plants

Plant screening values are not readily available for PAHs from literature sources, except for acenaphthene (Efroymson et al., 1997a), an LMW PAH, and benzo(a)pyrene (USEPA, 1999), an HMW PAH. Empirical toxicity data for naphthalene, another LMW PAH, are available in the U.S. Environmental Protection Agency (USEPA) ECOTOX database (USEPA, 2008a). A study reporting ecologically relevant adverse effects at the lowest concentration was used to develop plant screening values for naphthalene. Hulzebos et al. (1993) reported a 7-day EC50 of 100 mg/kg for reduced biomass in lettuce. This study tested nearly 40 organic contaminants in both soil and a nutrient solution to determine the relationship between toxicity thresholds in both matrices. In this study, an EC50 (i.e., concentration of a chemical causing an effect to 50 percent of the population) of 100 mg/kg was conservatively assumed to be equivalent to a lowest-observed adverse effects concentration (LOAEC) for more serious adverse effects. Following California Environmental Protection Agency (CalEPA) DTSC guidance (CalEPA, 1996), an uncertainty factor (UF) of

10 was applied to extrapolate to a no-observed adverse effects concentration (NOAEC) resulting in a value of 10 mg/kg, which was used as the plant screening value for naphthalene.

As naphthalene is a more common LMW PAH than acenapthene, the comparison value for total LMW PAHs for protection of plants was based on the NOAEC-based screening value of 10 mg/kg for naphthalene, and the comparison value for total HMW PAHs was based on the screening value of 1.2 mg/kg for benzo(a)pyrene (USEPA, 1999).

Polycyclic Aromatic Hydrocarbon Screening Values for Soil Invertebrates

PAH screening values for soil invertebrates are available in the USEPA's *Guidance for Developing Ecological Soil Screening Levels (EcoSSL)* (USEPA, 2008b). The EcoSSL for LMW PAH is 29 mg/kg and the EcoSSL for HMW PAH is 18 mg/kg (Table 1); these values were selected as comparison values for protection of soil invertebrates.

Soil Ecological Comparison Values Based on Wildlife Protection

For wildlife, soil ECVs were developed using a risk-based approach incorporating exposure pathways for food and soil ingestion, which are considered the most significant pathways for most sites (USEPA, 2008b). The wildlife indicator receptors were selected to represent a cross-section of feeding guilds for each assessment endpoint so that sufficient rates of survival, growth, and reproduction for their representative populations could be evaluated.

For each wildlife receptor (i.e., bird and mammal) listed above, soil ECVs were developed following USEPA guidance (USEPA, 1997; USEPA, 2008b) and were based on a food-web model integrating ecological receptor exposures and effects. The exposure assumptions and effects levels for wildlife described in the RAWP (ARCADIS, 2008) were used to develop soil ECVs. The exposure assumptions that were used to estimate exposure dose for the indicator species such as body weights, food ingestion rates, composition of diet, and bioaccumulation factors (BAFs) were obtained from guidance documents or widely accepted literature sources as described in the RAWP (ARCADIS, 2008). The exposure assumptions used in the soil ECV model for each wildlife receptor are presented in Attachment 1. The effects levels or toxicity reference values (TRVs) that were used in the soil ECV model were also obtained from guidance documents or widely accepted literature sources. A TRV is defined as a daily dose of a chemical expressed in milligrams of chemical per kilogram of body weight per day (mg/kg bw-day) and represents a dose associated with no-effect or lowest-effect at the population level of ecological organization, even if exposure occurs over an extended duration. The TRVs used in the model are presented in Tables 2 and 3 and the details are explained below.

Soil ECVs were developed by re-arranging the standard USEPA (1997) HQ model (Equation 1) to solve for a target HQ of 1, which is considered to be protective of ecological receptors. The model used to solve for ECVs is as follows:

$$HQ = \frac{Dose}{TRV} = \frac{(C_{soil} \times SIR) + (C_{tissue} \times FIR) \times SUF}{TRV \times BW} = \frac{(C_{soil} \times SIR) + (C_{soil} \times BAF \times FIR) \times SUF}{TRV \times BW} = 1$$

Equation 1

Or:

$$ECV = C_{soil} = \frac{HQ \times TRV \times BW}{(SIR + [FIR \times BAF]) \times SUF}$$

Equation 2

Where:

Dose = *exposure dose (mg/kgBW-day)*

HQ = *hazard quotient (unitless); set at a target value of 1*

TRV = *toxicity reference value (milligrams per kilogram body weight per day [mg/kgBW-day])*

C_{soil} = *concentration of constituent in soil (mg/kg soil)*

SIR = *soil ingestion rate (kilogram soil per day [kg soil/day])*

C_{tissue} = *concentration of constituent in biota or tissue (mg/kg tissue)*

FIR = *food or biota ingestion rate (kilograms tissue per day [kg tissue/day])*

BW = *body weight of receptor (kilograms [kgBW])*

BAF = *bioaccumulation factor or regression for media-to-biota uptake (kilogram tissue per kilogram soil [kg soil/kg tissue])*

SUF = *site use factor (unitless); represents the fraction of the exposure area for the receptor represented by the area of contamination generally calculated by dividing the area of contamination by the home or foraging range of the receptor.*

ECV = *ecological comparison value (mg/kg soil)*

Depending on the chemical, tissue concentrations (C_{tissue}) were calculated using different combinations of uptake regressions or uptake factors (referred to as soil-to-biota BAFs in the RAWP [ARCADIS, 2008]). Uptake regressions are linear exponential equations, while UFs are simple multipliers, as shown in Equation 3.

$$C_{tissue} = e^{a} \times \left(C_{soil}\right)^{b} \quad or \quad \ln\left(C_{tissue}\right) = a + b \times \ln\left(C_{soil}\right) \qquad \text{Equation 3}$$

Alternatively:

$$C_{tissue} = UF_{tissue} \times C_{soil}$$

Where:

C_{tissue} = *tissue concentration (mg/kg of tissue)*

C_{soil} = *soil concentration (mg/kg of soil)*

a = *compound specific regression equation constant (unitless)*

b = *compound specific regression equation constant (unitless)*

UF_{tissue} = *uptake factor from soil to tissue (unitless)*

Incorporating uptake regressions in lieu of a simple UF in the dose equation (Equation 2) significantly complicates the overall dose calculation. As the bioaccumulation regression places C_{soil} subject to an exponential term, solving for C_{soil} becomes extremely cumbersome. Because of the challenges associated with back-calculating ECVs with dose equations that rely on exponential regressions for modeling tissue concentrations, a forward-calculation methodology was developed to simplify the calculation steps and reduce the potential for mathematical error. An automated, iterative calculation algorithm was used to combine the dose equation and tissue regression equation(s) into a single forward calculation by using the Microsoft® Solver™ software. Solver™ is an add-on to Microsoft® Excel that finds a solution by iterative trial-and-error that satisfies calculation constraints introduced by having interdependent mathematical equations. In this case, the interdependent equations are the tissue uptake equation(s), which rely on a media concentration and a dose equation that rely on the same media concentration (as the tissue uptake equation) and the solution of the uptake equation(s). The media uptake regression(s) and dose equation were combined using Solver™ and used to calculate ECVs. Figure 1 depicts (as an example) a flowchart

of the iterative process that was followed, and the associated equations that were used to calculate ECV for the desert shrew.

An added benefit of using Solver™ to determine ECV is that it allows instant confirmation of accuracy. The spreadsheet cell representing C_{soil} (the results output from Solver™) is instantaneously fed back through the tissue uptake, dose, and HQ equations to calculate an HQ. As long as the resulting HQ value equals 1 (dose/TRV), it can be confidently concluded that the Solver™-based model performed the calculations correctly and that the resulting C_{soil} is the accurate ECV.

In the RAWP (ARCADIS, 2008), wildlife TRVs and BAFs were developed only for metals. To calculate soil ECVs for PAHs, wildlife TRVs and BAFs for PAHs were also developed as described below.

Bioaccumulation Factors for Polycyclic Aromatic Hydrocarbons

Bioaccumulation in animal tissue or uptake in plants is the process where COPECs in the surrounding media are accumulated within the tissues of ecological receptors, especially to concentrations higher than in the surrounding media. Any COPEC that is excreted or metabolized at a slower rate than its uptake through absorption and ingestion will increase in tissues over time, resulting in bioaccumulation. Constituents with high octanol-water partitioning coefficient (log K_{ow}) are more likely to bioaccumulate in tissues of prey (plants, invertebrates, and mammals) due to their lipophilic nature (USEPA, 2000). Additionally, some metals that are not readily excreted are also known to bioaccumulate (e.g., lead). COPECs that bioaccumulate have the potential to be passed up the food chain.

BAFs are multipliers that are used to estimate concentrations of constituents that can accumulate in tissues through any route of exposure (USEPA, 2000). For plants, the BAF is sometimes referred to as a plant uptake factor. In this memorandum, BAFs were used to estimate concentrations of COPECs in biota and food item tissue (i.e., prey) from soil.

The approach used to develop BAFs for metals in the RAWP (ARCADIS, 2008) was also used to develop soil-to-biota BAFs for PAHs. BAFs for soil-to-plants and soil-to-invertebrates for LMW and HMW PAHs are available in USEPA's EcoSSL guidance (USEPA, 2008b) and are not discussed in this memorandum. According to USEPA EcoSSL guidance, semivolatile organic compounds, including PAHs tend to metabolize rapidly in birds and mammals, and therefore, uptake of these constituents from soil-to-mammal were assumed to be zero (USEPA, 2008b). The BAFs for metals and PAHs used to develop soil ECVs are presented in Table 4.

Toxicity Reference Values

In the RAWP (ARCADIS, 2008), two sets of wildlife TRVs for metals were presented as shown in Tables 2 and 3, and these were:

- Proposed TRVs: these were primarily based on the TRVs used to develop USEPA's EcoSSLs (USEPA, 2008b); other sources included ORNL: Toxicological Benchmarks for Wildlife (Sample et al., 1996) and other published sources (e.g., USEPA Region 6 ERA Guidance [USEPA, 1999]).

- DTSC-recommended TRVs: these were preferably based on the Region 9 Biological Technical Assistance Group (BTAG) TRVs (CalEPA, 2002).

For each set of wildlife TRVs, a range of TRVs were developed to estimate a range of potential risks to wildlife (ARCADIS, 2008). The low TRVs were preferably based on chronic no observable adverse effects levels (NOAELs) and the high TRVs were preferably based on the lowest observed adverse effects levels (LOAELs). In the case of DTSC-recommended TRVs, the low BTAG TRVs are NOAEL-based and the high BTAG TRVs are based on a midpoint of a variety of adverse effects and are not necessarily LOAEL-based (CalEPA, 2002). Some of the TRVs were allometrically adjusted for account for significant difference in body weights between the test species and the representative indicator species based on CalEPA guidance (CalEPA, 1999). For the calculation of soil ECVs, the allometrically adjusted TRVs listed in Table 2 and 3 were used for the representative receptors.

Similarly, following the approach described in the RAWP (ARCADIS, 2008), a range of wildlife TRVs for PAHs were developed as described below.

Bird Toxicity Reference Values for Polycyclic Aromatic Hydrocarbons

The bird TRVs for PAHs used to develop soil ECVs are presented in Table 2 and 3. For birds, there are no TRVs for PAHs reported in the EcoSSL guidance (USEPA, 2007). Published TRVs are available in USEPA Region 6 guidance (USEPA, 1999). However, the study (Brunstrom et al., 1991) was based on egg injection tests that are not considered appropriate for developing TRVs (USEPA, 2008b). Several studies were reviewed, and the most appropriate study was selected to develop bird TRVs for PAHs.

For LMW PAHs, Patton and Dieter's study (1980) evaluating the effect of PAH mixtures on hepatic function in mallard duck livers using a mixture of paraffins and aromatic hydrocarbons was selected. There were visible signs of toxicity, indicated by significant increase in liver weight for the group that were administered 4,000 mg/kg PAH mixture, but livers appeared normal in texture and color. No effects were observed for the 400 mg/kg treatment group. Therefore, 400 mg/kg was selected as the NOAEC and the 4,000 mg/kg was selected as the LOAEC. The NOAEC and the LOAEC were then converted to a NOAEL-based TRV and a LOAEL-based TRV, respectively, using the standard dose equations shown below:

$$TRV_{NOAEL} = \frac{NOAEC \times IR}{BW} = \frac{400\ mg/kg \times 0.059\,kg/day}{1.04\,kgBW} = 22.8\,mg/kgBW - day$$

Equation 4

$$TRV_{LOAEL} = \frac{LOAEC \times IR}{BW} = \frac{4000\,mg/kg \times 0.059\,kg/day}{1.04\,kgBW} = 228\,mg/kgBW - day$$

Equation 5

Where:

TRV_{NOAEL}	*= no-observed adverse effects level based toxicity reference value (milligrams per kilogram body weight per day [mg/kgBW-day])*
TRV_{LOAEL}	*= lowest-observed adverse effects level based toxicity reference value (milligrams per kilogram body weight per day [mg/kgBW-day])*
IR	*= ingestion rate (kilogram soil per day [kg soil/day]); calculated from allometric equation for food ingestion rate in dry weight for all birds (USEPA,1993)*
BW	*= body weight of receptor (kilograms [kgBW]); assuming approximately 1.04 kg for the mallard ducks (from USEPA, 1993)*

For HMW PAHs, a study by Trust et al. (1994) reporting a NOAEL of 10 mg/kg bw-day and a LOAEL of 100 mg/kg bw-day for overt signs of toxicity, such as decreased body mass in European starlings exposed to 7,12-dimethylbenz(a)anthracene, was selected to develop TRVs. Immunosuppression was observed at higher doses. The exposures were via oral gavage, and the study was conducted on nestlings, a sensitive life-stage. No UFs were applied, and therefore, an avian low TRV of 10 mg/kg bw-day and an avian high TRV of 100 mg/kg bw-day were used for HMW PAHs.

There are no BTAG PAH TRVs for birds. Therefore, there are no separate DTSC-recommended PAH TRVs for birds.

Mammal Toxicity Reference Values for Polycyclic Aromatic Hydrocarbons

Mammal TRVs for PAHs are available in the EcoSSL guidance (USEPA, 2007). The NOAEL of 65.6 mg/kg bw-day was selected as the low TRV for LMW PAHs and the LOAEL of 0.6 mg/kg bw-day was selected as the low TRV for HMW PAHs. The EcoSSL guidance (USEPA, 2007; USEPA, 2008b) does not report LOAELs; therefore, LOAELs for PAHs were developed following the approach described in the RAWP (ARCADIS, 2008). For LMW and HMW PAHs, bounded NOAELs were reported as TRVs; therefore, the LOAELs from the same study and endpoint was selected.

BTAG TRVs are available for mammals (CalEPA, 2002). The BTAG TRVs for naphthalene was used for LMW PAHs and the BTAG TRVs for benzo(a)pyrene was used for HMW PAHs.

The mammal TRVs for metals and PAHs used to develop soil ECVs are presented in Table 3 and 4.

Selection of Soil Ecological Comparison Values

The soil ECVs based on plants and invertebrates are presented in Table 1. For wildlife, a range of soil ECVs were developed following the approach described above and presented in tables in Attachment 1. A summary of the soil ECVs developed, based on the proposed wildlife TRVs and the DTSC-recommended TRVs, is presented in Table 5. As discussed earlier, the purpose of this technical memorandum is to develop soil ECVs for data quality assessment and use in evaluating the Part A Phase 1 data and making further site characterization decisions. The ECVs are conservative values but are not intended to be used to screen out COPECs. ECVs are also specifically not intended to be used as cleanup goals.

In order to select the most appropriate soil ECVs for each constituent, the most conservative of all the ecological receptor-based soil ECVs was selected as the final soil ECV unless the screening value or TRVs used to calculate that soil ECV was low in confidence. In such cases, the next less conservative soil ECV was selected as the final (e.g., soil ECV for mercury). The minimum of all the soil ECVs from Table 1 (plants and invertebrates) and Table 5 (wildlife) for each constituent and the selected soil ECVs are presented in Table 6. It should be noted that certain ECVs (e.g. antimony, cadmium, lead, mercury, and selenium) are below the standard reporting limits defined in the *Quality Assurance Project Plan, PG&E Topock Program (*QAPP; CH2M HILL, 2004, 2006b, 2008). Additionally, certain ECVs will likely be lower than final background soil concentrations. In that case, background concentrations would be used to set analytical detection limits and to consider the need for additional characterization.

Notes:
TRVs for metals presented in the *Human Health and Ecological Risk Assessment Work Plan* (RAWP; ARCADIS, 2008).
TRVs updated in guidance since the RAWP was submitted.
TRVs developed for this technical memorandum.

a. TRVs allometrically adjusted significant difference in body weights using the following equation (Sample and Arenal, 1999):

Aw - At * (BWt/BWw)^1-b

where:

Aw - toxicity value of wildlife species
At - toxicity value of test species (TRV)
BWt - body weight of test species
BWw - body weight of wildlife species
b - allometric scaling factor (1.2 for birds, 0.94 for mammals)

-- - not applicable
BTAG - Biological Technical Assistance Group
CalEPA - California Environmental Protection Agency
LOAEL - lowest observed adverse effects level
mg/kgBW-day - milligrams per kilogram of body weight per day
NA - not available
NOAEL - no observed adverse effects level
TRV - toxicity reference value
USEPA - U.S. Environmental Protection Agency

Table 4
Bioaccumulation Factors

Technical Memorandum 3: Ecological Comparison Values for Metals and PAHs in Soil
PG&E Topock
Needles, California

Constituent	Soil-to-Biota Bioaccumulation Factors[a]		
	BAF_{plant} (dw) (kg soil/kg tissue)	BAF_{invert} (dw) (kg soil/kg tissue)	BAF_{mammal} (dw) (kg soil/kg tissue)
Antimony	$\ln(C_p) = 0.938 * \ln(C_s) - 3.233$	1.00	$0.05 * C_d$
Arsenic	0.03752	$\ln(C_i) = 0.706 * \ln(C_s) - 1.421$	$\ln(C_m) = 0.8188 * \ln(C_s) - 4.8471$
Barium	0.156	0.091	$0.0075 * C_d$
Beryllium	$\ln(C_p) = 0.7345 * \ln(C_s) - 0.5361$	0.045	$0.05 * C_d$
Cadmium	$\ln(C_p) = 0.546 * \ln(C_s) - 0.475$	$\ln(C_i) = 0.795 * \ln(C_s) + 2.114$	$\ln(C_m) = 0.4723 * \ln(C_s) - 1.2571$
Chromium, total	0.041	0.306	$\ln(C_m) = 0.7338 * \ln(C_s) - 1.4599$
Chromium, hexavalent	0.041	0.306	$\ln(C_m) = 0.7338 * \ln(C_s) - 1.4599$
Cobalt	0.0075	0.122	$\ln(C_m) = 1.307 * \ln(C_s) - 4.4669$
Copper	$\ln(C_p) = 0.394 * \ln(C_s) + 0.668$	0.515	$\ln(C_m) = 0.1444 * \ln(C_s) + 2.042$
Lead	$\ln(C_p) = 0.561 * \ln(C_s) - 1.328$	$\ln(C_i) = 0.807 * \ln(C_s) - 0.218$	$\ln(C_m) = 0.4422 * \ln(C_s) + 0.0761$
Mercury	$\ln(C_p) = 0.544 * \ln(C_s) - 0.996$	$\ln(C_i) = 0.3369 * \ln(C_s) - 0.078$	0.192
Molybdenum	0.25	5.50E-01	$\ln(C_m) = 0.006 * 50 * C_d$ [b]
Nickel	$\ln(C_p) = 0.748 * \ln(C_s) - 2.223$	1.059	$\ln(C_m) = 0.4658 * \ln(C_s) - 0.2462$
Selenium	$\ln(C_p) = 1.104 * \ln(C_s) - 0.677$	$\ln(C_i) = 0.733 * \ln(C_s) - 0.075$	$\ln(C_m) = 0.3764 * \ln(C_s) - 0.4158$
Silver	0.014	2.045	0.004
Thallium	0.004	5.50E-01	0.112
Vanadium	0.00485	0.042	0.0123
Zinc	$\ln(C_p) = 0.554 * \ln(C_s) + 1.575$	$\ln(C_i) = 0.328 * \ln(C_s) + 4.449$	$\ln(C_m) = 0.0706 * \ln(C_s) + 4.3632$
Total LMW PAH	ln(Cp) = 0.4544 * ln(Cs)-1.3205	3.04	0.0
Total HMW PAH	ln(Cp) = 0.9469 * ln(Cs)-1.7026	2.6	0.0

Notes:
BAFs for metals presented in the *Human Health and Ecological Risk Assessment Work Plan* (ARCADIS, 2008).
BAFs developed for this technical memorandum.

a. All BAFs from USEPA's Guidance for Developing Ecological Soil Screening Levels (EcoSSLs). U.S. Environmental Protection Agency, Office of Solid Waste and Emergency Response, Washington D.C. 2005 Revision, updated December 2006. 85 pp. http://www.epa.gov/ecotox/ecossl., except as otherwise noted.

b. Baes, C.F., R. Sharp, A. Sjoreen and R. Shor. 1984. A Review and Analysis of Parameters for Assessing Transport of Environmentally Released Radionuclides through Agriculture. Prepared by Oak Ridge National Laboratory for U.S. Dept. of Energy. 150 pp.

BAF - bioaccumulation factor
BAF_{invert} - soil-to-invertebrate uptake bioaccumulation factor (unitless)
BAF_{plant} - soil-to-plant uptake bioaccumulation factor (unitless)
C_p - constituent concentration in plants
C_i - constituent concentration in invertebrates
C_s - constituent concentration in soil
C_m - constituent concentration in mammals
C_d - concentration in diet
dw - dry weight
HMW PAHs - high molecular weight polycyclic aromatic hydrocarbons
In - natural log
LMW PAHs - low molecular weight polycyclic aromatic hydrocarbons
USEPA - U.S. Environmental Protection Agency

Notes:
Selected Final Soil ECV (see Table 6).

[1] Proposed TRVs based primarily on USEPA's EcoSSLs (USEPA, 2008b); from the *Human Health and Ecological Risk Assessment Work Plan* (ARCADIS, 2008).
[2] DTSC-recommended TRVs based primarily on Region 9 Biological Technical Assistance Group (BTAG) TRVs (CalEPA, 2002); from the Risk Assessment Work Plan (ARCADIS, 2008).
[3] Low ECVs based on low TRVs or no-observed adverse effects level (NOAEL) TRVs.
[4] High ECVs based on high TRVs or lowest-observed adverse effects level (LOAEL) TRVs.
[5] TRVs allometrically adjusted for representative receptors (ARCADIS, 2008).

CalEPA - California Environmental Protection Agency
DTSC - Department of Toxic Substance Control
ECV - ecological comparison value
HMW PAHs - high molecular weight polycyclic aromatic hydrocarbons
LMW PAHs - low molecular weight polycyclic aromatic hydrocarbons
mg/kg dw - milligrams per kilogram dry weight
NA - not available
TRV - toxocity reference values
USEPA - U.S. Environmental Protection Agency

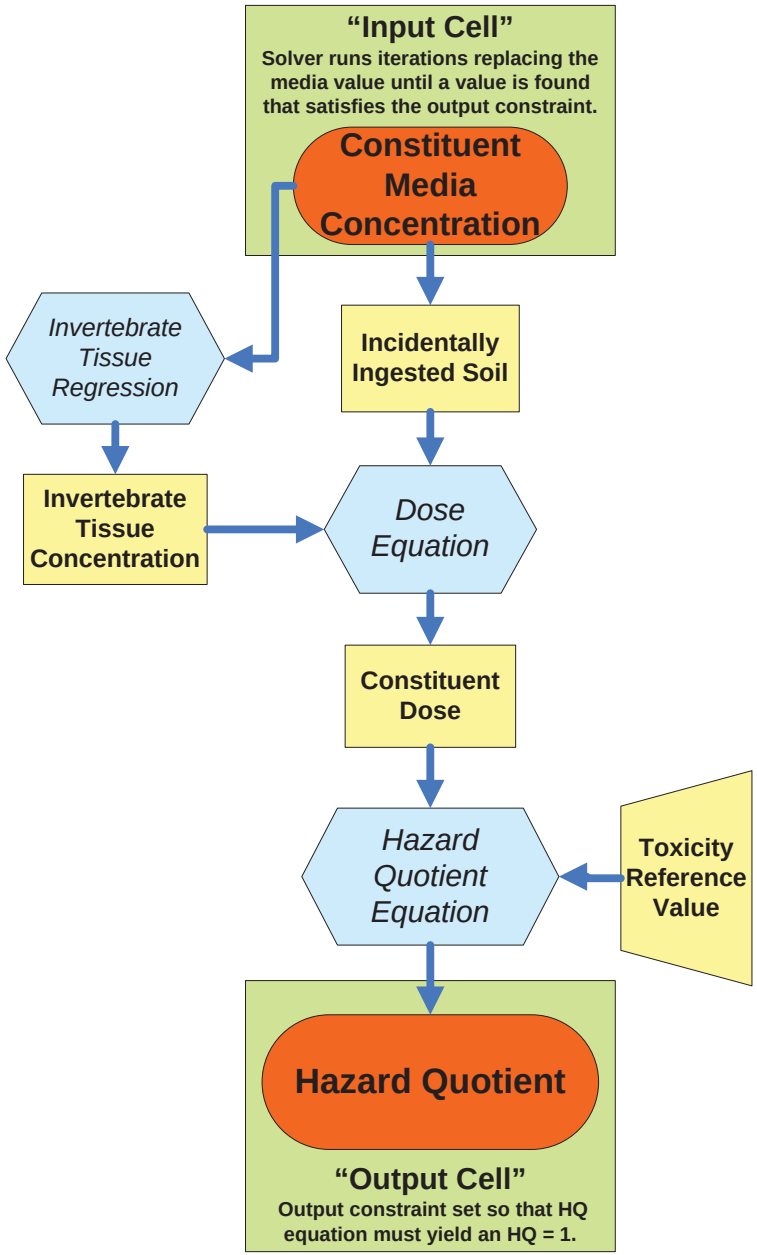
HMW PAHs	1.16	Desert Shrew	1.2	Plant	1.16	Desert Shrew

Notes:

*Confidence in this benchmark is low due to the low number of studies on which it is based or other factors. The soil type and test species (typically agricultural) may also vary significantly from site-specific conditions, or the toxic effects may be uncertain.

**Confidence in this benchmark is low due to the low number of studies on which it is based or other factors. The tests were conducted with earthworms.



a. The final soil ECV selected based on minimum of soil ECVs based on plants and invertebrates and wildlife. If the minimum soil ECV was based toxicity valu low confidence, then the next minimum soil ECV was selected.

ECV - ecological comparison value
HMW PAHs - high molecular weight polycyclic aromatic hydrocarbons
LMW PAHs - low molecular weight polycyclic aromatic hydrocarbons
mg/kg dw - miligrams per kilogram dry weight
NA - not available

Figures

Figure 1. Diagram Depicting ECV Derivation Methodology for the Desert Shrew

Formulae and Variables Description

Invertebrate Tissue Regression Equation

$$\ln(C_{tissue}) = a + b[\ln(C_{soil})] \quad \therefore \quad C_{tissue} = e^{a} \times (C_{soil})^{b}$$

Dose Equation

$$Dose = \frac{((C_{soil} \times SIR) + (C_{soil} \times BAF \times FIR)) \times SUF}{BW}$$

Hazard Quotient Equation

$$HQ = \frac{Dose}{TRV}$$

ECV Equation

$$ECV = C_{Soil} = \frac{HQ \times TRV \times BW}{(SIR + [FIR \times BAF]) \times SUF}$$

Where:

C_{tissue}	= concentration of constituent in biota or tissue (milligrams of constituent per kilogram tissue [mg/kg tissue])
a	= compound specific regression equation constant (unitless)
b	= compound specific regression equation constant (unitless)
C_{soil}	= concentration of constituent in exposure soil (mg/kg soil)
Dose	= daily exposure dose of constituent resulting from ingestion of media and invertebrates (milligrams per kilogram body weight per day [mg/kgBW-day])
SIR	= soil ingestion rate (kilograms soil per day [kg soil/day])
BAF	= bioaccumulation factor (kg soil/kg tissue)
FIR	= food or biota ingestion rate (kilograms tissue per day [kg tissue/ day])
SUF	= site use factor (unitless)
BW	= body weight of receptor (kilograms [kgBW])
HQ	= hazard quotient (unitless); set at target of 1
TRV	= toxicity reference value (milligrams per kilogram body weight per day)
ECV	= ecological comparison value (mg/kg soil)

Microsoft Solver used to calculate ECVs based one re-arranging the standard HQ equation (USEPA, 1997) below:

$$ECV = \frac{HQ \times TRV}{Dose} = \left(\frac{1 \times TRV \times BW}{SIR + (FIR \times BAF) \times SUF} \right)$$

Notes:

soil ECV.

1 bioaccumulation factors (BAFs; kilograms soil per kilogram tissue [kg soil/kg tissue]); from Table 2.

2 exposure parameters from Table 6-3 of the *Human Health and Ecological Risk Assessment Work Plan* (ARCADIS, 2008).

3 dose caluated for a target HQ of 1 (NOAEL and LOAEL based).

4 Low and High ECVs based on low and high TRVs (from Table 3), respectively.

ECV	ecological comparison value for soil.
dw	dry weight.
High	lowest-observed adverse effects level (LOAEL).
HMW PAHs	high molecular weight polycyclic aromatic hydrocarbons.
kg	kilograms.
kg/day	kilograms per day.
LMW PAHs	low molecular weight polycyclic aromatic hydrocarbons.
Low	no-observed adverse effects level (NOAEL).
mg/kg	milligrams per kilogram.
mg/kgBW-day	milligrams per kilogram body weight per day.
NA	not available or not applicable.

Body Weight (BW)	1.134	kgBW

Microsoft Solver used to calculate ECVs based one re-arranging the standard HQ equation (USEPA, 1997) below:

$$ECV = \frac{HQ \times TRV}{Dose} = \left(\frac{1 \times TRV \times BW}{SIR + (FIR \times BAF) \times SUF} \right)$$

Notes:

soil ECV.

1 bioaccumulation factors (BAFs; kilograms soil per kilogram tissue [kg soil/kg tissue]); from Table 2.

2 exposure parameters from Table 6-3 of the *Human Health and Ecological Risk Assessment Work Plan* (ARCADIS, 2008).

3 dose caluated for a target HQ of 1 (NOAEL and LOAEL based).

4 Low and High ECVs based on low and high TRVs (from Table 3), respectively.

ECV	ecological comparison value for soil.
dw	dry weight.
High	lowest-observed adverse effects level (LOAEL).
HMW PAHs	high molecular weight polycyclic aromatic hydrocarbons.
kg	kilograms.
kg/day	kilograms per day.
LMW PAHs	low molecular weight polycyclic aromatic hydrocarbons.
Low	no-observed adverse effects level (NOAEL).
mg/kg	milligrams per kilogram.
mg/kgBW-day	milligrams per kilogram body weight per day.
NA	not available or not applicable.

Body Weight (BW)	0.0343	kgBW

Microsoft Solver used to calculate ECVs based one re-arranging the standard HQ equation (USEPA, 1997) below:

$$ECV = \frac{HQ \times TRV}{Dose} = \left(\frac{1 \times TRV \times BW}{SIR + (FIR \times BAF) \times SUF} \right)$$

Notes:

soil ECV.

1 bioaccumulation factors (BAFs; kilograms soil per kilogram tissue [kg soil/kg tissue]); from Table 2.

2 exposure parameters from Table 6-3 of the *Human Health and Ecological Risk Assessment Work Plan* (ARCADIS, 2008).

3 dose caluated for a target HQ of 1 (NOAEL and LOAEL based).

4 Low and High ECVs based on low and high TRVs (from Table 3), respectively.

ECV	ecological comparison value for soil.
dw	dry weight.
High	lowest-observed adverse effects level (LOAEL).
HMW PAHs	high molecular weight polycyclic aromatic hydrocarbons.
kg	kilograms.
kg/day	kilograms per day.
LMW PAHs	low molecular weight polycyclic aromatic hydrocarbons.
Low	no-observed adverse effects level (NOAEL).
mg/kg	milligrams per kilogram.
mg/kgBW-day	milligrams per kilogram body weight per day.
NA	not available or not applicable.

Body Weight (BW)	0.0389	kgBW

Microsoft Solver used to calculate ECVs based one re-arranging the standard HQ equation (USEPA, 1997) below:

$$ECV = \frac{HQ \times TRV}{Dose} = \left(\frac{1 \times TRV \times BW}{SIR + (FIR \times BAF) \times SUF} \right)$$

Notes:

soil ECV.

1 bioaccumulation factors (BAFs; kilograms soil per kilogram tissue [kg soil/kg tissue]); from Table 2.

2 exposure parameters from Table 6-3 of the *Human Health and Ecological Risk Assessment Work Plan* (ARCADIS, 2008).

3 dose caluated for a target HQ of 1 (NOAEL and LOAEL based).

4 Low and High ECVs based on low and high TRVs (from Table 4), respectively.

ECV	ecological comparison value for soil.
DTSC	Department of Toxic Substances Control.
dw	dry weight.
High	lowest-observed adverse effects level (LOAEL).
HMW PAHs	high molecular weight polycyclic aromatic hydrocarbons.
kg	kilograms.
kg/day	kilograms per day.
LMW PAHs	low molecular weight polycyclic aromatic hydrocarbons.
Low	no-observed adverse effects level (NOAEL).
mg/kg	milligrams per kilogram.
mg/kg-bw/day	milligrams per kilogram body weight per day.
NA	not available or not applicable.

Operation and Maintenance Health & Safety Plan

Introduction

Health and Safety Plans (HSPs) are required by Environmental Impact Report (EIR) Mitigation Measure HAZ-2 and must be in place prior to the initiation of ground disturbing activities at the site. A separately-prepared Construction Health and Safety Plan (Construction HSP) covers all of the requirements of HAZ-2 during the construction period of the Final Groundwater Remedy (see Appendix D to the Construction/Remedial Action Work Plan). The purpose of the Operation and Maintenance (O&M) HSP is to comply with HAZ-2 requirements during the remedy O&M.

EIR Mitigation Measure HAZ-2

HAZ-2 Reasonably Foreseeable Releases of Chemicals from Excavated or Disturbed Soil.

Before initiating ground-disturbing operations, a health and safety plan shall be developed and implemented by qualified environmental professionals to ensure health and safety precautions are being met. It is not possible to prepare the health and safety plan at this stage of the planning process because final construction plans and other design documents have not been finalized in sufficient detail. However, at a minimum, the health and safety plan shall include procedures to mitigate potential hazards, and such procedures shall include the use of PPE, measures that provide protection from physical hazards, measures that provide protection from chemical hazards that may be present at the site, decontamination procedures, and worker and health and safety monitoring criteria to be implemented during construction. The worker health and safety plan shall include protective measures and PPE that are specific to the conditions of concern and meet the requirements of the U.S. Occupational Safety and Health Administration's (OSHA's) construction safety requirements and Hazardous Waste Operations and Emergency Response Standard (29 CFR 1910.120). In accordance with OSHA requirements, appropriate training and recordkeeping shall also be a part of the health and safety program. The worker health and safety plan shall be certified by a Certified Industrial Hygienist in accordance with OSHA regulations. The worker health and safety plan shall be explained to the construction workers and all workers shall be required to sign the plan, which will be kept on the construction site at all times.

Worker safety training shall occur prior to initiation of ground disturbing activities. Training shall include the review of all health and safety measures and procedures. All workers and engineering inspectors at the site shall provide written acknowledgement that the soils management plan (discussed below), worker health and safety plan, and community health and safety plan were reviewed and training was received prior to commencement of construction activities.

The following are specific elements and directives that shall be included in the health and safety plan and implemented by PG&E during construction, operation and maintenance, and decommissioning of this project:

a. Vehicles traveling on unpaved roadways or surfaces would be directed to avoid traveling in areas where contaminated soils are known to be present; vehicle speeds shall be controlled (e.g., limited to 15 mph or slower) to limit generation of dust; measures, such as wetting of surfaces, will be employed to prevent dust generation by vehicular traffic or other dust-generating work activities.

b. Pre-mobilization planning shall occur during which the likelihood of encountering contaminated soils shall be reviewed along with the HMBP, site-specific health and safety plan, and SOPs so that the procedures are followed and the contingencies for handling contaminated soils are in-place prior to implementing the field operations.

c. Should evidence of contaminated soil be identified during ground disturbing activities (e.g., noxious odors, discolored soil), work in this area will immediately cease until soil samples can be collected and analyzed for the presence of contaminants by the site supervisor or the site safety officer. Contaminated soil shall be managed and disposed of in accordance with a project-specific health and safety plan and soil management plan. The health and safety plan and soil management plan shall be approved by DTSC before beginning any ground disturbing activities. While the project is exempt from the requirements of the San Bernardino County Division of Environmental Health, the health and safety plan and soil management plan shall be prepared in general accordance with the substantive requirements of this agency.

d. In the event that drilling sites must be located within areas of suspected soil contamination, the appropriate PPE shall be worn by all personnel working in these areas and methods specified in the health and safety plan used to control the generation of dust. When working in these areas, personnel shall be required to follow all guidance presented in the site-specific health and safety plan and soil management plan. The site-specific health and safety plan shall include provisions for site control such as, but not limited to, delineation of the exclusion, contaminant reduction and support zones for each work area, decontamination procedures, and procedures for the handling of contaminated soils and other investigation derived wastes. Soil that is excavated shall be loaded directly into containers such as roll-off bins; dust suppression methods shall be used prior to and during loading of soils into the bins. Suspected contaminated soils shall be segregated from suspected uncontaminated soils.

e. Personnel working at the site shall be trained in Hazardous Waste Operations.

All soil excavated and placed in roll-off bins or trucks for transportation off-site shall be covered with a tarp or rigid closure before transporting, and personnel working in the area shall be positioned upwind of the loading location.

O&M Staffing Plan and HSP Requirements

PG&E has not yet made a final determination about the nature of the onsite staffing of the future Remedy O&M functions. The onsite staff will consist of field workers, supervision, administrative support, compliance support, and technical support. Some or this entire staff will be PG&E employees. Some or this entire staff may be contractors.

If the Remedy is staffed by PG&E employees, a comprehensive PG&E employee-specific HSP will be developed that addresses all of PG&E's applicable safety standards, plus it must be consistent with the requirements of HAZ-2. The HSP for PG&E's Topock employees must comply with PG&E's requirements in the Section below.

If the Remedy is staffed entirely by contractor employees, the contractor will develop a site-specific H&SP that is compliant with the requirements in HAZ-2 and their corporate H&SP standards. PG&E will review and accept the contractors' plan(s), prior to work being initiated.

If the Remedy is staffed with a combination of PG&E employees and contractors, PG&E will establish a site-specific H&SP as described above and each contractor will be required to establish their own H&SPs which comply with the requirements above.

PG&E Employee HSP Requirements

PG&E employee work groups are required to follow PG&E's internal policies, standards, and procedures when developing HSPs. The current PG&E Standard is titled "Safety and Health Standard SAFE-1001S", last issued on February 28, 2013.

If a PG&E employee HSP is needed (because PG&E employees are providing O&M services for the Remedy), PG&E's safety policies, standards, and procedures will be used for developing the O&M HSP prior to operation of the Remedy.

PG&E Safety Principles

PG&E has a long and proud history for promoting workplace safety. One of the ways that PG&E communicates this commitment is by publicizing these Safety Principles, which are built into PG&E procedures and H&SPs. All employees are expected to embrace these principles:

Nothing is more important than public, employee and contractor safety.

- We must create an environment at PG&E where employees feel that they can raise all safety-related issues without peer pressure or fear of reprisal. This includes near hits and unsafe situations of any kind.
- We encourage open and honest communication on safety, so that we identify and eliminate unsafe situations and avoid incidents and injuries.
- To enhance safety and prevent future incidents, we have adopted a voluntary non-punitive self-reporting system for unsafe occurrences and hazardous situations.
- We acknowledge and recognize safe behavior and practices to encourage our employees, and to reinforce continuous learning.
- Safety discussions are used as an opportunity for learning and coaching. When an incident occurs, our first priority is to understand what happened and the underlying causes, not to discipline.
- We have adopted a behavior-based approach to discipline. Discipline will only be considered when employees act in a reckless manner, demonstrate a pattern of carelessness or non-compliance, put themselves, their coworkers or the public at risk by intentionally violating the Keys To Life or Code of Conduct.

PG&E's Safety Commitment

- We will train, equip and qualify our people to work safety.
- We will design, build, operate and maintain our systems with the highest regard for the safety and well-being of all.
- We will identify and address the underlying causes of incidents to prevent them from recurring.

Personal Safety Commitment

- I will make my personal safety and the safety of my co-workers and the public my highest priority.
- I will make sure I understand how to do the work safely before I start the job.
- I will speak up about safety concerns.
- I will look for safety hazards and intervene to stop unsafe acts.
- I will close out and properly document my work.

Keys to Life

To assure your safety and that of your co-workers and the public:

- Follow safe driving principles.
- Use appropriate life-saving personal protective equipment (PPE).
- Follow electrical safety testing and grounding rules.
- Follow clearance and energy lock-out rules.
- Follow confined space rules.
- Follow suspended load rules.
- Follow safety at heights rules.
- Follow excavation procedures.
- Follow hazardous environment procedures.

Timing for Issuing Final O&M HSP(s)

Final O&M HSP(s) will be submitted to DTSC and DOI by PG&E during the start-up phase of the remedy.

PG&E Safety and Health Program Standard

Safety and Health Program Standard

Summary This standard describes Pacific Gas and Electric Company's (PG&E's) Safety and Health Program, which each organization is to integrate into all business systems and work processes. This standard and its implementing procedures are PG&E's written Injury and Illness Prevention Program (IIPP), which is required under California law and or Federal Law.

Target Audience Officers, directors, and their designees, all of whom are responsible for integrating the Safety and Health Program into their business systems and work processes.

Safety Performing the procedures that implement this standard will diminish the risk of specific hazards to personnel, the public, and equipment.

Safety and Health Program Standard

Requirements

1 Safety and Health Program Integration

1.1 Each officer, director, and designee is responsible for developing and implementing plans to integrate the four steps of the Safety and Health Program into all business systems and work processes:

1. Identify hazards
2. Evaluate hazards
3. Control hazards
4. Evaluate controls

1.2 The following methods are to be used to develop and implement these plans to ensure employees are familiar with and comply with the Safety and Health Program:

1. Training
2. Human Performance Tools
3. Adequate Communication
4. Basic Safety Rules
5. Employee Involvement
6. Performance Management
7. Measurement and Evaluation
8. Records Management

©2013 Pacific Gas and Electric Company. All rights reserved.

Safety and Health Program Standard

2 Training

2.1 Training includes the following:

1. Incorporate the four steps of the Safety and Health Program

   a. Take proactive steps to identify hazards (see the following procedures):

      - SH&C Procedure 201, Hazard Evaluation and Control
      - SH&C Procedure 202, Incident Notification, Investigation, and Analysis
      - SH&C Procedure 203, Inspections
      - SH&C Procedure 206, Design and System/Change Management Review

   b. Evaluate the hazards (see the following procedures):

      - SH&C Procedure 201, Hazard Evaluation and Control
      - SH&C Procedure 204, Tracking and Trend Analysis
      - SH&C Procedure 221, Ergonomics Program

   c. Control the hazards (see the following procedures):

      - SH&C Procedure 201, Hazard Evaluation and Control
      - SH&C Procedure 202, Incident Notification, Investigation, and Analysis

   d. Evaluate the hazard controls (see the following procedures):

      - SH&C Procedure 201, Hazard Evaluation and Control
      - SH&C Procedure 202, Incident Notification, Investigation, and Analysis

2. Teach employees, about the hazards relevant to the business systems and work processes they deal with and how to implement the necessary hazard controls.

3. Train employees when the hazards they will face change.

4. Familiarize each employee with group participation techniques.

5. Ensure contractors and temporary agency workers receive similar training from their employers before starting work for PG&E.

©2013 Pacific Gas and Electric Company. All rights reserved.

Safety and Health Program Standard

3 Human Performance Tools

3.1 Human performance tools found in the Safety & Performance Fundamentals Handbook include the following:

1. Tailboards

   a. Ensure organization leaders provide tailboards before performing work and when work conditions change.

   b. Include the task purpose, scope, sequence and nature of the work.

   c. Review applicable procedures, drawings, documents, prerequisites, or any other items needed to perform the work.

   d. Use three-way communication to validate that task assignments are understood and roles and responsibilities for the work are clear. This includes limits of the required work; work hand-offs, controlling authority or person-in-charge as, and emergency procedures and contacts.

2. Two-Minute Rule

   . Coach employees to STOP and take two-minutes (two-minute rule) to think through the work/task and understand the hazards and the controls to improve situational awareness before beginning a task and to check for changing conditions.

3. Self-Checking STAR (Stop, Think, Act, and Review)

   a. Stop

      (1) Take the time to pause and focus on the task to be performed

      (2) Eliminate distractions

   b. Think

      (1) Think about the task to be performed

      (2) Understand what is to be done

      (3) Know the expected responses and indications of that action

      (4) Determine if the task is appropriate for the given conditions

      (5) Identify the correct component

      (6) Plan the actions to take if the response is not as expected

©2013 Pacific Gas and Electric Company. All rights reserved.

c . Act

(1) Perform the task

d . Review

(1) Evaluate the results of the action

(2) Verify the correct, expected response

(3) Take planned actions if the response is not as expected

4. Stop When Unsure

- When a question on the job or while performing work arises, creating uncertainty, stop and ask questions to understand what the work is, the hazards involved and how to perform the work.

5. Questioning Attitude

- Foster situational awareness, encouraging thought about safety before action is taken.

6. Procedure Use and Adherence

- Work is to be performed in accordance with approved procedures and supporting documents. Understanding the overall purpose and strategy of the procedure promotes safer outcomes.

7. Placekeeping

- Documents completion of procedural steps.

8. Phonetic Alphabet

- Use when communicating information related to equipment or components.

9. Three-Way Communication

- Promote a reliable transfer of information and understanding ensuring the correct action is taken.

©2013 Pacific Gas and Electric Company. All rights reserved.

Safety and Health Program Standard

4 Adequate Communication

1. Includes, but is not limited to the following:

   - Workgroup meetings
   - Jobsite tailboards
   - Inter-departmental agreements
   - Contract language
   - Bulletin board postings
   - Electronic media

2. Collect input from stakeholders and ensure they are informed of the outcome when participating in an industry or regulatory forum, such as the American Society for Testing and Materials (ASTM) or OSHA-Advisory committee.

5 Basic Safety Rules

- Inform employees that compliance with the Code of Safe Practices and the Safety and Performance Fundamentals Handbook is a condition of employment.

  a. Communicate updates or revisions to all standards, procedures, and rules relevant to the employees' work.

6 Employee Involvement

- Involve employees in the Safety and Health Program on an on-going basis.

- When specific safety and health issues are to be resolved, use Grass Roots Teams, chartered safety/ad hoc teams, or workgroups comprised of critical stakeholders.

7 Performance Management

- Integrate the Safety and Health Program into all work through individual job expectations and team charters.

- To define team expectations, use a charter that defines purpose, scope of authority, roles and responsibilities, communication and documentation requirements, and required resources.

- Hold individuals and teams accountable through recognition and disciplinary action. Use PG&E's Human Resources programs of Performance Management for management and applicable A&T employees and Positive Discipline for bargaining unit employees.

Safety and Health Program Standard

8 Measurement and Evaluation

- Establish goals to measure Safety and Health Program progress.
- Evaluate integration of the Safety and Health Program into all work through work site observations, inspections or other observations.

9 Records Management

- Document and maintain training records until subsequent training is provided to employees.
- Document and maintain all other Safety and Health Program records for at least three years. Records identified in the Guide to Record Retention must be maintained for the period of time specified.

Safety and Health Program Standard

Definitions	A **hazard** is any existing or potential condition or act that can result in a loss such as death, injury, illness, or property damage.
Implementation Responsibilities	Each officer and director is responsible for implementing the Safety and Health Program within his or her organization and monitoring compliance with it. Safety is responsible for monitoring the company-wide compliance with this standard.
Governing Document	Safety and Health Policy
Compliance Requirement/ Regulatory Commitment	California Code of Regulations, Title 8, Section 3203 – Injury and Illness Prevention Program
Reference Documents	**Developmental References**: NA
	Supplemental References: • SH&C Procedure 201, Hazard Evaluation and Control • SH&C Procedure 202, Incident Notification, Investigation, and Analysis • SH&C Procedure 203, Inspections • SH&C Procedure 204, Tracking and Trend Analysis • SH&C Procedure 206, Design and System/Change Management Review • SH&C Procedure 221, Ergonomics Program • Code of Safe Practices (CSP) • Safety & Performance Fundamentals Handbook

Material Safety Data Sheets

NuWell 120

JOHNSON SCREENS

A Weatherford Company

Material Safety Data Sheet

SECTION 1 - CHEMICAL PRODUCT AND COMPANY INFORMATION

Product Name: NW-120
Part Number: **Chemical Family:** Inorganic acid

Manufacturer's Name: Johnson Screens / A Weatherford Company
Address: P.O. Box 64118 – St. Paul, MN 55164
Product/Technical Information Phone Number: 651-636-3900
Medical/Handling Emergency Phone Number: CHEMTREC 1-800-424-9300
Transportation Emergency Phone Number: CHEMTREC 1-800-424-9300

Issue Date: 06-06-03
Revision Date/Revision Number: 06-06-05 /01

SECTION 2 – COMPOSITION INFORMATION

	% by Weight	
Phosphoric Acid Orthophosphoric Acid (CAS # 7664-38-2)	65 – 80	Food Grade

SECTION 3 - HAZARDS IDENTIFICATION

Appearance & Odor: Colorless to lightly colored liquid; nil odor
Emergency Overview: Overexposure may aggravate disorders of the skin / respiratory system
Fire & Explosion Hazards: None currently known
Primary Route(s) of Exposure: Skin, eyes, digestive tract, respiratory system
Inhalation – Acute Effects: May cause irritation / coughing
Skin Contact – Acute Effects: May cause severe irritation; prolonged or repeated skin contact may cause burns, irreversible damage
Eye Contact – Acute Effects: May cause severe irritation / burns; prolonged or repeated eye contact may cause irreversible damage or blindness
Ingestion – Acute Effects: May cause irritation, burns, pain, nausea, vomiting, shock symptoms (rapid pulse, sweating, collapse)

SECTION 4 - FIRST AID MEASURES

Inhalation First Aid: Remove affected person from area to fresh air and provide oxygen if breathing is difficult. Give artificial respiration ONLY if breathing has stopped and give CPR ONLY if there is no breathing and no pulse. Obtain medical attention.

Skin Contact First Aid: Immediately remove clothing from affected area and wash skin for 15 minutes with flowing water and soap. Clothing should be discarded or washed before reuse. Obtain medical assistance if irritation develops.

Eye Contact First Aid: Immediately irrigate eyes with flowing water continuously for 15 minutes while holding eyes open. Contacts should be removed before or during flushing. Obtain medical attention immediately.

Ingestion First Aid: If victim is alert and not convulsing, rinse mouth with water and give plenty of water to drink. If spontaneous vomiting occurs, have affected person lean forward with head down to avoid breathing in of vomitus. Rinse mouth again and give more water to drink. Obtain medical attention.

Medical Conditions Aggravated: Persons with pre-existing skin disorders or eye problems, or impaired respiratory function may be more susceptible to the effects of the substance.

Note to Physician: May give oxygen if breathing difficulty following exposure. Observe for possible delayed reactions.

SECTION 5 - FIRE FIGHTING MEASURES

Flash Point/Method: N/A
Auto Ignition Temperature:
Upper/Lower Explosion Limits: Not determined
Extinguishing Media: Chemical type foam, CO_2 (Carbon Dioxide), dry chemical, water fog
Fire Fighting Procedures: Not considered a fire hazard
Fire & Explosion Hazards: Is not flammable, however the following can occur during a fire: phosphorus oxides and/or phosphine from thermal decomposition and hydrogen from reactive metals.
Hazardous Products of Decomposition and/or Combustion: Oxides of phosphorus
NFPA Ratings:

HEALTH	FLAMMABILITY	REACTIVITY	OTHER
3	0	0	

0 = Insignificant 1 = Slight 2 = Moderate 3 = High 4 = Extreme

SECTION 6 – ACCIDENTAL RELEASE MEASURES

Small spill: neutralize acid spill with alkali such as soda ash, sodium bicarbonate, limestone or lime. Absorb material with an inert material such as sand, vermiculite, diatomaceous earth or other absorbent material and place in chemical waste container to be disposed at an appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal. Adequate ventilation is required for soda ash due to the release of carbon dioxide gas. No smoking in spill area.

Large spill: contain with dikes and transfer the material to appropriate containers for reclamation or disposal. Absorb remaining spill with an inert material such as sand, vermiculite or other absorbent material and place in chemical waste container to be disposed at an appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal. Neutralize residue with alkali such as soda ash, sodium bicarbonate, limestone or lime. Adequate ventilation is required for soda ash due to the release of carbon dioxide gas. No smoking in spill area.

Release Notes: If spill could potentially enter any waterway, including intermittent dry creeks, contact the local authorities. If in the U.S., contact the US COAST GUARD NATIONAL RESPONSE CENTER toll free number 800-424-8802. In case of accident or road spill notify: CHEMTREC in USA at 800-424-9300; CANUTEC in Canada at 613-996-6666; CHEMTREC in other countries at (International code)+1-703-527-3887.

Comments: See Section 13 for disposal information and Section 15 for regulatory requirements. Large and small spills may have a broad definition depending on the user's handling system. Therefore, the spill category must be defined at the point of release by technically qualified personnel.

SECTION 7 – HANDLING AND STORAGE

Handling: For industrial use only. Heat is generated upon dilution with water. When diluting, add product slowly to water with agitation. Never add water to the acid as severe splashing and reactivity will result. Always add acid to water. ATTENTION: This container hazardous when emptied. Since emptied container contains product residues (vapor or liquid), all labeled hazard precautions must be observed.

Storage: Keep container closed when not in use. Keep out of reach of children.

General Comments: Wear protective equipment when handling. Use only with adequate ventilation. Wash thoroughly after handling. Do not breathe vapor, mist, or dust. Do not get in eyes, on skin, or clothing. Do not swallow.

SECTION 8 – PERSONAL PROTECTION/EXPOSURE CONTROL

Respiratory Protection: If exposure limits are exceeded, or if exposure may occur, use a NIOSH/MSHA respirator approved for your conditions of exposure. Refer to the most recent NIOSH publications concerning chemical hazards, or consult your safety equipment supplier. Respiratory protection programs must be in compliance with OSHA requirements in 29 CFR 1910.134. For emergencies, a NIOSH/MSHA approved positive pressure breathing apparatus should be readily available.

Skin Protection: Acid proof gloves; clean, body covering clothing; rubber apron; rubber boots

Eye Protection: Chemical goggles or faceshield (ANSI Z87.1 or approved equivalent). Always wear eye protection when working with chemicals. Do not wear contact lenses when working with chemicals.

Ventilation Protection: Adequate ventilation is required to minimize exposure or to maintain exposure levels below OSHA/ACGIH requirements. Mechanical general ventilation is usually adequate. Local mechanical ventilation may be required.

Other Protection: Safety shower, eye wash fountain, and washing facilities should be readily available. In case of emergency or when dusting, misting, or splashing may occur, wear respiratory protection, eye protection, gloves, helmet, boots, and complete protective body covering.

Exposure Limits:

OSHA TWA/TLV (ppm)	ACGIH TWA/TLV (ppm)	NIOSH	SUPPLIER
0.25	0.25		

SECTION 9 – PHYSICAL AND CHEMICAL PROPERTIES

Appearance & Odor: Colorless to lightly colored liquid, no odor

Vapor Pressure: 5.700 @ 68^{o} F.
Vapor Density (Air=1): Not determined
Boiling Point: 275^{o} F.
Melting Point: -17.5^{o} C (75% H_3PO_4)
Specific Gravity: 1.5850 @ 60^{o} F.
Solubility in Water: Complete
Volatile Percentage: Not determined
pH: aqueous approx. 1.000 to 2.000
Flash Point/method: N/A
Auto Ignition Temperature: None
Upper/Lower Explosion Limits: Not determined
Other:

SECTION 10 - STABILITY AND REACTIVITY

Stability: Stable under normal conditions of storage and use
Incompatibilities: Inorganic bases, metals/metal blends; contact with some metals can generate explosive hydrogen gas
Polymerization: Will not occur
Decomposition: Oxides of phosphorus and/or phosphine from thermal decomposition and hydrogen gas from reaction with metals
Conditions to Avoid: High temperature

SECTION 11 - TOXICOLOGICAL INFORMATION

Inhalation – Acute: LC_{50} (guinea pig, mouse, rat, rabbit): 61-1,689 mg/m^3
Inhalation – Chronic:
Skin Contact – Acute: LD_{50} (rabbit): >1,260 to > 3,160 mg/kg
Skin Contact – Chronic:
Eye Contact – Acute:
Ingestion – Acute: LD_{50} (rat): 1,530 mg/kg
Ingestion – Chronic:
Carcinogenicity/Mutagenicity: No components present in excess of 0.1% by weight are listed as carcinogens by IARC, NTP, or OSHA
Reproductive Effects: 375 mg/kg bw did not affect offspring growth in rats
Neurotoxicity: None known
Other Effects: In vitro bacterial genetic toxicity negative
Target Organs: Overexposure may cause damage to all body tissues

SECTION 12 – ECOLOGICAL INFORMATION

Ecotoxicity: acute toxicity to fish: 96 hour LC_{50}: 3.0 – 3.5 mg/L
Acute toxicity to Daphnia: survival rate depends on pH

Environmental Fate: phosphoric acid undergoes ionic dissociation in water.

Toxicity: Moderately toxic to aquatic organisms as defined by USEPA

Degradation Products: while acidity of this material is readily reduced in natural waters, the resulting phosphate may persist indefinitely or incorporate into biological systems.

SECTION 13 – DISPOSAL CONSIDERATIONS

Material that cannot be used or chemically reprocessed and empty containers should be disposed of in accordance with all applicable regulations. Product containers should be thoroughly emptied before disposal. Generators of waste material are required to

evaluate all waste for compliance with RCRA and any local disposal procedures and regulations. NOTE: State and local regulations may be more stringent than federal regulations.

SECTION 14 – TRANSPORTATION INFORMATION

DOT Shipping Description:

Proper Shipping Name: Phosphoric Acid
Hazard Class: 8, UN1805, PG III
Label Requirements: CORROSIVE
Reportable Quantity: None

European Transportation: ADR/RID Hazard Classification: 8 ADR/RID Item Number: 17°C
U.S. Custom Harmonization Number: 2809.20.00.30

SECTION 15 – REGULATORY INFORMATION

SARA Hazard Category: This product has been reviewed according to the EPA Hazard Categories promulgated under Section 311 and 312 of the Superfund Amendment and Reauthorization Act of 1986 (SARA Title III) and is considered, under applicable definitions, to meet the following categories:
Fire: No Pressure Generating: No Reactivity: No Acute: Yes Chronic: No

40 CFR Part 355 – Extremely Hazardous Substances: None
40 CFR Part 370 – Hazardous Chemical Reporting: Applicable

TSCA Inventory Status: Chemical components listed on TSCA Inventory

SARA Title III: This product contains the following substances to the reporting requirements of Title III (EPCRA) of the Superfund Amendments and Reauthorization Act of 1986 and 40 CFR Part 372:

Chemical	CAS No.	% by Wt.	CERCLA RQ (lbs)	SARA (1986) Reporting		
				311	312	313
Phosphoric Acid	7664-38-2	65 – 80	5,000	Yes	Yes	No

CERCLA/Superfund, 40 CFR Parts 117, 302: If this product contains components subject to substances designated as CERCLA Reportable Quantity (RQ) Substances, it will be designated in the above table with the RQ value in pounds. If there is a release of RQ Substance to the environment, notification to the National Response Center, Washington, D.C. (1-800-424-8802) is required.

SECTION 16 – OTHER INFORMATION

Disclaimer: The information contained herein is based on data considered accurate. However, no warranty is expressed or implied regarding the accuracy of this data or the results to be obtained from the user thereof. It is the buyer's responsibility to ensure that its activities comply with federal, state, provincial and local laws.

NuWell 310

JOHNSON SCREENS

A Weatherford Company

Material Safety Data Sheet

SECTION 1 - CHEMICAL PRODUCT AND COMPANY INFORMATION

Product Name: NW-310
Part Number: **Chemical Family:** Polymeric acid solution to enhance acid cleaning activity

Manufacturer's Name: Johnson Screens /A Weatherford Company
Address: P.O. Box 64118 – St. Paul, MN 55164
Product/Technical Information Phone Number: 651-636-3900
Medical/Handling Emergency Phone Number: CHEMTREC 1-800-424-9300
Transportation Emergency Phone Number: CHEMTREC 1-800-424-9300

Issue Date: 06-01-1997
Revision Date/Revision Number: 01/20/2012 / 06

SECTION 2 – COMPOSITION INFORMATION

****

No constituents of the formulae are listed or considered hazardous under OSHA 29CFR 1910.1200

All components are listed under TSCA

SECTION 3 - HAZARDS IDENTIFICATION

****

Appearance & Odor: Clear yellow liquid
Emergency Overview: Product is a mild acid – handle with caution
Fire & Explosion Hazards: Contact with metals may produce flammable hydrogen gas
Primary Route(s) of Exposure: Skin, eyes, and inhalation
Inhalation – Acute Effects: Irritation or corrosion of mucous membranes with upper and lower respiratory irritation
Skin Contact – Acute Effects: Skin discomfort or rash
Eye Contact – Acute Effects: Irritation, tearing, or blurring of vision
Ingestion – Acute Effects: Diarrhea

SECTION 4 - FIRST AID MEASURES

****

Inhalation First Aid: Remove affected person from area to fresh air and provide oxygen if breathing is difficult. Give artificial respiration ONLY if breathing has stopped and give CPR ONLY if there is no breathing and no pulse. Obtain medical attention.

Skin Contact First Aid: Immediately remove clothing from affected area and wash skin for 15 minutes with flowing water and soap. Clothing should be discarded or washed before reuse. Obtain medical assistance if irritation develops.

Eye Contact First Aid: Immediately irrigate eyes with flowing water continuously for 15 minutes while holding eyes open. Contacts should be removed before or during flushing. Obtain medical attention immediately.

Ingestion First Aid: If victim is alert and not convulsing, rinse mouth with water and give plenty of water to drink. If spontaneous vomiting occurs, have affected person lean forward with head down to avoid breathing in of vomitus. Rinse mouth again and give more water to drink. Obtain medical attention.

Medical Conditions Aggravated: None known

Note to Physician: Product has some surfactant qualities that may result in a laxative effect in cases of ingestion.

SECTION 5 - FIRE FIGHTING MEASURES

****

Flash Point/Method: None
Auto Ignition Temperature: N/D
Upper/Lower Explosion Limits: N/A
Extinguishing Media: That which is appropriate for surrounding fire

Fire Fighting Procedures: Wear self-contained breathing apparatus. Carbon monoxide, carbon dioxide, phosphorus oxides (extremely small) may be released in a fire.

Fire & Explosion Hazards: High heat fires could result in excessive carbon monoxide release.

Hazardous Products of Decomposition and/or Combustion: Carbon monoxide, carbon dioxide, and phosphorus oxides.

NFPA Ratings:

HEALTH	FLAMMABILITY	REACTIVITY	OTHER
1	0	1	None

SECTION 6 – ACCIDENTAL RELEASE MEASURES

****

Neutralize spills with lime or soda ash. Flush spill area with plenty of water. Keep spectators away. Treat as an acid material. Contain spill with inert material (e.g. sand, earth, absorbable material). Transfer diking material to suitable container for recovery or disposal. Material may be diluted and rinsed down a sanitary sewer system to a municipal wastewater plant. If quantities in excess of 500 gallons are rinsed to a sewer, the district should be notified of possible pH upset to the wastewater plant.

All disposal methods must be in compliance with all Federal, State, Local and Provincial laws and regulations. Regulations may vary in different locations. Waste characterizations and compliance with applicable laws are the responsibility solely of the waste generator.

SECTION 7 – HANDLING AND STORAGE

****

Handling: Minimize skin contact. Wash with soap and water before eating, drinking, smoking, or using toilet facilities.

Storage: Keep in well ventilated area. Keep package tightly closed. Store above 32^{o} F. (0^{o} C.) Product should not be stored with or near strong caustic or oxidizing agents.

General Comments: None

SECTION 8 – PERSONAL PROTECTION / EXPOSURE CONTROL

****

Respiratory Protection: None required for normal use

Skin Protection: Neoprene gloves or approved chemical protective gloves suitable for use in acid material

Eye Protection: Chemical splash goggles (ANSI Z871) or approved equivalent

Ventilation Protection: Standard plant ventilation should be sufficient

Other Protection: Safety showers, with quick opening valves which stay open, and eye wash fountains, or other means of washing the eyes with a gentle flow of cool to tepid tap water, should be readily available in all areas where this material is handled or stored. Water should be supplied through insulated and heat-traced lines to prevent freeze-ups in cold weather.

Exposure Limits:

OSHA	ACGIH	NIOSH	SUPPLIER
None	None	None	AEL=20mg/m^3 - 8&12 hrs TWA

SECTION 9 – PHYSICAL AND CHEMICAL PROPERTIES

****

Appearance & Odor: Clear yellow liquid

Vapor Pressure: Vapor is water
Vapor Density: 1.0 (vapor is water)
Boiling Point: 250° F.
Melting Point: N/A
Specific Gravity: 1.19
Solubilty in Water: Complete
Volatile Percentage: 34%
pH: 2.3
Flash Point/method: Will not flash
Auto Ignition Temperature: N/D
Upper/Lower Explosion Limits: N/A
Other:

SECTION 10 - STABILITY AND REACTIVITY

****

Stability: Stable
Incompatibilities: Metals, oxidizing agents such as nitric acid, cyanide, sulfides
Polymerization: No
Decomposition: Carbon monoxide, carbon dioxide, phosphorus oxides (extremely small)
Conditions to Avoid: Contact with strong oxidizing chemicals such as calcium hypochlorite

SECTION 11 - TOXICOLOGICAL INFORMATION

****

Inhalation – Acute: 4 hrs. LC_{50} (rats) – 14 mg/L
Inhalation – Chronic: Not established
Skin Contact – Acute: Dermal LD_{50} Rabbits > 3000 mg/kg
Skin Contact – Chronic: Skin irritation Rabbits (Draize Score 1.6 /8)
Eye Contact – Acute: Minimal Rabbits (Draize score 2.7 / 110)
Ingestion – Acute: Oral LD_{50} (Rats) > 5000 mg/kg
Ingestion – Chronic: 600 mg/kg (90 day study dogs) produced some kidney function changes *
Carcinogenicity/Mutagenicity: None
Reproductive Effects: None known
Neurotoxicity: None
Other Effects: Some calcium loss in long term feeding studies (Dogs) *
Target Organs: Kidneys, Bones

SECTION 12 – ECOLOGICAL INFORMATION

****

Biodegradability:

BOD (5) 1.0% solution	7950 mg O_2/L
BOD (5) 0.1% solution	725 mg O_2/L
Total Organic Carbon	2.2%
Non-bioaccumulating	

Fish toxicity: Bluegill (24 – 48 hrs) LC_{50} = 186 mg/L
Biological safe concentration is 56 mg/L
At 310 mg/L there was 90% mortality in 24 – 48 hrs
At 36 mg/L pH 5.4 there was 100% survival over 48 hrs

SECTION 13 – DISPOSAL CONSIDERATIONS

****

Comply with Federal, State, and local regulations. If approved, may be neutralized and flushed to wastewater treatment plant. Product is biodegradable, no discharge limitations are required.

Material that cannot be used or chemically reprocessed and empty containers should be disposed of in accordance with all applicable regulations. Product containers should be thoroughly emptied before disposal. Generators of waste material are required to evaluate all waste for compliance with RCRA and any local disposal procedures and regulations. NOTE: State and local regulations may be more stringent than federal regulations.

SECTION 14 – TRANSPORTATION INFORMATION

DOT Shipping Description: Not regulated as a hazardous material by the US Dept. of Transportation (DOT) 49CFR 172.101 Hazardous Materials Table

U.S. Custom Harmonization #: 3402.90

Canadian TDG:
Hazard Class: Non-Hazardous
Label Requirements: None Required
Reportable Quantity: None

SECTION 15 – REGULATORY INFORMATION

NSF Certified for use in well cleaning, pipe line cleaning, and filter cleaning

RCRA Status: Not a hazardous waste under RCRA 40 CFR 261. No reportable quantities.

SARA/TITLE III-CERCLA List: This product does not contain a “CERCLA” listed hazardous substance for emergency release notification under Sec. 304 (40CFR 302).

SARA/TITLE III-Toxic Chemicals List: This product does no contain a toxic chemical for routine annual “Toxic Chemical Release Reporting” under Sec. 313 (40CFR 372).

TSCA Inventory Status: Chemical components listed on TSCA Inventory.

California Proposition 65: This product does not contain any chemicals currently on the California list of known carcinogens and reproductive toxins.

Canadian WHMIS Classification: This product does not contain any hazardous materials under CPR and this MSDS discloses all information elements required by the CPR.

SECTION 16 – OTHER INFORMATION

Disclaimer: The information contained herein is based on data considered accurate. However, no warranty is expressed or implied regarding the accuracy of this data or the results to be obtained from the user thereof. It is the buyer's responsibility to ensure that its activities comply with federal, state, provincial and local laws.
