Warning: This data set only has 1 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Zinc, dissolved (mw-38s) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Zinc, dissolved (mw-39-60)

General Statistics

Warning: This data set only has 1 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Zinc, dissolved (mw-39-60) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Zinc, dissolved (mw-4)

General Statistics

Warning: There are only 4 Distinct Detected Values in this data

Note: It should be noted that even though bootstrap may be performed on this data set

the resulting calculations may not be reliable enough tp draw conclusions

It is recommended to have 10-15 or more distinct observations for accurate and meaningful results.

4078	Note: Data have multiple DLs - Use of KM Method is recommended									Number treated as Non-Detect		13
4079	For all methods (except KM, DL/2, and ROS Methods),									Number treated as Detected		1
4080	Observations < Largest ND are treated as NDs									Single DL Non-Detect Percentage		92.86%
4081												

4082	Warning: Data set has only 2 Distinct Detected Values.											
4083	This may not be adequate enough to compute meaningful and reliable test statistics and estimates.											
4084	The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).											
4085												
4086	Unless Data Quality Objectives (DQOs) have been met, it is suggested to collect additional observations.											
4087												
4088	The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.											
4089	Those methods will return a 'N/A' value on your output display!											
4090												
4091	It is necessary to have 4 or more Distinct Values for bootstrap methods.											
4092	It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

General UCL Statistics for Data Sets with Non-Detects		
User Selected Options		
From File	I:\pg&e\topock\GW_Risk_Assessment\Data_Analysis\ProUCL_Input\Final Input Table\Combined_chemical_data_	
Full Precision	OFF	
Confidence Coefficient	95%	
Number of Bootstrap Operations	2000	

Ammonia as nitrogen (background)

General Statistics

Number of Valid Data	149	Number of Detected Data	8
Number of Distinct Detected Data	8	Number of Non-Detect Data	141
		Percent Non-Detects	94.63%

Raw Statistics		**Log-transformed Statistics**	
Minimum Detected	0.586	Minimum Detected	-0.534
Maximum Detected	1.06	Maximum Detected	0.0583
Mean of Detected	0.751	Mean of Detected	-0.308
SD of Detected	0.178	SD of Detected	0.22
Minimum Non-Detect	0.5	Minimum Non-Detect	-0.693
Maximum Non-Detect	0.5	Maximum Non-Detect	-0.693

Warning: There are only 8 Detected Values in this data

Note: It should be noted that even though bootstrap may be performed on this data set

the resulting calculations may not be reliable enough tp draw conclusions

It is recommended to have 10-15 or more distinct observations for accurate and meaningful results.

General UCL Statistics for Data Sets with Non-Detects		
User Selected Options		
From File	I:\pg&e\topock\GW_Risk_Assessment\Data_Analysis\ProUCL_Input\Final Input Table\Combined_chemical_data_	
Full Precision	OFF	
Confidence Coefficient	95%	
Number of Bootstrap Operations	2000	

Antimony, dissolved (background)

General Statistics

Number of Valid Data	149	Number of Detected Data	1
Number of Distinct Detected Data	1	Number of Non-Detect Data	148
		Percent Non-Detects	99.33%

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Antimony, dissolved (background) was not processed!

Antimony, dissolved (flood)

General Statistics

Number of Valid Data	79	Number of Detected Data	5
Number of Distinct Detected Data	5	Number of Non-Detect Data	74
		Percent Non-Detects	93.67%

Raw Statistics		Log-transformed Statistics	
Minimum Detected	0.0088	Minimum Detected	-4.733
Maximum Detected	0.155	Maximum Detected	-1.864
Mean of Detected	0.0772	Mean of Detected	-3.054
SD of Detected	0.0712	SD of Detected	1.223
Minimum Non-Detect	0.002	Minimum Non-Detect	-6.215
Maximum Non-Detect	0.02	Maximum Non-Detect	-3.912
Note: Data have multiple DLs - Use of KM Method is recommended		Number treated as Non-Detect	75
For all methods (except KM, DL/2, and ROS Methods),		Number treated as Detected	4
Observations < Largest ND are treated as NDs		Single DL Non-Detect Percentage	94.94%

Warning: There are only 5 Detected Values in this data

Note: It should be noted that even though bootstrap may be performed on this data set

the resulting calculations may not be reliable enough tp draw conclusions

It is recommended to have 10-15 or more distinct observations for accurate and meaningful results.

From File	I:\pg&e\topock\GW_Risk_Assessment\Data_Analysis\ProUCL_Input\Final Input Table\Combined_chemical_data_	
Full Precision	OFF	
Confidence Coefficient	95%	
Number of Bootstrap Operations	2000	

Cadmium, dissolved (flood)

General Statistics

Number of Valid Data	79	Number of Detected Data	0
Number of Distinct Detected Data	0	Number of Non-Detect Data	79
		Percent Non-Detects	100.00%

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Cadmium, dissolved (flood) was not processed!

Cadmium, dissolved (no flood)

General Statistics

Number of Valid Data	295	Number of Detected Data	1
Number of Distinct Detected Data	1	Number of Non-Detect Data	294
		Percent Non-Detects	99.66%

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Cadmium, dissolved (no flood) was not processed!

General Statistics

Number of Valid Data	149	Number of Detected Data	4
Number of Distinct Detected Data	4	Number of Non-Detect Data	145
		Percent Non-Detects	97.32%

Raw Statistics		**Log-transformed Statistics**	
Minimum Detected	0.00101	Minimum Detected	-6.898
Maximum Detected	0.00164	Maximum Detected	-6.413
Mean of Detected	0.00136	Mean of Detected	-6.619
SD of Detected	0.0002611	SD of Detected	0.203
Minimum Non-Detect	0.001	Minimum Non-Detect	-6.908
Maximum Non-Detect	0.001	Maximum Non-Detect	-6.908

Warning: There are only 4 Distinct Detected Values in this data

Note: It should be noted that even though bootstrap may be performed on this data set
the resulting calculations may not be reliable enough tp draw conclusions

It is recommended to have 10-15 or more distinct observations for accurate and meaningful results.

Mercury, dissolved (flood)

General Statistics

Number of Valid Data	82	Number of Detected Data	1
Number of Distinct Detected Data	1	Number of Non-Detect Data	81
		Percent Non-Detects	98.78%

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Mercury, dissolved (flood) was not processed!

Mercury, dissolved (no flood)

General Statistics

Number of Valid Data	298	Number of Detected Data	0
Number of Distinct Detected Data	0	Number of Non-Detect Data	298
		Percent Non-Detects	100.00%

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Mercury, dissolved (no flood) was not processed!

Alkalinity, bicarb as CaCO3 (other)

General Statistics

Number of Valid Observations	2	Number of Distinct Observations	2

Warning: This data set only has 2 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Alkalinity, bicarb as CaCO3 (other) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Alkalinity, bicarb as CaCO3 (upstream)

General Statistics

Number of Valid Observations	6	Number of Distinct Observations	5

Raw Statistics		**Log-transformed Statistics**	
Minimum	128	Minimum of Log Data	4.852
Maximum	167	Maximum of Log Data	5.118
Mean	137.8	Mean of log Data	4.922
Median	131	SD of log Data	0.101
SD	14.89		
Coefficient of Variation	0.108		
Skewness	2.063		

Warning: A sample size of 'n' = 6 may not adequate enough to compute meaningful and reliable test statistics and estimates!

It is suggested to collect at least 8 to 10 observations using these statistical methods!

If possible compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Warning: There are only 6 Values in this data

Note: It should be noted that even though bootstrap methods may be performed on this data set,

the resulting calculations may not be reliable enough to draw conclusions

The literature suggests to use bootstrap methods on data sets having more than 10-15 observations.

General Statistics

Number of Valid Observations	6	Number of Distinct Observations	5

Raw Statistics		**Log-transformed Statistics**	
Minimum	68.7	Minimum of Log Data	4.23
Maximum	92.7	Maximum of Log Data	4.529
Mean	74.6	Mean of log Data	4.306
Median	70.1	SD of log Data	0.117
SD	9.381		
Coefficient of Variation	0.126		
Skewness	1.955		

Warning: A sample size of 'n' = 6 may not adequate enough to compute meaningful and reliable test statistics and estimates!

It is suggested to collect at least 8 to 10 observations using these statistical methods!

If possible compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Warning: There are only 6 Values in this data

Note: It should be noted that even though bootstrap methods may be performed on this data set,

the resulting calculations may not be reliable enough to draw conclusions

The literature suggests to use bootstrap methods on data sets having more than 10-15 observations.

Hexavalent chromium (downstream)

General Statistics

Number of Valid Data	547	Number of Detected Data	1
Number of Distinct Detected Data	1	Number of Non-Detect Data	546
		Percent Non-Detects	99.82%

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Hexavalent chromium (downstream) was not processed!

Hexavalent chromium (other)

General Statistics

Number of Valid Data	26	Number of Detected Data	0
Number of Distinct Detected Data	0	Number of Non-Detect Data	26
		Percent Non-Detects	100.00%

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Hexavalent chromium (other) was not processed!

Hexavalent chromium (upstream)

General Statistics

Number of Valid Data	420	Number of Detected Data	0
Number of Distinct Detected Data	0	Number of Non-Detect Data	420
		Percent Non-Detects	100.00%

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Hexavalent chromium (upstream) was not processed!

Iron, dissolved (downstream)

General Statistics

Number of Valid Data	8	Number of Detected Data	0
Number of Distinct Detected Data	0	Number of Non-Detect Data	8
		Percent Non-Detects	100.00%

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Iron, dissolved (downstream) was not processed!

Iron, dissolved (upstream)

General Statistics

Number of Valid Data	2	Number of Detected Data	0
Number of Distinct Detected Data	0	Number of Non-Detect Data	2
		Percent Non-Detects	100.00%

Warning: This data set only has 2 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Iron, dissolved (upstream) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

General Statistics

Number of Valid Observations	6	Number of Distinct Observations	5

Raw Statistics		**Log-transformed Statistics**	
Minimum	26.1	Minimum of Log Data	3.262
Maximum	27.9	Maximum of Log Data	3.329
Mean	26.8	Mean of log Data	3.288
Median	26.6	SD of log Data	0.0292
SD	0.785		
Coefficient of Variation	0.0293		
Skewness	0.484		

Warning: A sample size of 'n' = 6 may not adequate enough to compute meaningful and reliable test statistics and estimates!

It is suggested to collect at least 8 to 10 observations using these statistical methods!

If possible compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Warning: There are only 6 Values in this data

Note: It should be noted that even though bootstrap methods may be performed on this data set,

the resulting calculations may not be reliable enough to draw conclusions

The literature suggests to use bootstrap methods on data sets having more than 10-15 observations.

General Statistics

Number of Valid Observations	6	Number of Distinct Observations	4

Raw Statistics		**Log-transformed Statistics**	
Minimum	0.0042	Minimum of Log Data	-5.473
Maximum	0.007	Maximum of Log Data	-4.962
Mean	0.00527	Mean of log Data	-5.258
Median	0.005	SD of log Data	0.167
SD	0.0009352		
Coefficient of Variation	0.178		
Skewness	1.445		

Warning: There are only 4 Distinct Values in this data

There are insufficient Distinct Values to perform some GOF tests and bootstrap methods.

Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values to compute bootstrap methods.

It is recommended to have 10-15 or more observations for accurate and meaningful bootstrap results.

Warning: A sample size of 'n' = 6 may not adequate enough to compute meaningful and reliable test statistics and estimates!

It is suggested to collect at least 8 to 10 observations using these statistical methods!

If possible compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Potassium, dissolved (upstream)

General Statistics

Number of Valid Observations	6	Number of Distinct Observations	5

Raw Statistics		Log-transformed Statistics	
Minimum	4.2	Minimum of Log Data	1.435
Maximum	5.54	Maximum of Log Data	1.712
Mean	4.608	Mean of log Data	1.523
Median	4.5	SD of log Data	0.106
SD	0.511		
Coefficient of Variation	0.111		
Skewness	1.461		

Warning: A sample size of 'n' = 6 may not adequate enough to compute meaningful and reliable test statistics and estimates!

It is suggested to collect at least 8 to 10 observations using these statistical methods!

If possible compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Warning: There are only 6 Values in this data

Note: It should be noted that even though bootstrap methods may be performed on this data set,

the resulting calculations may not be reliable enough to draw conclusions

The literature suggests to use bootstrap methods on data sets having more than 10-15 observations.

General Statistics

Number of Valid Observations	6	Number of Distinct Observations	6

Raw Statistics		Log-transformed Statistics	
Minimum	80.8	Minimum of Log Data	4.392
Maximum	126	Maximum of Log Data	4.836
Mean	93.45	Mean of log Data	4.526
Median	89.05	SD of log Data	0.161
SD	16.57		
Coefficient of Variation	0.177		
Skewness	2.054		

Warning: A sample size of 'n' = 6 may not adequate enough to compute meaningful and reliable test statistics and estimates!

It is suggested to collect at least 8 to 10 observations using these statistical methods!

If possible compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Warning: There are only 6 Values in this data

Note: It should be noted that even though bootstrap methods may be performed on this data set,

the resulting calculations may not be reliable enough to draw conclusions

The literature suggests to use bootstrap methods on data sets having more than 10-15 observations.

Number of Distinct Detected Data	3	Number of Non-Detect Data	3
		Percent Non-Detects	50.00%

Raw Statistics		Log-transformed Statistics	
Minimum Detected	0.0022	Minimum Detected	-6.119
Maximum Detected	0.253	Maximum Detected	-1.374
Mean of Detected	0.0859	Mean of Detected	-4.509
SD of Detected	0.145	SD of Detected	2.715
Minimum Non-Detect	0.01	Minimum Non-Detect	-4.605
Maximum Non-Detect	0.01	Maximum Non-Detect	-4.605

Warning: There are only 3 Distinct Detected Values in this data set

The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.

Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values for bootstrap methods.

It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

AOC	Area of Concern
CDI	chronic daily intake
COPC	constituent of potential concern
EPC	exposure point concentration
OTM	of the mean
SWMU	Solid Waste Management Unit
UCL	upper confidence limit

1. Introduction

This appendix documents a sensitivity analysis of the groundwater human health risk assessment presented in the Human and Ecological Risk Assessment of Groundwater Impacted by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1 and SWMU 2 (main text). Estimated exposure point concentrations (EPCs) of constituents of potential concern (COPCs) are altered from the assumptions used in the main text, as discussed below, for the well-specific groundwater analyses. Calculations here are otherwise based on the same exposure assessment, toxicity assessment, and risk characterization presented in Sections 5 through 7 of the main text.

2. Exposure Point Concentrations

In the groundwater risk assessment presented in the main text, estimated EPCs of COPCs in groundwater (see Table 4-2) are based on maximum detected concentrations, for those datasets with too few results (less than eight results or less than five detections) to calculate 95 percent upper confidence limits (95% UCLs) of the mean (OTM) with ProUCL 4.0. This methodology is particularly conservative for those datasets with a large number of nondetects and few detections.

Evaluated here is the sensitivity of the risk assessment to this conservative use of maximum concentrations. In this sensitivity analysis, estimated EPCs are based on average, rather than maximum, detected concentrations. For the purpose of calculating these average chemical concentrations, nondetect results are assumed equal to one-half the laboratory reporting limit. EPCs calculated by this alternative method are presented in Table G-1 for individual groundwater wells. The mean concentrations presented here are generally lower than the maximum concentrations presented in the main text, although mean concentrations may be greater than maximum concentrations for datasets with nondetect results at high reporting limits. As indicated in Table G-1, the mean concentration of thallium at the two wells where thallium was detected is greater than the maximum detected concentration due to elevated detection limits.

3. Well-Specific Risk Characterization

Well-specific carcinogenic and noncarcinogenic chronic daily intakes (CDIs) are presented in Tables G-2 and G-3, respectively. Well-specific estimated cancer risks and noncancer hazards are presented in Tables G-4 and G-5, respectively. A well-specific comparison of estimated lead EPCs to the lead drinking water notification level is presented in Table G-6. The percent contributions of individual COPCs to cumulative noncancer hazard are presented in Tables G-7.

Overall, the results of the well-specific sensitivity analysis presented in this appendix were generally similar to the results of the primary analysis in the main text, with the primary analysis providing slightly more conservative results. Nonetheless, for specific wells and specific chemicals, the results of the sensitivity analysis provide important information for understanding well-specific risk conclusions. Most importantly, although the main analysis indicated that lead should be considered to be a low to moderate potential hazard to hypothetical future groundwater users, the sensitivity analysis presented here indicates that lead would be a low potential hazard to hypothetical groundwater user. Information in these tables is integrated into the risk characterization discussion (Section 7 of the main report) in order to provide the risk managers with a better understanding of the range of hypothetical future risks and noncancer hazards estimated for each well.

Table G-1. Estimated EPCs of Well-Specific COPCs in Groundwater: Sensitivity Analysis

Well	Number of Samples	Number of Detections	Minimum Detection (mg/L)	Maximum Detection (mg/L)	Mean Concentration (mg/L)	Result of Statistical Analysis	Estimated EPC (mg/L)
TW-1	4	4	0.0386	0.11	0.0804	NA	0.080
TW-2S	3	2	0.05	0.217	0.0907	NA	0.091

Notes:

(1) Data shown here fit one of two criteria

(a) For data with eight or more samples and five or more detections, statistical hypothesis tests conducted are presented in Table 4-1a to confirm the concentration in the well is greater than the background concentration. For these wells, the 95% UCL OTM calculated using ProUCL is used as the EPC.

(b) For data with fewer samples or detections, the maximum detected chemical concentration at individual wells exceed the UTL. For these wells the mean concentration is used as the EPC.

(2) Non-detects are assumed equal to one-half the reporting limit in calculating mean concentrations.

(3) Nitrate as NO_3^-, nitrate as nitrogen, and nitrate/nitrite as nitrogen are combined in this analysis.

COPC = constituent of potential concern
EPC = exposure point concentration
mg/L = milligram's) per liter
NA = not applicable – data do not meet minimum criteria to perform statistical tests
OTM = of the mean
UCL = upper confidence limit
UTL = upper tolerance limit
Y = statistical tests conclude site concentration is greater than background concentration

CW-4M	0.00163	0.015	0.11

Notes:
(1) Screening criteria for lead is the California Action Level for lead because no MCL is promulgated.
(2) California Action Level for lead provided in CCR Title 22, Division 4, Chapter 17.5, Article 3, Section 64678.
(3) Wells where lead was either not detected or not sampled are not shown.

EPC = exposure point concentration
mg/L = milligram(s) per liter

Zinc	5000 [c]	NA	NA	7400	26000	NA	NA	5000

Notes:
Values in units of micrograms per liter (µg/L).

a. The selection of surface water criteria is the lowest value of either the maximum contaminant level (MCL), or the California Toxic Rule (CTR) Criteria. If a CTR criteria doesn't exist, the chosen critieria is the lower of either the MCL or the National Ambient Water Quality Criteria (NAWQC). This hierarchy places preference on regulatory criteria (MCLs or CTR criteria) over recommended criteria (NAWQC).

b. For arsenic, although the NAWQC based on drinking water source is the lowest value, this value is not chosen because as indicated in the U.S. Environmental Protection Agency (USEPA) CTR, the USEPA is specifically not promulgating human health criteria for arsenic due to uncertainties associated with the health effects of arsenic.

c. California Secondary MCL provided when Primary MCL not promulgated.

d. California Action Level for lead provided in CCR Title 22, Division 4, Chapter 17.5, Article 3, Section 64678.

e. California Department of Public Health Drinking Water Notification Level provided when neither California Primary or Secondary MCL are promulgated.

NA = Not applicable or not available.
T = Total Recoverable.

Human Health and Ecological Risk Assessment Work Plan

Analytes	CTR Criteria (µg/L)	NAWQC Freshwater CCC (µg/L)	Tier II SCV (µg/L)	Chosen Criteria (µg/L)	Hardness Adjusted Criteria (µg/L)	Source	Comments
Thallium	NA	NA	12	12	NA	Tier II SCV	
Vanadium	NA	NA	20	20	NA	Tier II SCV	
Zinc	120	120	NR	120	300	CTR/NAWQC	Adjusted for hardness of 300 mg/L.

Notes:

The screening levels were selected from available water quality criteria using the following order of preference: CTR freshwater CCC, NAWQC freshwater CCC, Tier II SCVs. Tier II values were developed so that benchmarks could be established with fewer data than required for the NAWQC. Tier II values were obtained from Suter and Tsao (1996).

a. A total chromium value was not available, therefore the NAWQC value for trivalent chromium was used.

CCC = Criterion Continuous Concentration; highest concentration in surface water to which an aquatic community can be exposed indefinitely without resulting in an unacceptable effect.
CTR = California Toxics Rule
FAV = Final Acute Value
FCV = Final Chronic Value
NA = not available
NR = Not required and not calculated in the source document; NAWQC Freshwater CCC are available.
SCV = Secondary Chronic Value; derived by dividing the secondary acute value by the secondary acute-chronic ratio.
µg/L = microgram(s) per liter
USEPA = U.S. Environmental Protection Agency

Supplemental Ecological Risk Assessment to Address Regulatory Agency Comments

1. Introduction

This appendix was prepared in response to the March 26, 2009; June 17, 2009; and September 10, 2009; comments provided by the Human and Ecological Risk Division (HERD) (California Department of Toxic Substances Control [DTSC], 2009a,b,c) on the Pacific Gas and Electric (PG&E) Response to Comments (RTCs) for the Draft Groundwater Human Health and Ecological Risk Assessment (GWRA) for Topock Compressor Station in Needles, California (the site) (ARCADIS, 2009).

A detailed description of the transport mechanisms and exposure pathways is presented in Section 5 of the GWRA main text. Consistent with the approved Risk Assessment Work Plan (ARCADIS, 2008), the focus of the ecological risk assessment (ERA) in the main text of the GWRA was on evaluating the potential transport pathway to the Colorado River. In response to agency comments on the GWRA and on the RTCs, PG&E has expanded the GWRA via this appendix to include three additional potential exposure pathways for ecological receptors. These potential pathways are:

- Shallow-rooted wetland plant exposure to chemicals in groundwater via root uptake.

- Deep-rooted phreatophyte exposure to chemicals in first encountered groundwater via root uptake. Phreatophytes identified at the site are presented in Table I-1.

- Transfer of hexavalent chromium, nitrate, molybdenum, and selenium in groundwater to plant foliage via root uptake and translocation, then potential ingestion of hexavalent chromium, nitrate, molybdenum, and selenium in plant tissue by herbivorous mammals. Of particular interest to DTSC, was potential exposure of ruminants, specifically the desert bighorn sheep (*Ovis canadensis nelsoni*), to nitrate accumulated in phreatophyte tissue.

Groundwater from two exposure areas was evaluated due to the difference in chemical concentrations as discussed below in Section 2. The two exposure areas were groundwater underlying phreatophytes and shallow-rooted plants in: 1) the east side of the National Trails Highway, and 2) Bat Cave Wash (BCW). The remainder of this appendix discusses each of the potential exposure pathways listed above.

2. Conceptual Site Model

The conceptual site model (CSM) is presented in Figure 5-1 of the GWRA report. The primary chemical source is discharge of untreated wastewater to BCW. For the potential pathways listed in Section 1, only wells with beginning screened intervals shallower than 80 feet below ground surface (bgs) in both exposure areas (i.e., the east side of the National Trails Highway and BCW) were considered; wells where groundwater occurred deeper, or that were located outside the occurrence of phreatophytes, were not included. Wells with beginning screened intervals deeper than 80 feet were considered beyond depths of interest for potential phreatophyte exposure based on the root depths shown in Table I-1. Wells included in the assessment and corresponding depths to water are presented in Figure I-1.

The following describes the components of the CSM as it relates to the potential pathways listed above in Section 1.

2.1 Chemicals of Potential Concern

The focus of this assessment was on constituents of potential concern (COPCs) from the Revised Final Resource Conservation and Recovery Act Facility Investigation/Remedial Investigation (RFI/RI) Volume 2 (CH2M HILL, 2009), consisting of hexavalent chromium, molybdenum, nitrate, and selenium.

2.2 Background Screening

The dataset for the background screening consisted of maximum detected concentrations from January 2006 through July 2008 from wells shown on Figure I-1. These wells are shallow groundwater wells potentially co-located or nearest where phreatophytes or wetland plants occur in the Area of Potential Effect (APE) (Figure I-1). Maximum detected concentrations from these wells were compared with background Upper Tolerance Limits (UTLs) (Table I-2). Background UTLs are discussed in the main report (Section 3). If the maximum detected concentration of a COPC (i.e., hexavalent chromium, molybdenum, nitrate, and selenium) was greater than or equal to the background UTL for that COPC, the COPC was retained for further evaluation.

Figure I-2 presents the maximum detected concentrations in shallow wells co-located with phreatophytes along the east side of National Trails Highway. These wells are MW-21, MW-22, MW-27-20, MW-28-25, MW-29, MW-30-30, MW-32-20, MW-33-40, MW-35-60, MW-36-20, MW-39-40, MW-42-30, MW-43-25, MW-47-55, MW-56S,

PT-1S, PT-2S, PT-3S, PT-4S, PT-5S, PT-6S, and PTI-1S. Table I-2 presents the comparison of the maximum detected concentrations of each of the four COPCs to corresponding background UTLs. The maximum detected concentrations in selected wells on the east side of National Trails Highway exceed background UTLs for three COPCs (hexavalent chromium, molybdenum, and selenium). The results of the background comparison are summarized in Table I-2.

Figure I-2 presents the maximum detected concentrations in wells co-located with phreatophytes at BCW (see wells MW-41S, MW-13, and MW-11). Table I-2 presents the comparison of the maximum detected concentrations of each of the four COPCs to corresponding background UTLs. The maximum detected concentrations are based on recent groundwater samples collected from January 2006 to July 2008. The maximum detected concentrations in selected wells in BCW exceed background UTLs for two COPCs; these are hexavalent chromium and selenium. The maximum detected concentration of molybdenum in BCW wells did not exceed the background UTL. The results of the background comparison are summarized in Table I-2.

Based on comparison with background UTLs for groundwater, hexavalent chromium, molybdenum, nitrate, and selenium each had maximum detected concentrations that exceeded background along the east side of National Trails Highway and/or BCW and, therefore, were retained for further evaluation as COPCs in shallow groundwater that may be contacted by shallow-rooted plants as well as taken up by phreatophytes. However, it should be noted that only hexavalent chromium exceeded background in both exposure areas (Table I-2), reducing the potential for exposure via plant uptake for the other COPCs (nitrate, molybdenum, and selenium) because of the relatively small area with concentrations exceeding background that underlies phreatophytic or wetland/marsh plants.

3. Exposure Assessment

Groundwater level data for water table wells were obtained from Appendix B of the Revised Final RFI/RI Volume 2 (CH2M HILL, 2009) and Appendix B of the *Monitoring Report for the Floodplain Reductive Zone In-Situ Pilot Test* (ARCADIS, 2007). Figure I-1 displays the depth-to-water data for water table wells. As mentioned earlier, only wells with beginning screened interval shallower than 80 feet bgs were considered in this assessment; wells with deeper screened intervals were considered to be monitoring groundwater beyond depths of interest for phreatophyte exposure (see below for discussion of root depths). Depths to groundwater are as shallow as approximately 4 feet bgs near the river. Well-screened intervals and, therefore, depth of groundwater monitored, as well as an understanding of plant root depths, form the basis of the exposure evaluation for plants. Exposure of plants via root uptake from groundwater and subsequent translocation of COPCs from roots to foliage must occur for exposure of herbivorous mammals, including desert bighorn sheep, to nitrate, hexavalent chromium, molybdenum, and selenium originating in groundwater.

The following sections describe the potential exposure pathways for shallow-rooted wetland plants, deep-rooted phreatophytic plants, and herbivore ingestion of plant tissue.

3.1 Shallow-Rooted Wetland Vegetation

The potential exposure pathway for shallow-rooted wetland plants was evaluated qualitatively by reviewing well-screened intervals to select wells with monitoring results representative of potential exposure, reviewing depth-to-water data, considering geochemical processes that operate in wetland environments, and reviewing COPC concentrations in groundwater. Historical depth-to-water measurements suggest that shallow groundwater may not discharge at wetland areas (Figure I-1). Shallow-rooted plants such as common reed (*Phragmites communis*), cattails (*Typha sp.*), sedges (*Carex sp.*), and bulrush (*Scirpus sp.*) may not contact groundwater given that the shallowest depth to water measured near the river is approximately 4 feet (CH2M HILL, 2009), and these plants have ready access to surface water from the river. Deeper rooted plants, such as salt cedar and arrow weed, present immediately adjacent to the river or ponded water at the mouth of BCW, also have ready access to the surface water and, therefore, surface water would be the primary source of moisture for these plants rather than groundwater. As shown on Figure I-2, wetland/marsh plants (denoted in green) lie outside the plume line defined by the background UTL for hexavalent chromium in shallow groundwater.

3.2 Deep-Rooted Phreatophytic Vegetation

The exposure pathway for deeper rooted phreatophytes was evaluated quantitatively. The following describes the types of phreatophytes present at the site and their average rooting depths obtained from various literature sources.

Potential exposure to COPCs (hexavalent chromium, nitrate, selenium, and molybdenum) depends on depth to groundwater, root depths, and chemical distribution in the groundwater. Shallow groundwater wells that best represent COPC concentrations potentially contacting phreatophytic vegetation (Figure I-2) were selected based on the following criteria:

- Concentrations detected in wells with beginning screened intervals shallower than 80 feet bgs
- Co-location with phreatophytic vegetation
- Nearest upgradient well

MW-11 and MW-21 were the only wells selected that are not co-located with phreatophytic vegetation. MW-11 is the nearest upgradient well of phreatophytes at BCW. MW-21 is also very near phreatophytic vegetation.

The potential exposure pathway for phreatophytes was evaluated quantitatively by first assessing the potential for root contact with chemically affected groundwater, then considering groundwater concentrations of COPCs where contact may occur. Table I-1 provides maximum root depths for phreatophytes identified at the site showing that some species, such as honey mesquite (*Prosopis glandulosa*) can have roots up to 50 feet deep. Depths to groundwater in the BCW and on the east side of National Trails Highway where phreatophytes occur range from 30 feet bgs to 4 feet bgs. Deep-rooted phreatophytic upland plants may contact COPCs occurring in shallow groundwater. Such phreatophytes include mesquite (*Prosopis* spp.), palo verde (*Cercidium sp.*), salt cedar (*Tamarix ramosissima Ledeb.*), arrowweed (*Pluchea sericea*), and catclaw acacia, *(Acacia greggii*), which occur within upland areas near the river and in BCW where depths to water are also within potential root zones (Figure I-1). Consistent with this information, mesquite and palo verde grow in the BCW in areas with water table depths up to 50 feet bgs (Figure I-1 of this appendix and Figure 5-3 in CH2M HILL, 2009). The shallower rooted salt cedar (*Tamarix ramosissima Ledeb*.) is found where the depth to groundwater is 4 to 32 feet bgs (or where there is surface water) (Figure I-

1), which is consistent with its reported maximum rooting depths of about 25 feet (Table I-1). Therefore, it is indicated that phreatophytes may contact groundwater in the APE, and that the concentrations of COPCs in groundwater underlying the phreatophytes are of interest. These concentrations are further evaluated in Section 4.

3.3 Herbivorous Mammal Ingestion of Plant Tissue

Given that phreatophytic vegetation may contact groundwater in the APE, ingestion of chemicals in plant tissue is a potential exposure pathway to other ecological receptors. In particular, transfer of COPCs in groundwater to plant foliage via root uptake and translocation, then potential ingestion of COPCs in plant tissue by herbivorous mammals, particularly ruminants is a potential pathway of interest given:

- The presence of desert bighorn sheep in the area
- The presence of herbivorous mammals (as represented by the Merriam's kangaroo rat)
- Potential for toxicity in ruminants and other herbivorous mammals resulting from exposure to hexavalent chromium, molybdenum, and selenium, as well as nitrate in forage
- Specifically, known potential for nitrate toxicity in ruminants resulting from exposure to nitrate in feed.

Desert bighorn sheep are a federally listed sensitive species. This species is primarily associated with rugged terrain and mountainous areas but uses a variety of habitat types including desert riparian and desert scrub (Hopkins, as included in the California Wildlife Habitat Relationships System, 2009). The occurrence of this species included in the California Natural Diversity Database (CNDDB, 2009) is shown on Figure I-3. The nearest occurrence of the desert bighorn sheep to the site according to the CNDDB is in the Chemehuevi Mountains. However, desert bighorn sheep have been observed by Topock Compressor Station personnel and are a transient and infrequent visitor to the area around the APE (Russell, pers. comm. 2009). Available information indicates that the desert bighorn sheep are infrequently present and, therefore, infrequently feed on plants within the APE, but outside the area of desert bighorn sheep occurrence that is shown on Figure I-3.

The diet of the desert bighorn sheep is varied and has been reported to contain 50 percent browse with the remainder of the diet comprised of forbs, grasses, and succulents (Brewer and Harveson, 2007). In the APE, browse would include phreatophytes. Therefore, the diet composition likely further reduces the potential for exposure to COPCs in plant tissue accumulated from groundwater.

For herbivorous mammals including ruminants, plant tissue concentrations of nitrate were evaluated qualitatively based on the maximum nitrate concentration observed in shallow groundwater within the area where phreatophytes occur in the APE (Figure I-2).

Maximum nitrate concentrations between January 2006 and July 2008 exceeded background in one well of 25 wells (analyzed in 24 wells) selected to represent potential phreatophyte exposure (16.4 milligrams per liter [mg/L] in MW-11; Figure I-2). A study by McKeon et al. (2006) of nitrate uptake patterns over a nitrate-contaminated aquifer in northeast Arizona, showed that phreatophyte tissue concentrations did not exceed safe levels (see Section 4) for ruminants even when the plants were growing in the on-plume area. The phreatophyte, *Atriplex canescens*, growing over a shallow groundwater plume with high concentrations of nitrate (up to 1210 mg/L) accumulated a maximum average nitrate concentration of 727 milligrams per kilogram [mg/kg] nitrate-N in leaf tissue (plants harvested in 2000). Later analyses yielded an average nitrate concentration of 108 mg/kg nitrate-N in leaf tissue on the plume (estimated based on Figure 5 of the McKeon et al. (2006) study; plants harvested in July 2002). The on-plume area sampled was the most heavily contaminated part of the plume, presumably around the greater than 1000 mg/L contour for nitrate-N (Figure 1 of the McKeon et al. [2006] study).

The maximum nitrate-N concentration of 16.4 mg/L at Topock is well below the on-plume groundwater concentrations reported in the McKeon et al (2006) study (maximum was 1210 mg/L). Further, maximum concentrations from other wells selected to represent potential phreatophyte exposure did not exceed the background UTL. As a result, plant tissue concentrations at Topock are expected to be well below the maximum average concentrations detected in leaf tissue (951 mg/kg dry-weight for *Sarcobatus vermiculatus* and 727 mg/kg dry-weight for *A. canescens*) in the McKeon et.al. (2006) study. The reported nitrate-N concentrations in groundwater at the McKeon et.al. (2006) study site ranged from 12 to 1210 mg/L. The reported average leaf tissue nitrate-N concentrations ranged from 20 to 951 mg/kg dry-weight.

Similarly, for herbivorous mammals including ruminants, plant tissue concentrations of hexavalent chromium were evaluated qualitatively. In a study by Sorenson et al. (2009), uptake of hexavalent chromium from water to saltcedar (*Tamarix ramsissima*) was evaluated. In this study, 6-week-old saltcedar plants were placed in treatment solution containing tapwater (0.0007 mg/L) for control plants and tapwater with chromium (2 mg/L) trioxide, and results were reported as concentrations of elemental chromium. The concentration of chromium in plants grown in 2 mg/L of chromium in treatment solution contained an average of 1.89 mg/kg chromium. The accumulation factor based on this study is approximately 0.95 (i.e., concentration in plant tissue divided by the concentration in water).

The maximum hexavalent chromium concentration observed in shallow groundwater within the area where phreatophytes occur in the APE (Figure I-2), is 0.356 mg/L from MW-11 in BCW (Table I-2), which is similar to the chromium treatment solution in the study by Sorenson et al., (2009) and, therefore, the uptake at the Topock site can be conservatively assumed to be similar. Based on the uptake factor of 0.95, the maximum concentration of chromium in plants at the Topock site resulting from exposure to hexavalent chromium in groundwater is estimated to be 0.338 mg/kg. It should be noted that chromium in plants occurs primarily in the trivalent form (Eisler,1986; Aldrich et. al., 2003; Ramachandran, 1980).

Maximum selenium concentrations between January 2006 and July 2008 exceeded background in only one well of 25 wells selected to represent potential phreatophyte exposure (see MW-21 on Figure I-2). The single exceedance (0.038 mg/L in Well MW-21) only slightly exceeds the background of 0.0103 mg/L (Table I-2). Based on this observation, it can be assumed that uptake of selenium by plants from groundwater and exposure to herbivorous mammals is not a significant pathway and, therefore, does not require further evaluation.

Maximum molybdenum concentrations between January 2006 and July 2008 exceeded background in two wells of 25 wells (analyzed in 8 wells) selected to represent potential phreatophyte exposure (MW-22 with a concentration of 0.0482 mg/L and MW-21 with a concentration of 0.052 mg/L; Figure I-2). These two concentrations slightly exceed the background UTL (0.0363 mg/L) in a localized area. Based on this observation, it can be assumed that uptake of molybdenum by plants from groundwater and exposure to herbivorous mammals is not a significant pathway and, therefore, does not require further evaluation.

To summarize, given the concentrations of COPCs in groundwater underlying shallow-rooted and phreatophytic vegetation, potential exposure of ecological receptors to COPCs originating in groundwater is anticipated to be minimal. To satisfy DTSC's request for additional support for this conclusion, uptake of concentrations of hexavalent chromium and nitrate from groundwater to plants and then ingestion of plants by herbivorous mammals is further evaluated in the following section. Uptake of selenium and molybdenum from groundwater to plants and then ingestion of plants by herbivorous mammals is not considered a significant pathway and is not further evaluated.

4. Toxicity Assessment

A no-observable adverse effect concentration (NOAEC) was selected for each chemical to evaluate the toxicity of COPCs to plants. Table I-3 presents the NOAECs selected for this assessment. The following describes the plant toxicity values for hexavalent chromium, molybdenum, selenium and nitrate. Potential toxicity of hexavalent chromium and nitrate to herbivorous mammals including ruminants from ingestion of plant tissue containing these COPCs is also described.

4.1 Hexavalent Chromium

A NOAEC of 2 mg/L for hexavalent chromium was reported in Sorenson et al. (2009) for salt cedar. Mesquite (*Prosopis spp.*) tolerates hexavalent chromium in solutions of up to 125 mg/L when grown in agar and 80 mg/L when grown hydroponically (Aldrich et al., 2003) indicating a hexavalent chromium NOAEC for mesquite of 80 mg/L (Table I-3).

The USEPA (2008) reports that chromium has been shown to be an essential nutrient for animals. Trivalent chromium has been shown to have antioxidative properties in vivo, and it is integral to activating enzymes and maintaining the stability of proteins and nucleic acids. Its primary metabolic role is to potentiate the action of insulin through its presence in an organometallic molecule called the glucose tolerance factor. For example, studies with guinea pigs fed trivalent chromium for 21 weeks at concentrations up to 50 parts per million dietary trivalent chromium showed no adverse effects (Preston et al. 1976; as cited in Eisler, 1986).

4.2 Nitrate

Plants: An NOAEC of 1210 mg/L for nitrate was reported in McKeon et al. (2006) for fourwing saltbush and black greasewood (Table I-3).

Because desert plant communities are typically limited by nitrogen during growing periods (Zak and Whitford, 1988), nitrate uptake from the groundwater is expected to have beneficial rather than adverse effects on the plants. For example, in a desert system in Arizona the phreatophyte, *Atriplex canescens*, growing over a shallow groundwater plume with high concentrations of nitrate (maximum nitrate-N concentration = 300 mg/L), accumulated 5 times more nitrate in its leaves during summer than plants growing off the plume (up to 500 mg/kg nitrate-N in leaf tissue; McKeon et al., 2006). The study estimated that at the McKeon site, 40 kg of plume

water would supply sufficient nitrogen for production of 1 kg of plant biomass. Isotope analysis indicated most of the nitrate came from the groundwater plume. The increased nitrate in the plant tissues produced no phytotoxicity (McKeon et al., 2006).

Mammals: Under normal conditions, nitrate is converted to nitrite by microorganisms in ruminants (such as sheep and cattle), which is then converted to ammonia and on to proteins and other compounds. Nitrate can be toxic to animals if the rate of conversion of nitrate to nitrite is greater than the conversion of nitrite to ammonia, resulting in a buildup of nitrite in the animal (A&L Great Lakes Laboratories, 2002). Various factors can affect the nitrite accumulation including the plant species, section of the plant (e.g., stalks are higher in nitrate content), plant age, and weather conditions (conditions that reduce plant growth increase nitrate production). A&L Great Lakes Laboratories (2002) provide safety guidelines for nitrate in ruminant feed and 4,400 ppm dry weight is listed as a safe level to feed under all conditions. Further, using a generalized interpretation for laboratory forage nitrate tests, 0 to 3,000 parts per million (ppm dry weight) in feed is considered safe for all cattle; 3,000 to 5,000 ppm (dry weight) in feed is considered safe for non-pregnant beef cattle; 5,000 to 10,000 ppm (dry weight) in feed is a small risk for some cattle; and greater than 10,000 ppm (dry weight) in feed is considered toxic for all cattle (Denman et al., undated).

5. Risk Characterization

The following describes the risk characterization for the exposure pathways evaluated above.

5.1 Shallow-Rooted Vegetation

As HERD stated (DTSC, 2009a), sampling has not demonstrated movement of the groundwater plume with COPCs into the Colorado River (see Figure I-2). Hexavalent chromium was not detected in shallow wells nearest the river (MW-28-25, MW-29, and MW-27-20; Figure I-2). Further, the reducing conditions in wetland areas would result in precipitation of hexavalent chromium, selenium, and molybdenum binding the metals to soil/sediment particles and reducing bioavailability. Further, shallow-rooted vegetation in the riparian area has ready access to surface water as a source of moisture. The data suggest wetland/riparian plants along the river are unlikely to be impacted by COPCs from the groundwater. Therefore, this shallow-rooted wetland/riparian plant pathway is considered insignificant and will not be evaluated further.

5.2 Deep-Rooted Phreatophytic Vegetation and Risk to Ruminants from Nitrate in Plants

Hazard quotients were calculated for potential exposure of phreatophytes to COPCs in groundwater (Table I-4). All hazard quotients for phreatophytes were well below one indicating no significant risk of phytotoxicity.

The maximum nitrate-N concentration is 16.4 mg/L (at MW-11), much lower than the maximum concentration in the McKeon et. al. (2006) study (1210 mg/L). No phytotoxicity was reported in the McKeon et.al. (2006) study. Given that nitrate concentrations in groundwater at Topock were orders of magnitude lower than those observed at the McKeon et.al. (2006) study site, concentrations in leaf tissue at Topock are expected to be well below 951 mg/kg dry-weight, the maximum average nitrate-N concentration observed in the McKeon et.al. (2006) study.[1] Levels assumed to be safe in feed for ruminants are up to 3,000 mg/kg dry-weight [Denman et al., undated]. Therefore, toxicity due to nitrate would also not be predicted for ruminants. Further,

[1] Average leaf tissue nitrate-N concentrations ranged from approximately 20 mg/kg to 951 mg/kg dry-weight depending on the plant species, sampling event, and grazing pressure.

given the limited distribution of nitrate greater than background (see Section 3.3), toxicity due to nitrate would not be predicted for herbivorous small mammals.

The maximum hexavalent chromium concentration in the BCW (within or bounding the area occupied by phreatophytes) is below levels found to be toxic to phreatophytic plants such as salt cedar and mesquite (Table I-3). Hexavalent chromium concentrations in shallow groundwater in the upland east of National Trails Highway are many times lower than those observed in the BCW at MW-11; therefore, phytotoxicity due to hexavalent chromium would not be predicted in either area. The estimated maximum concentration of chromium in plant tissue (0.338 mg/kg) from uptake from groundwater is considered low. For example, studies with guinea pigs fed trivalent chromium for 21 weeks at concentrations up to 50 mg/kg dietary trivalent chromium showed no adverse effects (Preston et al. 1976; as cited in Eisler, 1986). This is as would be expected for trivalent chromium, an essential nutrient that is well-regulated in mammalian systems. Therefore, toxicity due to chromium would also not be predicted for herbivorous mammals or for ruminants.

As discussed in Section 3.3, the concentrations of selenium and molybdenum in groundwater are not considered significant and, therefore, toxicity would not be predicted for herbivorous mammals or for ruminants.

The maximum COPC concentrations in groundwater described above are not associated with phytotoxicity and, therefore, effects would not be predicted in the study area where phreatophytic vegetation is potentially exposed. Therefore, the exposure pathway from chemically affected groundwater to phreatophytes is insignificant because maximum concentrations in shallow groundwater underlying these plant communities are very low relative to concentrations known to be phytotoxic. Further, toxicity to herbivorous mammals resulting from potential exposure to COPCs is not predicted given the low concentrations in groundwater of molybdenum and selenium and the low concentrations of chromium and nitrate predicted in plant tissue.

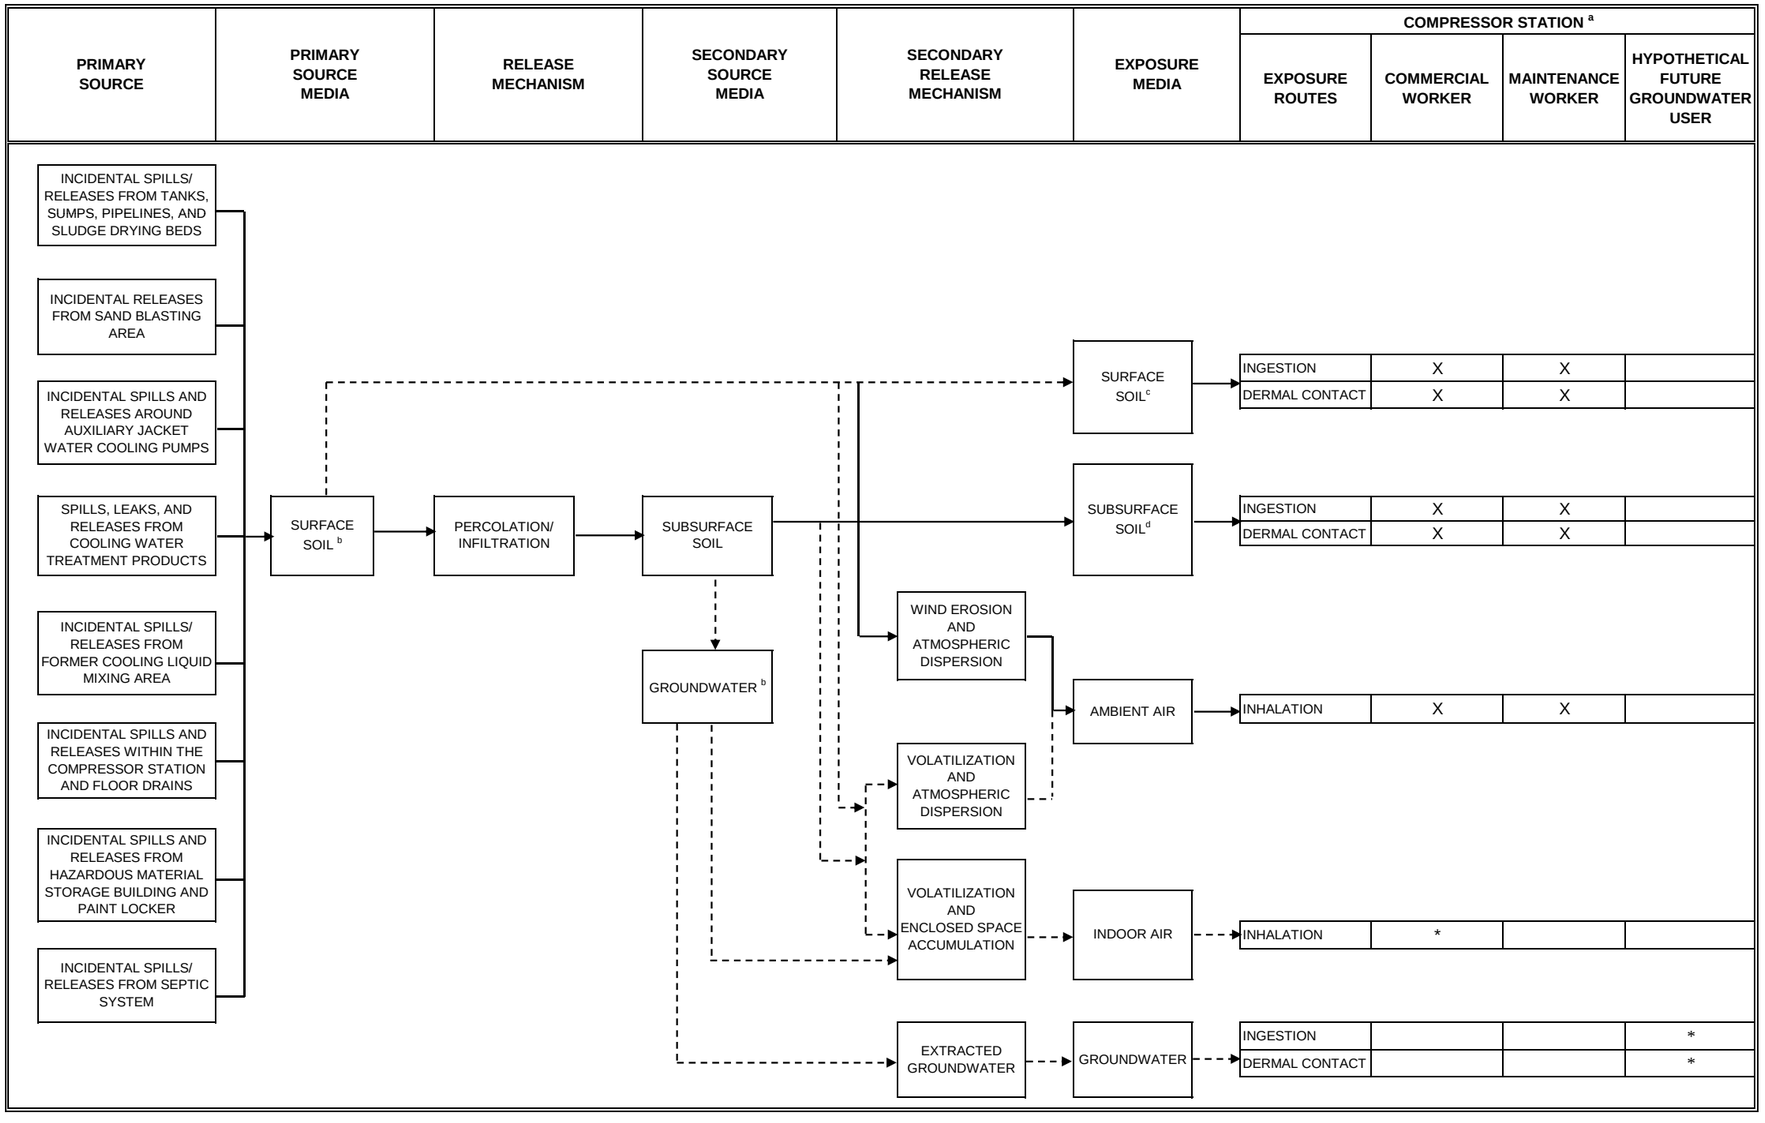
FIGURE 4-3
PRELIMINARY HUMAN HEALTH CSM FOR INSIDE THE COMPRESSOR STATION
PACIFIC GAS AND ELECTRIC COMPANY
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT



NOTES:

a The former sludge drying beds, chromate reduction tank, process pump tank, transfer sump, oil holding water tank, oil water separator, and wastewater transference pipelines inside the compressor station have already been closed (CH2MHILL, 2007i), but DTSC has requested additional investigation (CalEPA, 2007d). If complete pathways are identified based on the results, any of these areas will also be included in the HHRA.

b Potentially complete transport pathway from primary and secondary source media within the compressor station to exposure media outside of the compressor station and potentially complete exposure pathways will be further evaluated in the risk assessment in the context of areas outside of the compressor station (See Figures 4-1 and 4-2).

c Defined as soils collected at depths between 0 and 3 feet below ground surface (bgs).

d Defined as soils collected at depths between 3 and 10 feet bgs. A subset of this depth interval is near surface soil collected from 0 to 0.5 feet bgs.

→ Potentially complete transport pathway to be included in the quantitative risk assessment.

⇢ Potentially complete transport pathway to be further evaluated in the risk assessment.

X Potentially complete exposure route to be included in the quantitative risk assessment.

* Potentially complete exposure route to be further evaluated in the risk assessment.

1. Introduction

The Human and Ecological Risk Assessment of Groundwater Affected by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1 and SWMU 2 is based on the conceptual site model (CSM) presented on Figure 5-1 of the main text. Potential direct exposure pathways to humans include: direct dermal exposure to and ingestion of contaminated groundwater. A concern raised by the U.S. Department of the Interior (USDOI) is the possibility that secondary exposure pathways (e.g., ingestion of plants or animals that are exposed to polluted groundwater) could contribute materially to the overall exposure to humans. As requested by USDOI, presented in this appendix is a preliminary evaluation of the magnitude of human exposure to constituents in groundwater from these potentially complete secondary exposure pathways.

2. Evaluation of Secondary Exposure Pathways

An analysis of the ingestion of plant and animal products as a pathway for exposure to contaminated groundwater was conducted based on the California Environmental Protection Agency (CalEPA) Office of Environmental Health Hazard Assessment (OEHHA) in the *Air Toxics Hot Spots Guidelines* (CalEPA, 2003) to assess the potential relative magnitude of this pathway as compared to direct dermal exposure to and ingestion of contaminated groundwater.

Section 5 of the Hot Spots Guidance provides equations for calculating the exposure of humans to constituents of potential concern (COPCs) through ingestion of plants and animals impacted by COPCs. First, uptake of COPCs by plants and animals is estimated. Second, the ingestion of these plant and animal products is calculated to estimate human exposure to COPCs. Plant COPC concentrations are based on uptake from soil impacted by irrigation. Animal COPC concentrations are based the following:

- Uptake from ingestion of groundwater
- Uptake from ingestion of soil impacted by irrigation water (i.e., groundwater used for irrigation purposes)
- Uptake from ingestion of plants impacted by irrigation water (i.e., groundwater used for irrigation purposes).

Throughout the analysis, the most conservative assumptions are made to quantify the magnitude of the dose resulting from this pathway. The Hot Spots Guidance calculates the concentration of the contaminant in soil from the deposition of the pollutant from some concentration in air. Because this is a groundwater risk assessment, potential deposition of the pollutant occurs through theoretical irrigation and not through aerial deposition.

It is conservatively assumed that 100% of the irrigation water is impacted groundwater. Furthermore, it is assumed that all of the impacted groundwater stays within the root zone where plants could be exposed. These assumptions likely result in a conservative estimate for the concentration of COPCs in soil. Regardless, the calculation of the soil concentration is unlikely to impact the overall conclusions. Human uptake of COPCs from assumed ingestion of plants and animals is dominated by ingestion of animals. Moreover, the predicted COPC concentration in animals resulting from ingestion of groundwater is much larger than that resulting from uptake of soil (either through direct

ingestion or via plant uptake), as quantified below. Accordingly, only the potential animal uptake of drinking impacted groundwater is significant in the context of this analysis.

The analysis is conducted for hexavalent chromium, the primary COPC at the site. As noted above, the theoretical dominant contributor to the overall pathway is animal uptake from ingestion of drinking water, in particular, beef cattle. It is conservatively assumed that 100% of the water ingested by the animals is impacted groundwater. Ingestion of groundwater by animals contributes nearly 100% to the dose of the contaminant to animals. The assumed ingestion of animal products contributes nearly 100% to the overall dose to humans from the ingestion of animal and plant products. Calculations for these pathways are presented in Table K-1.

To evaluate the overall significance of the assumed plant and animal ingestion exposure pathway, the contributions of direct dermal exposure and groundwater ingestion (the pathways considered in the risk assessment) are added to the contribution calculated for ingestion of plant and animal products. Using conservative assumptions to calculate the exposure dose to humans from the ingestion of plant and animal products, this theoretical pathway contributes 3.2% and 1.4% to the estimated total hexavalent chromium exposure for adults and children, respectively, as presented in Table K-1. It is expected that conducting this analysis for other COPCs will produce similar results. Therefore, inclusion of these secondary pathways is highly unlikely to affect the overall conclusions of the groundwater risk assessment, across all COPCs.

Moreover, specifically for hexavalent chromium, there is some uncertainly as to the uptake of the hexavalent form. In this analysis, hexavalent chromium is conservatively assumed to remain in its oxidized form throughout the pathway. However, some studies have indicated that chromium accumulation in plants is predominately in roots and only a small fraction is translocated to the above-ground part of edible plants (Cary, 1982; World Health Organization [WHO], 1988). Hexavalent chromium is reduced to trivalent chromium at the surface of plant root cells (Ramachandran et al., 1980; Aldrich et al., 2003), indicating plant uptake/translocation of hexavalent chromium would be minimal. There has been no evidence of chromium biomagnification along the terrestrial food chain (soil-plant-animal) (Agency for Toxic Substances and Disease Registry [ATSDR], 2008). Furthermore, the metabolism of animals has been shown to reduce hexavalent chromium to trivalent chromium (Petrilli and DeFlora, 1978). Therefore, the exposure dose estimated in Table K-1 for ingestion of plants and animals is expected to be overestimated, and the percentage of the overall dose is also expected to be overestimated.

3. Conclusion

Based on the quantification of assumed human exposure to impacted groundwater through ingestion of plants and animals exposed to impacted groundwater, it is highly unlikely that secondary exposure pathways are significant to the overall conclusions of the groundwater health risk assessment. As indicated in this appendix, potential human exposure to contaminated groundwater is dominated by the assumed direct exposure routes that are included in the groundwater risk assessment: direct dermal exposure to and ingestion of contaminated groundwater.

Supplemental Evaluation to Address Nutritional Essentiality: Molybdenum and Selenium

1. Introduction

This appendix to the *Human and Ecological Risk Assessment of Groundwater Impacted by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern 1 and SWMU 2, Topock Compressor Station, Needles, California,* (GWRA) provides a supplemental evaluation of potential hazards associated with potential exposure to the essential nutrients molybdenum and selenium for the future hypothetical groundwater user for the site. According to the U.S. Environmental Protection Agency (USEPA) *Framework for Metals Risk Assessment* (USEPA, 2007) the essentiality of metals should be viewed as part of the overall dose-response relationship, and reference doses (RfDs) should not be set below doses identified as essential. This is important when evaluating the potential health risks for essential nutrients that may also be related to site processes, to ensure that exposures aren't estimated to pose a potential risk (and communicated to individuals as such) at levels that may be nutritionally essential. This molybdenum essential nutrient evaluation, conducted in addition to the standard baseline molybdenum evaluation, is not a typical component of the California Department of Toxic Substances Control's standard risk assessment protocols, although an essential nutrient screen is not an unusual request for USDOI sites.

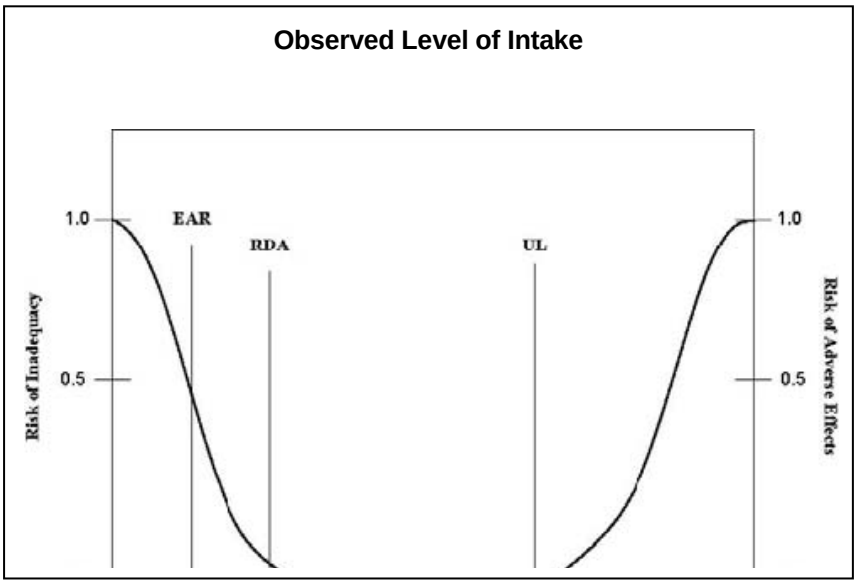
For this supplemental evaluation, site data were used to estimate intake of each of these two essential nutrients (in milligrams per day [mg/day]) from groundwater. The intake from groundwater was then added to the estimated dietary intake for each essential nutrient, and the total estimated intake of molybdenum and selenium at the site was compared to the upper intake level (UL) for each nutrient.

It is noted that all wells in the GWRA are evaluated blindly as if they could be potable wells in the future, without consideration for their location. However, there is only a portion of the site that the U.S. Department of the Interior (USDOI) has identified as having potential future residential use. Results of this supplemental evaluation are discussed with consideration of well locations and the potential for future hypothetical residential use.

2. Nutritional Essentiality for Metals Risk Assessment

According to USEPA risk assessment guidance on metals (2007) the essentiality of metals should be viewed as part of the overall dose-response relationship, and RfDs should not be set below doses identified as essential. Therefore, according to USEPA guidance on metals risk assessment (2007), molybdenum and selenium were further evaluated by considering the overall dose-response relationship and evaluating the entire dose-response relationship, from very low (inadequate) doses to high (toxic) doses, in order to determine an acceptable upper exposure limit.

The graph below shows a generic example of the relationships between potential health impacts both beneficial and adverse, and terms typically used to describe dietary criteria for any essential nutrient. The National Academy of Sciences Food and Nutrition Board (FNB) in conjunction with the Institute of Medicine (IOM) developed the Dietary Reference Intakes (DRIs) program (IOM, 2001; USEPA, 2007). These agencies reformulated the Estimated Safe and Adequate Daily Dietary Intake (ESADDI) now known as recommended daily allowances (RDAs). The terms below are used to describe critical points for the full dose response curve (typical example taken from USEPA, 2007) for an essential nutrient:



- EAR – estimated average requirements replaced adequate intakes

- RDA – recommended dietary allowance, which replaced ESADDI and represents the average daily dietary nutrient intake level sufficient to meet the nutrient requirements of nearly all health individuals in a particular life stage and gender group.

- UL – tolerable upper intake level.

The UL is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. The UL is based on similar risk models that are used by USEPA to set the RfDs and protects most of the population including sensitive subgroups (USEPA, 2007; USEPA, 1989). As with chemical agents, nutrients can produce adverse health effects in humans if their intake from a combination of food, water, nutrient supplements, and pharmacological agents is excessive. It is not possible to determine with certainty a single intake level for a nutrient that is risk free for all members of a population. However, it is possible to identify an intake level that is unlikely to result in adverse health impacts for most population members including sensitive subpopulations, something that the UL and RfD have in common (IOM, 2001; USEPA, 1989).

Use of ULs is endorsed by USEPA risk assessment guidance for metals (2007) to aid in the interpretation of site data in support of risk management decisions. USEPA Region 5 approved a site management strategy in 2005 for a site with molybdenum impacts to groundwater. The site, Northern Indiana Public Service Company and Brown, Inc., is under administrative order with USEPA and the state of Indiana to address contaminants associated with site activities that were related to coal combustion by-products. The Resource Conservation and Recovery Act Facility Investigation work plan for the Indiana site presented a site management strategy including evaluation of molybdenum in groundwater relative to the nutritional status and the UL. This work plan for the Indiana site was accepted by the agency and is currently being implemented.

3. Essential Nutrient Evaluation of Potential Molybdenum Intake

For molybdenum, this section describes the basis for the RfD, the IOM challenge to that value, and the use of the UL as an alternate method to evaluate potential hazard for estimated molybdenum intake for the future hypothetical groundwater user at Topock. Molybdenum is deemed nutritionally essential for humans as it has been shown to act as a cofactor for a limited number of enzymes in humans (IOM, 2001). In sum, the IOM, the agency tasked with evaluating essential nutrients and related dietary intake, has challenged the basis of the current Integrated Risk Information System (IRIS) RfD (USEPA, 2009a) and presents a UL that is above the current RfD (IOM, 2001).

3.1 USEPA IRIS Reference Dose for Molybdenum

The RfD established for molybdenum in 1993 and listed in IRIS cites three human studies (Kovalsky et al., 1961; Deosthale and Gopalan, 1974; and USEPA, 1979). The primary quantitative basis of the RfD is an epidemiologic study of a population in a province of Armenia characterized by high molybdenum content in the soil and low copper content (Kovalsky et al., 1961). The exposure period was from 6 years to a lifetime. The average adult person in the region was estimated to have a daily intake of 10 to 15 milligrams (mg) of molybdenum, and 5 to 10 mg of copper. This intake corresponds to molybdenum doses of 0.14 to 0.21 milligrams per kilogram body weight per day (mg/kg-bw/day) for a 70-kilogram (kg) adult. Control area intake values were 1 to 2 mg molybdenum and 10 to 15 mg copper. Based on the increased serum ceruloplasmin and urinary excretion of copper observed, USEPA determined that high levels of ingested molybdenum may be associated with potential mineral imbalance (USEPA, 2009a). USEPA determined that excretion of sufficient quantities of this element may put individuals at risk for the hypochromic microcytic anemia associated with a dietary copper deficiency (USEPA, 2009a). Based on the results of the Kovalsky et al. study (1961), USEPA determined that a molybdenum intake of 0.14 mg/kg-bw/day may result in serum uric acid levels elevated above the average range of the adult population and designated this level as a lowest observed adverse effect level (LOAEL). The LOAEL was divided by an uncertainty factor of 3 for protection of sensitive human populations and an uncertainty factor of 10 for the use of a LOAEL, rather than a no observed adverse effect level (NOAEL), from a long-term study in a human population (total uncertainty factor of 30), resulting in a RfD of 0.005 mg/kg-bw/day.

USEPA acknowledged in 1993 that increased copper excretion and elevated serum ceruloplasmin are not definitive adverse effects and no "frank" adverse effects were identified in the human studies cited. However, by virtue of the potential for mineral imbalance to occur, the RfD was established at a level similar to the ESADDI (National Research Council [NRC], 1989), a level established based on studies of the average American dietary intake (NRC, 1989), not on adverse health impacts. Thus, the RfD established by USEPA for molybdenum is not based on definitive adverse effects.

The current oral RfD for molybdenum is set at 0.005 mg/kg-bw/day, which also can be expressed as an allowable intake of 0.35 mg/day for adults, a value obtained by multiplying the RfD by body weight (i.e., 70 kg for an adult). The table below presents the RfD expressed as a daily intake along with the corresponding ESADDI available in 1993 when the RfD was developed. These ESADDI values are outdated and have been replaced by RDAs (IOM, 2001):

Receptors	Body Weight (kg)	Molybdenum RfD Intake (mg/day)	Molybdenum ESADDI (mg/day)
Adults (>19 years)	70	0.35	0.25
Child (4-9 years)	15	0.075	0.15
Child (1-3 years)	10	0.05	0.025

It should be noted that USEPA established the RfD at a level similar to the ESADDI based on the average American diet as it was understood at that time. As stated by USEPA (2009a), the ESADDI is not associated with any definitive adverse health effect. Further, the USEPA (USEPA, 2009a) had concerns that high levels of ingested molybdenum may be associated with potential mineral imbalance (e.g., copper depletion) based on the Kovalsky et al. study (1961). Thus, the RfD for molybdenum was set close to the ESADDI. This concern for relationship between copper and molybdenum intake was part of the rationale for selecting the Kovalsky et al. study (1961) as the basis for the RfD. The IRIS profile states:

> "it is important to note that the average level of copper intake in the American population from 1982 to 1986 was less than the lower limit of the ESADDI recommendation for all age and sex groups studied in the Food and Drug Administration (FDA) Total Diet Study (Pennington et al., 1989)"

To provide perspective on that statement in the IRIS profile, ARCADIS reviewed more current dietary intake information for copper. Dietary intake information for copper summarized in the table below was obtained from nutrition surveys and food intake studies to include the Third National Health and Nutrition Examination Survey (NHANES III) and the Continuing Survey of Food Intakes by Individuals (CSF II) (Centers for Disease Control and Prevention [CDC], 2009). The NHANES III is a program of studies designed to assess the health and nutritional status of adults and children in the United States and is a major program of the National Center for Health Statistics (NCHS). NCHS is part of the CDC and has the responsibility for producing vital and health statistics for the Nation. The CSF II was conducted in response to the Food Quality Protection Act of 1996, which required the U. S. Department of Agriculture to provide data from a larger sample of children for use by USEPA in estimating exposure to pesticide residues in the diets of children.

Copper Dietary Intake Data from Nutrition Surveys

Age (years)	Dietary Intake NHANES III (1988-1994)	CSF II (1994-1996)	RDA (IOM, 2001)
1-3	0.74	0.71	0.340
3-8	0.97	0.88	0.440
14-18 male	1.5	1.45	0.890
14-18 female	1.1	1.07	0.890
19-30 male	1.7	1.52	0.900
19-30 female	1.2	1.05	0.900

The intake data indicate that the average copper intake in the American diet is now above the RDA (IOM, 2001). This indicates that most individual's diets exceed the RDA, which is the average daily nutrient intake level sufficient to meet the nutrient requirements of nearly all (97 to 98%) of healthy individuals in a particular life stage and gender group.

This updated dietary intake information indicates that the American population is receiving adequate dietary copper.

3.2 Molybdenum Tolerable Upper Intake Level (UL)

The IOM reviewed the information on essential nutrients as it developed the DRI program and all associated values. The DRI profile for molybdenum (IOM, 2001) challenges the basis of the IRIS 1993 RfD (USEPA, 2009a). The adverse effects of molybdenum in the Kovalsky et al. study (1961) reflect the synergistic conditions of high molybdenum intake combined with low copper intake of the exposed population. Laboratory animal studies showed that the effects of molybdenum on growth and melanin synthesis are more pronounced under situations where dietary copper intake is low (USEPA, 2009a). Impaired copper utilization has also been observed in ruminants (Mills and Davis, 1987; as cited in IOM, 2001), but the digestive system differences for humans make this data not applicable. A study of a second population from an area where soil molybdenum concentrations were high but where copper intake was also high, showed no indication of elevated uric acid levels or increased incidences of gout-like disorders (Mertz, 1976). Another criticism of the Kovalsky et al. study (1961) is that there were serious methodological problems, including possible analytical difficulties in the assessment of blood and urinary copper levels, and the very small size of the control group compared to the group exposed to molybdenum (IOM, 2001). The IOM notes that other more recent human studies of exposure to molybdenum do not support the Kovalsky et al. (1961) results. In fact, the studies also cited in the development of the oral RfD for molybdenum (USEPA, 1979; Deosthale and Gopalan, 1974), do not support the manifestation of increased uric acid in plasma and urine with increased molybdenum exposure.

In summary, because of the weaknesses in the Kovalsky et al. study (1961), the IOM has determined that inadequate data exist to identify a causal association between excess molybdenum intake in normal, apparently healthy individuals and any adverse health outcomes (IOM, 2001). In addition, results of other studies have identified levels of dietary molybdenum intake that appear to be associated with no harm (Deosthale and Gopalan, 1974; Turnlund and Keyes, 2000; as cited in IOM, 2001). The UL for molybdenum is unique in that there were no human studies available that identified distinct adverse health effects associated with dietary ingestion of molybdenum. As a result, a UL was established using the same approach used by USEPA in establishing an RfD for nutritionally essential elements, focusing on dietary studies that resulted in adverse effects at levels above those deemed nutritionally essential to humans.

According to the IOM a number of dietary studies with mice, rats, rabbits, and guinea pigs have demonstrated reproductive effects from molybdenum intake (Jeter and Davis, 1954; Schroeder and Mitchener, 1971; Fungwe et al., 1990). In addition, a

recent human study has produced results that are consistent with the findings from animal studies, where the effects of molybdenum on reproduction has been evidenced based on observing an inverse association between molybdenum in blood and semen quality (Meeker et al., 2008). The study did not have a dietary component and due to the high percentage of blood samples that were below detection did not allow for the establishment of dose-response relationships and metal-metal interactions. Therefore, for this evaluation the dose-response information obtained from animal studies was used. The effects of molybdenum on reproduction and fetal development in rats and mice were determined to be the most sensitive and the basis for developing the UL. The study from Fungwe et al. (1990) provides the dose-response relationship for adverse reproductive effects in female rats. The NOAEL was established at 0.9 mg/kg-bw/day. Based on the same guidance in developing an RfD, the same uncertainty factors used in establishing RfDs were also applied to develop the UL. An uncertainty factor of 10 was applied to account for extrapolating from animal studies to humans, and another factor of 3 was applied to address intraspecies differences resulting in a UL of 0.03 mg/kg-bw/day. Therefore, the UL is considered to be protective of the most sensitive members of the general population from adverse effects of high nutrient intake. This UL was also expressed as an allowable intake of 2 mg/day for adults, a value obtained by multiplying the UL dose by body weight (i.e., 70 kg for an adult) and the corresponding values for children are presented in the table below along with the RfD expressed as a daily intake based on body weight for the receptor:

Receptors	Body Weight (kg)	Molybdenum UL (mg/day)	Molybdenum RfD (mg/day)
Adults	70	2	0.35
Child (1-3 years)	10	0.3	0.075
Child (4-8 years)	15	0.6	0.05

Because both the RfD and UL represent estimates of the upper level at which there are not likely to be adverse health effects in the general population to include sensitive individuals, these values would be expected to be in the same range. In the case of molybdenum, the uncertainty factor is the same in both cases – 30; however, the difference is in the studies used as the basis for the value.

Goldhaber (2003) states that many RfDs currently being used were set years ago and need to be updated based upon the newer data that has since become available and used to set the ULs and RDAs. Given the relevant data (Fungwe et al., 1990; Meeker et al., 2008; Jeter and Davis, 1954; Schroeder and Mitchener, 1971) not considered by

the IRIS RfD, and the adequacy of copper in the American diet, the UL for molybdenum is more appropriate to use than the RfD to assess the safety of site data. [Note: the 1993 IRIS profile states that there were no reproductive or developmental studies in the database for molybdenum. In addition, the screening-level literature review conducted by an USEPA contractor in August 2003 as a re-evaluation of the toxicity of molybdenum did not identify the following studies that were considered by the IOM evaluation of molybdenum: Fungwe et al., 1990; Jeter and Davis, 1954 ; Schroeder and Mitchener, 1971; or Turnlund and Keyes, 2000.]

3.3 Contributions of Molybdenum from Diet

Information on dietary intake of molybdenum is limited because of lack of a simple, reliable analytical method for measuring molybdenum in food. As a result, dietary data from the NHANES III and CSF II studies are not currently available for molybdenum. Therefore, the available scientific literature was reviewed to locate information regarding the daily intake of molybdenum from the diet. One U.S. study has reported intakes ranging from 120 to 240 micrograms per day (µg/day), with an average of 180 µg/day for all age groups (Tsongas et al., 1980). Another total diet study indicates an average molybdenum intake of 76 µg/day for women and 109 µg/day for men (Pennington and Jones, 1987). In 1989, the FNB of the Subcommittee on the Tenth Edition of the Recommended Dietary Allowances (RDAs) established ESADDI values for molybdenum (NRC, 1989) using these average American diet studies as a basis. As described above, ESADDIs set in 1989 were replaced in the DRI document by RDAs developed by the FNB of the Institute of Medicine (IOM, 2001), a branch of the National Academy of Sciences.

The values shown below represent the molybdenum nutritional RDA and UL amounts (IOM, 2001), and the dietary intakes are the levels of molybdenum that are obtained from an average American diet (Tsongas et al., 1980).

Age	Molybdenum Daily Dietary Intake (Tsongas et al., 1980)	Molybdenum RDA (IOM, 2001)	Molybdenum UL (IOM, 2001)
Child (1-3 years)	0.13	0.017	0.3
Child (4-8 years)	0.15	0.022	0.6
Adult	0.25	0.045	2.0

The UL, which is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects for almost all individuals in the specified life stage group, was used as the total acceptable molybdenum intake level. This UL can then be compared to an estimated total intake of molybdenum at the site, inclusive of diet and site groundwater as the only source of potable drinking water.

3.4 Estimation of Molybdenum Intake for Topock

Based on the results of the GWRA using the USEPA RfD, six wells of the wells sampled for molybdenum resulted in estimated noncarcinogenic hazard quotients (HQs) greater than 1.0 (calculated without considering contributions from the diet). The estimated HQs at these wells ranged from 1.1 to 2.5, and were calculated using the USEPA RfD established in 1993. However, molybdenum is classified as a nutritionally essential metal in the human diet; therefore, according to USEPA's *Framework for Metals Risk Assessment* (2007), essentiality must be considered in the overall dose-response relationship.

The USEPA senior toxicologist serving as the compound manager for molybdenum toxicity evaluations was consulted directly to determine the agency's view of using the IRIS oral RfD for molybdenum versus the UL for hazard estimates. USEPA's advice was that the oral RfD listed in IRIS is indeed flawed as indicated in the IOM document, and that the UL provides a better indication of potential health concerns for molybdenum hazard (Donohue, personal communication 2009).

To place site groundwater data for Topock into a proper health perspective for essential nutrient evaluation, the total intake of molybdenum from site groundwater and estimated molybdenum intake from the diet were combined. This estimated total intake was then compared to acceptable intake levels for molybdenum based on the UL dose as presented by the IOM (2001).

The UL was identified as the most relevant upper intake level for use in interpreting the Topock molybdenum data, because it is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects for almost all individuals in the specified life stage group to include the most sensitive members of the general population.

Table M-1 presents an estimate of the chronic daily intake of molybdenum for the hypothetical groundwater user as well as exposure point concentrations from each Topock well (see GWRA Table 4-2) where molybdenum was determined to be present above the background upper tolerance limit (UTL). This concentration was multiplied

by USEPA's default groundwater ingestion rate for the future hypothetical groundwater users (adult 2 liters per day [L/day] and child 1 L/day taken from GWRA Table 5-1) to give the estimated molybdenum intake in mg/day for each well. Note, dermal exposure intake of molybdenum from groundwater at the site was two orders of magnitude lower than ingestion exposure intake; therefore, dermal exposure did not contribute significantly to the overall intake and is not evaluated here.

To conservatively estimate additional intake of molybdenum from the diet, the upper end of the ranges for adult, child (1 to 3 years), and child (4 to 8 years) shown in the last table above were used. The sum of the daily intake of molybdenum from site groundwater and the diet represents the estimated total intake of molybdenum for the hypothetical groundwater users for each well.

The UL for each age group as shown on the last table above was compared to the total estimated intake, inclusive of intake from ingestion of groundwater and the diet. The total estimated intakes for all wells, plus the dietary contribution for both the adult and child hypothetical groundwater user are at or below the UL in all but one case. The use of data for MW-46-175 results in an estimated intake of 0.330 mg/day of molybdenum compared to the UL for the child (1 to 3 years) of 0.300 mg/day. This is a ratio of 1.1 if the intake is divided by the UL. MW-46-175 is located north of the I-40 corridor, near the Colorado River, on the USDOI parcel identified for potential future residential use. All other wells and ages had estimated intakes below the corresponding UL.

Based on more current dose-response information and consideration of daily contributions of molybdenum from the diet, the total molybdenum exposure from site groundwater and diet are, with one exception below the highest levels of daily nutrient intake that are likely to pose no risk of adverse health effects for almost all individuals in the specified life stage group.

4. Essential Nutrient Evaluation of Potential Selenium Intake

For selenium, this section describes the basis for the RfD, the UL for selenium, and the use of the UL as an alternate method to evaluate potential hazard for estimated selenium intake for the future hypothetical groundwater user at Topock.

Selenium functions primarily in association with proteins known as selenoproteins. It is deemed nutritionally essential for humans because the absence of selenium disrupts synthesis of selenoproteins, which is lethal for embryos. Selenium is known to be important for the following known biological functions: defense against oxidative stress, regulation of thyroid hormone action, and regulation of the redox status of vitamin C and other molecules (IOM, 2001).

4.1 USEPA IRIS Reference Dose for Selenium

The RfD established for selenium in 1991 and listed in USEPA's IRIS is based on human studies; the selenium profile was last updated by USEPA in 1993. The following paragraphs summarize the information and studies that form the basis of the RfD (USEPA, 2009b).

The principal support study was conducted by Yang et al. (1989b), which studied safe maximal daily dietary selenium-intake in a seleniferous area in China. This epidemiologic study involved a population of approximately 400 individuals living in an area of China with unusually high environmental concentrations of selenium. The subjects were evaluated for clinical and biochemical signs of selenium intoxication. Three geographical areas with low, medium, and high selenium levels in the soil and food supply were chosen for comparison in the studies (Yang et al., 1989b). Yang et al. (1989a,b) determined that selenium levels in soil and approximately 30 typical food types commonly eaten by the exposed population showed a positive correlation with blood and tissue selenium levels. The daily average selenium intake based on lifetime exposure, were 70, 195, and 1,438 µg for adult males and 62, 198, and 1238 µg for adult females in the low-, medium- and high-selenium areas, respectively (USEPA, 2009b). In addition, significant correlations demonstrated between selenium concentrations of various tissues were used to estimate the minimal daily selenium intake values that elicited various alterations in biochemical parameters indicative of possible selenium-induced liver dysfunction (i.e., prolongation of clotting time and serum glutathione titer) and clinical signs of selenosis (e.g., hair or nail loss and morphological changes of the nails).

Analysis of the results indicated that persistent clinical signs of selenosis were observed only in five of the 349 adults, and identified these five adults as a potentially sensitive subpopulation (USEPA, 2009b). Clinical signs observed included the characteristic "garlic odor" of excess selenium excretion in the breath and urine, thickened and brittle nails, hair and nail loss, lowered hemoglobin levels, mottled teeth, skin lesions, and central nervous system abnormalities (USEPA, 2009b). Alterations in the measured biochemical parameters occurred at dietary intake levels of 750 to 850 µg/day (i.e., increase in blood coagulation time and reduction in blood glutathione concentration) (USEPA, 2009b). However, these indicators were poorly characterized and are not typically used as an index for clinical selenosis resulting from chronic exposure to selenium (USEPA, 2009b). Based upon the blood selenium levels shown to reflect clinical signs of selenium intoxication, a whole-blood selenium concentration corresponding to 1,261 µg/day selenium intake was deemed indicative of the lowest correlative selenium intake causing overt signs of selenosis (USEPA, 2009b). The next lowest whole-blood selenium concentration corresponding to 853 µg/day, produced no clinical signs of selenosis (USEPA, 2009b).

A study by Longnecker et al. (1991) involved 142 volunteers in South Dakota and Wyoming randomly recruited from households listed in a telephone directory or from ranches with suspected high selenium intake based on previous cases of livestock selenosis (USEPA, 2009b). The subjects were followed for one year and completed health questionnaires; underwent physical examinations; provided blood samples for clinical assessment; and provided samples of blood, urine, toenails, and duplicate-plate food collections for selenium analysis. The average selenium intake was 239 µg/day, approximately two to three times higher than the national average. The concentration of selenium in whole blood, serum, urine, and toenails and the amount in diet were highly correlated. Blood selenium concentration was highly correlated with selenium intake. The correlation was very similar to that reported by Yang et al. (1989a); however, liver function, hematologic function, and clinical chemistry were not found to be altered as a result of selenium intake (USEPA, 2009b). High regression coefficient predictor variables for selenium toxicity were not found in increased frequency for this population, and there were no signs of selenium toxicity found in the population, including individuals whose selenium intake was as high as 724 µg/day.

Based on the results of the Yang et al. study (1989a,b) a selenium NOAEL of 853 µg/day, and the selenium LOAEL of 1260 µg/day was determined by USEPA. USEPA established the RfD based on the NOAEL adjusted for body weight in the study and applying an uncertainty factor of 3 (NOAEL = 0.853 mg/day / 55 kg x 1/3) to arrive at an oral RfD of 0.00516 mg/kg-bw/day. An uncertainty factor of 3 was applied to the

NOAEL to account for sensitive individuals instead of a full factor of 10, because similar NOAELs were identified in two moderately sized human populations exposed to selenium levels in excess of the RDA throughout a lifetime without apparent clinical signs of selenosis. Thus, the resulting RfD was established by USEPA of 0.005 mg/kg-bw/day, which equates to a selenium daily intake of 284 µg/day for a 55 kg adult. It should be noted, however, that the Longnecker et al. (1991) study corroborates that of Yang et al. (1989b), which showed that a selenium intake of up to 853 µg/day is not associated with characteristics of selenosis.

Essential nutrient intake is typically expressed as mg/day for a certain age group. In order to compare the health protective intake represented by the RfD to essential nutrient intake information, the RfD was used to calculate the related health protective daily intake for adults and children. The current oral RfD for selenium is set at 0.005 mg/kg-bw/day, which also can be expressed as an allowable daily intake of 284 µg/day for adults, a value obtained by multiplying the RfD by the adult body weight in the study (i.e., 55 kg). The RfD-based intake shown below for children was calculated the same as for the adult, except standard default assumptions of body weight for children were used as identified below. The RfD expressed as a daily intake along with the corresponding RDA are presented in the table below to compare the levels associated with no adverse health effects (RfD) versus the levels required in the diet (RDA):

Receptors	Body Weight (kg)	Selenium RfD Intake (mg/day)	Selenium RDA (mg/day)
Adults (>19 years)	55	0.284	0.055
Child (4-8 years)	15	0.077	0.030
Child (1-3 years)	10	0.052	0.020

4.2 Tolerable Upper Intake Level (UL)

The IOM reviewed the information on essential nutrients as it developed the DRI program and all associated values. The DRI profile for selenium (IOM, 2000) for establishing a UL for an adult is consistent with the basis of the IRIS 1993 RfD (USEPA, 2009b), except an uncertainty factor of 2 was applied to the NOAEL by IOM (2000) to develop a UL that is protective of sensitive individual adults instead of an uncertainty factor of 3 that USEPA applies for ensuring protection of sensitive receptors. The UL for adults was determined to be 400 µg/day (IOM, 2000).

The UL for children was based on a different epidemiologic study than that applied for the adult UL. For the child UL, IOM established a UL for a child (1 to 3 years) and a child (4 to 8 years) by using a study from Shearer and Hadjimarkos (1975), which showed that a human milk selenium concentration of 60 micrograms per liter (µg/L) was not associated with known adverse effects. Thus, the NOAEL for this study of 7 micrograms per kilogram per day (µg/kg/day) was adjusted for older infants and children based on body weight to arrive at ULs of 90 µg/day and 150 µg/day for children of 1 to 3 years and children of 4 to 8 years, respectively. It should be noted that this represents the upper NOAEL identified in this study; a LOAEL was not identified (Levander et al., 1987). This introduces the uncertainty that the actual health protective dose could be higher than the UL. Further, there is no known evidence indicating an age-related sensitivity to selenium toxicity (IOM, 2000).

In summary, although the USEPA-established RfD was based on a NOAEL for a sensitive population in the Yang et al. study (1989b) of 853 µg/day, USEPA still applied an uncertainty factor of 3 to further protect sensitive individuals to arrive at a daily intake of 284 µg/day. The IOM used the same study, Yang et al. (1989b), and identified an NOAEL daily intake of 800 µg/day and applied an uncertainty factor of 2 to address sensitive individuals to arrive at a UL of 400 µg/day versus the daily intake of 284 µg/day. Thus, the daily intake based on the RfD of 284 µg/day is lower but within the same order of magnitude as the UL of 400 µg/day.

Receptors	Body Weight (kg)	Selenium UL (mg/day)	Selenium RfD (mg/day)
Adults (>19 years)	55	0.4	0.284
Child (4-8 years)	15	0.15	0.052
Child (1-3 years)	10	0.09	0.077

Because both the RfD and UL represent estimates of the upper level at which there are not likely to be adverse health effects in the general population to include sensitive individuals, these values would be expected to be in the same range. In the case of selenium, the difference is the uncertainty factor for the adult values where an uncertainty factor of 2 was used for the UL and an uncertainty factor of 3 was used for the RfD; the basis for the child values is the difference in studies used.

4.3 Contributions of Selenium from Diet

Dietary intake of selenium varies tremendously among different populations due to factors that affect intake including the geographic origin of the food items and the meat content of the diet (IOM, 2000). Selenium intake in the United States has been estimated in several studies. A Maryland study indicated that selenium intake of 22 residents was 81 +/- 41 (standard deviation) µg/day (IOM, 2000). A study by the FDA (1995) analyzed food items purchased in different regions of the United States and calculated dietary selenium intake; median calculated intakes ranged from 79 µg/day to 104 µg/day (IOM, 2000). NHANES III intake data reported a higher median selenium intake of 106 µg/day from food for all individuals; the mean dietary intake for children 1 to 3 years of age is 65.5 µg/day, children 4 to 8 years of age is 86.8 µg/day, and highest adult mean is for males of 159 µg/day (IOM, 2000).

The values shown below represent the selenium nutritional RDA and UL amounts (IOM, 2000), and the dietary intakes are the levels of selenium that are obtained from an NHANES III.

Age	Selenium Daily Dietary Intake (CDC, 2009; NHANES) (mg/day)	Selenium RDA (IOM, 2000) (mg/day)	Selenium UL (IOM, 2000) (mg/day)	Selenium RfD Intake Level (mg/day)
Chile (1-3 years)	0.0655	0.020	0.09	0.007
Child (4-8 years)	0.0868	0.030	0.15	0.052
Adult	0.159	0.055	0.4	0.284

The UL, which is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects for almost all individuals in the specified life stage group, was used as the total acceptable selenium intake level. This UL can then be compared to an estimated total intake of selenium at the site, inclusive of diet and site groundwater as the only source of potable drinking water.

4.4 Estimation of Selenium Intake for Topock

Based on the results of the GWRA using the USEPA RfD, one well of the wells sampled for selenium resulted in an estimated noncarcinogenic HQ greater than 1.0 (calculated without considering contributions from the diet). The estimated HQs for the hypothetical child groundwater user at TW-1 was 2.0 calculated using the USEPA RfD.

However, selenium is classified as a nutritionally essential metal in the human diet; therefore, according to USEPA Framework for Metals Risk Assessment (2007), essentiality must be considered in the overall dose-response relationship.

To place site groundwater data for Topock into a proper health perspective, the total intake of selenium from site groundwater and estimated selenium intake from the diet were compared to total acceptable intake levels based on the UL dose as presented by the IOM (2001).

This supplemental selenium evaluation considered the overall dose-response relationship and evaluated the entire dose-response relationship, from very low (inadequate) doses to high (toxic) doses in order to determine an acceptable upper exposure limit. As summarized above, the UL was used in interpreting the Topock selenium data because it is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects for almost all individuals in the specified life stage group to include the most sensitive members of the general population.

Table M-2 presents an estimate of the chronic daily intake of selenium for the hypothetical groundwater user as well as exposure point concentrations from each Topock well (see GWRA Table 4-2) where selenium was determined to be present above the background UTL. This concentration was multiplied by USEPA's default groundwater ingestion rate for the future hypothetical groundwater users (adult 2 L/day and child 1 L/day taken from GWRA Table 5-1) to give the estimated selenium intake in mg/day for each well. Note, dermal exposure intake of selenium from groundwater at the site was two orders of magnitude lower than ingestion exposure intake; thus, dermal exposure did not contribute significantly to the overall intake and is not evaluated here.

To conservatively estimate additional intake of selenium from the diet, the upper end of the ranges for adult, child (1 to 3 years), and child (4 to 8 years) shown in Table M-2 were used. The sum of the daily intake of selenium from site groundwater and the diet represents the estimated total intake of selenium for the hypothetical groundwater users for each well.

The UL for each age group as shown on Table M-2 was compared to the total estimated intake, inclusive of intake from ingestion of groundwater and the diet. The total estimated intakes for all wells plus the dietary contribution for the adult hypothetical groundwater user are at or below the UL in all but one case, TW-1. The total estimated intakes for all wells plus the dietary contribution for the child

hypothetical groundwater user are at or below the UL in all but three cases, TW-1, and MW-21 and MW-24A for the child 1 to 3 years of age. The use of data for TW-1 results in an estimated intake of 0.479 mg/day of selenium for the adult compared to the UL of 0.400 mg/day, resulting in a ratio of 1.2. For the child 4 to 8 years of age and TW-1 data, the estimated intake is 0.247 mg/day compared to the UL of 0.150 mg/day, resulting in a ratio of 1.6. For the child 1 to 3 years of age and TW-1, the estimated intake is 0.226 mg/day compared to the UL of 0 09 mg/day, resulting in a ratio of 2.5. Dividing the estimated intake by the UL for wells MW-21 and MW-24A give ratios of 1.2 and 1.3, respectively, for the child 1 to 3 years of age. It is noted that all three wells (MW-21, MW-24A, and TW-1) are located south of the I-40 corridor. Therefore, none are located on the parcel identified by USDOI as an area for potential future residential use. All other wells and ages had estimated total intakes below the corresponding UL for selenium.

The estimated intake of selenium from groundwater is below the highest levels of daily nutrient intake that are likely to pose no risk of adverse health effects for almost all individuals. When estimated dietary intake is added to the estimated groundwater intake, the UL is exceeded for all three evaluated age groups for one well, TW-1, with the highest ratio being 2.5 for the child 1 to 3 years of age. The total intake is dominated by the dietary intake component. As was discussed above, the ULs or the child receptors were developed from an epidemiology study where no adverse dose was observed. The UL is based on the highest estimated exposure which is a NOAEL. A LOAEL was not identified for this study. Consequently, the safe allowable daily intake may be above the UL. This perspective is important because it is this uncertainty that indicates the exceedances of the UL for the child 1 to 3 years of age in wells MW-21 and MW-24A likely overestimate the potential health concern. In addition, as discussed above, there is no indication of an age-related sensitivity to selenium. The results for this supplemental evaluation of essential nutrient status for TW-1 are comparable to the findings in the risk assessment. TW-1 is the same well that produced a hazard index value of 2.0. It is noted that TW-1 is just outside the fenceline of the compressor station and located on Pacific Gas and Electric Company property. This location is not part of the parcel identified by USDOI as an area for potential future residential use.

There is only one well slightly above the UL for selenium for all age groups when both dietary and potential groundwater consumption are combined for selenium. This well is not on the USDOI parcel identified for potential future residential use. Consequently, it is unlikely that selenium in groundwater at the Topock site presents a risk of adverse health effects.

5. Conclusions

The following conclusions are based on the information and analysis described above:

5.1 Molybdenum

- The USEPA RfD for molybdenum is overly conservative given more recent relevant human and animal studies.

- The adverse effects of molybdenum in the study that is the basis of the USEPA RfD reflect the synergistic conditions of high molybdenum intake combined with low copper intake of the exposed population.

- The average American dietary intake of copper is estimated to be nutritionally adequate according to the NHANES III and CSF II diet studies, which are more recent than NHANES II information referenced in USEPA 2009a.

- Consistent with USEPA guidance for metals risk assessment, DRI UL values should be considered in evaluating the potential health impacts associated with future hypothetical exposures to molybdenum in site groundwater.

- Total estimated intakes of molybdenum, including hypothetical domestic use of the groundwater and reasonable assumptions regarding dietary intake, are at or below safe concentrations (i.e., the UL), as determined by current essential nutrient information published by the IOM for all but one well.

- The estimated total intake based on data from MW-46-175 is only 10% above the nutritionally safe UL, and is based on a single data point from the only sample analyzed for molybdenum from this well.

- Accordingly, as levels of molybdenum in only one well (1% of wells) only slightly exceed the nutritionally safe UL, even when considering the contribution of molybdenum from the diet, it may be concluded that molybdenum is unlikely to pose adverse health effects to future hypothetical receptors including the most sensitive members of the general population that hypothetically could use site groundwater as a potable source of water.

5.2 Selenium

- Consistent with USEPA guidance for metals risk assessment, DRI UL values should be considered in evaluating the potential health impacts associated with future hypothetical exposures to selenium in site groundwater.

- The estimated intake of groundwater from all wells is below the safe concentrations (i.e., the UL) as determined by current essential nutrient information published by the IOM.

- When estimated dietary intake for selenium is added to potential groundwater intake for the future hypothetical groundwater user, total estimated intakes of selenium are comparable to or below safe concentrations (i.e., the UL) for all but three wells (MW-21, MW-24A, and TW-1) as determined by current essential nutrient information published by the IOM.

- Levels of selenium in MW-21 and MW-24A exceed the UL (when considering intake from both groundwater and diet) only for the child 1 to 3 years by 20% and 30 % respectively.

- The selenium UL for the child receptors is based on a different study than the adult. The UL for the child (both age groups) is based on the highest NOAEL noted. A LOAEL was not determined. Consequently, the safe intake for a child could be higher than noted for the UL.

- Levels of selenium in only one well (TW-1 – 1% of wells) exceed the nutritionally safe UL, for all three age groups. The highest exceedance is only by a factor of approximately 2, when considering the contribution of selenium from both groundwater and the diet.

- None of the three wells noting estimated exceedances of the UL (when considering intake from both groundwater and diet) are located on the portion of the site identified by USDOI as having potential future residential use.

- Therefore, selenium is unlikely to pose adverse health effects to future hypothetical groundwater users including the most sensitive members of the general population.

Notes:

Bold indicates total estimated intake value exceeding the corresponding UL.

(1) Note that ingestion intake from molybdenum is two orders of magnitude higher than dermal exposure; thus, only ingestion is evaluated since dermal exposure does not significantly impact overall intake of molybdenum. Daily intake was calculated by multiplying the EPC times the ingestion rate (Adult = 2L/day; Child = 1L/day).

(2) Based on calculated daily intake of molybdenum from diet based on study evaluating dietary intake of molybdenum in the United States (USEPA, 2009; Tsongas et al., 1980). Child (1 to 3 yrs) = 0.130; Child (4 to 8 yrs) = 0.150 mg/day; Adult (>16 years) = 0.250 mg/day.

EPC = exposure point concentration
L = liter
mg = milligram(s)
UL = tolerable upper intake level

Table M-2. Comparison of Selenium Site Intake from Groundwater and Diet to the Tolerable Upper Intake Level

Notes:

Bold indicates total estimated intake value exceeding the corresponding UL.

(1) Note that ingestion intake from selenium is two orders of magnitude higher than dermal exposure; thus, only ingestion is evaluated since dermal exposure does not significantly impact overall intake of selenium. Daily intake was calculated by multiplying the EPC times the ingestion rate (Adult = 2L/day; Child = 1L/day).

(2) Based on calculated daily intake of selenium from diet based on study evaluating dietary intake of selenium in the United States (USEPA, 2009; Tsongas et al., 1980). Child (1 to 3 yrs) = 0.130; Child (4 to 8 yrs) = 0.150 mg/day; Adult (>16 years) = 0.250 mg/day.

(3) UL = Tolerable Upper Intake Level is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects for almost all individuals in the specified life stage group; ULs are based on total intake of a nutrient from food, water, and supplements. UL for adult = 0.4 mg/day; child (1 to 3) =0.090 mg/day; and child (4 to 8) = 0.150 mg/day.

* Note that the UL for infants and children were based on the highest tested dose which resulted in no observable adverse effect level (NOAEL); thus, the safe amount is likely higher than that tested.

EPC = exposure point concentration
L = liter
mg = milligram(s)
UL = tolerable upper intake level

Target Organs Impacted by Selenium, Nitrate, Molybdenum, and Hexavalent Chromium

1. Target Organs Impacted by Selected Chemicals

The purpose of this appendix is to present Table N-1, which summarizes the critical target organs that are impacted by exposure to selenium, nitrate, molybdenum, and hexavalent chromium. As stated in the main text of the groundwater risk assessment (GWRA), the approach for evaluating noncarcinogenic effects from exposure to constituents of potential concern (COPCs) assumes that simultaneous subthreshold exposures to several chemicals could result in an adverse health effect. This approach also assumes that the magnitude of the adverse effect will be proportional to the sum of the ratios of the subthreshold exposures to acceptable exposures (i.e., the sum of the hazard quotients [HQs]; referred to as the hazard index [HI]). As noted in the GWRA, when the noncancer HI exceeds unity, there may be a concern for potential noncancer health effects. The assumption of dose additivity is most properly applied to compounds that induce the same effect by the same mechanism of action (U.S. Environmental Protection Agency [USEPA], 1989). Consequently, the summing of HQs for all chemicals that are not expected to induce the same type of effects or that do not act by the same mechanism, as done in the risk assessment, could overestimate the potential for noncancer health effects. Accordingly, and consistent with USEPA risk assessment guidance (USEPA, 1989), the target organs/critical effects posed by each of the four subject compounds were identified in order to assess whether the summing of HQs for each of these four compounds may result in overly conservative estimates of the potential for noncancer health effects[1]. Typically, although a compound may impact multiple target organs at different doses, the target organ that is identified as the 'critical target organ' is the target organ that was used in the development of the noncancer reference dose (RfD) (and is typically the most sensitive target organ); the critical target organ is used in assessing whether it may be overly conservative to sum the HQs calculated from selenium, nitrate, molybdenum, and hexavalent chromium.[2]

Table N-1 summarizes the critical target organs for selenium, nitrate, molybdenum, and hexavalent chromium. The target organs identified in this table were obtained from USEPA's Integrated Risk Information System (USEPA, 2008), which summarizes the

[1] We note that California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control risk assessment guidance also supports the segregation of noncancer impacts by critical effect/target organ. See page 10 of CalEPA (2009).

[2] According to *Risk Assessment Guidance for Superfund* (RAGS) Part A (USEPA, 1989), Exhibit on page 8-15, "Segregation of hazard indices requires identification of the major effects of each chemical, including those seen at higher doses than the critical effect. Although higher exposure levels may be required to produce adverse health effects other than the critical effect, the RfD can be used as the toxicity value for each effect category as a conservative and simplifying step."

noncancer RfDs and the target organ that elicited the critical effect. As indicated in the table, the key target organs impacted by selenium, molybdenum, and hexavalent chromium and those upon which these reference doses have been based, are different from each other. In contrast, as indicated in Table N-1, both hexavalent chromium and nitrate, at specified doses, affect the blood. Accordingly, per USEPA risk assessment guidance (1989), to sum the individual HQs for selenium, molybdenum, and hexavalent chromium (i.e., three compounds that are not expected to induce the same type of effects or that do not act by the same mechanism), can result in overestimating the potential for noncancer effects. Rather, a more reasonable estimate of the potential for noncancer hazards for these three compounds can be obtained by examining the chemical-specific HIs for each of these three compounds. At those locations where both nitrate and hexavalent chromium are present, it is reasonable to evaluate the potential for adverse noncancer health effects on the blood system by examining the sum of the HQs for these two compounds.[3]

The information presented in this appendix provides additional perspective on the significance of the cumulative risk estimates for the four facility-related COPCs (selenium, nitrate, molybdenum, and hexavalent chromium), presented in the main text of the GWRA.

[3] As indicated in Appendix R, there are only five out of 165 groundwater wells where nitrate contributes materially to an elevated HI: MW-9 (with a nitrate HI of 0.9 and a hexavalent chromium HI of 7.5), MW-24A (with a nitrate HI of 0.74 and a hexavalent chromium HI of 73); MW-40D (with a nitrate HI of 0.79 and a hexavalent chromium HI of 1.8); MW-51 (with a nitrate HI of 0.57 and a hexavalent chromium HI of 100), and PT-8M (with a nitrate HI of 1.3 and a hexavalent chromium HI of 85). Each of these five wells is located south of I-40, on land where residential use is not considered a reasonable future land use. The total noncancer HI at each of these five wells is dominated by hexavalent chromium.

Table N-1. Target Organs Impacted by Selenium, Nitrate, Molybdenum, and Hexavalent Chromium

Chemical	Critical Effect/Target Organ (1)
Hexavalent Chromium	No Observable Adverse Effect Level (NOAEL) (2)
Molybdenum	Kidney: Increase in uric acid levels
Nitrate as Nitrogen	Blood: Methemoglobinemia
Selenium	Skin and hair - Dermatitis, brittle nails, loss of hair and nails, mottled and eroded teeth, and skin lesions Central nervous system (CNS) abnormalities - peripheral anesthesia, acroparesthesia, and pain in the extremities

Notes:

(1) Critical Effect/Target Organ on which oral RfD is based.

(2) Although the RfD for hexavalent chromium was based on a study in which no adverse effects were observed (the RfD was derived from a NOAEL, California's Office of Environmental Health Hazard Assessment identifies effects on red blood cells as the critical effect for oral exposure to hexavalent chromium (specifically, decreased mean corpuscular volume and mean corpuscular hemoglobin in mice). http://www.oehha.ca.gov/air/hot_spots/2008/AppendixD3_final.pdf#page=138.

Determination of Material Contributors to Elevated Cumulative Noncancer Hazard at Individual Groundwater Wells

1. Introduction

At each site groundwater well included in the well-specific groundwater risk assessment (see Section 7.1 of the Human Health and Ecological Risk Assessment of Groundwater Impacted by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1 and SWMU 2 [main text]), an estimated potential noncancer hazard index (HI) for the future hypothetical child groundwater user is calculated for each chemical detected above background levels in the well, based on the estimated well-specific exposure point concentration (EPC) of that chemical. The cumulative noncancer HI at that well is calculated by summing the chemical-specific HI values. The results of this analysis are presented in Table 7-2 of the main text. It is evident that any estimated chemical-specific HI in excess of the threshold value of 1.0 is indicative of a potentially material impact with respect to that chemical at that well. Less obvious, however, is the significance of a chemical's contribution to cumulative (i.e., multi-chemical) noncancer hazard, particularly when the estimated chemical-specific HI is less than 1.0 and the cumulative HI for the well is greater than 1.0.

As described in Section 6.3 of the main text, the noncarcinogenic hazard from lead is not evaluated using the traditional reference dose approach because most human health effects data are based on blood-lead concentration rather than external dose (California Environmental Protection Agency [CalEPA], 1992). Therefore, the concept of contribution to cumulative hazard is not applicable to lead, and the noncancer health effects associated with lead are not included in the cumulative noncancer HI. Estimated well-specific lead EPCs are compared to the California Action Level[1] (CAL) for lead, which is a legally enforceable drinking water standard designed to protect public health. The ratio of the estimated lead EPC to the lead CAL is, therefore, approximately analogous to an HI; a ratio above the threshold value of 1.0 indicates potential for adverse health effects to the hypothetical future groundwater user.

The purpose of this appendix is to twofold:

1. Document the methodologies used to characterize the significance of:
   - Chemical-specific contributions to elevated cumulative hazard at individual wells
   - Lead impacts at individual wells.

[1] California Action Level for lead provided in CCR Title 22, Division 4, Chapter 17.5, Article 3, Section 64678

2. Identify, for each chemical, those specific groundwater wells where the chemical is determined to contribute materially to estimated noncancer hazard, and to provide additional analysis of those specific wells, to help evaluate the overall impact of the chemical on site groundwater.

The results of the process used to identify those constituents that contribute materially to an elevated noncancer hazard are summarized in Table 7-6 of the main text and are incorporated into the discussion of risk assessment results that is presented in Section 7.3 of the main text.

2. Methodology

2.1 Chemicals Other than Lead

Once the estimated potential noncancer HI for the hypothetical future child groundwater user is calculated for each chemical at a particular groundwater well (see Table 7-2 of the main text), the chemicals are ranked (i.e., the table of hazard results is sorted) by chemical-specific HI, from high to low. An example, using the results from well MW-24A, is provided in the table below; at this well, the estimated cumulative noncancer HI is 82. The chemicals detected at this well are ranked from highest (hexavalent chromium; HI of 73) to lowest (nickel; HI of 0.021) noncancer hazard. Once the chemicals are ranked from high to low hazard contribution, a running cumulative (multi-chemical) HI is calculated for each chemical, starting with the lowest noncancer hazard, as illustrated in the table below. The chemical that pushes the cumulative hazard above the threshold value of 1.0 is identified; in the example shown below, this chemical is selenium. A "line is drawn" before (under) this chemical (see dashed line in example below).

Those chemicals that fall "below the line" are determined to not be material contributors to cumulative hazard at this well (e.g., as shown below, nickel, copper, zinc, barium, and molybdenum combine to produce a cumulative HI of 0.90) and, therefore, it may be concluded these chemicals, even in combination, are not contributing materially to cumulative noncancer hazard at this well. Those chemicals that fall "above the line" are determined to be potentially material contributors to cumulative hazard at this well. Note, in the example shown below, two chemicals – selenium and nitrate as nitrogen – are determined to be material contributors to cumulative noncancer hazard at this well, even though their estimated chemical-specific HIs are below the threshold value of 1.0. As discussed above, the overall purpose of this ranking process is to identify those chemicals that individually may be determined to be below a level of concern, but where the cumulative impact associated with the presence of the chemical, in combination with the others, could potentially alter the overall conclusion of risk at that location.

Example Determination: Well MW-24A

COPC	Chemical-specific Hazard	Cumulative Hazard	
Chromium, hexavalent	73	82	Are material contributors to cumulative hazard
Arsenic	7.2	9.5	
Nitrate as nitrogen	0.74	2.3	
Selenium	0.65	1.6	
Molybdenum	0.51	0.90	Are not material contributors to cumulative hazard
Barium	0.30	0.39	
Zinc	0.045	0.089	
Copper	0.023	0.044	
Nickel	0.021	0.021	

2.2 Lead

As described above, the concept of contribution to cumulative hazard is not applicable to lead; the significance of lead in groundwater is evaluated individually by comparison of estimated well-specific lead EPCs to the CAL for lead of 0.015 milligrams per liter (mg/L). These results are presented in Table 7-5 of the main text. Lead is determined to be of potential concern at those individual wells with an estimated lead EPC greater than the CAL (i.e., with a ratio of EPC to CAL greater than 1.0).

3. Application to Risk Assessment

3.1 Chemicals Other than Lead

The process of identifying constituents contributing materially to elevated noncancer hazard described above is performed for all groundwater wells included in the well-specific groundwater risk assessment that is presented in Section 7.1 of the main text. For each constituent of potential concern (COPC) included in the well-specific assessment, the number of wells at which the COPC is determined to be a material contributor to cumulative hazard is tallied. The results of this tally are summarized in Table 7-6 of the main text, in the column titled, “Number of Wells Exceeding Cumulative Hazard Threshold.” This information describes the frequency at which each COPC materially contributes to elevated noncancer hazard, and is referenced in the risk characterization discussion presented in Section 7.3 of the main text. For each chemical that is a material contributor to any well, an average HI is calculated. The calculation averages the HI of that chemical from each well where it was determined to contribute materially to cumulative hazard. These average HI values are summarized in Table 7-6 of the main text, in the column titled, “Average Hazard Index at Wells where Chemical is Driving Risk.” This information describes the magnitude at which each COPC contributes to elevated noncancer hazard and is referenced in the risk characterization discussion presented in Section 7.3 of the main text.

3.2 Lead

The process for lead described above is performed for all groundwater wells included in the well-specific groundwater risk assessment that is presented in Section 7.1 of the main text. The number of wells at which the estimated lead EPC exceeds the lead CAL is tallied in Table 7-6 of the main text in the column titled “Number of Wells Exceeding Cumulative Hazard Threshold.” This information describes the frequency at which lead has been detected in site groundwater wells at concentrations in excess of the CAL and is referenced in the risk characterization discussion presented in Section 7.3 of the main text. The average ratio of lead EPC to lead CAL at those wells where the ratio exceeds 1.0 is also calculated and presented in Table 7-6 of the main text, in the column titled, “Average Hazard Index at Wells where Chemical is Driving Risk.” (Note, these column headings are misnomers, with respect to lead because the ratio is not an HI.) This information describes the magnitude of those exceedances and is referenced in the risk characterization discussion presented in Section 7.3 of the main text.

4. Application to Sensitivity Risk Assessment

4.1 Chemicals Other than Lead

The process of identifying constituents contributing materially to elevated noncancer hazard described earlier is also performed for all groundwater wells included in the sensitivity well-specific groundwater risk assessment that is presented in Appendix G. As described in Appendix G, the sensitivity risk assessment bases COPC EPCs on average, rather than maximum, detected concentrations for those datasets with too few results (fewer than eight results or fewer than five detections) to allow calculation of a 95 percent upper confidence (95% UCL) of the mean (OTM) with ProUCL 4.0. The number of wells at which the COPC is determined to be a material contributor to cumulative hazard is tallied; the results of this tally are summarized in Table 7-6 of the main text, in the column titled, “Number of Wells Exceeding Cumulative Hazard Threshold – Sensitivity Analysis.” Also calculated for each COPC is the average chemical-specific HI at those wells where the COPC is determined to be a material contributor to cumulative hazard; these average HI values are summarized in Table 7-6 of the main text, in the column titled, “Average Hazard Index at Wells where Chemical is Driving Risk – Sensitivity Analysis.” This information is referenced in the risk characterization discussion presented in Section 7.3 of the main text.

4.2 Lead

The process for lead described earlier is also performed for all groundwater wells included in the sensitivity well-specific groundwater risk assessment that is presented in Appendix G. The number of wells at which the lead EPC exceeds the lead CAL is tallied in Table 7-6 of the main text in the column titled “Number of Wells Exceeding Cumulative Hazard Threshold – Sensitivity Analysis.” The average ratio of lead EPC to lead CAL at those wells where ratio exceeds 1.0 is also calculated and presented in Table 7-6 of the main text, in the column titled, “Average Hazard Index at Wells where Chemical is Driving Risk – Sensitivity Analysis.” (Again, these column headings are misnomers, with respect to lead since the ratio is not an HI.) This information is referenced in the risk characterization discussion presented in Section 7.3 of the main text.

5. Well-by-Well Analysis of Material Contributors to Elevated Noncancer Hazard

Chemicals contributing materially to elevated noncancer hazard are identified for each site groundwater well by the methodologies described above. In addition, this section identifies each chemical determined to contribute materially to elevated cumulative noncancer hazard, and the list of wells so impacted by that chemical. Key information about each of these wells is presented in Table P-1. For the reader's convenience, the order in which the chemicals are presented in Table P-1 matches the order in which the chemicals are discussed in Section 7.3 of the main text. A well-by-well comparison of lead EPCs to the CAL is presented in Table P-2, for those wells where the lead EPC exceeds the CAL.

Also presented in Table P-1, for each chemical and well, is the number of nondetect results where the detection limit is above the risk-based concentration. Risk-based concentrations are calculated for each chemical in Appendix Q. High detection limits introduce uncertainties into the calculations, as discussed in Section 9 of the main text.

5.1 Barium

As shown in Table P-1, barium is a material contributor to elevated noncancer hazard at MW-23 (total HI of 2.2; barium-specific HI of 1.7) and MW-32-20 (total HI of 1.7; barium-specific HI of 1.7). At MW-23, barium was detected in three of eight samples; because there are too few data points to calculate a 95% UCL OTM, the EPC used in the well-specific risk assessment is the maximum detected concentration of 5.3 mg/L, which is an order of magnitude greater than the next highest detected concentration in that well of 0.28 mg/L. Similarly, at MW-32-20, barium was only analyzed for once and was detected at a concentration of 5.1 mg/L. Interestingly, aside from these two detections of approximately 5 mg/L, the next highest concentration of barium detected anywhere across the site is 1.1 mg/L (which, as indicated in Table 7-2, corresponds to an HI of 0.35), detected at MW-30-30. Barium was detected above 1.0 mg/L in only four of 559 total samples collected across the site (frequency of 0.72 percent) and was detected below 0.50 mg/L in 99 percent of all samples.

MW-23 is located to the east of the Topock Compressor Station, near the west bank of the Colorado River. MW-32-20 is located approximately 750 feet to the north of MW-23. Therefore, the two wells in which barium contributes materially to elevated noncancer hazard are geographically distinct from each other.

5.2 Cadmium

As shown in Table P-1, cadmium is a material contributor to elevated noncancer hazard at OW-5M (total HI 7.1; cadmium-specific HI of 1.4), where it was detected at a concentration of 0.011 mg/L in one of 14 samples collected at this location. The EPC used in the well-specific risk assessment is, therefore, the maximum detected concentration of 0.011 mg/L. Clearly this is an overly conservative assumption, particularly for a compound that has only been detected in one of 374 total samples. This is further supported by the sensitivity analysis presented in Appendix G, in which the estimated cadmium-specific HI at OW-5M is estimated to be 0.22, based on the average (rather than maximum) concentration. Cadmium is not a material contributor to elevated noncancer hazard at any wells in the sensitivity analysis. OW-5M is not in the hexavalent chromium plume.

5.3 Cobalt

As shown in Table P-1, cobalt is a material contributor to elevated noncancer hazard at MW-22 (total HI of 4.6; cobalt-specific HI of 1.1) and OW-5M (total HI of 7.1; cobalt-specific HI of 2.1). At each of these locations, however, cobalt was detected in only one sample, suggesting that the presence of cobalt, both across the site and at individual wells, is sporadic and inconsistent. Specifically, at MW-22 and OW-5M, cobalt was detected in one of three and one of 14 samples, respectively. As shown in the uncertainty analysis presented in Appendix G, use of the average rather than maximum concentrations results in estimated cobalt-specific HIs of 0.71 at MW-22 and 0.52 at OW-5M.

It is also informative to note that the two locations where cobalt contributes materially to cumulative noncancer hazard are not in close geographic proximity to each other; MW-22 is located in the area of the floodplain (although outside the hexavalent chromium groundwater plume) and OW-5M is located approximately 3,500 feet north-west, in the area of the Interim Measure (IM) injection well field (also outside the hexavalent chromium plume). Cobalt was either not detected or was detected below levels of concern for cumulative impacts in the wells surrounding both MW-22 and OW-5M. As indicated in Table 7-2, the estimated noncancer HIs are all at or below 0.28 for the other six wells where cobalt was detected above background levels.

5.4 Nickel

As shown in Table P-1, nickel is a material contributor to elevated noncancer hazard at MW-22 (total HI of 4.6; nickel-specific HI of 0.48) and MW-30-30 (total HI of 5.0; nickel-specific HI of 0.84). Both wells are outside the hexavalent chromium groundwater plume. The estimated nickel-specific HI does not exceed 1.0 at any location and is less than 0.1 (i.e., is more than an order of magnitude below the level of concern) at 30 (79 percent) of the 38 wells where nickel was detected above background levels. Sufficient nickel data is available at MW-22 and MW-30-30 to calculated EPCs as the 95% UCL OTM; therefore, nickel HIs in Appendix G do not change for MW-22 and MW-30-30.

5.5 Selenium

As shown in Table P-1, selenium is a material contributor to elevated noncancer hazard at TW-1 (total HI of 100; selenium-specific HI of 2.0) and MW-24A (total HI of 82; selenium-specific HI of 0.65). TW-1 and MW-24A are within the hexavalent chromium groundwater plume. The third-highest estimated selenium-specific HI is 0.49 (at MW-21) and the estimated selenium-specific HIs are all at or below 0.26 for the remaining 10 wells where selenium was detected above background levels. At TW-1, selenium was detected in four of four samples; because there are too few data points to calculate a 95% UCL OTM, the EPC used in the well-specific risk assessment is the maximum detected concentration of 0.16 mg/L. As shown in the uncertainty analysis presented in Appendix G, use of the average rather than maximum concentrations results in estimated selenium-specific HIs of 1.4 at TW-1 and 0.25 at MW-24A. Selenium is not a material contributor to elevated noncancer hazard at MW-24A in the sensitivity analysis.

5.6 Silver

As shown in Table P-1, silver is a material contributor to elevated noncancer hazard at TW-1 (total HI of 100; silver-specific HI of 1.1), MW-10 (total HI of 75; silver-specific HI of 0.79), and OW-5S (total HI of 1.9; silver-specific HI of 0.83). TW-1 and MW-10 are within the hexavalent chromium groundwater plume. In each of the seven wells where silver was detected above background levels, it was detected above the laboratory reporting limit in only one or two samples, suggesting that the presence of silver, both across the site and at individual wells, is sporadic and inconsistent. Further, as silver was only detected in one or two samples from each well, the EPCs used in the well-specific risk assessment are maximum detected concentrations (because there are too few data points to calculate 95% UCLs OTM). This is overly conservative for a compound that has been detected in only 2.1 percent of all groundwater samples, as

the bulk of the evidence indicates that silver is not actually present in site groundwater above the laboratory reporting limit. This is further supported by the sensitivity analysis presented in Appendix G, in which estimated silver-specific HIs are based on average, rather than maximum, concentrations. In Appendix G, estimated silver-specific HIs are 0.34 at TW-1, 0.069 at MW-10, and 0.081 at OW-5S. Silver is not a material contributor to elevated noncancer hazard at any wells in the sensitivity analysis.

5.7 Thallium

As shown in Table P-1, thallium is a material contributor to elevated noncancer hazard at MW-12 (total HI of 58; thallium-specific HI of 1.1) and CW-3D (total HI of 3.2; thallium-specific HI of 1.2). Thallium was detected in only one of 17 and one of seven samples in MW-12 and CW-3D, respectively, and was not detected anywhere else at the site.

The fact that thallium was detected above the laboratory reporting limit in only two samples from the entire site suggests that the presence of thallium, both across the site and at individual wells, is sporadic and inconsistent. Further, as thallium was only detected in one sample from each of the two wells where it was detected, the EPCs used in the well-specific risk assessment are maximum detected concentrations (because there are too few data points to calculate 95% UCLs OTM). This is overly conservative for a compound that has been detected in only 0.53 percent of all groundwater samples, as the bulk of the evidence indicates that thallium is not actually present in site groundwater above the laboratory reporting limit.

It is worth noting that the two detections of thallium are geographically distinct from one another; MW-12 is located within the hexavalent chromium plume, and CW-3D is located outside the plume on the far west side of the site, in the IM injection area, approximately 2,800 feet to the northwest.

5.8 Fluoride

As shown in Table P-1, fluoride is a material contributor to elevated noncancer hazard at 5 wells: MW-1 (total HI of 9.9; fluoride-specific HI of 8.5), MW-6 (total HI of 9.2, fluoride-specific HI of 9.2), MW-10 (total HI of 75, fluoride-specific HI of 26), MW-33-40 (total HI of 9.5, fluoride-specific HI of 9.4), and CW-2D (total HI of 6.7, fluoride-specific HI of 4.7). MW-10 is the only well in this list within the hexavalent chromium groundwater plume. It is notable that background concentrations for fluoride exceed the noncancer hazard threshold of 1.0. Specifically, the background upper tolerance limit

(UTL) for fluoride of 7.12 mg/L corresponds to a noncancer hazard of 7.6, exceeding the threshold of 1.0. The background mean concentration of fluoride is 1.4 mg/L, which corresponds to an HI of 1.5. In sum, for a compound like fluoride, where the background concentrations exceed a risk-based threshold, it is most common to focus on understanding and identifying those wells where the representative exposure concentration could be greater than background. Based on a comparison of the well-specific EPCs to the background UTL of 7.12 mg/L, wells MW-1, MW-6, MW-10, and MW-33-40 all have representative EPCs that exceed the background UTL (with EPCs of 8 mg/L, 8.6 mg/L, 25 mg/L, and 8.8 mg/L, respectively). Similarly, based on a comparison of the average concentration of fluoride at each well to the average background fluoride concentration of 1.4 mg/L, wells MW-1, MW-6, MW-10, MW-30-44, and CW-2D all exceed the average background fluoride concentration (with average wells concentrations of 2.1 mg/L, 7.9 mg/L, 16.2 mg/L, 8.5 mg/L and 2.9 mg/L, respectively).

5.9 Lead

As shown in Table P-2, lead is present in concentrations above the CAL for lead at seven wells: MW-20-100 (EPC to CAL ratio of 1.1), MW-20-130 (EPC to CAL ratio of 2.8), MW-22 (EPC to CAL ratio of 5.1), MW-23 (EPC to CAL ratio of 1.8), MW-27-20 (EPC to CAL ratio of 1.6), MW-30-30 (EPC to CAL ratio of 4.9), and MW-31-60 (EPC to CAL ratio of 1.4). Of these wells, MW-20-100, MW-20-130, and MW-31-60 are within the hexavalent chromium groundwater plume. As presented in Appendix G, use of average rather than maximum concentrations results in exceedances of the CAL at only two wells, MW-22 (EPC to CAL ratio of 1.1) and MW-30-30 (EPC to CAL ratio of 2.5) both located outside the hexavalent chromium groundwater plume.

5.10 Molybdenum

As shown in Table P-1, molybdenum is a material contributor to elevated noncancer hazard at 17 wells, including 12 wells inside the hexavalent chromium plume: MW-10 (total HI of 75; molybdenum-specific HI of 2.1), MW-20-130 (total HI of 190; molybdenum-specific HI of 0.62), MW-24B (total HI of 110; molybdenum-specific HI of 0.84), MW-26 (total HI of 82; molybdenum-specific HI of 0.55), MW-38S (total HI of 20; molybdenum-specific HI of 0.82), MW-38D (total HI of 6.3; molybdenum-specific HI of 1.0), MW-44-115 (total HI of 30; molybdenum-specific HI of 1.1), MW-44-125 (total HI of 10; molybdenum-specific HI of 1.6), MW-46-175 (total HI of 6.3; molybdenum-specific HI of 2.5), and PGE-7 (total HI of 120; molybdenum-specific HI of 0.72); and seven wells outside the hexavalent chromium plume: MW-1 (total HI of 9.9; molybdenum-

specific HI of 1.0), MW-5 (total HI of 2.3; molybdenum-specific HI of 1.2), MW-21 (total HI of 1.4; molybdenum-specific HI of 0.67), MW-22 (total HI of 4.6; molybdenum-specific HI of 0.72), MW-30-30 (total HI of 5.0; molybdenum-specific HI of 1.3), OW-5M (total HI of 7.1; molybdenum-specific HI of 0.41), and PGE-8 (total HI of 1.1; molybdenum-specific HI of 1.0). Those wells where the molybdenum-specific HI exceeds 1.0 or where molybdenum contributes materially to cumulative hazard are distributed across the site.

In the sensitivity analysis presented in Appendix G, molybdenum is a material contributor at 14 wells. In the sensitivity analysis, the set of wells where molybdenum is a material contributor changes; molybdenum is a material contributor at MW-12, CW-2D, and CW-3D and is not a material contributor at MW-1, MW-21, MW-26, MW-30-30, MW-44-115, or PGE-8. The average molybdenum-specific HI at these 17 wells decreases slightly in the sensitivity analysis, from 1.1 to 1.0.

5.11 Nitrate as Nitrogen

As shown in Table P-1, nitrate as nitrogen is a material contributor to elevated noncancer hazard at eight wells, including five wells inside the hexavalent chromium plume: MW-9 (total HI of 8.7; nitrate-specific HI of 0.91), MW-10 (total HI of 75; nitrate-specific HI of 0.65), MW-24A (total HI of 82; nitrate-specific HI of 0.74), MW-51 (total HI of 100; nitrate-specific HI of 0.57), and PT-8M (total HI of 87; nitrate-specific HI of 1.3); and two wells outside the hexavalent chromium plume: MW-5 (total HI of 2.3; nitrate-specific HI of 0.76) and Park Moabi-4 (total HI of 1.2; nitrate-specific HI of 1.0).

In the sensitivity analysis presented in Appendix G, nitrate as nitrogen is a material contributor to elevated noncancer hazard at only three wells. Two of these wells (MW-51 and PT-8M) have only one sample for nitrate as nitrogen and consequently the mean and maximum concentrations are identical.

5.12 Vanadium

As shown in Table P-1, vanadium is a material contributor to elevated noncancer hazard at 17 wells, including five wells inside the hexavalent chromium plume: MW-10 (total HI of 75; vanadium-specific HI of 0.54), MW-12 (total HI of 58; vanadium-specific HI of 0.75), MW-20-70 (total HI of 210; vanadium-specific HI of 0.53), MW-20-130 (total HI of 190; vanadium-specific HI of 0.93), and MW-31-60 (total HI of 85; vanadium-specific HI of 1.1); and 12 wells outside the hexavalent chromium plume: MW-22 (total HI of 4.6; vanadium-specific HI of 1.6), MW-30-30 (total HI of 5.0; vanadium-specific HI

of 1.8), MW-34-55 (total HI of 7.6; vanadium-specific HI of 2.7), OW-1D (total HI 1.2; vanadium-specific HI of 0.69), OW-5M (total HI of 7.1; vanadium-specific HI of 0.56), OW-5D (total HI of 1.4; vanadium-specific HI of 0.66), CW-1D (total HI of 1.4; vanadium-specific HI of 0.82), CW-2M (total HI of 1.2; vanadium-specific HI of 1.1), CW-2D (total HI of 6.7; vanadium-specific HI of 1.1), CW-3M (total HI of 1.5; vanadium-specific HI of 0.90), CW-3D (total HI of 3.2; vanadium-specific HI of 1.1), and CW-4D (total HI of 1.6; vanadium-specific HI of 1.0). These 17 wells are distributed across the site, including within the IM No. 3 injection well field area, the floodplain area, and within the general footprint of the hexavalent chromium plume.

In the sensitivity analysis presented in Appendix G, when vanadium EPCs are based on mean concentrations instead of maximum concentrations, the average vanadium-specific HI at these 17 wells is 0.58. However, as presented in Table P-1, in the sensitivity analysis vanadium is a material contributor to elevated noncancer hazard in only nine of these wells, with an average vanadium-specific HI of 0.87.

5.13 Antimony

As shown in Table P-1, antimony is a material contributor to elevated noncancer hazard at seven wells, including five wells inside the hexavalent chromium plume: MW-12 (total HI of 58; antimony-specific HI of 3.4), MW-20-70 (total HI of 210; antimony-specific HI of 1.4), MW-20-100 (total HI of 170; antimony-specific HI of 6.9), TW-2S (total HI of 130; antimony-specific HI of 25), and TW-2D (total HI of 140; antimony-specific HI of 25); and two wells outside the hexavalent chromium plume: MW-34-55 (total HI of 7.6; antimony-specific HI of 4.2) and OW-5M (total HI of 7.1; antimony-specific HI of 1.8).

At each of these locations, antimony was detected in only one or two groundwater samples, suggesting that the presence of antimony, both across the site and at individual wells, is sporadic and inconsistent. Because antimony was only detected in one or two samples at each of these wells, the EPCs used in the well-specific risk assessment are maximum detected concentrations (because there are too few data points to calculate 95% UCLs OTM). This is very conservative for a compound that has been detected in only 2.3 percent of all groundwater samples, as the bulk of the evidence indicates that antimony is not actually present in site groundwater above the laboratory reporting limit. This is further supported by the sensitivity analysis presented in Appendix G, in which estimated antimony-specific HIs are based on average, rather than maximum, concentrations. When antimony EPCs are based on average concentrations at each well, the antimony-specific HI exceeds the threshold value of 1.0 at only three wells: MW-20-100, TW-2S, and TW-2D.

5.14 Arsenic

As shown in Table P-1, arsenic is a material contributor to elevated noncancer hazard at three wells: MW-24A (total HI of 82; arsenic-specific HI of 7.2), MW-12 (total HI of 58; arsenic-specific HI of 23), and MW-43-25 (total HI of 5.3; arsenic-specific HI of 5.2). MW-12 and MW-24A are located within the hexavalent chromium plume. Arsenic was detected in 17 of 17 samples from MW-12; therefore, the EPC used in the well-specific risk assessment at this location is the calculated 95% UCL OTM. At wells MW-24A and MW-43-25, arsenic was detected in three of four samples and in three of three samples, respectively; therefore, the EPCs used in the well-specific risk assessment at these locations are maximum detected concentrations. Average arsenic concentrations at MW-24A and MW-43-35 are still above the average background concentration. However, it is notable that the maximum detected concentrations at MW-24A (0.034 mg/L) and MW-43-25 (0.0244 mg/L) are only marginally greater than the background UTL of 0.0243 mg/L. Further, the three wells where arsenic was detected above background levels are not geographically near one another; therefore, the elevated concentrations at MW-12 and the marginally elevated concentrations at MW-43-25 and MW-24A do not appear to collectively represent a reasonable future exposure area.

As was described in the RFI/RI Volume 2 (CH2M HILL, 2009), there is little evidence that correlates the elevated arsenic concentrations with SWMU 1/AOC 1 or SWMU 2. The arsenic concentration measured at MW-24A increased from 0.0054 mg/L in July 2007 to 0.034 mg/L in May 2008, above the UTL of 0.0243 mg/L. This increase in arsenic concentration is an anticipated effect of the in-situ pilot study being conducted on the MW-24 bench. Arsenic concentrations showed increases to similar levels in the nearby in-situ pilot wells (ARCADIS, 2008).

As was stated in the RFI/RI Volume 2 (CH2M HILL, 2009), whatever the source of arsenic, elevated concentrations in groundwater are not widespread (arsenic was detected above background levels in only 2.7 percent of wells), and do not appear to be associated with SWMU 1/AOC 1 or SWMU 2. In fact, the 95% UCL OTM concentration of arsenic calculated for those wells located within the hexavalent chromium plume is 0.023 mg/L, which is approximately equal to the background UTL.

In sum, the concentrations of arsenic measured at MW-12 are clearly elevated above the background UTL, and the estimated arsenic-specific HI at this well of 23 is well above the threshold of 1.0. Concentrations of arsenic measured in MW-24A and MW-43-25 are only slightly greater than the background UTL, however, and arsenic

concentrations at MW-24A appear to have increased to a level slightly above background as a result of the in-situ pilot study.

5.15 Hexavalent Chromium

As shown in Table P-1, hexavalent chromium is a material contributor to elevated noncancer hazard at 65 groundwater wells, 56 of which are inside the hexavalent chromium groundwater plume. The wells with the largest hexavalent chromium-specific HIs are PT-9D (total HI of 340; hexavalent chromium-specific HI of 340), MW-50-200 (total HI of 240; hexavalent chromium-specific HI of 240), MW-20-70 (total HI of 210; hexavalent chromium-specific HI of 210), MW-20-130 (total HI of 190; hexavalent chromium-specific HI of 180), MW-39-100 (total HI of 170; hexavalent chromium-specific HI of 170), MW-20-100 (total HI of 160; hexavalent chromium-specific HI of 160), PT-7D (total HI of 160; hexavalent chromium-specific HI of 160), PT-8D (total HI of 140; hexavalent chromium-specific HI of 140), PT-5D (total HI of 130; hexavalent chromium-specific HI of 130), and PT-4D (total HI of 130; hexavalent chromium-specific HI of 130). All of these wells are located inside the identified hexavalent chromium groundwater plume.

The set of wells at which hexavalent chromium contributes materially to elevated noncancer hazard changes only slightly in the sensitivity analysis presented in Appendix G. MW-24BR, with only one hexavalent chromium detection, is no longer a material contributor to elevated noncancer hazard when the EPC is based on the mean rather than maximum concentration.

Table P-1. Well-by-Well Hazard Characterization Summary

Location	In/Out of Plume	No. Samples	No. Detections	No. of NDs with the Detection Limit above the RBC	EPC Method	Primary Analysis of the GWRA		Sensitivity Analysis	
						Cumulative HI	Chemical-Specific HI	Cumulative HI	Chemical-Specific HI

Notes:

(1) In the primary analysis of the GWRA, estimated EPCs are based on maximum detected concentrations when 95% (UCLs) OTM cannot be reliably calculated with ProUCL 4.0 because there are less than eight samples or less than five detections In the dataset. The sensitivity analysis bases EPCs on mean concentrations when 95%UCLs of the mean cannot be reliably calculated with ProUCL 4.0.

(2) Wells shown are those determined to be material contributors to elevated noncancer hazard based on the methodologies In Appendix P.

(3) NA = Not applicable. Either:

(a) This well was not determined to be a material contributor to elevated noncancer hazard In this analysis.

(b) There are no non-detect results at this well.

EPC = exposure point concentration
HI = hazard Index
ND = not detected
OTM = of the mean
RBC = risk-based concentration
UCL = upper confidence limit
GWRA = groundwater risk assessment

Table P-2. Well-by-Well Lead Summary

Location	In/Out of Plume	No. Samples	No. Detections	EPC Method	Primary Analysis of the GWRA		Sensitivity Analysis	
					Lead EPC (mg/L)	Ratio of EPC to CAL	Lead EPC (mg/L)	Ratio of EPC to CAL
MW-20-100	In	4	2	Max/mean	1.7E-02	1.1	5.7E-03	NA
MW-20-130	In	15	1	Max/mean	4.2E-02	2.8	3.8E-03	NA
MW-31-60	In	5	1	Max/mean	2.1E-02	1.4	5.5E-03	NA

MW-23	Out	6	2	Max/mean	2.7E-02	1.8	6.4E-03	NA
MW-27-20	Out	3	3	Max/mean	2.4E-02	1.6	9.7E-03	NA
MW-30-30	Out	4	2	Max/mean	7.3E-02	4.9	3.8E-02	2.5
Average						2.7		1.8

Notes:

(1) In the primary analysis of the GWRA, estimated EPCs are based on maximum detected concentrations when 95% UCLs OTM cannot be reliably calculated with ProUCL 4.0 because there are less than eight samples or less than five detections In the dataset. The sensitivity analysis bases EPCs on mean concentrations when 95% UCLs of the mean cannot be reliably calculated with ProUCL 4.0.

(2) CAL for lead provided In CCR Title 22, Division 4, Chapter 17.5, Article 3, Section 64678.

CAL = California Action Level
CCR = California Code of Regulations
EPC = exposure point concentration
mg/L = milligram(s) per liter
NA = not applicable, this well was not determined to have a lead EPC above the CAL In this analysis
OTM = of the mean
UCL = upper confidence limit

Risk-Based Concentrations of Constituents of Potential Concern

1. Introduction

Risk-based concentrations (RBCs) are calculated for constituents of potential concern (COPCs) in the groundwater human health and ecological risk assessment and presented in this appendix. As described in the Risk Assessment Work Plan (RAWP; ARCADIS, 2008), an RBC for groundwater is the concentration of a chemical in groundwater that corresponds to a threshold level of cancer risk or noncancer hazard under a set of assumed exposure assumptions. RBCs are considered health protective and are used as human health screening criteria for discussion purposes at various junctures in the risk assessment.

When applicable or relevant and appropriate requirements are not available, RBCs for groundwater are calculated using the same information regarding chemical-specific toxicities, physicochemical properties, and receptor-specific exposure conditions that were used in the baseline estimate of risks/hazard. Carcinogenic RBCs are calculated based on a target cancer risk, and likewise noncarcinogenic RBCs are calculated based on a target noncancer hazard index (HI). The target cancer risk level is the "acceptable" cancer risk level as defined and endorsed by relevant state and federal agencies. The National Contingency Plan (NCP) is cited by the U.S. Environmental Protection Agency (USEPA, 1990) as the basis for defining acceptable incremental cancer risk levels. According to the NCP, lifetime incremental cancer risk levels posed by a site should be within the risk range of one in a million (1×10^{-6}) to 100 in a million (1×10^{-4}). Thus, USEPA and the California Environmental Protection Agency typically consider the 1×10^{-6} risk level to be an insignificant risk, and consider a calculated excess cancer risk between 1×10^{-6} and 1×10^{-4} to be within the acceptable risk range. For noncancer health hazards, an HI of unity (1.0) is identified as the target level of concern. Chemical exposures that yield HIs of less than 1.0 are not expected to result in adverse noncancer health effects (USEPA, 1989). Therefore, as specified in the RAWP (ARCADIS, 2008), for purposes of developing RBCs, the target cancer risk level is 1×10^{-6}, and the target noncancer hazard quotient is 1.0.

The most conservative receptors are used for carcinogenic (a future hypothetical age-adjusted groundwater user) and noncarcinogenic (a future hypothetical child groundwater user) RBCs to obtain a health protective RBC applicable to all populations. As presented in Equation 1 of Section 7.1.1 and Equation 3 of Section 7.1.2 of the main text, risks and hazards are calculated as the product of a toxicity parameter and the chronic daily intake, which is defined in Table 5-3. Consistent with standard risk assessment protocols, the RBC is calculated by re-arranging these equations and

solving for the concentration in water (C_w) term; in this manner, C_w is the equivalent of the RBC, as indicated in the equations presented in Table Q-1.

2. Results

Carcinogenic and noncarcinogenic RBCs are calculated for COPCs in groundwater and are presented in Table Q-2. These concentrations represent health-protective screening levels that are used at various junctures in the groundwater risk assessment report for discussion purposes. For comparison purposes, maximum contaminant levels (MCLs) are also shown for chemicals, when available.

Appendix R

Contributions of SWMU 1/AOC 1 Constituents of Potential Concern to Elevated Cumulative Noncancer Hazard

1. Introduction

Based on information in the RFI/RI Volume 2 (CH2M HILL, 2009), only selenium, nitrate as nitrogen, molybdenum, and hexavalent chromium were carried forward as constituents of potential concern (COPCs) associated with groundwater at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1. Cumulative cancer risks and noncancer hazard indices (HIs), discussed in Section 7.3 of the main text, are estimated for all COPCs identified in Section 4 of this groundwater risk assessment. The final list of constituents to be carried forward to the Corrective Measures Study/Feasibility Study, however, will consist of those constituents that could potentially pose an unacceptable risk/hazard to future hypothetical groundwater users and that are considered to be associated with SWMU 1/AOC 1.

The purpose of this appendix is to present an analysis of the contributions of the COPCs to estimated potential cumulative noncancer hazard at individual wells, considering only the COPCs that are potentially associated with SWMU 1/AOC 1: selenium, nitrate as nitrogen, molybdenum, and hexavalent chromium. As part of this evaluation, a sensitivity analysis is conducted to evaluate the impact of using mean concentrations instead of maximum concentrations for constituents with inadequate datasets to calculate a 95% upper confidence limit (UCL) of the mean (OTM).

Based on the methods presented in Appendix P, a constituent with an HI of less than 1.0 can be determined to be a material contributor to cumulative hazard at a particular well when the sum of the constituent-specific HI, and the HIs of all other constituents with lesser HIs, is above 1.0. Accordingly, the determination of the individual wells in which a particular constituent is materially contributing to cumulative noncancer hazard is not independent of contributions by other constituents. Therefore, only selenium, nitrate as nitrogen, molybdenum, and hexavalent chromium will be included in the evaluation of the estimated potential cumulative noncancer hazard at individual wells, as these are the only constituents that are potentially associated with SWMU 1/AOC 1, as defined in the RFI/RI Volume 2 (CH2M HILL, 2009). Essentially, the approach used in Appendix P will be repeated in this appendix considering only selenium, nitrate as nitrogen, molybdenum, and hexavalent chromium.

Then, the results obtained using only these four constituents will be further refined following the methods presented in Appendix G, where the evaluation is repeated using mean concentrations instead of maximum concentrations for constituents with inadequate datasets to calculate a 95% UCL OTM.

2. Primary Analysis

As was done in Appendix P, constituents potentially associated with SWMU 1/AOC 1 are evaluated to determine the material contributors to cumulative hazard at all wells where the sum of the constituent-specific HIs is estimated to be above 1.0. In order to reliably calculate 95% UCLs OTM, a constituent dataset at an individual well must have at least five detections and eight samples. For this primary analysis, maximum concentrations are used as the exposure point concentrations (EPCs) for constituents not meeting these minimum sample size requirements.

The estimated constituent-specific HIs associated with selenium, nitrate as nitrogen, molybdenum, and hexavalent chromium are ranked from lowest to highest at each individual well. A running cumulative (multi-constituent) HI is then calculated for each constituent, starting with the lowest noncancer hazard. The constituent that pushes the cumulative estimated hazard above the threshold value of 1.0, and all constituents with greater HIs, are identified as material contributors to cumulative estimated noncancer hazard at that well. See Appendix P for more detail on the determination of material contributors to cumulative estimated noncancer hazard at individual wells. The results of this analysis are presented in Table R-1 and summarized below:

- Selenium is determined to be a material contributor to cumulative estimated noncancer hazard at 2 of 76 (2.6 percent) wells in which selenium was sampled.

- Nitrate as nitrogen is determined to be a material contributor to cumulative estimated noncancer hazard at 5 of 165 (3.0 percent) wells in which nitrate as nitrogen was sampled.

- Molybdenum is determined to be a material contributor to cumulative estimated noncancer hazard at 13 of 83 (16 percent) wells in which molybdenum was sampled.

- Hexavalent chromium is determined to be a material contributor to cumulative estimated noncancer hazard at 64 of 167 (38 percent) wells in which hexavalent chromium was sampled.

As compared to the primary analysis presented in Appendix P that considers all constituents (i.e., including those thought not to be associated with SWMU 1/AOC 1), selenium is a material contributor at the same number of wells, nitrate as nitrogen at

three fewer wells, molybdenum at seven fewer wells, and hexavalent chromium at one fewer wells.

3. Sensitivity Analysis

In order to calculate 95% UCLs OTM, a constituent dataset at an individual well must have at least five detections and eight samples. In the sensitivity analysis, mean concentrations instead of maximum concentrations are used as EPCs for constituents not meeting these minimum sample size requirements. The determination of material contributors to cumulative noncancer hazard in the sensitivity analysis is identical to the primary analysis. The results of this analysis are presented in Table R-1 and summarized below:

- Selenium is determined to be a material contributor to cumulative estimated noncancer hazard at 1 of 76 (1.3 percent) wells in which selenium was sampled.

- Nitrate as nitrogen is determined to be a material contributor to cumulative estimated noncancer hazard at 2 of 76 (2.6) percent wells in which nitrate as nitrogen was sampled.

- Molybdenum is determined to be a material contributor to cumulative estimated noncancer hazard at 9 of 83 (11 percent) wells in which molybdenum was sampled.

- Hexavalent chromium is determined to be a material contributor to cumulative estimated noncancer hazard at 63 of 167 (38 percent) wells in which hexavalent chromium was sampled.

As compared to the sensitivity analysis in Appendix P that considers all constituents (i.e., including those thought not to be site-related), selenium is a material contributor at the same number of wells, nitrate as nitrogen at one fewer well, molybdenum at five fewer wells, and hexavalent chromium at one fewer well.

Table R-1. Well-by-Well Hazard Characterization Summary

Location	In/Out of Plume	No. Samples	No. Detections	No. of NDs with the Detection Limit above the RBC	EPC Method	Primary Analysis of the GWRA		Sensitivity Analysis	
						Cumulative HI	Chemical-Specific HI	Cumulative HI	Chemical-Specific HI
TW-1	In	3	3	NA	Max/mean	1.0E+02	1.0E+02	9.1E+01	8.9E+01
TW-2S	In	10	10	NA	95%UCLOTM	1.1E+02	1.1E+02	1.1E+02	1.1E+02
TW-2D	In	12	12	NA	95%UCLOTM	1.2E+02	1.2E+02	1.2E+02	1.2E+02
TW-3D	In	22	22	NA	95%UCLOTM	6.1E+01	6.1E+01	6.1E+01	6.1E+01
Average							6.7E+01		6.6E+01

Notes:

(1) In the primary analysis of the GWRA, estimated EPCs are based on maximum detected concentrations when 95% (UCLs) OTM cannot be reliably calculated with ProUCL 4.0 because there are less than eight samples or less than five detections In the dataset. The sensitivity analysis bases EPCs on mean concentrations when 95%UCLs of the mean cannot be reliably calculated with ProUCL 4.0.

(2) Wells shown are those determined to be material contributors to elevated noncancer hazard based on the methodologies In Appendix R.

(3) NA = Not applicable. Either:

(a) This well was not determined to be a material contributor to elevated noncancer hazard In this analysis.

(b) There are no non-detect results at this well.

EPC = exposure point concentration
HI = hazard Index
ND = not detected
OTM = of the mean
RBC = risk-based concentration
UCL = upper confidence limit
GWRA = groundwater risk assessment

Appendix S

Resolution of Comments from Agencies and Stakeholders on the Draft GWRA for Topock

1. Introduction

The purpose of this appendix to the final groundwater risk assessment report (GWRA) is to document the resolution of comments on the draft GWRA. The final GWRA incorporates the resolution of comments that is documented in this appendix. It should be noted that some of the responses to comments issued by Pacific Gas and Electric Company (PG&E) on May 29, 2009, have been modified somewhat by subsequent dialogue and comment resolution. As such, this appendix documents the final resolution. Rather than edit and reissue the response to comments document (originally submitted on 5/29/09), this appendix was prepared to document the interactions and resolutions represented by ongoing dialogue between PG&E and the agencies. This approach provides a clearer way to also incorporate additional comments provided by the agencies and stakeholders over the time period from June through September 2009. Table S-1 summarizes the communications between PG&E representatives and agency representatives to resolve questions and comments on the draft GWRA.

In Table S-1, communications are presented chronologically and assigned an item number. The item numbers correspond to the attachments to this appendix. The attachments are hard copies of written communications in the form of memos, letters, documents, and email. This list and the attachments provide a record of the resolution of the comments provided by agencies and stakeholders. In cases where email is used to transmit key information, and there are also documents attached to the email, those documents are given sub-item numbers. For example, Item 10 is an email with two documents attached, Items 10a and 10b. In cases where the communication was a phone call, and call summary notes were not exchanged, there is no corresponding attachment. This is the case for the following items on Table S-1: 4, 14, 15, 16, 17, and 20.

All attachments have been previously submitted to the agencies except Item 25, the response to Fort Mojave Indian Tribe comments on the draft GWRA response to comments. The PG&E responses to those comments are provided here.

Table

Table S-1. Chronology of Response to Comments for Draft GWRA

Item No.	Document/ Meeting	Date Submitted	From	To	Notes
1	PG&E submits GWRA RTC	5/29/09	PG&E	DTSC USDOI	RTC included substantive data to address the two additional pathways for ecological concerns identified by DTSC in 3/30 letter.
2	DTSC comments on GWRA RTC	6/25/09	DTSC	PG&E	Mike Eichelberger (DTSC) accepted RTC (requests information be included in Final GWRA) and introduced additional concern about desert bighorn sheep ingesting nitrate taken up by plants from groundwater. Memo dated 6/17/09.
3	DTSC comments on GWRA RTC	6/29/09	DTSC	PG&E	Shukla Roy-Semmen (DTSC) accepted RTCs with some provisions. Memo dated 6/15/09.
4	Call with DTSC to discuss comment memos and resolution of issues	7/2/09	PG&E	DTSC	Call with PG&E and DTSC representatives (Aaron Yue and Karen Baker) to discuss DTSC comments on RTCs, specifically focusing on the COCs to be carried forward to the CMS/FS. No call notes were exchanged, so there is no attachment for this item.
5	Email – notes summarizing agreed resolution to issues discussed 7/2/09	7/7/09	PG&E	DTSC	Summary of discussions and agreements with DTSC regarding their RTC comments.
6	Email from Aaron Yue providing edits to summary of 7/2 call notes	7/8/09	DTSC	PG&E	Aaron Yue provided suggested edits to the summary of 7/2/09 call notes.
7	Email response from Yvonne Meeks to Aaron Yue's email on 7/2/09 call notes	7/13/09	PG&E	DTSC USDOI	Yvonne Meeks acknowledged receipt of Aaron Yue's comments and that USDOI need not respond to the discussion of DTSC comments.
8	Email from Yvonne Meeks with path forward on issues from 7/2/09 call	7/16/09	PG&E	DTSC	Summary follow up of outstanding issues from 7/2/09 call and path forward suggestions.
9	Comment letters from DTSC and FMIT on PG&E's GWRA RTCs	7/16/09	DTSC FMIT	PG&E	Final comments on RTCs from DTSC (Shukla Roy-Semmen and Mike Eichelberger) [note; the attached DTSC documents were the same comment memos dated 6/17/09 and 6/15/09, cited in Items 2 and 3]; Letter by Mike Sullivan dated 7/10/09 with comments on GWRA on behalf of FMIT (document 9a), and letter dated 7/13/09 from FMIT Chairman Timothy Williams to DTSC's Maziar Movassaghi (Item 9b).
10	Email from PG&E for path forward on resolving DTSC response comments on GWRA RTC	7/28/09	PG&E	DTSC	Provided suggestions on resolving outstanding issues for the GWRA, including supplemental eco information on desert bighorn sheep distribution (Item 10a) and nitrate concentrations in GW (Item 10a) and references (Item 10b).
11	Final comments from USDOI on GWRA RTCs, and USDOI response to FMIT	8/3/09	USDOI	PG&E	USDOI provided comment letter on RTCs for the GWRA (Item 11b). Letter from USDOI response letter to Taylor, FMIT dated 7-31-09 also included (Item 11a).
12	Email - DTSC response to PG&E's 7/28/09 email on suggested path forward to resolve GWRA RTCs.	8/3/09	DTSC	PG&E	Aaron Yue provided additional information on DTSC direction for RTC resolution, including Mike Eichelberger's requests regarding specific attention to Curt Russell's information on observations of desert bighorn sheep outside the area shown in the CNDDB.
13	Email - DTSC additional response to PG&E's 7/28/09 suggested path forward	8/6/09	DTSC	PG&E	Aaron Yue provided additional input on path forward following 8/5/09 RCRA/CERCLA meeting discussion and further internal DTSC discussion.
14	Call with DTSC re: nitrate	8/12/09	PG&E	DTSC	Discussion with Mike Eichelberger on desert bighorn sheep and potential exposure to nitrate in plants. No call notes were exchanged, so there is no attachment for this item.
15	Call with USDOI re: seeps	8/18/09	PG&E	USDOI	Call with Carrie Marr to discuss potential eco exposure to water in seeps. No call notes were exchanged, so there is no attachment for this item..
16	Call with USDOI re: comments on human health RTCs	8/20/09	PG&E	USDOI	Call with Dennis Smith to resolve outstanding USDOI comments on human health evaluation in GWRA and RTCs. No call notes were exchanged, so there is no attachment for this item.
17	Call with USDOI re: seeps	8/24/09	PG&E	USDOI	Call between Yvonne Meeks and Pam Innis to discuss seeps in canyon wall of East Ravine. No call notes were exchanged, so there is no attachment for this item.
18	Email response to outstanding USDOI comments on GWRA RTCs	8/25/09	PG&E	USDOI	Email to respond to USDOI's 8/3/09 comments on the GWRA RTCs.
19	PG&E submits draft eco Appendix "X" [1] to Mike Eichelberger for advance review.	8/28/09	PG&E	DTSC	Appendix "X"[1] contains additional information to address DTSC's comments on the three issues raised after development of RAWP: • Risk to deep-rooted plants to contaminated GW • Risk to shallow-rooted plants to contaminated GW • Risk to desert bighorn sheep from nitrate exposure
20	Call with DTSC to discuss DTSC's comments on Appendix "X" [1]	9/8/09	PG&E	DTSC	Call with Mike Eichelberger, who concurred with approach to nitrate/bighorn sheep assessment. Requested additional detail supporting no risk to shallow-rooted plants. Made additional request for evaluation of risk to upper trophic levels via plant uptake and subsequent eco consumption. No call notes were exchanged, so there is no attachment for this item.
21	Email from Pam Innis to PG&E	9/8/09	USDOI	PG&E	Pam Innis confirmed USDOI acceptance of PG&E's suggested comment resolution sent via email 8/25/09.

Table S-1. Chronology of Response to Comments for Draft GWRA

Item No.	Document/ Meeting	Date Submitted	From	To	Notes
22	DTSC final comments on Appendix "X"[1]	9/16/09	DTSC	PG&E	Mike Eichelberger submitted final comments on draft Appendix "X" in memo dated 7/10/09.
23	Email from PG&E's suggested path forward for Appendix "X" [1] comments	9/17/09	PG&E	DTSC	Provided path forward to resolve comments from Mike Eichelberger on draft Appendix "X." [1]
24	Email from DTSC re: Appendix "X" [1]	9/21/09	DTSC	PG&E	Aaron Yue sent concurrence with acceptance of COPECs and responses for Appendix "X." [1]
25	Emails between Yvonne Meeks and Pam Innis re: East Ravine groundwater	10/5/09 10/7/09	PG&E USDOI	USDOI PG&E	Yvonne Meeks suggested an alternative to previous USDOI direction (see item 11) to prepare a screening level risk assessment for East Ravine groundwater as an appendix to the CMS/FS. Pam Innis agreed that a separate document would be acceptable, since East Ravine groundwater data collection may not be completed in time for the CMS/FS.
26	Response to FMIT comments on RTCs	10/12/09	PG&E	DTSC FMIT	Responses to comments from FMIT on GWRA RTCs are included in Appendix S of final GWRA.
27	DTSC final comments on October 2009 GWRA RLSO	10/28/09	DTSC	PG&E	Aaron Yue submitted final comments on the October 2009 GWRA. RLSO
28	USDOI/USFWS comments on October 2009 GWRA RLSO	11/5/09	USDOI USFWS	PG&E	Carrie Marr submitted final comments on the October 2009 GWRA RLSO.
29	Email from PG&E re: USDOI/USFWS comments on October 2009 GWRA RLSO	11/9/09	PG&E	USDOI USFWS DTSC	Response to USDOI/USFWS final comments on the October 2009 GWRA RLSO. PG&E responded to the general comment, which required no change to the GWRA. PG&E will make the changes suggested in Specific Comments 1 through 8 in their entirety as modified in the response email.
30	Email from USDOI/USFWS re: PG&E response to USDOI/USFWS comments on October 2009 GWRA RLSO	11/10/09	USDOI USFWS	PG&E	Pam Innis responded that PG&Es responses were acceptable to USDOI/USFWS final comments on the October 2009 GWRA RLSO.
31	Email from DTSC re: PG&E response to USDOI/USFWS comments on October 2009 GWRA RLSO	11/10/09	DTSC	USDOI USFWS PG&E	Aaron Yue responded that DTSC does not object to PG&Es proposed responses to USDOI/USFWS final comments on the October 2009 GWRA RLSO.

Notes:

(1) Appendix X discussed in this table and attached email communication became Appendix I when incorporated into the revised GWRA.

CERCLA/RCRA = Comprehensive Environmental Response, Compensation and Liability Act/ Resource Conservation and Recovery Act
CMS/FS = Corrective Measures Study/Feasibility Study
CNDDB = California Natural Diversity Database

Comment Number	Section/ Page	Comment	Response	Comment Category
FMIT GC1		Sequencing of Project Reports. The overall timing of the various deliverables for the Topock project is out of proper sequence according to Resource Conservation and Recovery Act (RCRA) and Comprehensive Environmental, Response, Cleanup, and Liability Act (CERCLA) guidance. The draft Corrective Measures Study/Feasibility Study (CMS/FS) report for chromium in groundwater was submitted on January 27, 2009. This was followed by the GWRA risk assessment (focus of this review). In practice, the GWRA is the basis for the CMS/FS. However, even the GWRA was delivered only a very short time after the finalization of the risk assessment work plan (RAWP) addendum was published. DTSC management should insist on an appropriate report delivery order and schedule for future deliverables. The ability of the Tribe to provide appropriate and meaningful comments on these documents would be helped by a proper delivery schedule.	Comment noted. Pacific Gas and Electric Company (PG&E) has followed scheduling of deliverables according to California Department of Toxic Substances Control (DTSC) and federal agency direction.	2
FMIT GC2		Description of Ecosystem. The report provides several broad statements regarding terrestrial wildlife. For example, the text states that terrestrial wildlife has 'low diversity' because the area is disturbed and the wildlife corridor is incomplete (pg 2-3, pp2), the BCW is 'relatively barren of vegetation' (page 2-3, pp3) and that only 'small patches of emergent vegetation exist along the banks of the Colorado River' (page 2-3, pp2). These text descriptions do not accurately reflect the ecosystem at and including the site. The Tribe's view is that the local desert ecosystem and plant/animal life are worthy of protection, especially when the cumulative land disturbance impacts of both groundwater and soil remediation activities are considered and when a less transitory view of animal and plant life usage is considered. Second, the area surrounding and adjacent to the remediation include areas designated as wildlife refuges, thereby showing that at least the federal government understands the nature of area's typical desert environment. Third, this text does not address any plants at the site that the Tribe considers important for ceremonial or medicine purposes. Both Mesquite and Creosote plants are related to Tribal activities at the site and are harvested for its sacred and Tribal uses of this area.	PG&E concurs that the local desert ecosystem is worthy of protection and is proposing the following text revisions to more clearly reflect that position. The following sentence will be inserted as the first sentence of paragraph 2 on page 2-3: "Upland areas of the APE include the Havasu National Wildlife Refuge, which was established to protect and conserve wildlife." The text on page 2-3 in paragraph 2 regarding terrestrial wildlife diversity will be replaced with "Terrestrial wildlife found at the site is characteristic of desert environments and is adapted to the interrelated conditions of drought, temperature extremes, and the sparse or unpredictable food supply of the desert habitats found at the site." The text on page 2-3 in paragraph 3 regarding the distribution of vegetation in Bat Cave Wash (BCW) will be replaced with "BCW consists of areas of unvegetated sand, gravel, and cobblestone substrate interspersed with widely spaced desert wash vegetation including mesquite and creosote." The text on page 2-3 paragraph 4 regarding small patches of emergent vegetation will be expanded to include "…such as common reed (*Phragmites communis*), cattails (*Typha* sp.), sedges (*Carex* sp.), and bulrush (*Scirpus* sp.),…" to focus and better define the discussion.	3
FMIT GC3		Description of Tribal Interests in Maze Area. There is only a single sentence that identifies the Topock area as having spiritual meaning to the Tribes. The Tribe reiterates its request that the following text be used in project documents to describe the relationship of the land with the tribal cultural and spiritual values. "The compressor station is located in a sparsely-populated, rural area, comprising a series of benches and terraces overlooking the Colorado River floodplain. The land surrounding and including the compressor station, including the benches and terraces on both sides of the river, the floodplain, the river itself, and the surrounding hills and mountains, comprises a cultural landscape that figures importantly in the traditional spiritual and cultural life of the Aha Makav or Fort Mojave Indian Tribe. One important component of this landscape, known as the Topock Maze, directly surrounds and includes the compressor station. The Maze is a complex of windrows raked in the desert pavement, running in several directions for many tens of meters. Although portions of this site have been disturbed by construction and unsympathetic land use (as have some other parts of the cultural landscape	This comment is similar to a comment received by FMIT on the *Revised Final RCRA Facility Investigation /Remedial Investigation Report Volume 2* (Revised Final RFI/RI Volume 2; CH2M HILL, February 2009). As previously indicated by DTSC in their October 21, 2008, letter to PG&E, "DTSC believes the statements currently in the Volume 2 RFI Report reflect the importance of the area to all Tribes. Additional clarifications and cultural significances of the area by specific Native American Tribes should be a topic of documentation for the up coming Environmental Impact Report." For consistency, the final GWRA will incorporate the same language regarding Tribal cultural and spiritual values as was used in the Revised Final RFI/RI Volume 2. Specifically, the following language will be added to the GWRA for consistency with the Revised Final RFI/RI Volume 2: "The compressor station is located in a sparsely-populated, rural area. The surrounding land lies within an area of significant cultural and sacred Tribal resources. Portions of the Topock Maze are located nearby. The maze is a geoglyph (ground marking) and is of importance to the local Native American community. The area is within the traditional territory of the Aha Makav or	3

Comment Number	Section/ Page	Comment	Response	Comment Category
		surrounding and including it), the Maze and its surroundings continue to play significant roles in the lives and cultural beliefs of the Fort Mojave Indian Tribe and other tribes along the Colorado River. The Fort Mojave Indian Tribe has expressed the opinion that whatever happens in the overall cultural landscape is of concern to the Tribe, which wishes to be consulted about all activities planned or proposed in the area." In addition, the text lists the current river recreational activities as sightseeing, bird watching, fishing, hunting, camping and canoeing (pg 2-5, pp5). Other activities Tribal members have observed include tubing, rafting, sunning, swimming and tours. However, there are also Tribal activities along the river shoreline that are related to the religious, cultural, and ceremonial activities (as opposed to public recreation). These activities are an integral and necessary component of Tribal culture and must therefore be considered by risk managers.	Mojave tribe. While the material remains of the past are important to these tribes, this area of traditional and spiritual use knows no boundaries for the Mojave." As indicated in the *Human Health and Ecological Risk Assessment Work Plan* and subsequent Addendum (RAWP; ARCADIS, 2008; 2009), a Tribal-use scenario will be included in the soil risk assessment considering input to be provided by the Tribes for their religious, cultural, and ceremonial activities. In accordance with the RAWP, the GWRA determined that the river has not been adversely impacted by site constituents of potential concern (COPCs). Therefore, Tribal activities along the river shoreline related to the religious, cultural, and ceremonial activities that include contact with the surface water are not adversely impacted by the site COPCs. Please note that we will expand the list of activities on pg 2-5 (paragraph 5) to include religious, cultural, and ceremonial activities and recreational activities, such as bird watching, fishing, canoeing, tubing, rafting, and swimming.	
FMIT GC4		Future Land Uses. There are future land-use issues in the GWRA that need to be clarified. First, DOI has requested that a stretch of the floodplain area along old Route 66 be evaluated for potential future scenario involving the development of housing and recreational areas (pg 2-6, pp5). This results in the risk assessment assumption of future residential use of groundwater produced from local wells. This proposed future land use scenario poses Tribal concerns, especially if such development were to occur in the vicinity of the Maze. In a separate letter, the Tribe will provide text that describes appropriate land uses for this area. Second, the future ownership of the IM land as well as potential repatriation of the Topock Compressor site to the Tribe is not mentioned. The potential for future control of these lands by the Tribe further increases the importance of current Tribal concerns regarding protecting the land as well as defining future land uses that should be evaluated in the GWRA.	The future land use discussion in the GWRA is based on assumptions regarding current and future land use, as provided by the agency and the landowner (USDOI, 2007), for lands outside the compressor station. As we have previously stated, we believe that the currently proposed land uses and receptors will provide the risk managers with the necessary information to make informed management decisions for the known and anticipated future land uses for all areas of the site. PG&E has not yet received the letter referred to in this comment, but understands that the FMIT will be submitting such a letter at some point in the future. Under the terms of the settlement of the Sacramento Superior Court Action No. 05CS00437, filed with the court on April 4, 2005, title to that property referred to generally as the IM3 property is expected to transfer to the FMIT. The property will be subject to a site-wide easement in favor of PG&E also on file with the Court as set out above and recorded in the official records of San Bernardino County. The allowed use of the IM3 property during remediation activities as required by DTSC and USDOI are set out in the settlement agreement and easement documents. Other than use for remediation purposes, the IM3 property is subject to a recorded Covenant and Environmental Restriction on Property, recorded in the official records of San Bernardino County that sets out possible future use of ground water. For groundwater, residential potable use of groundwater is typically considered to be the upper bound (i.e., most conservative) use pattern for groundwater. The default exposure scenario represented in the GWRA assumes that groundwater is the only source of potable water and it is used for a lifetime. The GWRA evaluates this intense contact with groundwater on a well-by-well basis. It is likely that consideration of concentrations that are health protective for unrestricted potable drinking water use for each well are also health protective for other or additional Tribal activities that may include direct contact with groundwater.	3

			As to the future use of the compressor station property, it will remain in its current use and potentially in support of remediation activities until PG&E determines that it is no longer needed for utility or remediation purposes. This condition is not anticipated to occur in the foreseeable future. If and when PG&E makes such a determination, the FMIT has the option to purchase the property. The terms of the option to purchase and of its exercise are set out in the settlement agreement and option agreement that is attached thereto as an exhibit, as referred to above.	
FMIT GC5		Use of non-health-based comparison criteria. The GWRA in several steps of the assessment utilizes non-health-based criteria to eliminate COPCs and groundwater well locations from the risk assessment and consideration in the CMS/FS, respectively. A few examples include frequency of COPC detection in wells (pg 3-2, pp2), elimination of 'data collected by others' (pg 3-2, pp4), consideration of general chemical parameters (pg 3-7. pp2), and the use of MCLs (pg 3-10, footnote). While some of these actions do not significantly impact site risk estimates, they are not appropriate risk assessment methodologies. Future risk assessments should present a comprehensive understanding of project risks so that informed risk management decisions can be made.	The GWRA does not use non health-based criteria to eliminate COPCs or well locations from consideration in the GWRA. Screening of site data for selection of COPCs was conducted consistent with the technical approach presented in the approved RAWP and associated regulatory guidance. Frequency of detection was not used as a COPC selection criterion for detected compounds. As described in paragraph 2 on page 3-2, a compound was not selected as a COPC if it was never detected at the well in the RFI/RI site dataset. Paragraph 4 on page 3-2 points out that, consistent with the approved RAWP and regulatory guidance, the GWRA evaluated the dataset for the site as identified in the Revised Final RFI/RI Volume 2 (CH2M HILL, 2009) and the RFI/RI Volume 2 Addendum (CH2M HILL, 2008a). The GWRA did not further eliminate any data or data sources accepted in the RFI/RI documents, and relied on the site dataset as defined by the RFI/RI documents. As the same paragraph further points out, the GWRA did, however, include one additional surface water dataset collected by the Metropolitan Water District, which was made available after the closing date for data to be considered in the RFI/RI documents. Maximum contaminant levels (MCLs) were not used as a general COPC selection criterion. They were used as a screening tool only for a subset of chemicals, per the approved RAWP. The last two paragraphs on page 3-9 and first paragraph on page 3-10 (and associated footnote) describe how the RFI/RI documents identified the extent of the hexavalent chromium plume by using the chromium MCL. The GWRA used this same definition of the hexavalent chromium plume to categorize wells as being within or outside the plume. The purpose of this grouping for the wells was to provide perspective for wells outside the hexavalent plume to see if planned future treatment of that plume area might miss any key wells or compounds of significant hypothetical health risk to a future domestic user of the groundwater. The categorization of wells either within or outside the plume, however, was not used as a basis for eliminating COPCs from the risk assessment. In accordance with the approved RAWP, appropriate risk assessment methodologies were used in the GWRA that can form the basis of informed risk management decisions.	3
CRIT C1		A site-specific groundwater background level of 32 µg/L hexavalent chromium (Cr-6) is used in the risk assessment. We do not agree that the natural background groundwater conditions should be equally applied from the upland area to the fluvial aquifer near the Colorado River. Although within the upper background range reported for this region (Ball and Izbicki, 2004), this is unusually high relative to most locations in the United States. For example, at the Hinkley PG&E site, the average background	The *Revised Groundwater Background Study Steps 3 and 4: Final Report of Results* (Groundwater Background Study; CH2M HILL, 2008c) upper threshold limit (UTL) represents the 95% statistical upper tolerance level, meaning that only 5% of all wells would be expected to exceed 31.8 micrograms per liter (µg/L). The fact that average values (50% values in terms of statistics) are much lower does not mean that this UTL is particularly elevated compared to other areas. The mean chromium concentration in the	1

		concentration of Cr-6 was 1.2 µg/L with a maximum of 2.7 µg/L. In a survey of California drinking water sources, Cr-6 was not even detected in 70% of the sources (detection limit 1 µg/L), and in almost 90% of the sources in which it was detected, the maximum concentration was 10 µg/L or less (California Department of Public Health [CDPH], 2007). Even though there is an entire report referenced regarding development of background concentrations, some explanation of this high background, for example a brief discussion of how local geology, pH and/or oxidation state of the groundwater cause the higher background, should be provided in the risk assessment itself. Cr-6 is the main focus of this risk assessment yet neither of the main sections that discuss groundwater background (Sections 3.2.1.1 or 3.2.3.1) even mention Cr-6, much less explain the high background level of Cr-6 assumed for the risk assessment. CRIT is in the process of conducting a technical review of the groundwater background report.	Groundwater Background Study was 8.9 µg/L. Having 90% of samples be below detection limit also would not apply: it is the upper half of the remaining 10% of the dataset that determines the UTL, not the average or number of non-detects (NDs). The UTL calculated for this study is in general agreement with the U.S. Geologic Survey (USGS) observations for groundwaters eminating from granitic source rocks in the Mojave Desert, which showed chromium concentration up to 36 µg/L. The nearby Sacramento Valley, Arizona, groundwater study determined a mean total chromium concentration of 42 µg/L. The greater value may be influenced by more mafic volcanic source rocks in some parts of the surrounding mountains of that valley. More mafic rocks tend to contain higher concentrations of transition metals, including chromium. We also note that to the extent there are uncertainties/questions regarding the background hexavalent chromium concentrations, these uncertainties/questions are related to the characterization efforts, not the risk assessment efforts. Thus, discussions regarding the different variables that can result in higher background concentrations for hexavalent chromium belong in the characterization studies, not the risk assessment.	
CRIT C2		Although the risk assessment clearly states that the objective is to address risks related to groundwater, there should be statements added to the introduction explaining how and when other health risks at the site (e.g. due to exposure to contaminated soil) will be addressed. In other words, this groundwater risk assessment needs to be placed in context with the risk assessment of soils. In addition, there should be statements indicating why the groundwater risks are being addressed in this manner (i.e. as a separate risk assessment) rather than together with other site health risks (i.e. soils).	See also responses to comments FMIT GC1 and DOI SC21. Language will be added to clarify that both groundwater and soil contributions to overall potential risk will be ultimately addressed for the site once data collection, site characterization, and risk assessments have been completed for both media. Preparation of separate risk assessment documents for groundwater and soil is being done to comply with DTSC's request that the groundwater remedy be developed prior to the completion of all soil investigations, which is entirely consistent with our experience on other sites in which decisions regarding operable units (OUs) to be made independently.	3
CRIT C3		Because risks at the site are presently being addressed separately (i.e. groundwater risk assessment, soils risk assessment) there is a need to account for cumulative risks across all media. For example, cumulating risks due to groundwater pathways with risks due to soil exposure. This point should be addressed in the introduction as part of the context discussion noted above.	See response to comment CRIT C2.	3
CRIT C4		Given the focus of the risk assessment on groundwater, a section of text needs to be added which clearly states where the closest wells in the area are that are known to be used by local individuals for drinking water, irrigation, or watering livestock, etc. A map showing these wells in relation to the plume boundary would be appropriate. This map should be included in the risk assessment and not incorporated by reference. It is very important to make it clear to the reader how likely it is that the plume could actually reach wells that are in fact currently used for drinking water, irrigation, or other uses.	As suggested, the final GWRA will incorporate language that identifies the known active supply wells in the area of potential effects (APE), and will identify these wells on a figure. The proposed figure is presented as an attachment to these Responses to Comments (RTCs). As indicated on the attached Figure 1, there are two known active supply wells in the APE: PM-04, located in Park Moabi (on the northwest section of the APE), and Sanders, located on the Arizona side of the Colorado River.	3
CRIT C5		The Conceptual Site Model (CSM) included in the risk assessment is not specific for groundwater which is the scope of this report. A revised CSM should be prepared which focuses on groundwater and	Figure 5-1 in the GWRA provides the conceptual site model (CSM) for potential exposures resulting from chemically affected groundwater. The CSM is discussed in the text in Sections 5.1 through 5.5. Use of	3

		groundwater related exposure pathways. In addition, the risk assessment does not discuss the CSM to any extent, in particular how it was developed, even though the CSM is the foundation of any risk assessment. The CSM is a graphical representation showing the primary source of the contamination, mechanisms for release into the environment, secondary sources, potential exposure pathways, and receptor populations. The CSM should be accompanied by a text discussion in the main report which states how it was developed, including assumptions used. The risk assessment apparently relegates this discussion to the risk assessment workplan. This is not sufficient. In particular, the discussion should explain why some potential groundwater exposure pathways (e.g. crop irrigation, home garden produce irrigation and consumption, use in cooking, livestock watering, Tribal traditional cultural practices, etc.) were not included in the quantitative risk assessment, whether that is because the exposure pathway was determined to be incomplete, or complete but negligible. The risk assessment does not adequately justify limiting the scope of this groundwater risk assessment to drinking water ingestion and dermal contact. For example, hypothetical future residents are considered the relevant receptor population in the risk assessment. Could future residents realistically use the groundwater for irrigation of home gardens? If this or other potential exposure pathways are considered not relevant or negligible an explanation should be provided to justify excluding them from the risk assessment.	groundwater as a potable drinking water source and designing remediation to meet those goals are typically considered to be the most stringent criteria available. The GWRA used default exposure assumptions for hypothetical future potable use to include direct dermal contact and ingestion pathways suitable to address use of the groundwater for drinking, cooking, and bathing, as presented in the approved RAWP. Please refer to response to comment DOI SC20 for a discussion of potential secondary pathways associated with exposure to groundwater (i.e., ingestion of plant and animal products as a pathway for exposure to contaminated groundwater). As indicated, the final GWRA will include an appendix that describes why these secondary pathways associated with use of impacted groundwater would not materially change the conclusions of the groundwater risk assessment.	
CRIT C6		Section 5.6 Exposure Point Concentrations (EPC) This section states that the EPC is defined as the "average concentration" and "represents a reasonable estimate of the concentration likely to be contacted over time". The EPC is actually an upper-bound or at least conservative estimate of the concentration expected to be contacted over time since it typically consists of either the 95% upper confidence limit of the mean or the maximum detected concentration.	Comment noted. We agree that the EPC is a conservative, upper-bound estimate of the concentration expected to be contacted over time.	3
CRIT C7		The risk assessment assumes that Cr-6 is not carcinogenic via the oral route of exposure. However, a recent National Toxicology Program (NTP) study demonstrated that Cr-6 is carcinogenic in both mice and rats via the oral route of exposure (drinking water) (NTP, 2008; Stout et al., in press). This confirms findings of earlier studies. It is expected that as a result of this study, the California Office of Environmental Health Hazard Assessment (OEHHA), currently charged with developing a drinking water Public Health Goal for Cr-6, is going to soon reclassify Cr-6 as carcinogenic via the oral route of exposure. It is further expected that a cancer potency factor for Cr-6 will be developed by OEHHA as part of the development of the Public Health Goal. This new development should be noted in the risk assessment. In addition, the risk assessment should eventually be revised to reflect the carcinogenic effect of Cr-6 via the oral route of exposure using the new cancer potency factor expected to be developed and released by OEHHA soon.	See response to comment HERD-SRS GC3. A discussion of the uncertainty associated with the potential classification of hexavalent chromium as an oral carcinogen is presented in Section 9.5 of the GWRA. A peer-reviewed value is not yet available from the Office of Environmental Health Hazard Assessment (OEHHA). According to the U.S. Environmental Protection Agency (USEPA) Integrated Risk Information System (IRIS) website (USEPA, 2009), toxicity evaluation of hexavalent chromium is scheduled to complete peer review in late 2012.	No change
HERD-JME		HERD found little to review in regards to hazard to ecological receptors from groundwater underlying the Topock Compressor Station. The report provides tables listing ecological receptors found on site and a listing of surface water criteria taken from the 2008 from the Remedial Action Work Plan (RAWP). What is	PG&E concurs with HERD's request to expand the GWRA to incorporate additional evaluation of two additional potential exposure pathways for ecological receptors. PG&E also notes that the scope of the GWRA was established in the approved RAWP. The approved RAWP contains Figure 6-1, Ecological	2

		lacking from the report is a discussion of potential exposure pathways to ecological receptors. Without this information there is little to review. From the HERD standpoint there is potentially three potential pathways for exposure to ecological receptors; 1) Deep rooted phreatophytic upland plants extending their roots down to the groundwater (i.e., .Mesquite-Prosopis glandulosa), 2) More shallow rooted plants along the margins of the river and the wetland at the mouth of Bat Cave Wash such as tamarisk (Tamarix sp.), and 3) movement of groundwater to the river. Each of these potential pathways should be described in the report. To date, sampling has not demonstrated movement of the groundwater plume to the Colorado River. There is also no evidence that tamarisk or other plants adjacent to surface water such as the river or the pond at the mouth of Batcave Wash have their roots at depth where they would intercept groundwater plumes containing site COPECs. It is more likely that these plants do not have deep roots since they have ready access to adjacent surface water. The pathway to upland phreatophytes is more problematic and difficult to quantify. These types of questions should be included in the report with substantive data regarding potential rooting depths and depth to groundwater plumes containing COPECs. The report needs to go beyond a description of exiting habitat and describe how the habitat and ecological receptors could be exposed to COPECs in groundwater. It may well be that impacts are minimal or non-existent but the reasoning must be presented.	Conceptual Site Model, explaining that the groundwater pathway to be assessed in the GWRA is a potential connection with interstitial water (i.e., porewater) and surface water. PG&E implemented the approved RAWP and the scope of the discussion that appears in the GWRA is consistent with the CSM in the RAWP; that is, the discussion focuses on the potential transport pathway to the river. Nevertheless, PG&E will expand the GWRA to address HERD's new request. HERD has observed that there are two additional pathways (in addition to potential transport to the river) of interest to HERD at the site: 1) shallow-rooted plants in the riparian area contacting chemically affected groundwater and 2) phreatophytic upland plants contacting chemically affected groundwater. To address HERD's concerns, PG&E has performed an evaluation of the additional potential pathways below and will expand the revised GWRA accordingly. The evaluation focuses on chemicals of potential concern (COPCs) from the Revised Final RFI/RI Volume 2 (CH2M HILL, 2009): hexavalent chromium, selenium, molybdenum, and nitrate. Nitrate in the groundwater is a nutrient beneficial to the terrestrial ecosystem. Because desert plant communities typically are limited by nitrogen during growing periods (Zak and Whitford, 1988[1]), nitrate uptake from the groundwater is expected to have beneficial rather than adverse effects on the plants. For example, in a desert system in Arizona the phreatophyte, *Atriplex canescens*, growing over a shallow groundwater plume with high concentrations of nitrate (maximum nitrate-N concentration = 300 milligrams per liter [mg/L]), accumulated 5 times more nitrate in its leaves during summer than plants growing off the plume (up to 500 milligrams per kilogram [mg/kg] nitrate-N in leaf tissue; McKeon et al., 2006[2]). The study estimated that at the McKeon site, 40 kg of plume water would supply sufficient nitrogen for production of 1 kg of plant biomass. Isotope analysis indicated most of the nitrate came from the groundwater plume. The increased nitrate in the plant tissues produced no phytotoxicity (McKeon et al., 2006). In Topock shallow groundwater wells that were selected to best represent concentrations potentially contacting phreatophytic vegetation[3], the maximum nitrate-N concentration is 16.4 mg/L (at MW-11), much lower than the concentrations in the McKeon et. al. (2006) study. Therefore, nitrate will not be considered further as a COPC in the groundwater ecological risk assessment. Potential exposure to the remaining COPCs (hexavalent chromium, selenium, and molybdenum) depends on depth to groundwater, root depths, and chemical distribution in the groundwater. These factors are discussed further below. Groundwater level data for water table wells were obtained from Appendix B of the Revised Final RFI/RI Volume 2 (CH2M HILL, 2009) and Appendix B of the *Monitoring Report for the Floodplain Reductive Zone In-Situ Pilot Test* (ARCADIS, 2007[4]). Depth-to-water data for water table wells are displayed on Figure 2. Only wells with depths to groundwater shallower than 80 feet below ground surface (bgs) were

2 McKeon, C., E.P. Glenn, W.J. Waugh, C. Eastoe, F. Jordan, and S.G. Nelson. 2006. Growth and water and nitrate uptake patterns of grazed and ungrazed desert shrubs growing over a nitrate contamination plume. Journal of Arid Environments 64:1-21.

3 The wells were selected based on the following criteria: maximum depth to groundwater of 80 feet below ground surface (ft bgs), co-location with phreatophytic vegetation, or, where wells were not available in phreatophytic vegetation, the nearest upgradient well. MW-11 was the only well selected that is not co-located with phreatophytic vegetation. MW-11 was selected to represent concentrations upgradient of phreatophytes in Bat Cave Wash.

			considered in this assessment; wells where groundwater occurred deeper were considered beyond depths of interest for phreatophyte exposure (see below for discussion of root depths). Depths to water are as shallow as approximately 4 feet bgs near the river. Depth-to-water data, as well as an understanding of plant root depths, form the basis of the exposure evaluation. The potential exposure pathway for shallow-rooted riparian plants was evaluated qualitatively by reviewing depth-to-water data, considering geochemical processes that operate in wetland environments, and reviewing COPC concentrations in groundwater. Historical depth-to-water measurements suggest that shallow groundwater may not discharge at wetland areas (Figure 2). Shallow-rooted plants such as common reed (*Phragmites communis*), cattails (*Typha* sp.), sedges (*Carex* sp.), and bulrush (*Scirpus* sp.) may not contact groundwater given that the shallowest depth to water measured near the river is approximately 4 feet (CH2M HILL, 2009) and these plants have ready access to surface water. Deeper-rooted plants, such as salt cedar and arrowweed, present immediately adjacent to the river or ponded water at the mouth of BCW also have ready access to the surface water. As HERD stated, sampling has not demonstrated movement of the groundwater plume with COPCs into the Colorado River. Further, the reducing conditions in wetland areas would result in precipitation of hexavalent chromium, selenium, and molybdenum binding the metals and reducing bioavailability. Hexavalent chromium and selenium were not detected in shallow wells nearest the river (MW-28-25, MW-29, and MW-27-20); molybdenum was either not detected or present at a concentration below the background UTL in these wells (Figure 3). The data suggest riparian plants along the river are unlikely to take up the COPECs from the groundwater. Therefore, this shallow-rooted riparian plant pathway is considered insignificant and will not be evaluated further. The potential exposure pathway for deeper rooted upland plants (phreatophytes) was evaluated quantitatively by first assessing the potential for root contact with chemically affected groundwater, then considering groundwater concentrations of COPCs where contact may occur. Table 1 (attached) provides maximum root depths for phreatophytes identified at the site showing that some species, such as honey mesquite (*Prosopis glandulosa*) can have roots up to 50 feet deep. Depths to water in the BCW and on the east side of National Trails Highway where phreatophytes occur range from 30 feet bgs to 4 feet bgs. Deep-rooted phreatophytic upland plants may contact COPCs occurring in shallow groundwater. Such phreatophytes include mesquite (*Prosopis* spp.), palo verde (*Cercidium* sp.), salt cedar (*Tamarix ramosissima* Ledeb.), arrowweed (*Pluchea sericea*), and catclaw acacia, *(Acacia greggii*), which occur within upland areas near the river and in the BCW where depths to water are also within potential root zones (Figure 2). Consistent with this information, mesquite and palo verde grow in the BCW in areas with water table depths up to 50 feet bgs (Figure 3; Figure 5-3 in CH2M HILL, 2009). The shallower-rooted salt cedar (*Tamarix ramosissima* Ledeb.) is found where the depth to groundwater

			is 4 to 32 feet bgs (or where there is surface water) (Figure 2), which is consistent with its reported maximum rooting depths of about 25 feet (Table 1). Therefore, the concentrations of COPCs in groundwater underlying the deeply-rooted plants are of interest and are evaluated further below. The maximum detected concentrations of COPCs in shallow groundwater wells collocated, or nearest, the areas where mesquite, palo verde, salt cedar, catclaw acacia, and arrowweed occur were evaluated as screening level exposure point concentrations. The maximum detected hexavalent chromium concentration in a shallow well co-located with salt cedar and arrowweed along the east side of National Trails Highway is 0.148 mg/L in well PE-1 (by comparison the background UTL is 0.0318 mg/L), and the maximum molybdenum concentration in this area is 0.1 mg/L in well MW-30-30 (versus a background UTL of 0.0363 mg/L) (Figure 3). Selenium concentrations in these wells did not exceed the background UTL of 0.0103 mg/L. The maximum detection of hexavalent chromium in the BCW where the phreatophytes grow or bounding areas where they grow (see MW-41S, MW-13, MW-11 on Figure 3) is 1.71 mg/L. The maximum selenium concentration was 0.0136 mg/L at MW-11, slightly greater than the background UTL (0.0103 mg/L). The maximum molybdenum concentration (0.035 mg/L) in this area did not exceed the background UTL. The maximum COPC concentrations in groundwater described above are not associated with phytotoxicity, and therefore, effects would not be predicted in the study area. The maximum hexavalent chromium concentration in the BCW (within or bounding the area occupied by phreatophyes) is below levels believed to be toxic to phreatophytic plants such as salt cedar and mesquite. A no observable adverse effects concentration (NOAEC) of 2 mg/L for hexavalent chromium was reported in Sorenson et al. (2009[5]) for salt cedar. Mesquite (*Prosopis* spp.) tolerates hexavalent chromium in solutions of up to 125 mg/L when grown in agar and 80 mg/L when grown hydroponically (Aldrich et al., 2003[6]) indicating a hexavalent chromium NOAEC for mesquite of 80 mg/L. Hexavalent chromium concentrations in shallow groundwater in the upland east of National Trails Highway are at least an order of magnitude lower than those observed in the BCW at MW-11; therefore, phytotoxicity due to hexavalent chromium would not be predicted in either area. Similarly, the maximum concentrations for selenium are below the NOAEC of 2 mg/L reported for salt cedar in Sorenson et al. (2009). Molybdenum concentrations are orders of magnitude below the lowest observable adverse effects concentration (LOAEC) of 96 mg/L reported for the molybdenum-sensitive species such as bush bean (Adriano, 2001[7]). Assuming a factor of 10 reduction in concentration to extrapolate from the LOAEC to a NOAEC for molybdenum, the maximum groundwater concentration (0.1 mg/L) is still well below the NOAEC (9.6 mg/L). Therefore, the exposure pathway from chemically affected groundwater to phreatophytes is insignificant because maximum concentrations in shallow groundwater underlying these plant communities are very low relative to concentrations known to be phytotoxic.

HERD-SRS GC Intro		In general, the approach taken in evaluating cancer risks and non-cancer hazards (in individual wells) to potential future receptors using groundwater (impacted by activities at SWMU1/AOC1 and SWMU2) as a potable source is acceptable to HERD. Standard methodologies and default exposure assumptions recommended by the USEPA and California EPA were used to estimate risks/hazards to potential future residents. However, as discussed below (comments # 9, 10 and 11), HERD does not recommend the use of site-wide averaging of contaminant concentrations or the sensitivity analysis as a means for eliminating chemicals of potential concern (COPC). For estimating non- cancer hazards resulting from exposures to molybdenum in groundwater, HERD recommends using USEPA's existing oral reference dose (RfDo) for the metal, rather than the tolerable upper intake level (UL) developed by the Institute of Medicine (IOM). Finally, HERD recommends that COPCs in groundwater should be remediated to levels where the cumulative cancer risks and non-cancer hazards for each individual well, meets risk management goals (comment # 12).	See responses to comments HERD-SRS GC7, HERD-SRS GC 9, HERD-SRS GC 10, and HERD-SRS GC 11 below.	
HERD-SRS GC1		Title of report: Please modify the title of the report as follows: "Human and Ecological Risk Assessment of Groundwater Impacted by Activities at SWMU1/AOC1 and SWMU2, PG&E Topock Facility, Needles, California". The current title of the report implies that the risk assessment pertains to groundwater located beneath the entire area, regardless of source of contamination.	We concur with the recommended change in the title. Although the risk assessment presents estimated risks and noncancer hazards for chemicals detected in groundwater anywhere across the site, including chemicals that are determined to not be associated with releases from SWMU1 /AOC 1 and SWMU 2, the chemicals of concern (COCs) that get carried forward to the Corrective Measures Study/Feasibility Study (CMS/FS) being prepared for SWMU 1/AOC 1 are: 1) those constituents that are determined to be present in site groundwater at levels of potential concern to future hypothetical residential groundwater users, and 2) likely associated with groundwater at SWMU 1/AOC 1.	3
HERD-SRS GC2		Chemicals of Potential Concern (COPC) selection process: HERD defers to DTSC geologist/project manager for issues regarding the COPC selection process for groundwater impacted by activities at SWMU1/AOC1 and SWMU2. Communications with DTSC management indicates that COPCs in groundwater have already been selected for this site, based on comparisons with appropriate background data for the region. Details of these analyses can be found in the RFI/RI Volume 2 document. Based on this evaluation, the following chemicals were selected (and approved by DTSC) as COPCs in groundwater affected by activities at SWMU1/AOC1 and SWMU2: hexavalent chromium, molybdenum, nitrate, and selenium. As such, HERD evaluated only those chemicals that were determined to be COPCs in site groundwater, for cancer risks and non-cancer hazards to potential future residents. It should be noted here that the groundwater risk assessment will be revisited if ongoing monitoring or investigation (e.g., soil sampling results) indicate that additional COPCs may be present in site groundwater. As noted in the current report, the groundwater risk assessment (GWRA) was conducted prior to completion of contaminant delineation in site soils.	Comment noted. No response necessary.	No change
HERD-SRS GC3		Hexavalent chromium risk assessment: HERD notes that PG&E may be required to revise the risk assessment portion for hexavalent chromium, should it be reclassified (in the future) as an oral carcinogen	Comment noted about the potential reclassification of hexavalent chromium as an oral carcinogen. The GWRA acknowledges this uncertainty in Section 9.5. We want to clarify, however, that the GWRA does	No change

		by either the USEPA or California EPA. Recent studies by the National Toxicology Program (NTP) of the U.S. Department of Health and Human Services, reveal that hexavalent chromium can cause cancer in laboratory animals at multiple sites when administered in drinking water (http://ntp.niehs.nih.gov/index.cfm?objectid=EIC04561-F1F6-975E-7B21E8B231BAB44F). This may affect groundwater remediation goals for the site. Currently, PG&E is proposing to remediate hexavalent chromium to the California Maximum Contaminant Level (MCL) for total chromium, which is 50 ug/L.	not make statements about proposing to cleanup to the California MCL for total chromium of 50 µg/l. The selection of the ultimate cleanup goal will be determined in the CMS/FS.	
HERD-SRS GC4		Cleanup goal for hexavalent chromium: HERD does not recommend using the MCL for total chromium (50 ug/L) as the groundwater cleanup goal for hexavalent chromium, instead of the calculated risk-based value (46 ug/L). Although the values are similar, the approach of using an ARAR for total chromium, in place of the calculated risk-based cleanup goal is not an acceptable procedure. The GWRA states that "as an ARAR exists for hexavalent chromium (i.e., the California MCL of 50 ug/L for total chromium), the ARAR will be used in preference over the risk-based criteria as the applicable drinking water criteria in the upcoming CMSIFS process". HERD also notes that the MCL of 50 ug/L applies to total chromium, and should not be used interchangeably with hexavalent chromium.	The GWRA will be revised to clarify that the risk assessment does not determine the ultimate level of remediation that needs to occur at the site. Discussions about the remedial action objectives, and decisions regarding the final remedial goals will be determined in the CMS/FS. Section 8 of the GWRA will present both the legally enforceable drinking water criteria (MCLs), and the risk-based criteria for all COCs, and will clarify that this range of potential remedial goals may be considered in the CMS/FS.	3
HERD-SRS GC5		Selenium: Review of groundwater data indicate that selenium concentrations are significantly elevated above background concentrations (1 0.3 ug/L) in one (TW-1) out of 76 wells. TW-1 is located within the PG&E property. According to DTSC project geologist, elevated levels of selenium track with fluctuations in hexavalent chromium within this well, and thus may be related to releases at the site (see March 4,2009, memorandum titled "Responses to PG&E February 18,2009 Comments Regarding the December 2008 RFI/RI Volume 2 Addendum Report, PG&E Topock Compressor Station, Needles, California"). Based on non-cancer hazard estimates, selenium alone exceeds a non-cancer hazard quotient of 1 (HQ = 2.0) at TW-1, and therefore contributes significantly to unacceptable cumulative non-cancer hazard for the well, and subsequently for the site. According to the report, site-wide averaging of selenium concentrations for "in-plume" and "out-of-plume" wells will result is non-cancer hazards below 1 (see page 7-18). As discussed in comment # 9, site-wide averaging of data will dilute out localized hot-spots of contamination (e.g., TW-1), and result in underestimation of risks/hazards to potential future receptors. For example, combining the elevated levels of selenium within TW-1, with results from the other 75 wells, artificially lowers the exposure point concentrations (EPC) and therefore the non-cancer hazard associated with selenium within this particular area. Although the groundwater within the PG&E property is not currently being used as a potable source, it is designated for beneficial use and could be implemented for such purposes in the future.	The current GWRA concludes that selenium is not likely to pose adverse health effects to hypothetical future groundwater users because there is only one well, across the entire site, where selenium exceeds the hazard index (HI) of 1 (with an HI of 2.0). The in-plume and out-of-plume discussions in the risk assessment do not affect the ultimate recommendation in the GWRA that selenium is not a significant risk issue; the information about in-plume and out-of-plume concentrations is merely an additional line of evidence presented to help provide context to the overall significance of selenium. Nonetheless, as directed by DTSC and DOI, the text of the GWRA will be revised to indicate that they consider any individual well with an HI> 1 to be of potential concern, and selenium will be retained as a COC for evaluation in the CMS/FS.	1

HERD-SRS GC6		Nitrate: As demonstrated in the report, non-cancer hazards resulting from potential future exposures to nitrates in groundwater exceeds an HQ of 1 in several wells, and therefore contributes significantly to unacceptable hazards to potential future residents at the site, who may be exposed to groundwater originating from these individual wells. As discussed in comment # 9, site-wide averaging of groundwater data from all wells on-site will dilute out hot-spots of contamination and lead to underestimation of non-cancer hazards. Similarly, when estimating EPCs, replacing maximum detected concentrations (in wells with fewer than eight samples, or greater than five non-detects), with average concentrations may result in underestimation of non-cancer hazards from nitrates.	The site-wide averaging is not used in the GWRA as a means of dismissing nitrate. Nitrate was dismissed in the GWRA because at the time it was not believed to be related to releases from SWMU 1/AOC 1. The DTSC, in their comments on the RFI/RI Volume 2 Addendum (CH2M HILL, 2008a), requested that nitrate be a COPC; therefore, the GWRA will be revised consistent with DTSC's direction. The final GWRA will recommend that nitrate be retained as a COC for evaluation in the CMS/FS.	1
HERD-SRS GC7		Molybdenum non-cancer hazard estimates: HERD does not concur with the approach taken in evaluating non-cancer hazards associated with molybdenum in site groundwater. In the GWRA, revised non-cancer hazards for molybdenum were estimated where USEPA's existing oral reference dose (RfDo) for molybdenum (0.005 mg/kg/d) was replaced with Institute of Medicine's (10M) tolerable upper intake levels (UL), for the metal (0.03 mg/kg/d). The GWRA states that the RfDo for molybdenum listed on USEPA's website" has serious flaws", and therefore should not be used in the risk assessment. HERD does not recommend using toxicity factors that have not been officially peer-review and accepted by the appropriate regulatory agencies. The hierarchy for source of toxicity values is as follows: California EPA's Office of Environmental Health Hazard Assessment (OEHHA), USEPA's Integrated Risk Information System (IRIS), USEPA's Provisional Peer-Reviewed Toxicity Values (PPRTV), USEPA's Health Effects Assessment Summary Tables (HEAST) and Centers for Disease Control and Prevention (CDC)'s Agency for Toxic Substances and Disease Registry (ATSDR). Based on this hierarchy, USEPA's current RfDo for molybdenum (0.005 mg/kg/day) should be used in estimating non-cancer hazards to populations who may use the groundwater as a potable source. The objective of having a hierarchy for toxicity values is that a consistent approach for risk assessments is followed for all sites. As an example, although more recent data suggests that hexavalent chromium is a carcinogen via the oral route of exposure (NTP, 2007), the GWRA does not incorporate this information into the current assessment, since neither the California EPA nor the USEPA have officially adopted these values (see comment #3). In the current report, hexavalent chromium was only evaluated as a non-carcinogen.	The GWRA presents two approaches to evaluation of the non-cancer toxicity of molybdenum. The first uses the USEPA IRIS oral reference dose (RfDo) of 0.005 mg/kg/day. Use of the IRIS RfDo follows the DTSC hierarchy for selection of toxicity value. Per DTSC's request, the GWRA will be revised to present conclusions for molybdenum as a COC based solely on this evaluation, and the main text of the GWRA will remove the discussions related to the essential nutrient evaluation. However, the alternate evaluation based on consideration of molybdenum as an essential nutrient will be retained to provide perspective for risk management decisions to be made in the CMS/FS. The alternative evaluation is presented in Appendix M, and will be modified to include an acknowledgement that the appendix is not being approved by DTSC but is being presented for additional information and context. Evaluation of molybdenum as an essential nutrient was conducted and presented for the following reasons: 1) The well-by-well evaluation in the GWRA indicated the molybdenum was a potential health concern for some wells (i.e., HI > 1). 2) *Framework for Metals Risk Assessment* (FMRA) *g*uidance (USEPA, 2007b) advises consideration of essential nutrient status for metals, balancing both beneficial and toxicity characteristics in the approach for human health risk assessment (see pages 1-10, 2-15, 4-15, and 4-16 of that document). 3) The government resource publication for essential nutrient standards *Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicone, Vanadium, and Zinc* (DRI) (IOM, 2001) challenges the validity of the 1993 IRIS RfDo for molybdenum, and presents an alternate upper bound safe consumption level, the tolerable upper intake level (UL).	1

			4) USEPA staff serving as the compound manager for molybdenum toxicity evaluations was consulted directly to determine that agency's view of using the IRIS RfDo for molybdenum versus the UL for hazard estimates. USEPA's advice was that the RfDo listed in IRIS is indeed flawed as indicated in the IOM document, and that the UL provides a better indication of potential health concerns for molybdenum hazard (Donohue, personal communication 2009). In accordance with the FMRA (USEPA, 2007) "Essentiality this should be viewed as part of the overall dose-response relationship for those metals shown to be essential, and the shape of this relationship can vary among organisms. For a given population, 'reference doses' designed to protect from toxicity of excesses should not be set below doses identified as essential. Essential doses are typically life stage and gender specific." See pages 1-10 and 4-16 of that document. In accordance with FMRA, consideration of essential intake requirements for various age ranges (and both genders), dietary intake for molybdenum, and toxicity responses were all factors included in the alternate evaluation for molybdenum presented in Appendix M of the GWRA. The FMRA also cites the DRI as the source for essential nutrient information (see page 4-17) and describes the UL found in the DRI document as follows: "They also developed a tolerable upper intake level (UL), which is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. The UL is based on a risk assessment model similar to that used by EPA to set the RfDs and is intended to protect the population from adverse health effects resulting from excess exposure to a compound." ARCADIS' review of the DRI chapter for molybdenum (IOM, 2001) revealed that IOM deemed the IRIS 1993 RfDo to be flawed, and that the UL was recommended for use in risk assessment hazard evaluation for this essential nutrient. It is notable that safe levels of intake for molybdenum cover a broad range, the low end being the recommended daily allowance (RDA) of 34 µg/day and the high end being the UL of 2,000 µg/day. PG&E agrees that adequate peer review and acceptance by appropriate regulatory agencies of toxicity values is a preferred approach. Before presenting the alternate evaluation of molybdenum in the GWRA, PGE contacted USEPA Headquarters and spoke to the molybdenum compound manager for IRIS. Dr. Joyce Donohue confirmed that the IRIS RfD is outdated and that the UL presented in the DRI document (IOM, 2001) is the more scientifically valid and appropriate value for hazard evaluation of molybdenum for oral intake such as drinking water (Donohue, personal communications February 2009). In a subsequent conversation (Donohue personal communication, April 2009) she pointed out that the 1993 IRIS RfDo was only peer reviewed internally in the agency (consistent with requirements at that time). However, the peer review requirements for IRIS have been updated since then and are consistent with the peer review process conducted for the IOM DRI publication, which underwent both internal agency peer review and external peer review. Dr. Donohue is available to speak directly with DTSC toxicologists

			to discuss the use of the molybdenum UL versus the IRIS RfDo for hazard evaluation and the toxicity of molybdenum. She can be contacted in her office in Washington D.C via email (Donohue.Joyce@epamail.epa.gov) or by phone at 202-566-1098. In addition to molybdenum, selenium is also an essential nutrient. The revised GWRA will include both molybdenum and selenium as COCs. To be consistent with current guidance for addressing metals risk assessment for essential nutrients (USEPA, 2007), both molybdenum and selenium will be evaluated for toxicity considering both the RfD as indicated in IRIS and information on essentiality as indicated by the IOM. This alternate evaluation was presented in the draft GWRA for molybdenum. A section will be added to the appendix containing the information on molybdenum to include a similar evaluation for selenium for consideration in risk management decisions. ARCADIS is not aware of a peer reviewed value as being available for hexavalent chromium as an oral carcinogen, and thus did not include this in the GWRA, as it would be speculative at this point. However, the GWRA does acknowledge that OEHHA is likely going to be publishing an oral cancer slope factor for hexavalent chromium at some point in the future (see Section 9.5 of the GWRA). Further, the USEPA IRIS website shows tracking for the development of the fully peer reviewed hexavalent chromium assessment as projected to be completed in late 2012. At such time as a peer reviewed value is available, as is the case for any COPC, it will be considered in the risk assessment and associated risk management decisions.	
HERD-SRS GC8		Surface water evaluation: As noted in comment #I, hexavalent chromium, molybdenum, selenium and nitrate were the only COPCs (resulting from activities at SWMUIIAOCI) identified in groundwater at the site. As such, HERD evaluated only the above-mentioned COPCs, for impacts of activities at SWMU1/AOC1 and SWMU2 to the Colorado River. A review of the surface water data, collected between 1997 and 2007 and presented in Appendices B and C, indicates that the upstream and downstream concentrations of the four COPCs are similar (communications with DTSC management). Based on these results, the four identified COPCs do not appear to pose unacceptable risks/hazards to receptors who may have come in contact with the surface waters at the site, over that ten (10) year monitoring period. This does not take into consideration future conditions at the site, where release of COPCs into surface waters may occur.	Comment and concurrence with GWRA conclusions noted.	No change
HERD-SRS GC9		Well-by-well vs. site-wide risk assessment: HERD found that the human health risk assessment (HHRA) conducted on a well-by-well basis is a more appropriate approach for evaluating risks/hazards to receptors who may use the groundwater as a potable source. Each well potentially represents a separate exposure scenario, and is therefore most representative of situations where individuals may come in contact with the contaminated groundwater through use of private wells. Using site-wide averaging will result in underestimation of EPCs, since contaminants localized in one area will be diluted out during the averaging process. For example, see selenium data.	Site-wide averaging is not used as a basis for recommendations. It is just an additional line of evidence, consistent with our approach set forth in the approved RAWP, which provides the risk managers with useful information for consideration along with the CMS/FS findings.	No change

Comment Number	Section/ Page	Comment	Response	Comment Category
HERD-SRS GC10		In-plume vs. out-of plume HHRA for COPC: HERD notes that the groundwater plume delineated at the site applies only to hexavalent chromium, and should not be used interchangeably with other COPCs. As such, estimating risks/hazards for all other groundwater COPC using "in-plume" and "out-of- plume" wells is not reasonable, and therefore unacceptable to HERD.	In-plume versus out-of-plume analysis is provided as an additional line of evidence, but it is not used to dismiss chemicals or risk issues. It is consistent with the approach set forth in the RAWP, and we recommend the analysis be presented in the document. Further, we note that releases of hexavalent chromium from SWMU 1/AOC 1 provides a reasonable and conservative tracer of the flow of groundwater from SWMU 1/AOC 1, and thus provides a footprint that would contain the area of any other chemicals that may have been transported by groundwater from SWMU 1/AOC 1. This fact was part of the rationale for proposing the "in-plume" and "out-of-plume" analysis in the RAWP.	2
HERD-SRS GC11		Sensitivity analyses: HERD does not recommend using the sensitivity analyses as a means for eliminating COPCs from the list of chemicals posing unacceptable non-cancer hazards for groundwater at the site. In the report, average concentrations were used as the EPCs in cases where maximum concentrations (in the wells with fewer than eight samples or greater than five non-detects) predicted unacceptable risks/hazards. Average concentrations are more representative of central tendency exposure (CTE), rather than reasonable maximum exposure (RME) concentrations. In the absence of an adequate number of data points, using the maximum concentration is more representative of the upper-bound risks/hazards. Another alternative to using maximum concentration as the EPC is to collect more data points through additional sampling. HERD recommends that the sensitivity analyses discussion be transferred to uncertainty assessment section (chapter 9) of the GWRA.	Currently, the sensitivity analysis is not used to eliminate any COPCs from the list of chemicals posing unacceptable noncancer hazards for groundwater at the site. We do believe, however, that the sensitivity analysis is an important part of the analysis, and that is it very important for risk managers to understand the extent to which decisions might be made by relying on one detected concentration (as an example). The sensitivity analysis is currently presented in Appendix F of the GWRA, and the major implications of the sensitivity analysis are presented in the body of the risk assessment. We recommend that the sensitivity analysis remain integrated into the GWRA, as currently presented. However, as discussed with the agencies, the text will be reviewed and revised, as appropriate, and clarified to explain that the sensitivity analysis is not used to eliminate chemicals as COPCs from the GWRA.	2
HERD-SRS GC12		Remediation goals: HERD recommends that contaminants in groundwater be remediated such that estimated cumulative cancer risks and non-cancer hazards in each individual well meet risk-management goals.	See responses to comments HERD-SRS GC 5, HERD-SRS GC6, and HERD-SRS GC 7 above.	
HERD-SRS SC1	Section 3	Page 3-12: The report did not include total chromium in the GWRA evaluation. This is acceptable to HERD, as long as the total chromium concentration detected in groundwater is approximately equivalent to the hexavalent chromium concentration in the same groundwater well. If this observation changes significantly in the future, total chromium should be evaluated separately in the GWRA.	Prior to the initiation of the GWRA, we discussed the issue of total chromium versus hexavalent chromium at length with the members of the RFI team. As stated in the Revised Final RFI/RI Volume 2, (CH2M HILL, 2009) "Dissolved total chromium (Cr[T]) is not specifically used for plume delineation because essentially all of the dissolved chromium species measured in groundwater at the Topock site by the Cr(T) analysis method is Cr(VI). For the Topock site dataset as a whole, there is no statistically significant difference between Cr(VI) and dissolved Cr(T) concentrations, as illustrated in graphical cross-plots of the RFI/RI chromium groundwater data (Appendix F4)." Based on this information, total chromium was not included in the GWRA.	3
HERD-SRS SC2	Section 7	Table 7-2: Please include a column showing cumulative non-cancer hazards for each of the wells.	This requested column exists; it is the far right hand column of the table.	No change
HERD-SRS SC3	Section 7	Table 7: Please include a table showing non-cancer hazards for a potential future adult resident.	The revised GWRA will include a table showing non-cancer hazards for a potential adult resident, as requested.	3

Comment Number	Section/ Page	Comment	Response	Comment Category
HERD-SRS SC4	Section 7	Table 7-8: Please remove the word "cumulative" from the headings for the columns. These values correspond to non-cancer hazards for individual contaminants in the wells.	The use of the term "cumulative" is appropriate here, as this column is showing the number of wells where the individual chemical is a material contributor to a cumulative HI of greater than 1 (as described in Appendix K).	No change
HERD-SRS Closing		Overall, the HERD found that the risk assessment for individual wells was conducted in a manner that is acceptable to HERD. However, HERD does not concur with the use of site-wide averaging of contaminant concentrations and sensitivity analyses, in eliminating chemicals from the COPC list. Groundwater should be remediated such that the cumulative risks/hazards to potential future receptors meet risk management goals. HERD notes that the decisions made in this document are site specific and should not be construed as a policy decision applicable to other sites. If you have additional questions please feel free to contact me at (714) 484-5448 or Sroysemm@dtsc.ca.gov.	See responses to comments HERD-SRS GC7, HERD-SRS GC9, HERD-SRS GC10 and HERD-SRS GC 11 above.	No change
MWD C1		MWD does not have any comments on the Risk Assessment.	No response required.	No change
DOI GC1		The Groundwater Risk Assessment (GWRA) is generally a high quality offering that provides significant clarification of the potential human health risks associated with site groundwater contamination. The document itself is a superior quality production exhibition. The assessment and exposition is transparent and generally reproducible. On the whole, the assessment by and large complies with prevailing guidance; however, there are notable exceptions which we discuss below.	No response required.	No change
DOI SC1	ES	The format of the Executive Summary is satisfactory; however, based on our comments below, we anticipate that it will be revised.	No response required.	Changes below
DOI SC2	ES.2.2, Page ES-4, Paragraph 1, 3rd sentence	Remove the following words "sparsely vegetated, and".	The requested revision will be incorporated into the final GWRA.	3
DOI SC3	ES.2.2, Page ES-4, Paragraph 2, Last sentence	Dense monotypic stands of salt cedar do not allow any other plant growth under the canopy. Typically, arrowweed grows around the margins of salt cedar and/or around the margins of riparian areas.	The text will be revised to state: "This plant community is characterized by dense thickets of tamarisk, or salt cedar (*Tamarix* sp.), sometimes with an understory of arrowweed (*Pluchea sericea*). Salt cedar is highly successful in arid climates with saline or alkaline soils and often occurs in monotypic stands in riparian areas."	3

DOI SC4	ES.2.3, Page ES-5, Paragraph 2, Last sentence	Remove the entire sentence.	We do not agree that the following sentence should be removed from the GWRA: "As discussed in the RAWP, although future residential use of the USBLM land is unlikely, USDOI has specifically requested an evaluation of future residential use on USBLM property". This is a factual statement, was presented in the RAWP, and is an important point to communicate. Please refer to comment DOI SC 13 for additional details.	3
DOI SC5	ES.3, Page ES-7, 3rd bullet	Do the SVOCs and TPHs analyzed for encompass all of the PAHs that were detected?	Please refer to Table 3-4b in the GWRA for a summary of all constituents sampled for and detected in site groundwater.	No change
DOI SC6	ES.4, Page ES-8, Paragraph 1, 1st sentence	Delete the word 'relevant' because this implies that pH and TDS are not important to human health or the environment. Changing the sentence to 'constituents or general chemistry parameters that are not applicable to human health or environmental risk assessments' would express your original intent without the negative connotation.	The requested revision will be incorporated into the final GWRA.	3
DOI SC7	ES.6, Page ES-11, Paragraph 2	Since soil characterization is still revealing additional constituents of potential concern, it will be necessary for PG&E to verify that those new constituents (e.g., dioxins) are not in the groundwater. We expect groundwater wells to be sampled and analyzed for dioxins.	Additional analyses of groundwater are currently underway. Nonetheless, as discussed in the RAWP, a cutoff date for the analytic data needed to be established in order to proceed with the current GWRA. As stated in both the RAWP and the GWRA, the additional groundwater monitoring data may be incorporated into the Groundwater Risk Assessment Addendum, if necessary and appropriate. We note, however, that the current GWRA is a GWRA for SWMU 1/AOC 1, and the upcoming CMS/FS describes the remedy for groundwater associated with SWMU 1/AOC 1.	No change
DOI SC8	ES.7.1, Page ES-13, Paragraph 1, 2nd sentence Section 6.1, Page 6-1, 2nd paragraph	The term 'response potency' is a redundant. Use one or the other but not both.	As requested, we will remove the term 'response' from this sentence.	3

DOI SC9	ES.8.1, Page ES-16, Paragraph 2, 2nd sentence	The word 'estimated' in "estimated EPC" is an unnecessary qualifier. An EPC by definition on page ES-12 is 'the estimated average concentration.'. Please check and delete all occurrences of this unnecessary qualifier.	We agree that the definition, up front, of the EPC conveys that the EPC is an estimated value. However, because we believe that it is an important point that the exposure concentrations are estimated values of potential exposure, we specifically wanted to remind the reader, throughout the report, that the exposures presented in the GWRA are estimated values. For these reasons, we believe the 'estimated' qualifier is important, and we would propose to leave it in.	3
DOI SC10	ES.8.4, Page ES-18, Table	There are no superscripts for notes 3 and 4 in the table. Please add superscripts to notes 3 and 4. Categorizing frequency and magnitude of contribution is a way to break down the estimated risk so it can be explained easily. However, low, medium, and high should have been defined in the RAWP or in a Technical Memo for the human health risk assessment. The Synthesis technique summarized here was not presented in the RAWP, it does not conform to USEPA RAGS, and the information is insufficient for determining which COCs to move forward into the CMS/FS. See comments on Section 7.0.	The superscripts will be added to the table. We developed the categorization technique merely as a way to help organize like-chemicals with other like-chemicals, with the idea that it would help the reader absorb a large amount of complicated information. When preparing the RAWP, we provided the risk assessment methods consistent with Risk Assessment Guidance for Superfund (RAGS) and other applicable guidance. The categorization is not a method for estimating risk, it is merely a risk communication tool developed with the benefit of the completed risk estimates (which were not available when the RAWP was prepared), and provides perspective on relative contribution to risk useful for risk management purposes. We do not believe that the categorization provided is *inconsistent* with risk assessment guidance, although we acknowledge that it does not specifically appear as an example synthesis tool in the guidance documents. See response to comment DOI SC22 for additional discussion regarding the selection of COCs.	3
DOI SC11	Section 2.2.2, Page 2-3, 5th sentence	Delete the sentence describing terrestrial wildlife diversity. DTSC requested you to remove it from Eco TM #3 and it does not belong here either. The sentence is not true because 1) terrestrial wildlife diversity is not low – it is a typical community for the Mojave Desert. The upland, terrace slopes of the lower Colorado River around the Topock Compressor Station very disturbed closest to the PG&E fenceline surrounding the station, but this disturbance decreases with distance from the facility. Also, the wildlife corridor outside of the TCS is not incomplete. We challenge the use of this reference from CH2M Hill (2005a) and request that it not be used again.	Please see response to comment FMIT GC2 for proposed revision to address this comment. Natural barriers such as the Chemehuevi Mountains and Colorado River do interrupt movement of some terrestrial wildlife species. The text will be revised to narrow the scope of the statement.	3
DOI SC12	Section 2.3.1, Page 2-5, 3rd paragraph	A portion of the Topock Maze occurs within the boundary of the Havasu NWR. Please adjust the text accordingly.	The revised GWRA will acknowledge the presence of the Topock Maze.	3

DOI SC13	Section 2.3.2	Discusses anticipated future use of the site and adjacent environs and seems to reach a conclusion that any future use of groundwater is highly improbable. The assessment acknowledges a potential use of groundwater north of I-40 as plausible. This description evolves into a theme that is repeated though-out the assessment and which may to lead some readers to downplay and perhaps misunderstand the significance of site related constituents impacting groundwater quality. As discussed below, DOI request further evaluation on this subject and requests that the thematic expression be modified accordingly. The conclusions regarding potential for future groundwater use are reached based on an incomplete consideration of factors that contribute a groundwater useability assessment. Aspects that the reader needs to be assured have been comprehensively researched and well thought-out include, but are not limited to: 1) the existence of legal prohibitions on groundwater use (e.g., covenants, deed restrictions), 2) potential need for beneficial uses of groundwater in the future beyond direct human consumption (e.g., irrigation), 3) opportunity for groundwater use in a recreational setting (e.g., an extraction well used by campers), 4) forthcoming overall water utilization needs in light of regional growth pressures in conjunction with resource commitments and availability of the Colorado River to support those needs (e.g., implementation of Colorado River Compact in light of pending actions in upper basin states), 5) aquifer characteristics and potential future uses (e.g., is their adequate yield to supply a range of plausible uses?). Please investigate, complete, and revise this section, and ensuing sections which draw from this section, based on this examination. As a guide for this assessment, a premise embracing resource protection and renewal in the arid southwest and recognizing the potential opportunities for future population expansion and the need for valuable water resources to support that development is recommended.	We acknowledge that the topic of potential future land use is a complicated subject at the site, in part because the site consists of property under federal ownership and property that is designated as a Wildlife Refuge. The discussion regarding future potential land used was agreed upon in 2007, and the descriptions of reasonable future land use were developed based on input from the landowners (as specified in DOI 2007). Further, these future land-use descriptions presented in the GWRA were all presented in the approved RAWP. As discussed during the May 5, 2009, meeting, DOI concurs that the language presented in Section 2.3.2 should remain as currently presented in order to be consistent with previous direction from the landowner. We do note, however, that the GWRA mentions the beneficial use aspects of the groundwater in Section 5.4 of the report, and most importantly, evaluates every single groundwater monitoring well under the assumption that the groundwater is being used as a potable water source.	2
DOI SC14	Section 3.2.1, Page 3-4,	In consideration of recent findings during the East Ravine investigation, the results of groundwater analysis from the new wells in the East Ravine need to be further evaluated in the overall groundwater risk assessment.	As stated in the GWRA, information from the East Ravine, and any other relevant and pertinent groundwater data collected after the completion of the Revised Final RFI/RI Volume 2 (CH2M HILL, 2009) and Addendum (CH2M HILL, 2008a) documents and the associated GWRA, will be incorporated into a Groundwater Risk Assessment Addendum, if necessary.	2
DOI SC15	Section 3.2.1.2, Page 3-9, 3rd paragraph	Please compare the data on PAHs in the groundwater data set with the PAHs detected in the soil sampling investigation. Provide us with the names of any PAHs that were detected in surface soils but not analyzed in groundwater. It will be necessary to collect more groundwater samples to demonstrate that the dioxins and pesticides detected in soils have not migrated to the groundwater.	To address the first part of the comment, PG&E identified the polycyclic aromatic hydrocarbons (PAHs) detected in surface soil but not analyzed in groundwater. Only one PAH, 1-methylnaphthalene, was detected in surface soil but not analyzed for in groundwater. As indicated above in response to comment DOI SC14, any other relevant and pertinent groundwater data that is collected after the completion of the GWRA will be incorporated into a Groundwater Risk Assessment Addendum, if necessary.	No change
DOI SC16	Section 3.3 Data Useability	DOI is not convinced that the data set used in the GWRA has been suitably scrutinized and evaluated for useability and, in turn, whether the GWRA can be relied upon as the foundation to reach conclusions regarding its stated purposes.	Given the length of this comment, the response will be separated into sections, in accordance with the numerous topics identified in the comment.	2

		Section 3-2 of the RAWP in essence defers data validation and useability issues to the RFI/RI Vol. 2 (Jan 2009) and RFI/RI Addendum (Dec 2008) noting that useability will be evaluated in those RFI/RI documents in accordance with four conventional risk assessment guidance's (see pp 3-14 RAWP). Section 3.3 of the GWRA basically defers back to the RAWP. This circular path leads the reader to the RFI/RI Volume 2 and its Appendix H (Feb 2009) as the principal source for data quality and useability information. We note that there is summary discussion of data quality in Section 3.3 of the GWRA; however, there is no detailed analysis and the reader is left with the impression that the GWRA took what was provided in the RFI/RI Vol. 2 and Addendum at face value. As noted below, Appendix H does not meet the expectations set forth in the RAWP. Supporting observations include: 1) Appendix H is a summary of groundwater data spanning the period 2002 – 2007. Has data collected since that time been validated and evaluated for GWRA useability (the topic is not addressed in the RFI/RI Addendum). 2) Appendix H provides only cursory information and does not conform to the risk assessment data useability guidance (i.e., those cited in the RAWP). Moreover, neither Appendix H nor the RFI/RI Vol. 2 main text addresses data useability for risk assessment purposes. In fact, neither even cites the four risk assessment data useability guidance's set forth in the RAWP. 3) None of the "data trail" documents (RFI/RI Vol. 2 [and Appendix H] or the RFI/RI Vol. 2 Addendum) speak straightforwardly to risk assessment data useability. DOI requests PG&E to prepare a risk assessment data useability matrix in tabular form that can provide the reader summary information by appropriate time or phase interval. The matrix should pull from existing data validation, quality, and useability summaries and should include all topics discussed in Section 3.3.1 through 3.3.7. Special emphasis should be placed on the following: • Analytical suites evaluated • Data validation status (percentage validated, number flagged (J R B, etc.) any pertinent validation narrative discussing useability issues. • Quantitative summary of detection limit performance noting: o Number of analysis achieving specified deletion limits	First, the project has followed regulatory guidance and procedure such that all stakeholders reached the conclusion that groundwater impacts associated with releases from SWMU 1/AOC 1 have been adequately characterized by approving the Revised final RFI/RI Volume 2 (CH2M HILL, 2009) and RFI/RI Volume 2 Addendum (CH2M HILL, 2008a). This review and acceptance was conducted so that the project could move forward to the risk assessment/remedy stage of the project. Therefore, we believe that the stakeholders had agreed that the dataset used in the GWRA has been suitably scrutinized and evaluated for usability and, in turn, that the GWRA can be relied upon as the foundation to reach conclusions regarding its stated purpose. If there is sufficient data to reach reasonable conclusions regarding the nature, extent, and magnitude of impacts associated with the historical releases (untreated releases that occurred between 1951 and 1964), and sufficient data to enter the remedy stage of the project, then it is our experience that there is more than sufficient data upon which to make reasonable risk-based conclusions. We disagree that the GWRA defers back to the RAWP with respect to data usability. It does, as agreed upon in the RAWP, refer to the RFI/RI Volume 2, as the document that is intended to describe and fulfill essential data usability criteria. The reason the data usability criteria were intended to be set forth and discussed in the RFI/RI Volume 2 is that any conclusions that the data are inadequate could lead to the corresponding conclusion that data gaps exist and more data needs to be collected. Regardless of whether data quality discussions of the RFI/RI Volume 2 were specifically organized into the 'typical' five data usability criteria, stakeholders agreed that the data was of sufficient quantity and quality to meet the fundamental data objectives of the RFI. Appendix H, referred to in this comment, was specifically prepared in response to a comment from DOI in which they were concerned that the RFI contained no discussion of the data quality objectives (DQOs) or data quality indicators (DQIs) that assure the reader that the data is of acceptable quantity and quality to support the conclusions presented. The data quality discussions, presented in Appendix H and throughout the rest of the RFI, were approved by USDOI and other stakeholders and regulators. It is PG&E's position that approval of the RFI and its data quality discussions is sufficient to move forward to the next step of the project. Further, the GWRA provided many additional evaluations with respect to risk assessment data usability (e.g., adequacy of detection limits), which support that data from the RFI is of sufficient quality to develop a risk assessment and CMS/FS. Further, where it was determined that additional data usability information, not highlighted in the RFI/RI Volume 2, would be useful to the risk assessment, this information was analyzed and presented in the GWRA (e.g., percentage of qualified data; impact of elevated detection limits). And, the overall strengths and weaknesses of the dataset for individual constituents/monitoring wells are discussed in Sections 7 and 9 of the GWRA. With respect to comments on the approved Appendix H of the RFI/RI Volume 2:

		o Specific analytes where detection limit problems are encountered o Number of analyses achieving detection limits relative to Risk Based Concentrations (RBCs) o Number of analysis affected by matrix effects • An explicit data quality useability statement. This objective presentation and evaluation there of will help ensure that data quality and useability has been scrutinized in accordance with expectations set forth in the RAWP and those of comparable CERCLA/RCRA projects. Moreover, the presentation and evaluation ease concerns stemming from well intended , but caveat laden general statements occasionally found in text (e.g., pp 3-21 "For these reasons, data collected over the 10-year investigation period are generally considered comparable, within the general limitations expressed during the individual data validation efforts"). Simply stated, we need to have a presentation of the information to address question such "what are the limitations, what are the data sets with limitations, and how do they affect the analysis"? Please see our comment below regarding Figure 4-1 for information related to the request.	1) The PG&E Program QAPP (CH2M HILL, 2004b) defines four types of laboratory deliverables. The data deliverable requested depends on the DQOs of the individual project. All Topock data packages associated with the groundwater investigation are requested at a level 3 or above type deliverable. As defined in the PG&E Program QAPP "Level 3 data is appropriate for investigative, confirmatory, or closure results. Critical project decisions may be made using this data." ALL (100%) of the data presented in the RFI/RI Volume 2 Addendum was validated to a level 3 as defined in Section 8.2 of Appendix D, *Quality Assurance Project Plan for Water Quality Sampling and Analysis*, of the *PG&E Topock Program Procedures Manual* (CH2M HILL, 2005). 2) The information presented in Appendix H and elsewhere in the RFI/RI Volume 2 has been specifically organized in the GWRA into the five data usability criteria presented in the RAWP. As such, although the information in the RFI wasn't specifically organized according to the five data usability sections referred to by DOI, we believe that much of the fundamental data usability information was contained in this document, and where certain additional pieces of information were needed, additional analyses were discussed and presented in the GWRA. 3) As stated in number 2 above, where the 'data trail documents' didn't speak straightforwardly to data usability (e.g., detection limits), this information was presented in the GWRA, and organized according to the five data usability criteria. The specific elements DOI has requested in item number 3 are contained in the current version of the GWRA in the sections noted below. • Analytical suites evaluated (Tables 3-4a to 3-4e present these in detail). • Data validation status (percentage validated, number flagged [J R B, etc.]) and any pertinent validation narrative discussing usability issues: o Information on the percent of the data that is J-flagged and rejected is specifically mentioned in Section 3.3.4. o Information regarding blank flags was not provided in the draft GWRA, but will be incorporated into the final GWRA. Specifically, the following information regarding blanks will be added to Section 3.3.4: "Blank flags are not used in data validation for the PG&E Program and are not found in the guidance document *Contract Laboratory National Functional Guidelines for Inorganic*

			Data Review (USEPA, 1999)." • Quantitative summary of detection limit performance noting: o Number of analysis achieving specified detection limits: This is discussed in Section 3.3.3 and Section 9 text/tables. o Specific analytes where detection limit problems are encountered: This is discussed in Section 3.3.3.1 and Section 9 text/tables. o Number of analyses achieving detection limits relative to Risk Based Concentrations (RBCs): This is discussed in Section 3.3.3.2 and Section 9 text/tables. o Number of analysis affected by matrix effects: The GWRA doesn't specifically mention the number of analyses affected by matrix effects. However, as matrix effects act to raise reporting limits, Sections 9.2.3 and 9.4.2.1 specifically mention the impacts of elevated detection limits on the risk assessment. • An explicit data quality usability statement was not contained in the RFI/RI. Nonetheless, the fundamental elements that contribute to the development of a dataset that is usable for ascertaining that characterization is complete (i.e., the conclusion of the approved RFI/RI Volume 2) and that the project can move forward to the risk assessment and remedy selection stage of the project, are contained in both the RFI/RI Volume 2 and the GWRA. Based on the above, we believe that the data quality and usability have been scrutinized in accordance with expectations set forth in the RAWP and those of comparable CERCLA/RCRA projects. Section 9 presents a thorough discussion of the key uncertainties associated with each step of the risk assessment, including the implications of the dataset, its limitations, and the ultimate impact on the analysis and conclusions. As discussed with DOI, the various requested data usability elements requested by DOI, that are currently presented in the GWRA in the sections identified above, are attached as a Data Usability Table (Table 2), and will be presented as an appendix to the revised GWRA.	
DOI SC17	Figure 4-1	DOI is concerned with sole reliance on the logic in Figure 4-1 and the goal of erring on the side of	The COPC selection process, outlined in Figure 4-1 and related text in the GWRA is robust, entirely	2

	and related text.	protectiveness. The concern is that when an individual well ICOPC maximum concentration exceeds the UTL, the ICOPC is subjected to further statistical tests which, in some cases, can lead to an ICOPC being deleted from the analysis when, possibly it should be retained for reasons beyond the rationale illustrated in Figure 4-1. A case in point is Cr VI in MW 23 where the following is observed: • Cmax = 1.02 mg/l (1,020 µg/l) which exceeds the Background UTL of 0.0318 mg/L (by a factor of 32) (Table 4-1a). • Following the logic and statistical tests, Cr VI at MW 23 is omitted from the GWRA because it passes the Gehan test (Table 4-1b). • On further inspection of MW 23 results (See pages 23 and 24 of 96 in Table A-1a in Appendix A) however, it is apparent that there are considerations other than the mathematic surety and logic of the approach that can affect the screening and which should be understood. Consider: o Prior to June 12, 2004, Cr VI was consistently reported as 10u (non detect at 10 µg/l. Note there are 18 consecutive 10u reports. o After June 12, 2004, a pattern of Cr VI detections begins to emerge, some detections less to 10 µg/l (perhaps there was a change in sampling or analysis resulting in lower detection limits?). o The emerging pattern seems to suggest: a) presences of Cr VI in a well supposedly considered un affected prior to 2004 and, b) increasing concentrations. o The pattern continues though the cut off date of May 6, 2008. DOI entered the MW 23 Cr VI data into ProUCL 4 (Did PG&E exclude the 05/06/2008 Field Dup of 23.2 µg/l J?), computed summary statistics*(see table at end of document) and got the following results. These results indicate: • The mean (including all 36 entries with 14 non detections treated by ProUCL's routines) concentration just exceeds the background UTL (31.8 µg/l) as do two of non parametric estimates of the UCL95% OTM. • The mean of "just the 14 detections" – all of which occur after June 12, 2004; however, is 83.6 µg/l which is more that double the "all entries" mean and, accordingly about 2.5 times the background UTL.	consistent with risk assessment guidance, standard practice, and the approved RAWP. In general, this approach errs on the conservative side. The example that DOI points out, the exclusion of hexavalent chromium from the MW-23 risk evaluation is a good example of the situation where an alternative approach (i.e., the inclusion of hexavalent chromium in the quantitative risk assessment for MW-23) would not result in any material changes in the project. The risk assessment culminates with the identification of the COCs to be carried forward to the CMS/FS; this conclusion is unchanged by MW-23 (i.e., regardless of MW-23, hexavalent chromium is very clearly a COC that gets carried forward to the remedy stage of the project). It is the role of the CMS/FS rather than the GWRA to determine how and where to cleanup the hexavalent chromium. There are two principal points/concerns raised in this comment, both of which question the overall 'validity' of the process used to identify the chemicals to be included in the quantitative risk assessment. The first concern pertains to those situations in which the maximum detection of a chemical in a well was greater than the background UTL, but the additional statistical tests (i.e., the Gehan and the Quantile test) support that the presence of the chemical is likely within background concentrations, and thus the chemical was not included, at that well, in the quantitative risk assessment. The second concern has to do with the use of the background UTLs, as set forth in the approved Groundwater Background Study (CH2M HILL, 2008c), as the initial point of comparison to determine whether a chemical is likely present above background concentrations. Each of these concerns is discussed further below. **Concern 1: Use of statistical population comparison tests (i.e., Gehan and Quantile test) to conclude that a chemical is present within background concentrations (and thus not included in the risk assessment at that well).** Discussion of MW-23: The comment identifies one well, well MW-23, as an example of situations where the maximum detected concentration is greater than the background UTL (for hexavalent chromium), but where hexavalent chromium was screened from MW-23 because it passed both populations tests: Gehan and Quantile. The Quantile test compares the upper tail of the site and background datasets, which includes the single high detection of 1.02 mg/L. Because the Quantile test supports the conclusion that the population is below background, it seems likely that the single high detection of 1.02 mg/L is an outlier. To check the validity of this conclusion, the outlier test was run in ProUCL to assess the likelihood that this single elevated concentration is an outlier. According to the Rosner's Outlier Test, there is 99% likelihood that this result is an outlier. While ProUCL recommends conducting statistical analyses both with and without potential outliers, we have conservatively conducted our statistical analysis with the inclusion of outliers. In fact, the next highest sample of hexavalent chromium from MW-23 is 23.2 µg/L, a level that is actually below the background UTL and the RBC of 46 µg/L, calculated and presented in the

		• Both UCL95% OTMs both exceed the Cal Groundwater Standard of 50 µg/l. • Both UCL95% OTMs also exceed the Risk-Based Concentration (RBC) of 46 µg/l. This summary would indicate that we are 95% confident that the mean Cr VI concentration at MW 23 exceeds: the background UTL, the Cal Groundwater Standard, and the Site-Specific RBC. Based on these comparisons, it appears that, although it was screened out by through Figure 4-1, Cr VI in MW 23 poses a significant health risk. On this basis, please add MW 23 back into the GWRA. This illustration points to other issues discussed below. This illustration is concerning because there are other entries in Table 4-1b where an ICOPC with a maximum concentration exceeding the background UTL is deleted via the follow on statistical tests. Our concern deals not only with the possibility of missing a health risk, but also with other issues stemming from sole reliance on purely numerical techniques. Issues that might have been examined and considered in the Cr VI / MW 23 example includes, but are not limited to: • Is the detection that dominates this assessment (1,020 µg/l) valid? (See DOI comment regarding Data Usability.) • Why wasn't the trend of emerging Cr VI and increasing detections observed and factored into the analysis? (Reports provided to the risk assessors in the data useability assessment should have noted this.) • Are the early year data (before 2004) comparable to the later year's data? (Again, see our comment regarding Data Usability.) • In assessing future risks in a dynamic situation, how should time trends be considered? • Is the more recent data actually more indicative of what could be expected in the future at MW 23? • What is the extent of this type of phenomena throughout the 10 year groundwater surveillance history and subsequently the GWRA? Please note we are not criticizing PG&E's use of the screening method; the technique is very powerful screening tool that generates an abundance of useful information in a cost-effective manner. However, as illustrated, when used in isolation, it is not without potential shortcomings.	GWRA. Note that the validity of this elevated result was assessed in Appendix 2 of CH2M HILL's *Groundwater and Surface Water Monitoring Report, Second Quarter 2007*. Because MW-23 is a bedrock monitoring well, it is "a low-yield well that typically pumps dry during purging and recovers at a very slow rate." Typically, sampling occurred the day following purging; however, during this sampling event, groundwater recovery was more rapid allowing the sample to be collected soon after purging. CH2M HILL conducted a focused test in June to July 2007 and was not able to recreate the elevated results under various purging trials. The origin of the anomalous high result was not determined, so the sample result was not rejected and has been included in the dataset. We concur with DOI that there does appear to be an increasing trend in hexavalent chromium concentrations in MW-23 since 2003. However, evaluation of the data at MW-23 indicates that the maximum detection of 1.02 mg/L does not appear to be reflective of the overall trend, and as described above, the next highest concentration of hexavalent chromium is 23.2 µg/L. Most importantly, the treatment of hexavalent chromium in MW-23 in the GWRA does not represent an example of "unseen and unintended faults." The conclusion of the risk assessment is that hexavalent chromium is a COC, and the CMS/FS will address how and where the remediation will occur. None of this is changed by the fact that MW-23 was not included in the quantitative risk assessment. And, as the stakeholders are aware, the elevated concentrations of hexavalent chromium around MW-23 are being further explored through the additional data collection efforts occurring around the East Ravine. General Discussion of Approach We reiterate that we used a conservative screening approach whereby well/chemical pairs were screened out only when both the median population test (Mann-Whitney or Gehan) and the quantile test (comparing the upper tails) agreed that site concentrations are less than or equal to background concentrations. Of 440 well/chemical pairs that had a maximum detection greater than the associated UTL, 192 (44 percent) well/chemical pairs were further analyzed by population tests. Only 19 (4.3 percent) well/chemical pairs were screened out of the risk assessment. In order to further evaluate the concern posed by DOI, the 19 well/chemical pairs that were screened out of the risk assessment because of the statistical population comparison tests were examined in further detail. The summary statistics for each of the chemical/wells pairs, including number of detections, number of samples greater than the background UTL, and the 95% upper confidence limit (UCL) are all presented in the attached Table 3. Also attached, as Table 4, are the results of each of the individual sampling events for these chemicals, to facilitate the reviewers more detailed evaluation of the data. As indicated in Table 3 (attached), of the 19 well/chemical pairs screened out of the risk assessment,

<tr><td></td><td></td><td>This concern with confidence in the screening process is exacerbated when it is recognized the background UTL95%95% used as the initial screening tool is not a highly conservative screening metric. As indicated in USEPA Guidance, the UTL is actually an upper end of the range yardstick often used to identify outliers (Guidance for Comparing Background and Chemical Concentrations in Soil for CERCLA Sites). When set at the 95% 95% gauging point, an IPCOC is flagged for consideration only if its maximum concentration is a high end outlier. There could be numerous IPCOC detections just below the gauging level; well outside the background distribution's central tendency range and the IPCOC dismissed from the analysis. For reference, at the Department of Energy's Rocky Flats Environmental Technology Site, the UTL95%95% was rejected by stakeholders because it was not a conservative tool. Please note that this comparison technique does not recognize the statistical issue of multiple comparison which further underscores the need to use it with some caution and consideration of other factors, particularly involving close calls.

DOI requires that PG&E consider these issues and develop a management system that will ensure that COPC screening processes such as those set forth in 4-1, 4-2, 4-3, and 4-4 do not contain unseen and un intended faults such as that describe above and, importantly, that the GWRA results are trued with RI/RFI observations and that the data used in the screening process has been adequately examined to ensure its useability for the GWRA.

<tr><td>Mean (of all 36 entries)</td><td>34.6 µg/l</td></tr>
<tr><td>Mean (of 14 detections)</td><td>83.8 µg/l</td></tr>
<tr><td>UCL 95 OTM (Chebyshev)</td><td>160.2 µg/l</td></tr>
<tr><td>UCL 95 OTM (ProUCL "Suggested)</td><td>94.2 µg/l</td></tr>
<tr><td colspan="2">These results basically match PG&E's.</td></tr>
</table></td><td>only four (0.9 percent) have a calculated 95%UCL above the associated background UTL. These four well/chemical pairs are hexavalent chromium in MW-23, vanadium in MW-34-80, vanadium in MW-37D, and zinc in OW-5M. Each of these four chemical/well pairs has a single distinct elevated concentration, with ratios of the highest to second highest observed concentration of 44, 16, 10, and 7.5, respectively. The 95%UCLs are dominated by the single elevated concentration. The outlier test using ProUCL was run for these four chemical/well pairs. In every case, ProUCL reports that the single elevated concentration is 99% likely to be an outlier.

The zinc outlier of 278 µg/L was "J" flagged as estimated because zinc was not detected in the associated field duplicate with an RL of 10 µg/L (see CH2M HILL's *Groundwater and Surface Water Monitoring Report, Fourth Quarter 2007*.). As indicated in the GWRA, all data containing "J" flags were included in the GWRA. We note that not only is zinc not a COPC associated with SWMU 1/AOC 1, the maximum detection of zinc, 0.278 mg/L, is more than an order of magnitude below the RBC of 4.7 mg/L (as presented in Appendix N). Accordingly, we do not believe that the one high hit of zinc, at this one well, affects any of the conclusions established in the GWRA.

The RFI/RI Volume 2 discusses the high vanadium concentrations, and states that they are likely due to laboratory analytical issues. "Of the 14 [vanadium] samples in plume or plume flowpath wells that have exceeded UTL, ten were from a single sampling event in March 2005. Nine of these ten were reported as anomalous at the time (CH2M HILL, 2005a)[8] and re-sampling in June 2005 showed vanadium values back in normal range (below UTL), suggesting that laboratory analytical issues were the source of the elevated concentrations." (CH2M Hill, RFI/RI Volume 2, 2009) Both outlier vanadium samples are from the single sampling event in March 2005 mentioned above. Accordingly, these two potential vanadium samples were not overlooked, do not represent an example of unseen and unintended faults, and were deliberately and conservatively included in the GWRA dataset because they were not rejected from the database during the data quality assessment process (which occurs per the approved QAPP). As vanadium is not a COPC that is associated with potential releases from SWMU 1/AOC 1, additional focus on these two particular wells was not deemed necessary or relevant to the overall conclusions of the GWRA or the CMS/FS.

As requested, the temporal trends of vanadium in MW-34-80, vanadium in MW-37D and zinc in OW-5M were evaluated. There does not appear to be increasing concentrations over time in any of these chemical/well pairs.

In summary, based on this analysis, we believe that the approach documented in the GWRA is sufficiently conservative, has appropriately excluded wells based on a conservative comparison to background populations, and is not resulting in unseen and unintended faults that in any manner that affect the overall conclusions of the GWRA. We propose to include the above analysis and discussion in</td><td></td></tr>

			the uncertainty section of the GWRA. **Concern 2: Use of the background UTLs as the initial point of comparison to determine whether a chemical is likely present above background concentrations.** As indicated in the comment, if the maximum concentration of a chemical at a given well is below the background UTL, as established in the Groundwater Background Study (CH2M HILL, 2008c), the chemical is determined to be within background concentrations and thus is not evaluated further. This approach was very specifically and clearly set forth in the RAWP, which was approved by all stakeholders, and is entirely consistent with CalEPA guidance (CalEPA, 1997[9]). Based on our conference call with DOI and DTSC on April 20, 2009, we understand that DOI will not require further evaluation, analysis, or discussion of this approach.	
DOI SC18	Section 4.1.1, Page 4-2 to 4-4.	Please discuss how PG&E arrived at using the Form 1 Hypothesis Test for the background comparison tests and evaluate GWRA implications for its use. In ProUCL the selection of Form 1 (Ho: Site <= Background) or Form 2 (Ho: Site => Background) shifts the power of the test. For close calls and other reasons discussed below (i.e., data sets that are similar) Form 2 is the more conservative test. That is, Form 2 of the test is more likely to result in including rather than rejecting an ICOPC; from a protectiveness perspective, Form 2 is preferred. One USEPA Guidance (Multi-Agency Radiation Survey and Site Investigation Manual), recommends the Form 2 hypotheses for this reason. USEPA's Guidance for Comparing Background and Chemical Concentrations in Soil for CERCLA Sites does not make a policy recommendation on the issue; however, the guidance does identify two serious problems with the Form 1 test; one dealing with lack of power to detect small difference when larger data sets are involved (as could be the case with the Site wide comparisons) and the second dealing with a lack of power when situations where insufficient data are available (as might be the case when the well-by-well comparison are made). USEPA Guidance for Comparing Background and Chemical Concentrations in Soil for CERCLA Sites urges users to give careful consideration to selection of the form of the hypothesis test.	The use of Form 1 of the null hypothesis is based on and consistent with DTSC's guidance (Cal/EPA, 1997[9]) Moreover, the USEPA MARSSIM recommends Form 2 of the null hypothesis in cases where the primary goal is to evaluate compliance with a radiological release criterion. However, this guidance recommends Form 1 of the null hypothesis in cases where the primary goal is to evaluate whether a radiological release is distinguishable from background. The latter case is much more closely related to our use of the null hypothesis: to evaluate if chemical concentrations in groundwater are distinguishable from background concentrations (USEPA, 2000; Appendix D, page 17). Considering USEPA's background guidance, we believe the reviewer has misinterpreted the first concern regarding Form 1 of the hypothesis. The guidance states "If the site exceeds background by only a small amount, there is a very high probability that the null hypothesis will be rejected if a sufficiently large number of samples is taken" (Page 3-6). Said differently, the site dataset could be negligibly above the background dataset, but if the dataset is large enough the population test will conclude site concentrations are above background concentrations – this would be conservative. Therefore, if the sole goal is to be conservative, the GWRA has followed an approach consistent with that goal. The second concern regarding the Form 1 hypothesis is valid. If sample sizes are too small, the test becomes more unlikely to reject the null hypothesis – as DOI notes, this is potentially non-conservative. However, based on guidance presented in the RAWP, a minimum number of samples and detections were specified to ensure that sample sizes were not too small to conduct the statistical tests. In particular, the cutoff of eight or more samples and five or more detections was defined in the approved	2

			RAWP for calculating 95%UCLs in ProUCL. Accordingly, population tests were performed only on well/chemical pairs with eight or more samples and five or more detections. Well/chemical pairs with smaller datasets were assumed to be above background. Based on these factors, we believe that Form 1 is consistent with agency guidance, consistent with standard risk assessment practice, and sufficiently conservative for our application. We do not believe that going back and questioning the basic rationale behind the agency guidance, and what is standard practice at sites throughout California, particularly for a topic that affects only 4 percent of the dataset for the entire site, is a useful exercise nor likely to in any material way affect the conclusions of the GWRA.	
DOI SC19	Section 4.1.1, Page 4-2	Please describes how the Upper Tolerance Limits (UTLs) were computed and evaluate the significance of the type UTLs used in the background screening (i.e., Figure 4-1 et al.,). Specifically, are they parametric, non parametric, or more a mixture of both? Parametric UTLs are appropriate when the underlying data is normally or lognormally distributed. In general, if the data are not normally or lognormally distributed, non parametric UTLs are appropriate. The significance is that a parametric UTL will usually be lower value than a non parametric counterpart for the same data. When used to screen maximums for outliers (as the case in GWRA) using a lower UTL is more conservative than using a higher UTL. See also our discussion of the UTL as a conservative screening tool the in previous comment. If non parametric UTL95%95% were used, the initial screening step in Figure 4-1 could be highly non conservative and the significance may have to be evaluated.	The methodology used in calculating background threshold values was documented in the Groundwater Background Study (CH2M HILL, 2008c), which was reviewed and approved by DOI. The RAWP very clearly states that it will rely on these UTLs in certain steps of the risk assessment process, and presumes that details regarding the methods used in the development of the UTLs do not need to be re-iterated or re-evaluated for appropriateness. Please refer to the approved Groundwater Background Study for details regarding the methods used in calculating the UTLs. In brief, and as described in the approved background study (CH2M Hill, 2008c), parametric 95%UTL are used when datasets fit a normal or lognormal distribution as determined by the Shapiro-Wilke test. When a nonparametric UTL is developed, the upper percentile is based on the size of the dataset, and not strictly the 95th percentile as is the case with parametric UTLs. In general, background datasets contained 25 values except in cases where outliers were thrown out (e.g., zinc has 24 values). As documented in the background study: "When 25 values were available, the non-parametric UTL is a 95 percent upper confidence bound of the 89th percentile. For zinc, where 24 values were available, the non-parametric UTL is a 95 percent upper confidence bound of the 88th percentile. Thus, there is a slightly higher opportunity for declaring a result to be in exceedance of background when a non-parametric UTL is calculated." (CH2M Hill, 2008c, page 3-3) Thus, all nonparametric UTLs were calculated as the 95%UCL bound of the 89th or 88th percentile. No nonparametric 95%UTLs are used. Nonparametric UTLs were calculated for aluminum, antimony, beryllium, cadmium, chromium, cobalt, hexavalent chromium, lead, mercury, nickel, silver, thallium, vanadium, and zinc. Parametric UTLs were calculated for arsenic, barium, copper, fluoride, molybdenum, nitrate as nitrogen, and selenium. We note that the UTLs for nitrate and fluoride were not presented in the groundwater background study; they were calculated using the dataset and rules presented in the background study and were presented in the RFI Volume 2 Report.	2

			The comment that "using a lower UTL is more conservative than using a higher UTL" goes against the objectives of the UTL process. The third and fourth sentences of the comment correctly describe the process of using parametric versus non-parametric UTLs. When this process is followed, there is no choice involved in using UTLs — if the distribution is not normal or lognormal, we cannot (and did not) use the presumably more conservative parametric UTL. The use of a non-parametric UTL is neither a choice nor a shortcoming — it is a statistically appropriate approach, given the properties of the dataset.	
DOI SC20	Figure 5-1, Related Discussion and Ensuing Analysis.	Figure 5-1 is incomplete; all pertinent groundwater pathways are not included in the exposure and risk models. • The hypothetical future use of groundwater to water plants and poultry exposure pathway has not been included. These pathways have been acknowledge as necessary for DOI's unrestricted land use consideration must be incorporated for the GRRA to be complete. Please develop the pathways, transport and fate models and parameters, and perform and integrate the calculations. • The recreational use and aquatic ecological receptor pathways should also acknowledge the ingestion and dermal contact pathways. Evaluation of the pathways should be performed or credible rationale provided as to why not. Please revise Section 5 accordingly and perform all consequential analysis.	Based on our experiences at numerous other sites with impacted groundwater, where the goal of groundwater cleanup is to allow for future domestic (unrestricted) use of the groundwater, uptake of chemicals by plants/livestock from irrigation/agricultural and other livestock-support uses of the water does not alter the final cleanup goals for water (i.e., our experiences have been that risk-based cleanup goals for water, and/or MCLs, are assumed by the regulatory agencies to be protective of any and all uses of the water). Accordingly, we had proposed to address the potential uptake into plants/livestock in the upcoming soils risks assessment, when the information regarding the concentrations of chemicals in soil was available and could be incorporated into the evaluation. Based on our discussions with DOI, they appear to be concerned that the water could be safe for human consumption, and yet contribute to unacceptable exposures via other secondary pathways, and thus, result in the need to clean up the groundwater to a lower level than would be required for the protection of direct human consumption/domestic use pathways. Although we have never seen such a situation, and examples were not provided, PG&E conducted some preliminary calculations, as requested by DOI, to ensure that these secondary groundwater exposure pathways would not likely alter the risk-based cleanup levels currently presented in the GWRA. Specifically, an analysis of the ingestion of plant and animal products as a pathway for exposure to contaminated groundwater was conducted based on the OEHHA *Air Toxics Hot Spots Guidelines* (CalEPA, 2003[10]) to assess the potential relative magnitude of this pathway as compared to direct dermal exposure to and ingestion of contaminated groundwater. Section 5 of the Hot Spots Guidance provides equations for calculating the exposure of humans to COPCs through ingestion of plants and animals impacted by COPCs. First, uptake of COPCs by plants and animals is estimated. Second, the ingestion of these plant and animal products is calculated to	2

			estimate human exposure to COPCs. Plant COPC concentrations are based on uptake from soil impacted by irrigation. Animal COPC concentrations are based the following: • Uptake from ingestion of drinking water • Uptake from ingestion of soil impacted by irrigation water • Uptake from ingestion of plants impacted by irrigation water Throughout the analysis, the most conservative assumptions are made to quantify the magnitude of the dose resulting from this pathway. The Hot Spots Guidance calculates the concentration of the contaminant in soil from the deposition of the pollutant from some concentration in air. Because this is a groundwater risk assessment, potential deposition of the pollutant occurs through irrigation and not through aerial deposition. It is conservatively assumed that 100% of the irrigation water is polluted groundwater. Furthermore, it is assumed all of the contamination stays within the root zone where plants could be exposed. The calculation of the soil concentration is unlikely to impact the overall conclusions as the contribution of plant uptake from soil impacted by irrigation water and animal uptake from ingestion of soil and plants impacted by irrigation water is insignificant in comparison to animal uptake from ingestion of drinking water; in other words, only the animal uptake from drinking water is significant in the context of this analysis. The analysis is conducted for hexavalent chromium, the primary COC at the site. As noted above, the dominant contributor to the overall pathway is animal uptake from ingestion of drinking water, in particular beef cattle. It is conservatively assumed that 100% of the water ingested by the animals is polluted groundwater. The ingestion of water by animals contributes 100% (99.99997%) to the dose of the contaminant to animals. The ingestion of animal products contributes 100% (99.99995%) to the overall dose to humans by the ingestion of animal and plant products. To evaluate the significance of the plant and animal ingestion exposure pathway, the contributions of direct dermal exposure and water ingestion (the pathways considered in the risk assessment) are added to the contribution calculated for ingestion of plant and animal products. Using conservative assumptions to calculate the exposure dose to humans from the ingestion of plant and animal products, this pathway contributes 3.2% and 1.4% to the estimated hexavalent chromium cumulative noncancer hazard to adults and children, respectively. It is expected that conducting this analysis for other COPCs will result in similar results. Therefore, inclusion of this pathway is highly unlikely to affect the overall conclusions of the risk assessment, across all COPCs.

			Moreover, specifically for hexavalent chromium, there is some uncertainly as to the uptake of the hexavalent form. Some studies have indicated that chromium accumulation in plants is predominately in roots, and only a small fraction is translocated to the above-ground part of edible plants (Cary, 1982[11]; WHO, 1988[12]). In this analysis, hexavalent chromium is conservatively assumed to remain in its oxidized form throughout the pathway. Hexavalent chromium is reduced to trivalent chromium, a less toxic form of chromium, at the surface of plant root cells (Ramachandran, 1980[13]; Aldrich et al., 2003[14]), indicating plant uptake/translocation of hexavalent chromium would be minimal. Other studies have indicated that chromium accumulation in plants is predominately in roots and only a small fraction is translocated to the above-ground part of edible plants (Cary, 1982[15]; WHO, 1988[16]). There has been no evidence of chromium biomagnification along the terrestrial food chain (soil-plant-animal) (ATSDR, 2008[17]). Furthermore, the metabolism of animals has been shown to reduce hexavalent chromium to trivalent chromium (Petrilli, 1978[18]). Therefore, human exposure to hexavalent chromium through ingestion of plants and animals is potentially an incomplete/insignificant pathway. This discussion and corresponding conclusions will be added as an appendix to the final GWRA.	
DOI SC21	Section 7 Overall and Future Integration.	As PG&E reviews and revises the GWRA, it is important to recognize that groundwater is only one exposure pathway in the overall conceptual site model (CSM). A concern that should be addressed in the GWRA, and in the CMS/FS, is how will forthcoming soil exposure risks (and cumulative HI's) be factored into the overall site wide risk assessment? DOI is concerned that situations analogous to that "summing of HI's and risks for individual groundwater chemicals" discussed above will occur again when the "summing of HI's and risks for individual chemicals from multiple pathways" occurs when the soil risks are evaluated. The simplified model below illustrates this concern: • Summed HI all pathways = GW HI + Soils HI • Summed HI all pathways 1.8 = GW 0.9 (no action) + Soils 0.9 (no action). • Summed HI risk all pathways Risk Management Need ≠ GW (no action) + Soils (no action) This takes on added significance in light of the rapid pace of the CMS/FS. For this reason, we ask PG&E to propose a risk management plan to anticipate those situations in future. Since the GWRA precedes the soil assessment, and groundwater risk management plans are in balance, we urge PG&E's risk management plan leave some safeguard space for the forthcoming soils.	We have been discussing the implications of separating the groundwater and soil risk assessments/remedies for quite some time with all stakeholders. The project proceeded with the separate risk evaluations at the request of DTSC to expedite addressing the CMS/FS for groundwater impacts associated with SWMU 1/AOC 1. All in all, although there are clearly some advantages of evaluating risks and developing remedies for the groundwater and the soil at the same time, separating the media (i.e., soil and groundwater) into different OUs is common, and allows the risk-managers to move forward with a needed remedy for one media (e.g., groundwater), while the data collection efforts and evaluations are still being conducted for another media (e.g., soil). We have proceeded in such a manner here, at the request of the agencies, in order to continue to move forward and select a remedy for the known significant groundwater impacts associated with the site, while continuing the characterization efforts for the soil. As we have discussed, it is impossible, at this juncture, to completely understand the significance of hypothetical cumulative risk issues associated with the groundwater and soil media, because we don't have a sense of the overall magnitude of the soil-related components. However, risk management decisions are routinely made for one environmental media (groundwater) prior to the development of the risk-management decisions for another environmental media (soil). We have discussed this issue with DOI, and have asked for practical solutions to these hypothetical problems, and there were no suggestions that provide insight as to how this issue has been addressed at other sites. One key factor to keep in mind during the remedy selection process for both soils and groundwater: when cleanup goals are established, either for soil or groundwater, the practical reality is that post-	2

			remedial conditions rarely result in media-specific concentrations exactly meeting the cleanup goal. For soil, as the most obvious example, if it is determined that remediation is needed, then chemical-specific remediation goals are developed and a remediation plan is developed and implemented in order achieve the overall goals of the protection of human health and the environment. However, typically one or two chemicals are the principal contributors to risk, and the remedial plan invariably winds up reducing the target compounds to concentrations that are lower than the initial goal. Accordingly, the assumption that all chemicals, in all media, are going to remain at residual concentrations exactly equal to the initial target goal is unrealistic, and unlikely to occur. More common, particularly for soil, is that one sets a risk-based goal, and then the remedial efforts typically wind up reducing the soil concentrations to much lower than the original goal (particularly true for excavations). At this stage, a logical and efficient program would be to continue in the current path for the development of a protective remedial plan for the groundwater. Groundwater cleanup goals to be set forth in the CMS/FS are likely to include ARARs (i.e., MCLs), background levels, and RBCs. Once we have a better sense of how many chemicals are present in the soil, and what the soil risk-drivers are at the various AOCs across the site, then the potential cumulative impact associated with compounds in soil and the compounds likely to remain in groundwater (following the implementation of the remediation plans) can be discussed, brought to the stakeholders, and solutions can be put forth by all with the benefit of a more comprehensive understanding of overall site-wide conditions. Practical solutions can be discussed once we understand the number of chemicals that are potentially driving the risks for the soil. That will be the time to set soil remedial goals at levels that account for all COCs and can allow for a 'margin' of safety due to the presence of residual chemicals in the groundwater. That is, once we understand which chemicals are driving the risks for soil, we can decide in the soil CMS/FS to set the remedial goals for the soil at a level that balances overall cumulative risks and hazards in order to account for the mix of chemicals in both soil and groundwater. Ultimately, the decisions for soil residual concentrations will have to address both human and ecological concerns and also combine that with groundwater cleanup goals. In sum, it is impossible at this juncture, to provide a definitive detailed solution for all chemicals in all media for all relevant receptors (both human and ecological), given that we know very little about one large set of variables at the site (soil conditions). However, once we have a better understanding of the types and number of chemicals that are present in the soil, and the receptor and exposure pathways of concern, we can develop a remedial plan for soil that accounts for projected residual concentrations that may remain in the groundwater following the implementation of the groundwater remedy, if appropriate.	
DOI SC22	Section 7.2.1.2 and 7.2.2	The Site-Wide groundwater interpretation provided in Section 7 (and the Executive Summary), is intended provide the reader an understanding of groundwater contamination, from a health risk perspective, in relation to the existence of the Cr VI plume. The chemical-by-chemical assessment of frequency and magnitude of detection, sensitivity to the use of maximums etc. in Section 7 does lend perspective on a	As discussed with the agencies, and as presented in the GWRA, chemicals to be carried forward as COCs in the groundwater CMS/FS for SWMU 1/AOC 1 are those chemicals that are: 1) determined to be present in site groundwater at levels of potential concern to future human health or the environment, and 2) likely associated with groundwater at SWMU 1/AOC 1. Thus, a chemical like fluoride, which is not	1

		site-wide basis. However; the synthesis of the chemical-by-chemical "site-wide" perspective leads to some problematic issues when individual wells are considered as single points of exposure. DOI considers each well as a potential source of exposure. In essence, the fusion leads to a finding that, for remediation purposes, only Cr VI needs to be considered as a driving COPC. DOI does not agree that the data and analysis support this conclusion. Problems with this conclusion**(see table at end of document) can be gleaned from the table below: This table, derived from a brief inspection of Table 7-2, indicates that constitutes other than Cr VI, either individually (e.g., Fl), or in combination can affect the findings and the remediation decision(s). As illustrated, under the rationale advanced in Section 7, the groundwater represented by these four wells, located outside of the Cr VI plume, would not be considered for remediation in the CMS/FS. DOI cannot support an assessment rationale that could lead to findings whereby groundwater(s) that pose a substantial risk can be knowingly left unaddressed. Moreover, the synthesis, while clearly informative and resourceful, conflicts with standard CERCLA and RCRA risk-based assessment (Risk Assessment Guide for Superfund (RAGS) and does not reflect how assessing this situation was originally understood in the RAWP. In order to gauge the impact of site related contaminants on groundwater, PG&E must determine the areal extent of groundwater that exceeds risk management thresholds. Those thresholds, which are discussed in the RAWP and in numerous guidance are 1E-4 to 1E-6 lifetime excess cancer risk, and cumulative hazard index's of 1.0 and greater. In order for PG&E and stakeholders to understand the site-wide groundwater impacts, and in order to not miss focus the CMS/FS site-wide groundwater risk assessment issues, we request PG&E to prepare site-wide maps illustrating: • Iso-Contours of cumulative estimated cancer risk exceeding 1E-6 and E-4. This illustration should correspond with Table 7-1 (following revisions as discussed above) • Iso-contours of cumulative estimated non cancer hazard index exceeding 1.0, 5.0, 10, and 20. This illustration should correspond with Table 7-2 (following revisions as discussed above). Interpretation of these iso-contours, in terms of the areal of groundwater exceeding reasonable maximum exposure (RME) based risk management metrics, should serve as a point of departure for risk-based CMS/FS efforts. Moreover, interpreting the iso-contours in this light could suggest areas where additional information could be useful in determining the scope of groundwater remedial actions. If PG&E seeks to refine the iso-contours, from a risk assessment perspective, they must use, as a minimum, the "risk-based" approach discussed in RAGS Section 8 the RAWP. This technique uses	associated with groundwater at SWMU 1/AOC 1, would not be carried forward to the CMS/FS for SWMU 1/AOC 1. As directed by DTSC and DOI, the text of the GWRA will be revised to indicate that they consider any individual monitoring well with an HI > 1 to be of potential concern (refer to response to comment HERD-SRS GC5). Accordingly, as the GWRA indicates an HI > 1 at one or more monitoring wells for hexavalent chromium, selenium, nitrate and molybdenum, and as all four of these chemicals are potentially associated with groundwater at SWMU 1/AOC 1, the final GWRA will recommend that the following chemicals be considered COCs in the CMS/FS for SWMU 1/AOC 1: hexavalent chromium, selenium, nitrate, and molybdenum. Based on our discussions with both DTSC and DOI, we believe that both agencies are in agreement with these recommendations. The CMS/FS may discuss other chemicals, not associated with SWMU 1/AOC 1, that were identified in the GWRA as having an HI of >1, but the only chemicals that would be considered COCs would be hexavalent chromium, selenium, nitrate, and molybdenum. As requested, the final GWRA will present figures indicating the cumulative HIs and cancer risks at each location.

Notes:

(1) Only detection limits from nondetect samples are included in these analyses. The percentage shown is the percentage of nondetect samples.

(2) The implications of elevated detection limits on the risk assessment are discussed in detail in Section 9 and presented in Tables 9-1 thru 9-4. Data usability is also discussed in Sections 3.2.3 and 3.3 and presented in Table 3-9.

(a) In particular see discussion in Section 9.2.3 and Table 9-1 regarding the possibility of incorrectly excluding a chemical from the assessment, and the likelihood that this could result in a material underestimation of risk and/or hazard.

(b) In particular see discussion in Section 9.4.2.1 and Table 9-4 regarding the possibility of that elevated detection limits could result in the underestimation of risk/and or hazard.

(c) In particular see discussion in Section 9.3 and Tables 9-2 and 9-3 regarding the possibility detection limits could impact the significance of the groundwater-to-surface water transport pathway.

(3) NA = Not available, one of the folllowing applies:

(a) Cadmium and mercury were not detected in background wells, and therefore UTLs were not calculated in the background study, CH2MHILL (2008).

(b) As described in Section 6.3 of the text, the noncarcinogenic hazard from lead is not evaluated using the traditional reference dose approach and therefore a risk-based concentration cannot be calculated for lead.

(c) MCLs are not promulgated for cadmium or molybdenum.

(4) Laboratory qualifiers:

J = Estimated

UJ = Estimated nondetect

R = Rejected

UR = Rejected nondetect

B = The analyte was detected above MDL in the lab blank

Table 3. Statistical Summary of Initial Chemical of Potential Concern (ICOPC) Concentrations in Groundwater – Well-Specific – Population Comparision

Extracted from Table 4-1b from the GWRA for chemical/well pairs screened-out of the risk assessment by population tests.

Notes:

(1) Data shown here have a detection above the background upper tolerance limit (UTL) and a minimum of eight samples and five detections.

(2) The Quantile Test and a median test (either the Mann-Whitney Test or Gehan Test) were preformed in ProUCL to test the hypothesis that the distribution of concentrations at a given well is below the background distribution.

(3) 95% upper confidence limits (UCL) calculated in ProUCL.

(4) Nitrate as NO_{3}-, nitrate as nitrogen, and nitrate/nitrite as nitrogen are combined in this analysis.

(5) Based on the ProUCL manual recommendations, the Gehan test is used for chemicals for which either the background or sample data set has more than 40% nondetects or multiple detection limits. The Mann-Whitney test is used for all other cases.

SUBJECT: RESPONSE TO COMMENTS, COMMENTS ON THE FEBRUARY DRAFT GROUNDWATER HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT, PACIFIC GAS AND ELECTRIC COMPANY, TOPOCK COMPRESSOR STATION, NEEDLES, CALIFORNIA

PCA: 22120 SITE CODE: 540015-48 MPC: 44

Background

The PG&E Topock facility entered service in 1951 as a compressor station for pipelines delivering natural gas from production fields in the southwestern United States to the PG&E service area in Southern California. Facility operations include compression of natural gas, cooling of the natural gas and lubricating oil, wastewater treatment, and equipment and facility maintenance. Hexavalent chromium and later trivalent chromium were discharged to Bat Cave Wash and soil sampling has detected concentrations of trivalent chromium in excess of 3,300 mg/kg in the East Ravine soils. The following comments offered by HERD are in response to the PG&E response to comments to HERD comments regarding the February 2009 Groundwater Human Health and Ecological Risk Assessment. The comments below reflect only those directed at the

ecological portion of the report, specifically identified by PG&E as HERD-JME, as found on pages 5-8.

Document Reviewed

HERD reviewed "Response to comments, Comments Draft Groundwater Human Health and Ecological Risk assessment, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California." The report containing the responses was prepared by Arcadis (Walnut Creek, California) but is not dated. HERD received the report for review and comment in June.

Scope of the Review

The report was reviewed for scientific content related to ecological risk assessment. Grammatical or typographical errors that do not affect the interpretation of the text have not been noted.

General Comments

Page 6, PG&E Response to HERD General Comment, first paragraph. The request to consider evaluation of groundwater exposure pathways to upland and riparian phreatophytes is not new. HERD has discussed this with PG&E many times.

Page 6, PG&E Resoponse to HERD General Comment, third paragraph. HERD believes that PG&E has presented a sufficient argument for not including nitrate as a COPEC to plants based on the paper by McKeon *et al.*, 2006. However, an additional implication of the paper is the bioaccumulation of nitrate in the foliage (500 mg/kg). Nitrate toxicity to ruminants foraging on plants with high nitrate concentrations in the plant tissue is well documented:

http://www.algreatlakes.com/pdf/factsheets/ALGLFS04_Nitrate_Toxicity_in_Feed.PDF.

Nitrate is converted to nitrite by bacteria in the rumen. If sufficient nitrite is absorbed by the blood, the nitrite oxidizes the hemoglobin heme ferrous iron (Fe^{+2}) to ferric iron (Fe^{+3}). Hemoglobin containing ferric iron is known as methemogolobin and cannot bind oxygen, thus causing functional anemia. Oxygen cannot be delivered to tissue which subsequently becomes anoxic. Nelson's bighorn sheep (*Ovis Canadensis nelsoni*) are known to occur in the area of the Topock Gorge. Although the species may not normally range over the Topock Compressor Station site this pathway should be described in the Human Health and Ecological Risk Assessment (HHERC) with supporting evidence that significant exposure via this route is not significant or is *deminimus*.

Page 6, PG&E Response to HERD General Comment, fourth paragraph. The HHERC should be viewed as a stand alone document. Figure 2 should be imported from the Monitoring Report for the Floodplain Reductive

Printed on Recycled Paper

Zone *In-Situ* Pilot Test to the HHERC. The table should be referenced in the text and the wells identified as relevant to phreatophyte exposure identified on the figure.

Page 8, PG&E Response to HERD General Comment, second paragraph. Please construct a table that shows the No Observable Adverse Effect Concentration (NOAEC), the background UTL, the maximum concentration and the hazard quotients. Since the PG&E Response to HERD Comments is material not discussed in the Draft HHERC, please include this paragraph as text in the Draft HHERC. This can be considered a global comment that applies to the entire Response to Comments.

Page 8, PG&E Response to HERD General Comment, bottom paragraph. Please construct a table containing the toxicity reference values, COPECs, background UTL and hazard quotients. Provide the complete references in the HHERC for the NOAECs. Although the Response to Comments identifies sources for the NOAECs in the text and annotates them, HERD did not see where the references were placed in the Response to Comments. Please provide the full references in the HHERC.

Conclusions

Many of the PG&E responses contain the information HERD requested. An evaluation of nitrate toxicity to ruminants should be presented in the HHERC. The text presented in the PG&E Response to Comments needs to be incorporated into the HHERC. Tables depicting maximum COPEC concentrations, background UTLs, NOAECs and hazard quotients should be constructed and inserted into the HHERC. After HERD's comments have been incorporated into the Draft HHERC the report should be resubmitted to HERD for review.

DATE: June 15, 2009

SUBJECT: Review of PG&E's Response to Agency Comments on the Groundwater Risk Assessment, Topock Compressor Station, Needles, California.

PCA: 22120 Site Code: 540015-48

The Human and Ecological Risk Division (HERD) reviewed "Response to Comments, Comments on the February 2009 Draft Groundwater Human Health and Ecological Risk Assessment, Pacific Gas and Electric, Topock Compressor Station, Needles, California". The document was prepared by Arcadis, for the Pacific Gas and Electric Company (PG&E), and was submitted to DTSC for review on May 29, 2009. HERD found responses (to DTSC's comments) and clarification of various issues to be acceptable in all cases, except for responses to comments GC3, GC7, and GC10. Details are provided below.

Response to comments on HERD SRS GC3: PG&E states that "the GWRA does not make statements about proposing to cleanup to the California MCL for total chromium of 50 ug/L." HERD notes that there is an extensive discussion of remediation goals for hexavalent chromium in section 8 of the GWRA where it is stated that "This section presents groundwater remediation goals for those constituents identified in the risk characterization section of the quantitative HHRA"; "In accordance with the RAWP...drinking water criteria, in compliance with ARARs, are relevant remediation goals for all COCs where such criteria are available", and "Consistent with the RAWP, as an ARAR for hexavalent chromium (i.e., the California MCL of 50 ug/L for total chromium), the ARAR will be used in preference over risk-based criteria as the applicable drinking water criteria in the CMS/FS process". Individuals reviewing this section will get the impression that the MCL for total chromium is indeed being considered as the remediation goal (i.e., a cleanup goal) for hexavalent chromium. The response provided for GC4 would suffice in this case also. Please include similar language in this response as well.

Response to comments on HERD SRS GC7: Please remove all sections of this response, except for the first paragraph and last two paragraphs. It is not necessary to reiterate information already included in Appendix M, in the responses to comments document.

It should be noted that HERD contacted USEPA's IRIS hotline to inquire on the status of molybdenum toxicity value. The Toxicologist on duty at the IRIS hotline specifically stated that the existing RfDo for molybdenum is not being considered for revision at this time, and that IRIS is still recommending use of the RfDo listed on its website. The Toxicologist also mentioned that the USEPA takes no position on Institute of Medicine's tolerable upper intake level of 0.03 mg/kg/day. Moreover, this compound does not appear on IRIS Track, a list of substances that are currently being assessed for revision. HERD would also like to point out that the IRIS profile for molybdenum includes the following: "A screening-level review conducted by an EPA contractor of the more recent toxicology literature pertinent to the RfD for molybdenum conducted in August 2003 did not identify any critical new studies." Note that the IOM study was published in 2001.

Response to comments on HERD SRS GC10: HERD does not concur with the "in plume" vs. "out of plume" analyses presented in the GWRA, and recommends the use of well-by-well assessment (see HERD SRS GC9). Furthermore, as previously stated, the plume in question refers specifically to hexavalent chromium and not other COPCs. Although the COPCs may be originating from a common SWMU/AOC, one should not automatically assume that the size and shapes of these plumes will be identical to each other, or that hexavalent chromium plume is the perfect "tracer of flow" because the boundaries are defined by a statistical background value of 32 ug/l. Furthermore, the hexavalent chromium plume boundary is of the plume as it exists today, not of potential flow paths during discharge (based on communications with DTSC management).

Subject: Path forward on GWRA and CMS/FS per recent discussions

---

Karen, Aaron, and Pam

Last week DTSC and PG&E discussed the management of additional constituents of concern in the Topock Groundwater Risk Assessment (GWRA) and the CMS/FS Report, as well as the schedule assumptions for incorporating East Ravine into the CMS/FS Report and reaching resolution on comments. The purpose of this email is to document our understanding of that discussion and make sure we are all on the same page as we move forward in finalizing the GWRA and the CMS/FS. While DOI representatives were not on the phone, Aaron indicated DTSC had discussed these topics with Pam, and that DOI is in general agreement with DTSC on the issues. Pam, please let us know if you have any feedback on, or any disagreement with, the direction that DTSC has provided as summarized below.

COCs in the Topock Groundwater Risk Assessment and CMS/FS

DTSC stated that the Topock GWRA should include PG&E's conclusions and recommendations including which chemicals PG&E's experts believe should be considered Chemicals of Concern (COCs) and which should get carried forward to the CMS/FS stage of the project. It is understood that the recommendations would be PG&E's recommendations and that DTSC may not agree with the recommendations (and could state that in a conditional approval). Specifically, consistent with the draft GWRA, PG&E may conclude that selenium, nitrate and molybdenum are not a source a significant risk, that these three chemicals are not drivers for groundwater remediation, do not need to be considered COCs, and thus do not need to get carried forward to the CMS/FS. PG&E may also consider modifying some of these conclusions.

DTSC agrees that selenium, nitrate and molybdenum do not represent significant risk at the site, and are expecting to approve these conclusions of the Topock GWRA. However, DTSC believes that selenium, nitrate and molybdenum need to be carried forward to the CMS/FS, and thus would provide a 'qualified' or conditional approval of the GWRA if the PG&E recommends that selenium, nitrate and molybdenum NOT get carried forward to the CMS/FS.

In carrying forward these three chemicals into the CMS/FS, DTSC stated that that selenium, nitrate and molybdenum do not need to be considered equivalent to Cr(VI). Specifically, DTSC indicated that there do not need to be any stated remedial action objectives for these three additional COCs and the alternatives do not need to be evaluated for attainment of a cleanup standard for these additional COCs. DTSC expects that the three COCs would be discussed in the upfront chapters of the CMS/FS report, with a general discussion of how these COCs do not pose a significant risk to human health or the environment, and are addressed in a global manner by all alternatives that focus on Cr(VI) remediation. DTSC expects that monitoring for these additional COCs would be performed to confirm these conclusions, and that these additional COCs would be evaluated in future characterization efforts (e.g., soil).

Schedule Assumptions for the CMS/FS Report

DTSC has looked at the assumptions in the June 17 RCRA/CERCLA meeting handout pertaining to incorporation of East Ravine data into the CMS/FS, and reaching resolution on comments on the CMS/FS report. DTSC is in agreement with all the assumptions, except that DTSC would like to clarify that the target remediation area for Cr(VI) in the East Ravine is considered to be 32 ppb because this is below the risk-based concentration of 46 ppb, not because it is background. While noting that there is no established background value for Cr(VI) in bedrock, DTSC does not see value in establishing a background value since the proposed cleanup value is less than the risk-based concentration.

Yvonne pointed out that there is no documentation of the agency direction to deviate from the existing schedule by including the East Ravine into the current CMS/FS. To document the agreement on the revised schedule, Aaron sent an email to Yvonne on July 2. In response to Aaron's email, PG&E will update the June 17 RCRA/CERCLA meeting handout dates and assumptions after further adjustments are made to the Rainbow Schedule based on inputs from both DTSC and DOI. This update will serve as the agreed on CMS/FS schedule. At this time, due to the continuing development of aspects beyond the CMS/FS Report such as the PA and the EIR, DTSC is not inclined to publish the next official version of the Project Schedule at the July 15 CWG.

Subject: Re: Path forward on GWRA and CMS/FS per recent discussions

---

Yvonne, there are some minor but fundamental differences between our thinking and as memorialized in your email. Please see my edits in red below.

COCs in the Topock Groundwater Risk Assessment and CMS/FS

DTSC stated that the Topock GWRA may include PG&E's <strike out: conclusions and> recommendations on which chemicals PG&E's experts believe should be considered Chemicals of Concern (COCs) and which should get carried forward to the CMS/FS stage of the project. It is understood that the recommendations would be PG&E's recommendations and that DTSC may not agree with the recommendations (and could state that in a conditional approval). Specifically, consistent with the draft GWRA, PG&E may recommend that selenium, nitrate and molybdenum are not a source and of significant risk, that these three chemicals are not drivers for groundwater remediation, do not need to be considered COCs, and thus do not need to get carried forward to the CMS/FS. PG&E may also consider modifying some of these conclusions.

DTSC agrees that selenium, nitrate and molybdenum do not represent significant risk at the site, and are expecting to approve the risk numbers as calculated in the Topock GWRA. However, DTSC believes that selenium, nitrate and molybdenum need to be carried forward to the CMS/FS due to several wells having hazard index greater than 1 for the individual COC and that neither site wide COPCs in soil nor the cumulative risks between soil and groundwater have been studied at this point. DTSC would provide a 'qualified' <strike out: or conditional> approval of the GWRA and will specifically disagree with the recommendation if PG&E recommends that selenium, nitrate and molybdenum NOT get carried forward to the CMS/FS.

In carrying forward these three chemicals into the CMS/FS, DTSC stated that selenium, nitrate and molybdenum do not need to be considered equivalent to Cr(VI) in the evaluation effort. Specifically, DTSC indicated that there do not need to be any stated numeric remedial action objectives for these three additional COCs and the alternatives do not need to be evaluated for attainment of a cleanup standard for these additional COCs. DTSC expects that the three COCs would be discussed in the upfront chapters of the CMS/FS report, with a general discussion of the conservative nature and uncertainties associated with the risks as calculated in the GWRA and <strike out: how these COCs do not pose a significant risk to human health or the environment, and> are addressed in a global manner by all alternatives that focus on Cr(VI) remediation. DTSC expects that monitoring for these additional COCs would be performed to confirm these conclusions, and that these additional COCs would be evaluated in future characterization efforts (e.g., soil).

Schedule Assumptions for the CMS/FS Report

DTSC has looked at the assumptions in the June 17 RCRA/CERCLA meeting handout pertaining to incorporation of East Ravine data into the CMS/FS, and reaching resolution on comments on the CMS/FS report. DTSC is in agreement with all the assumptions, except that DTSC would like to clarify that the target remediation area for Cr(VI) in the East Ravine is considered to be 32 ppb because this is below the risk-based concentration of 46 ppb, not because it is background. While noting that there is no established background value for Cr(VI) in bedrock, DTSC does not see value in establishing a background value at this time since the proposed cleanup value is less than the risk-based concentration for oral non-cancer affects from Cr(VI).

Yvonne pointed out that there is no documentation of the agency direction to deviate from the existing schedule by including the East Ravine into the current CMS/FS. To document the agreement on the revised schedule, Aaron sent an email to Yvonne on July 2. In response to Aaron's email, PG&E will update the June 17 RCRA/CERCLA meeting handout dates and assumptions after further adjustments are made to the Rainbow Schedule based on inputs from both DTSC and DOI. This update will serve as the agreed on CMS/FS schedule. At this time, due to the continuing development of aspects beyond the CMS/FS Report such as the PA and the EIR, DTSC is not inclined to publish the next official version of the Project Schedule at the July 15 CWG.

Subject: RE: Path forward on GWRA and CMS/FS per recent discussions

---

Thanks Aaron for your clarification of DTSC direction. This will help ensure we produce work product that meets agency expectations.

Pam -- We do not specifically need anything from DOI re: path forward email. That email (and Aaron's edits) documents DTSC direction to PGE on the GWRA and CMS. We will be proceeding per that DTSC direction in finalizing those documents and will let the CWG know that approach in our upcoming CMS/RA presentations this week. I just wanted to make sure you were aware and had a chance for any feedback, especially if there was any disagreement before the CWG presentations. If not, we're good to go and will proceed as directed by DTSC.

Yvonne

Subject: Re: Path forward on GWRA and CMS/FS per recent discussions

---

Yvonne, there are some minor but fundamental differences between our thinking and as memorialized in your email. Please see my edits in red below.

COCs in the Topock Groundwater Risk Assessment and CMS/FS

DTSC stated that the Topock GWRA may include PG&E's <strike out: conclusions and> recommendations on which chemicals PG&E's experts believe should be considered Chemicals of Concern (COCs) and which should get carried forward to the CMS/FS stage of the project. It is understood that the recommendations would be PG&E's recommendations and that DTSC may not agree with the recommendations (and could state that in a conditional approval). Specifically, consistent with the draft GWRA, PG&E may recommend that selenium, nitrate and molybdenum are not a source and of significant risk, that these three chemicals are not drivers for groundwater remediation, do not need to be considered COCs, and thus do not need to get carried forward to the CMS/FS. PG&E may also consider modifying some of these conclusions.

DTSC agrees that selenium, nitrate and molybdenum do not represent significant risk at the site, and are expecting to approve the risk numbers as calculated in the Topock GWRA. However, DTSC believes that selenium, nitrate and molybdenum need to be carried forward to the CMS/FS due to several wells having hazard index greater than 1 for the individual COC and that neither site wide COPCs in soil nor the cumulative risks between soil and groundwater have been studied at this point. DTSC would provide a 'qualified' <strike out: or conditional> approval of the GWRA and will specifically disagree with the recommendation if PG&E recommends that selenium, nitrate and molybdenum NOT get carried forward to the CMS/FS.

In carrying forward these three chemicals into the CMS/FS, DTSC stated that selenium, nitrate and molybdenum do not need to be considered equivalent to Cr(VI) in the evaluation effort. Specifically, DTSC indicated that there do not need to be any stated numeric remedial action objectives for these three additional COCs and the alternatives do not need to be evaluated for attainment of a cleanup standard for these additional COCs. DTSC expects that the three COCs would be discussed in the upfront chapters of the CMS/FS report, with a general discussion of the conservative nature and uncertainties associated with the risks as calculated in the GWRA and <strike out: how these COCs do not pose a significant risk to human health or the environment, and> are addressed in a global manner by all alternatives that focus on Cr(VI) remediation. DTSC expects that monitoring for these additional COCs would be performed to confirm these conclusions, and that these additional COCs would be evaluated in future characterization efforts (e.g., soil).

Schedule Assumptions for the CMS/FS Report

DTSC has looked at the assumptions in the June 17 RCRA/CERCLA meeting handout pertaining to incorporation of East Ravine data into the CMS/FS, and reaching resolution on comments on the CMS/FS report. DTSC is in agreement with all the assumptions, except that DTSC would like to clarify that the target remediation area for Cr(VI) in the East Ravine is considered to be 32 ppb because this is below the risk-based concentration of 46 ppb, not because it is background. While noting that there is no established background value for Cr(VI) in bedrock, DTSC does not see value in establishing a background value at this time since the proposed cleanup value is less than the risk-based concentration for oral non-cancer affects from Cr(VI).

Yvonne pointed out that there is no documentation of the agency direction to deviate from the existing schedule by including the East Ravine into the current CMS/FS. To document the agreement on the revised schedule, Aaron sent an email to Yvonne on July 2. In response to Aaron's email, PG&E will update the June 17 RCRA/CERCLA meeting handout dates and assumptions after further adjustments are made to the Rainbow Schedule based on inputs from both DTSC and DOI. This update will serve as the agreed on CMS/FS schedule. At this time, due to the continuing development of aspects beyond the CMS/FS Report such as the PA and the EIR, DTSC is not inclined to publish the next official version of the Project Schedule at the July 15 CWG.

Subject: Path forward on GWRA RTC per recent discussions

Dear Aaron,

As a follow up from our July 2nd 2009 conference call and subsequent emails below documenting the discussions between DTSC and PG&E regarding the path forward for the GWRA and the CMS/FS, PG&E has reviewed the following documents to identify any material inconsistencies between what was originally presented in these documents and our subsequent discussions/emails on the path forward for the GWRA and the CMS/FS:

1) Memo from Shukla Roy-Semmen, Staff Toxicologist, Human and Ecological Risk Division (HERD), Review of a Groundwater Huyman Health Risk Assessment for the PG&E Topock Compressor Station Located in Needles, Claifornia, dated March 26, 2009.

2) *Response to Comments (RTCs), Comments on the February 2009 Draft Groundwater Human Health and Ecological Risk Assessment*, submitted to stakeholders on May 29, 2009;

3) Memo from Shukla Roy Semmen, Staff Toxicologist, Human and Ecological Risk Division (HERD), Review *of PG&E's Response to Agency Comments on the Groundwater Risk Assessment, Topock Compressor Station, Needles, California,* dated June 15, 2009;

4) Memo from J. Michael Eichelberger, Staff Toxicologist, HERD, Response to Comments, *Comments on the February Draft Groundwater Human Health and Ecological Risk Assessment, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California,* dated June 17, 2009 (no issues that need to be resolved before receiving the final comments).

In our review of these documents, there are two items that appear to be inconsistent with the direction provided by DTSC during the July 2nd conference call which we would like to highlight to you before you transmit final DTSC comments on the GWRA RTCs. Each of these items is discussed below.

Molybdenum

The original written direction provided by DTSC in March 2009 (item 1 above) was to remove all discussions surrounding the essential nutrient evaluation of molybdenum from the main text of the GWRA and include the essential nutrient evaluation as an Appendix to the GWRA (General Comment 7). Specifically, based on our conversations with DTSC in March 2009, and our understanding of the specific direction being provided by DTSC, PG&E stated the following in the May 2009 RTCs: "Per DTSC's request, the GWRA will be revised to present conclusions for molybdenum as a COC based solely on this evaluation [using the USEPA IRIS oral reference dose approach] and the main text of the GWRA will remove the discussions related to the essential nutrient evaluation."

Based on the subsequent discussions between DTSC and PG&E on July 2, 2009, and our understanding that DTSC accepts that the technical evaluations and recommendations of the GWRA would be PG&E's evaluations and recommendations (and that DTSC may not agree with all aspects of PG&E's recommendations), PG&E is proposing to keep the technical evaluations of molybdenum as currently presented in the Draft GWRA. We raise this issue to DTSC's attention before finalization of additional comments (item 3 above) because the direction in HERD's June 15, 2009 written comments differ from understanding reached during recent discussions between PG&E and DTSC. In the June 15, 2009 memo prepared by HERD, submitted to PG&E by DTSC in Draft form on June 29, 2009, HERD is requesting (under Response to comments on HERD SRS GC7) modifications to our original response, asking that PG&E remove much of the text presented in our May 29, 2009 response to HERD SRS GC7. We would like your concurrence that our proposal to keep the technical molybdenum evaluation as currently presented in the Draft GWRA is consistent with the overall theme of our discussions on July 2. Specifically, because the GWRA is a PG&E document, the GWRA can present PG&E's technical evaluations and recommendations.

Process for Moving Forward and Submitting Revised GWRA

Based on the June 15, 2009 memo prepared by HERD (item number 3 above), it appears that HERD is requesting that the RTCs, submitted to the agencies on May 29, 2009, be revised and re-submitted for agency review. With respect to HERD's June 15, 2009 memo (item 3 above), it would seem that re-submittal of the RTCs may not be a necessary step to ensuring that the revised GWRA meets agency expectations. Specifically, as requested by HERD, PG&E agrees to incorporate the response provided to GC4 to GC3 (in item 2 above), and to clarify throughout the revised GWRA that the risk assessment does not determine the ultimate level of remediation that needs to occur at the site, but rather that discussions about the remedial action objectives and decisions regarding the final remedial goals will be determined in the CMS/FS. Further, the revised GWRA will address the topics as described in the call summary for the July 2 discussion (previously submitted separately).

We propose that this letter, the associated supporting documents identified herein, and your upcoming cover letter transmitting the finalized comments (re item 3 above), serve as adequate documentation of the discussions, agreements, and resolution to key issues between PG&E and DTSC regarding the comments and responses for the Draft GWRA. PG&E would appreciate input and/or concurrence from DTSC on this recommended path forward for submittal of the revised GWRA, and ideas as to how PG&E can help facilitate the process. We will plan to implement these agreements and resolutions in the revised or redline, at your direction) GWRA once we receive your final input.

Thanks Aaron. We do appreciate DTSC's willingness to work efficiently and openly with PG&E in order to maintain focus and maintain the current schedule.

Subject: Path forward on GWRA RTC per recent discussions

Aaron and Karen -- As our RAers have been reviewing the GWRA RTC correspondance to date with respect to DTSC/PGE recent telecon and the email summary below, they are noting that there are some discrepencies (e.g., Shukla's comments say to change specific text, while July 2 direction was that the GWRA is a PG&E document and that we can include our language regarding our recommendations). We hope to finish this comparison and provide more detail to you in the next day or so, for your consideration in preparing DTSC's final letter with direction on incorporating the RTC into the revised GWRA.

Thank you, Yvonne

Subject: PG&E: Comments on the proposed GWRA response to comments (RTC) package

---

Greetings,

Attached are the responses to the RTC package from within DTSC and from the Fort Mojave Indian Tribe (FMIT). On June 10, 2009 DTSC forwarded PG&E's proposed RTC on the draft Groundwater Human Health and Ecological Risk Assessment (GWRA) to the parties that have provided original comments for review. Of all the external parties that provided original comments (including MWD, CRIT, DOI and FMIT), DTSC only received additional response from Dr. Michael Sullivan representing FMIT on July 10, 2009 and a separate letter dated July 13, 2009 from Chairman Williams to Mr. Maziar Movassaghi of DTSC and Dr. Willie R. Taylor of DOI. Pursuant to the July 14, 2009 email request by Ms. Nora McDowell-Antone, DTSC is also forwarding the July 13 letter to you as record of their comments.

With respect to the FMIT comments from Dr. Michael Sullivan, DTSC believes that PG&E can further refine the proposed RTCs to address the concerns raised. DTSC, however, has the following position to be incorporated to your RTCs.

FMIT GC1: Although the documents for the Groundwater Risk Assessment (GWRA) and the CMS/FS are produced on a parallel track, agencies and PG&E agree that the GWRA should be completed so that the conclusion of the GWRA is properly reflected in the CMS/FS for evaluation. Please note that in practice, the GWRA is being completed before the CMS/FS.

FMIT GC3 and GC4: DTSC believes that the language from the RFI/RI Volume 2 provides a broad view that captures the cultural sensitivities of the area. Statement that "portions of the site have been disturbed by construction and unsympathetic land use..." suggests impacts that are either outside the control of the current project or that there are unmitigated impacts as a result of agency activities. DTSC maintains that this FMIT view should be captured in the upcoming Environmental Impact Report where impacts can be fully discussed and analyzed.

With respect to the letter from Chairman Williams, DTSC will be preparing a separate response to the letter. DTSC will clarify that land use decisions are the responsibility of the land owner. In this case, the Department of Interior issued a Final Land Use Memorandum on October 5, 2007 detailing the land use assumptions to be used for the risk assessment and the development of remedial alternatives at the project area. DTSC will defer any decisions on the proposed land use to the DOI.

Aside from these specific statements, DTSC directs PG&E to provide responses to all comments attached. If you have any questions regarding this matter, please feel free to contact me.

Sincerely,

Aaron Yue

Re: Response to Pacific Gas and Electric Company Response to Comments on draft Groundwater Risk Assessment for Topock Compressor Station, Needles, California.

Dear Mr. Yue and Ms. Innis:

On March 20, 2009, I submitted a comment letter on behalf of the Fort Mojave Indian Tribe (The Tribe, FMIT) summarizing my review of the Pacific Gas and Electric Company's (PG&E) February 9, 2009, draft document titled, *Groundwater Human Health and Ecological Risk Assessment for Chromium* (GWRA) for the Topock Compressor Station, Needles, California. My comments focused on overarching issues which are of great importance to the Tribe. On May 29, 2009, a draft response to comments was sent out by Lisa Kellogg of Arcadis on behalf of PG&E. This letter addresses the responses to the Tribe's General Comment (GC) 1 through GC 5 by Arcadis/PG&E. While specific issues are listed below, the proposed responses to the Tribe's issues are insufficient and do not address the Tribe's concerns. The GWRA must be updated to address these Tribal issues by editing and/or adding provided language. It is the responsibility of your agencies as the lead regulatory agencies to require PG&E and its consultants to properly address stakeholder comments. Will DTSC and the US Department of Interior (DOI) require PG&E to address our comments by revising the risk assessment?

FMIT GC1 – The response simply refers to the project schedule. CERCLA and RCRA documents should follow a logical order: characterization, risk assessment, remediation feasibility and then remediation implementation. When documents are prepared and provided out of sequence, however, the review process is disrupted. For example, the groundwater FS should not be completed until the GWRA is finalized. An additional concern is that the illogical order of reports may have resulted in an agency recommendation to address Tribal comments in some future report but not the

appropriate update of the reviewed report. This just perpetuates erroneous assumptions and faulty text. It is DTSC's responsibility as the lead regulatory agency to ensure that documents are provided in the correct order and with sufficient time for meaningful comment. DOI comment SC 16 reiterates the basic premise of our position that the documents must be presented in a comprehensive format and appropriate order so that full reviews can be completed. Additionally, the response to DOI comment SC 7 (among others) suggests that updates to the GWRA will only be evaluated in an addendum and not as an updated GWRA. The complete GWRA must be reissued so that reviewers have a complete and comprehensive document to review rather than multiple documents.

FMIT GC2 – The intent of my comment was to have the GWRA, and all subsequent reports, contain language that describes and acknowledges the significance of the local ecosystem (both river and upland areas) as well as the unique and significant relationship between Tribal culture and the environment. Neither the original text nor the suggested edits accurately addresses this important issue. DOI's comment SC 11 reiterates the Tribe's concerns regarding the inappropriate description of the desert environment. We request that PG&E provide the entire updated text from this section so the entire text can be reviewed with the added sentences.

FMIT GC3 – The response to comments does not fully address the Tribe's position that the land, the Maze, the River, etc. (all the inter-related areas of the landscape) are significant, sacred and all tied intimately to the Tribe's culture. DTSC must insist that the GWRA and future documents include the recommended language provided by the Tribe. Risk managers need to have full and accurate descriptions of the Tribal interests in the site and surrounding land in order to make appropriate remediation decisions. DOI comment SC 12 also notes that the GWRA's references to Tribal areas are incomplete or inaccurate. Why do DTSC and PG&E continue to refuse to include text provided by the Tribe? It is the Tribe's view that this text should be included in <u>all</u> project reports.

FMIT GC4 – The response to comments addresses many of the issues raised in my comments but does not propose to update the text to include the description of the Tribe's future interests in the IM3 and Topock compressor sites. DTSC must insist that the GWRA and future documents include recommended language provided by the Tribe. Risk managers need to have full and accurate descriptions of the Tribal interests in the site and surrounding land in order to make appropriate remediation decisions. Why do DTSC and PG&E continue to refuse to include text provided by the Tribe? It is the Tribe's view that this text should be included in <u>all</u> project reports. It is further interesting that in comment SC 4, DOI requests removal of any reference to its request for evaluating potential future residential development. If the basis for the inclusion of the residential receptor was based on the DOI request, then DOI's withdrawal of its comment should

result in the exclusion of the residential receptor. This DOI position seems to be further stated in its comment SC 13 where it cites the appropriate criteria to be used in selecting future land and resource (i.e., groundwater) uses. What is the rationale for not honoring DOI's request to remove the residential receptor?

It is disappointing to both the Tribe and its technical team that significant and focused comments are provided on draft documents yet PG&E and its consultants have dismissed these comments by not responding with appropriate document changes. As in the past, I remain available to work with PG&E on text updates to the GWRA and future documents to ensure that the reports adequately address Tribal issues. I can be contacted at michael.sullivan@csun.edu. I believe that the project can achieve the objective of sufficient characterization, risk estimation and remediation while also protecting the land from further unnecessary disturbances.

Sincerely,

Michael J. Sullivan, Ph.D., CIH

Re: Fort Mojave Indian Tribe follow-up letter to March 20, 2009, comment letter on Pacific Gas and Electric Company draft Groundwater Risk Assessment for Topock Compressor Station, Needles, California.

Dear Mr. Movassaghi and Dr. Taylor:

On March 20, 2009, Dr. Michael J. Sullivan submitted a comment letter to you on behalf of the Fort Mojave Indian Tribe (the Tribe) regarding the Pacific Gas and Electric Company's (PG&E) February 9, 2009, draft document titled, *Groundwater Human Health and Ecological Risk Assessment for Chromium* (GWRA) for the Topock Compressor Station, Needles, California. In his General Comment CG4, Dr. Sullivan discussed the need for clarification of future land uses in the vicinity of the Topock Compressor Station Site. Accordingly, I am writing this letter to clarify the Tribe's view as to what constitutes appropriate land uses for this area and to further express the Tribe's serious concerns regarding the appropriate use of DOI-managed land in the area.[1] Moreover, I wish to point out some inconsistencies in DOI's recent programs involving management of the land in this culturally sensitive area.

[1] Dr. Sullivan noted in his March 20 letter that the Tribe would send a separate letter for this purpose. General Comment CG4 provides:

> *There are future land-use issues in the GWRA that need to be clarified. First, DOI has requested that a stretch of the floodplain area along old Route 66 be evaluated for potential future scenario* [sic] *involving the development of housing and recreational areas (pg 2-6, pp. 5). This results in the risk assessment assumption of future residence use of groundwater produced from local wells.*

Appropriate Land Uses

In particular, the Tribe's concerns regarding the land uses in the vicinity of the Topock Compressor Station Site and surrounding area were triggered by the text in Section 2.3.2 ("Future Land Use") of the draft GWRA and the graphic presented as Figure 2-5.[2] In that section of the draft GWRA, DOI proposed evaluating the development of housing and recreational areas as an appropriate future use for the Topock area. The Tribe's concerns were exacerbated by the recent facility construction within the nearby Pirate Cove Marina (including the vulgar-named "Naked Pirate Beach Bar"). The new construction at this site is quite visible from the cultural sites and seriously interferes with the sanctity of the sacred landscape. The operational impacts of the expanded recreational facility includes increased traffic and noise, off-road tours, opportunistic off-road excursion into sensitive areas, website exposure of sensitive areas, and vehicular parking outside designated areas. These impacts only further aggravate an already undesirable situation. Within the first weeks of operation of the Naked Pirate Beach Bar, there have already been direct and indirect impacts to the Tribe's nearby cultural sites that have been extremely hurtful and demoralizing to tribal practitioners. Considering the assumptions regarding future land use in the GWRA, the Tribe is becoming increasingly concerned with other projects that the DOI may promote in the future, particularly in light of future land-use assumptions suggested for the GWRA.

While overall this concern extends beyond the scope of the GWRA, the Tribe believes that it must be spoken to and addressed now. The fact that in previous Topock Project documents presented for Tribal and public review, such as the RFI/RI Volume 2, similar language has been presented regarding future land uses and, despite the Tribe's appeals for the need to focus and clarify such language with regard to cultural preservation, it seems that the issue has strategically and consistently been ignored or put off to some unspecified future consideration. When such concerns have been raised by the Tribe during Topock Technical Review Group (TWG) and Consultative Working Group (CWG) meetings, the Tribe was given explanations to

---

> *This proposed future land use scenario poses Tribal concerns, especially if such development were to occur in the vicinity of the Maze.* ***In a separate letter, the Tribe will provide text that describes appropriate land uses for this area.***
>
> *Second, the future ownership of the IM land as well as the potential repatriation of the Topock Compressor site to the Tribe is not mentioned. The potential for future control of these lands by the Tribe further increases the importance of current Tribal concerns regarding protecting the land as well as defining future land uses that should be evaluated in the GWRA.* [Emphasis added].

[2] The Tribe notes that the "Anticipated Future Land Use" graphic in the GWRA was not of sufficient scale or detail to understand fully the magnitude of DOI's proposed future land uses in the Topock area. For example, where would the "new pull-through recreational vehicle camping sites and tent camping areas" be found on the map? The Tribe requests a larger area be shown on map, along with an indication in separate zones of potential residential, recreational, and unrestricted uses on DOI-managed land with an overlay of management designations, such as ACEC, refuge, etc. The zones' uses should also be defined (*e.g.*, what does "unrestricted use" mean?).

the effect that such cultural issues were being deferred in favor of addressing them in the context of the Environmental Impact Report (EIR) pursuant to the California Environmental Quality Act (CEQA).

Deferring the Tribe's concerns about land use and its cultural resources is neither reasonable nor acceptable. Each step in this process has further whittled away at the remnants of what once was undisputedly (and what we still hold as) our Tribal landscape, the essence of our cultural and religious beliefs. Looking forward, the land uses as viewed by DOI trigger what the Tribe believes are unnecessarily high remediation standards causing otherwise avoidable disruptions. The Tribe is concerned that such assumptions will further adversely impact its precious cultural resources and religious values. A consistent application of risk assumptions made in soil, groundwater, and any other risk assessment attendant to the Topock Project must be maintained. Because its interests cannot be adequately represented by DTSC or DOI in this process, the Tribe must be given the opportunity to participate in the decision making process whereby such assumptions are identified and agreed upon.

Land Use Consistency with Adopted Management Plans and Policies

The mission statement of DOI's Bureau of Land Management (BLM) itself asserts its responsibility for:

> *"... **stewardship of our public lands**. The BLM is committed to manage, **protect** and improve these lands in a manner to serve the needs of the American people. Management is based upon the principles of multiple use and sustained yield of our nation's resources within a framework of environmental responsibility and scientific technology. These resources include recreation, rangelands, timber, minerals, watershed, fish and wildlife habitat, wilderness, air and scenic quality, as well as scientific and **cultural values**."*[3] [Emphasis added].

While the Tribe understands the concept of multiple use, we question how the future use assumptions in the GWRA would be consistent with BLM's concurrent responsibilities to protect cultural values, when the proposed use and the protection of cultural values already present are mutually exclusive. How is DOI's proposed land use therefore consistent with BLM's mission as a whole?

It also seems inappropriate for DOI to be asserting a particular land use, such as residential, when such uses may directly or indirectly conflict with its own recently adopted management plans and policies. The GWRA failed to reference or analyze these DOI planning and guidance documents which direct or influence the land uses in this area. Without including such an analysis in the GWRA, use of the proposed DOI land uses in the GWRA is unjustifiable.

[3] Available at http://www.nv.blm.gov/wilderness/WSA_mission_statement.pdf.

In 2005, the U.S. Bureau of Reclamation (BOR), another DOI agency, and other cooperators completed a document titled *Lower Colorado River Multi-Species Conservation Plan* (the Plan). The Plan represents a comprehensive species conservation approach for both Federal and non-Federal actions on the Lower Colorado River. All participating DOI officials were directed to cooperate and implement such agreements to achieve the important species conservation actions identified within the Plan.[4]

In the amendments to the *Lake Havasu Field Office Resource Management Plan and Final Environmental Impact Statement* (RMP), the Tribe worked closely with BLM to identify the Beale Slough Riparian and Cultural Area as an Area of Critical Environmental Concern (ACEC), which includes the current cleanup project area. In that document, BLM stated:

> [L]and use allocations and management . . . will provide protection for the Topock Maze and surrounding lands that are sacred to the Fort Mojave Indian Tribe. BLM will ensure that the Tribe is consulted on proposed actions that could affect those lands.[5]

The Beale Slough ACEC Management Plan has not yet been developed and is an important management tool that BLM must begin drafting as soon as possible, in close consultation with the Tribe. The Tribe would like to know the schedule for preparation and completion of this management plan as it relates directly to Topock remediation activities currently under consideration. But even without this management plan, BLM is obligated to protect the Topock area in a manner consistent with the adopted RMP, which provides for more than just consistency with recreational goals. How are DOI's proposed land uses consistent with the RMP in general, and the ACEC in particular? If the land uses are not consistent with adopted plans, they should not form the basis for risk assumptions in the GWRA. The Tribe hereby requests to see a map of the specific areas that might be "disposed" of by DOI, as referred to in the GWRA.

The Lake Havasu Resource Management Plan identified Topock-Needles as a conservation area with 1,127 acres set aside for "future use and traditional use." The document also recognized Special Cultural Resource Management Areas (SCRMA), the Chemehuevi Mountains Wilderness Area, Wildlife Habitat Management Areas, Desert Tortoise Habitat, and Biological Resources Management-Conservation Measures applicable to the Lake Havasu Field Office planning area.[6] The proposed future land uses discussed in the GWRA are inconsistent with the Lake Havasu Resource Management Plan. Only those future uses consistent with the Resource Management Plan should be evaluated.

---

Area of Critical Environmental Concern – Land Use Allocations Beale Slough Riparian and Cultural ACEC pgs. 2-154 – 2-155.

[5] PRMP/RMP FEIS pg. 5-59.

[6] *Id.*

It is the responsibility of the agencies to implement management plans in the best interests of all affected parties, including the Tribe. Presenting plans that assume DOI's relinquishing control of its property, prior to any discussion or consultation with affected stakeholders, is inconsistent with this charge. Instead, DOI should uphold its commitment to protect the area's resources. Moreover, DOI again appears to be acting inconsistently with its own adopted plans and with federal policy and Executive Orders[7] requiring government-to-government consultation.

Conclusions and Requests for Further Action

It is the Tribe's view that DOI must follow its own policies and plans for the Topock area, and not open up this area for additional recreational or new commercial or residential infrastructure, even in a theoretical context. These types of infrastructure would be inconsistent with the cultural resources and tribal values associated with the area. Such problems further complicate remedial action decisions because they could result in a determination of the need for a higher level of clean-up than necessary, and thereby result in further desecration of this sacred area in violation of tribal beliefs.

Given that it is the Tribe's ultimate responsibility to protect and safeguard this sacred and culturally sensitive area, it is incumbent on the DOI to assure the Tribe's participation in current and future decisions involving proposed undertakings or land disposal considerations in the area. The Tribe's concerns for the Topock area extend well beyond the avoidance of visual impacts from the Maze features, as suggested in the GWRA language. The Tribe's concerns encompass both direct and indirect intrusions, to the cumulative impacts of diverse actions, and to the need for decision makers to consider an appropriate range of alternatives for any development in the area. **Through this letter, the Tribe requests a face-to-face meeting with DOI and its subordinate agencies, including the BLM and BOR, to discuss these concerns further.**

Finally, because this land is ancestral property, **the Tribe should be given a first right to repatriate the land prior to any offering of the land to any other entity for use, lease, or purchase.** It is also worth noting that, under Tribal ownership, allowable land uses or risks to human health and the environment may be different, and lesser intrusive remedial options might become available.

In sum, from the Tribe's viewpoint, appropriate land uses for the area include Mojave tribal ownership or federal ownership as protected open space, without additional active recreation or commercial operations. Further, the Tribe believes inappropriate uses cannot coexist with an active remediation over the long period of time anticipated to implement each of the proposed remedial actions. It is simply too much activity for this sensitive area and tribal practitioners to withstand.

[7] See, for example, E.O. 13007, 13175.

I look forward to your prompt consideration and action on this letter and stand ready to work with you toward an equitable resolution.

Sincerely,

Timothy Williams, Chairman
Fort Mojave Indian Tribe

Subject:

Aaron,

On behalf of PG&E, ARCADIS is submitting this email as a follow up to the DTSC's comments sent to PG&E on July 16, 2009 on the response to comments to the Groundwater Risk Assessment. Based on our discussions, PG&E is providing additional information for the comments that we consider outstanding and needing resolution and have summarized the three items in the following email.

As a follow up from our July 2nd 2009 conference call and subsequent emails on July 8, 2009 (attached) documenting the discussions between DTSC and PG&E regarding the path forward for the GWRA and the CMS/FS, PG&E has reviewed the following documents to identify any material inconsistencies between what was originally presented in these documents and our subsequent discussions/emails on the path forward for the GWRA and the CMS/FS:

- Memo from Shukla Roy-Semmen, Staff Toxicologist, Human and Ecological Risk Division (HERD), Review of a Groundwater Human Health Risk Assessment for the PG&E Topock Compressor Station Located in Needles, California, dated March 26, 2009.
- *Response to Comments (RTCs), Comments on the February 2009 Draft Groundwater Human Health and Ecological Risk Assessment*, submitted to stakeholders on May 29, 2009;
- Memo from Shukla Roy Semmen, Staff Toxicologist, Human and Ecological Risk Division (HERD), Review *of PG&E's Response to Agency Comments on the Groundwater Risk Assessment, Topock Compressor Station, Needles, California,* dated June 15, 2009, (final version transmitted to PG&E on July 21. 2009);
- Memo from J. Michael Eichelberger, Staff Toxicologist, HERD, Response to Comments, *Comments on the February Draft Groundwater Human Health and Ecological Risk Assessment, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California,* dated June 17, 2009 (final version transmitted to PG&E on July 16, 2009).

As we discussed, the GWRA will be revised in accordance with the topics discussed during the July 2, 2009 conference call (documentation of the discussion and agreements reached is attached). The purpose of this email is to document where we believe our previous responses to comments (number 2 above) are inconsistent with the direction provided by DTSC during the July 2nd conference call and to clarify our proposed methods for addressing these comments in the revised GWRA. Additionally, this email identifies our proposed resolution to the recent comments (numbers 3 and 4 above) which were transmitted to PG&E on July 21 and July 16, respectively.

Molybdenum (GC number 7, item 1 above; Response to GC number 7, item 2 above; Response to SRA GC 7, item 3 above)

The original written direction provided by DTSC in March 2009 (GC number 7, item 1 above) was to remove all discussions surrounding the essential nutrient evaluation of molybdenum from the main text of the GWRA and include the essential nutrient evaluation as an Appendix to the GWRA. Specifically, based on our conversations with DTSC in March 2009, and our understanding of the specific direction being provided by DTSC, PG&E stated the following in the May 2009 RTCs (response to GC number 7, item 2 above): "Per DTSC's request, the GWRA will be revised to present conclusions for molybdenum as a COC based solely on this evaluation [using the USEPA IRIS oral reference dose approach] and the main text of the GWRA will remove the discussions related to the essential nutrient evaluation."

Based on the subsequent discussions between DTSC and PG&E on July 2, 2009, and our understanding that DTSC acknowledges that the technical evaluations and recommendations of the GWRA would be PG&E's evaluations and recommendations (and that DTSC may not agree with all aspects of PG&E's recommendations), PG&E proposes to retain the technical evaluations of molybdenum as originally presented in the Draft GWRA.

Similarly, in the June 15, 2009 memo prepared by HERD, and provided to PG&E by DTSC on July 21, 2009 (Response to SRS GC7, item 3 above), HERD requested modifications to our original response, asking that PG&E remove much of the text presented in our May 29, 2009 response to HERD SRS GC7. As described above, PG&E proposes to retain the technical evaluation of molybdenum as an essential nutrient (in addition to the traditional RfD based evaluation) as originally presented in the Draft GWRA, consistent with the overall direction provided by DTSC in our discussions on July 2.

Resolution of Additional Comments in Item 3 (Memo from Shukla Roy Semmen, Staff Toxicologist, Human and Ecological Risk Division (HERD), Review *of PG&E's Response to Agency Comments on the Groundwater Risk Assessment, Topock Compressor Station, Needles, California,* dated June 15, 2009, (final version transmitted to PG&E on July 21. 2009))

As requested in Response to comments on HERD SRS GC3 (item 3 above), PG&E agrees to incorporate the response provided to GC4 to GC3 (in item 2 above), and to clarify throughout the revised GWRA that the risk assessment does not determine the ultimate level of remediation that needs to occur at the site, but rather that discussions about the remedial action objectives and decisions regarding the final remedial goals will be determined in the CMS/FS.

In Response to comments on HERD SRS GC10 (item 3 above), HERD reiterates that they do not concur with PG&E's "in-plume" versus "out-of-plume" analysis, and recommends the use of the well-by-well assessment. This same comment was made in HERD's original comments to the GWRA (in SRS comments GC9 and GC 10, item 1 above). As presented in our original responses to these comments, PG&E proposes to retain the in-plume versus out-of-plume analysis in the revised GWRA, with the clarification that such analysis will not be used to dismiss chemicals or risk issues. We believe that it is appropriate for the analysis to remain in the revised GWRA as it provides one additional line of evidence for risk managers to consider in the upcoming CMS/FS, and because the analysis was agreed to by all stakeholders in the approved Risk Assessment Workplan (RAWP).

Resolution of Additional Comments in Item 4 (Memo from J. Michael Eichelberger, Staff Toxicologist, HERD, Response to Comments, *Comments on the February Draft Groundwater Human Health and Ecological Risk Assessment, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California,* dated June 17, 2009 (final version transmitted to PG&E on July 16, 2009))

PG&E concurs with HERD's observation that high concentrations of nitrate in feed can produce toxic effects in ruminants. In response to the question of whether this pathway might be significant for desert bighorn sheep in the vicinity of the Topock Compressor Station, PG&E reviewed information on the distribution of desert bighorn sheep as well as the distribution of nitrate at concentrations greater than background in shallow groundwater. Figure 1 (enclosed) shows the distribution of desert bighorn sheep (recorded in the California Natural Diversity Database [CNDDB]) in relation to the Area of Potential Effects (APE) defined in the Final Programmatic Biological Assessment (CH2M HILL, 2005) As shown in Figure 1, there is very little overlap between the range cited in the CNDDB and the APE. Nevertheless, the distribution of nitrate in shallow groundwater was explored to further evaluate this potential exposure pathway. The southernmost wells with nitrate observed at concentrations greater than background are wells MW-1 near the evaporation ponds and MW-9 in Bat Cave Wash. Neither of these wells overlaps the desert bighorn sheep range cited in the CNDDB (Figure 1). Therefore, this potential exposure pathway is judged incomplete.

Figure 2 (Depth to Groundwater in Water Table Wells and Potentially Exposed Vegetation) was provided in the Response to Comments dated 5/29/09 and is enclosed as well.

As requested by HERD, PG&E will construct tables of information provided in the text responses. The tables will appear in the Final GWRA. Most of the references in the RTC dated 5/29/09 were included in the GWRA. Those not included in the GWRA were either included in the text of the response or in a footnote to the response. A reference list for the RTC is enclosed for convenience.

We look forward to concurrence with these last outstanding items and finalization of the Groundwater Risk Assessment. If you have any questions, please feel free to contact Bob Doss at (415) 973-7601.

United States Department of the Interior

OFFICE OF THE SECRETARY
Washington, D.C. 20240

Mr. Timothy Williams
Chairman
Fort Mojave Indian Tribe
Merriman Avenue
Needles, California 92363

JUL 3 1 2009

Dear Chairman Williams:

Thank you for your letter dated July 13, 2009, in which you share the views of the Fort Mojave Indian Tribe (Tribe) with regard to appropriate land uses for the area surrounding the Pacific Gas and Electric Company (PG&E) Topock Compressor Station. As you know, pursuant to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) the Department of the Interior (Department) is overseeing PG&E's preparation of a Remedial Investigation and Feasibility Study (RI/FS) to characterize the nature and extent of contamination released from the Topock Compressor Station and to evaluate remedial alternatives designed to protect public health, welfare, and the environment from this contamination. In this effort, the Department is coordinating closely with the California Department of Toxic Substances Control which is overseeing the investigation pursuant to State authorities.

Your letter shares the Tribe's concerns regarding the future land use assumptions contained in the draft Groundwater Risk Assessment that PG&E prepared as a part of this RI/FS process. In particular, your letter expresses a concern that these assumptions may lead to "unnecessarily high" cleanup standards. Your letter also expresses concerns that these future land use assumptions may be inconsistent with existing resource management plans, including the existing designation of the Beale Slough area as an Area of Critical Environmental Concern (ACEC), and may lead to future uses that do not protect important cultural resources and religious values.

To address these concerns, it is helpful to understand the purpose of the baseline risk assessment prepared during the RI/FS process and, specifically, the role played by future use assumptions in that process. Future use assumptions are developed relatively early in the process to identify human exposures to hazardous substances that can be expected if no response action is taken. Response actions may include access and land use restrictions, which are characterized under CERCLA as "institutional controls." In order to assess baseline (i.e. current) risks posed at a site, CERCLA regulations counsel that assumptions about future uses of the area should be conservative and generally should not include such institutional controls. As described by the Environmental Protection Agency (EPA), "the role of the baseline risk assessment is to address the risk associated with a site in the absence of any remedial action or control, including institutional controls."[1]

---

[1] *Final Rule, National Oil and Hazardous Substances Pollution Contingency Plan,* 55 Fed. Reg. 8666, at 8710-11 (March 8, 1990).

As described in the EPA CERCLA regulations, the baseline risk assessment should:

> Characterize the current and potential threats to human health and the environment that may be posed by contaminants migrating to the groundwater or surface water, releasing to air, leaching through soil, remaining in the soil and bioaccumulating in the food chain. The results of the baseline risk assessment will help establish acceptable exposure levels for use in developing remedial alternatives in the FS…[2]

The exposure levels developed in the baseline risk assessment do not dictate the type of cleanup required. Instead, exposure levels are used in evaluating whether remedial alternatives can be protective. Remedial alternatives may be protective using a variety of approaches including, for example, removal or treatment of hazardous substances, interrupting complete exposure pathways by containing hazardous substances, reducing exposure to hazardous substances through the use of institutional controls, or some combination of these measures.

It is also important to note that the future use assumptions utilized in a baseline risk assessment will not dictate land management decisions. Instead, unrestricted future use assumptions simply inform decision makers of the residual risk that may remain if a remedial alternative does not adequately control exposure pathways. This allows them to make risk management decisions regarding the implementation of access or use restrictions or other institutional controls that may be necessary to reduce risks to acceptable levels. These land use restrictions may include existing restrictions or may involve the development of new land use restrictions that are adopted during remedy selection for a site. If the selected remedial action includes land use restrictions the additional actions necessary to reduce risks to acceptable levels may be lessened. In any event, decisions about the future use of an area are not limited by the conservative land use assumptions employed in the baseline risk assessment.

As your letter rightly points out, the Department's Bureau of Land Management (BLM) is responsible for land use decisions for the BLM-managed land in the vicinity of the Topock Compressor Station. These decisions are considered and adopted through the Resource Management Plan process in consultation with the Tribe, other tribes, and other stakeholders. I encourage you to continue to work closely with the BLM Colorado River District Office and Lake Havasu Field Office throughout this planning process.

Thank you for your interest and continued active participation in the CERCLA remedial action process underway at the Topock site. If I can be of any further assistance in this effort, please contact me at 202-208-3891 or Mr. William Lodder of my staff, at 202-208-6128.

Sincerely,

Willie R. Taylor
Director
Office of Environmental Policy and Compliance

DOI Responses to PG&E GWRA RTC

The Department of Interior (DOI) has reviewed the Response to Comments (RTC) on the Draft Groundwater Human Health and Ecological Risk Assessment, Topock Compressor Station, Needles, California". The report, dated February 2009, was prepared by Arcadis for the Pacific Gas and Electric Company (PG&E). Comments on the RTC are provided below.

Comment	DOI Response to PG&E GWRA RTC
FMIT GC 2	See text below in DOI SC11.
HERD JME	Accepted under Provision. Provision DOI accepts the response to JME's comments, dependent upon the review of PG&E's text to be provide in the revised redlined/strikeout (RLSO) of the GWRA for review and approval.
DOI SC1	Accept under Provision. <u>Provision</u> DOI is accepts the response to JME's comments, dependent upon the review of PG&E's text to be provide in the revised RLSO of the GWRA for review and approval.
DOI SC2	Accepted
DOI SC3	Accepted under Provision <u>Provision</u> The revised text will read: "This plant community is characterized by dense thickets of tamarisk, or salt cedar (*Tamarix* sp.), sometimes surrounded by arrowweed (*Pluchea sericea*) at the edges. Salt cedar…. Please provide RLSO for review and approval.
DOI SC4	Accepted.
DOI SC5	Not accepted. There is some confusion. Does Table 3-4b mean the PAH's were analyzed for and naphthalene was the only constituent detected? Also, Table 3-4b does not identify DRO and MRO as indicated in the bullet. Finally, was GRO analyzed for? Please clarify the response.
DOI SC6	Accepted.
DOI SC7	Accept under Provision. <u>Provision</u> It is DOI's expectation that PG&E will prepare for review and approval a GWRA Addendum addressing items such as the East Ravine and other studies not yet identified that may be necessary. It is also our expectation that any findings arising from the soils investigation impacting groundwater be included in an GWRA addendum or the soil risk assessment.
DOI SC8	Accepted.
DOI SC9	Accepted.

DOI SC10	Accepted. See discussion. Discussion Please be aware that the use of qualitative descriptors (low, medium, high, etc) is subjective and reliant on the perspective of both the writer and the reader. We note that the synthesis technique used in the GWRA, while informative, did not affect the outcome or the implications for the CMS/FS. Please note that use of similar qualitative synthesis in the future, beyond risk communication, will not be accepted as rationale in conclusions or steering the interpretation of outcomes having implications for determining the need or extent of remedial actions.
DOI SC11	Accept under Provision. <u>Provision</u> We note that much of the Ecosystem Description(s) (e.g., FMIT GC3) has only tangential relevance the GWRA and were included largely for information and completeness; they were essentially immaterial. However, the details of these and other ecological risk assessment descriptions may have material significance in other pending assessments (e.g., Soils Risk Assessment). Please be aware that use of descriptions and ecological risk elements herein does not connote DOI's approval of them for use in the future. DOI strongly urges PG&E to contact us if in your forthcoming risk assessment work you are relying on descriptions and ecological risk elements in the GWRA. DOI will not accept "As described in the GWRA……." premises for ecological risk assessment arguments.
DOI SC12	Accepted.
DOI SC13	Accept. See Discussion. <u>Discussion</u> We acknowledge PG&E's response in its context. Our main objection was (and is) the implications that there was a thorough resource evaluation which formed the basis for the land use determination relating to groundwater usage.
DOI SC14	Accept under Provision. <u>Provision</u> See Comment DOI SC7.
DOI SC15	Accepted.
DOI SC16	Accepted. See discussion. <u>Discussion</u> DOI expects that in the future, the risk assessment professionals, as the end users of the data with experience in application of the data usability guidance, will be more closely involved in the data quality review and assessment. In so doing, risk assessment processes and practices can be better integrated and more easily verified. This concept applies to the actual data specification and sampling strategy as well.
DOI SC17	Accepted under Provision. <u>Provision</u>

	Based on our review of the Groundwater Risk Assessment and PG&E's responses, DOI finds that the Risk Assessment Work Plan (RAWP) does not provides sufficient detail on data analysis and statistical methods, in all cases. DOI accepts PG&E's response on the following condition. Prior to initiation of material work on the soils risk assessment, PG&E will prepare and submit for approval a detailed technical memorandum that sets forth, in site - specific detail, how the soil data will be analyzed to: 1) select COPCs, 2) compute exposure point concentrations, 3) evaluate background issues, 4) designate hot spots, 5) integrate COPCs and their concentrations over the spatial domains that will be evaluated in the human health and ecological risk assessment. . The technical memorandum must also address the how data to be used in the risk assessment integrates, from a useability standpoint (including PARCC parameters), the data, and analysis thereof, in the RFI/RI, the ongoing Data Useability Matrix, and the Background Soils Investigation. It must also identify and evaluate data gaps and discontinuities between data sets to be used in the risk assessment and supporting analysis including those used in the RFI/RI and Background Studies. This technical memorandum must be submitted, along with pertinent reference materials cited therein (e.g., guidance documents, literature, etc., as necessary), in sufficient time to permit DOI to review and comment on the approaches before material work on the soils risk assessment is conducted
DOI SC18	Response Accepted under Provision. Provision set forth in comment DOI SC17.
DOI SC 19	Response Accepted under Provision. Provision set forth in comment DOI SC17.
DOI SC 20	Accepted as Discussed below. 1) We look forward to reviewing PG&E's calculations and will approve as appropriate. 2) Please add the ecological receptor pathway. DOI apparently misspoke on a conference call. DOI will need to see the impact of terrestrial species (e.g., foxes) consuming contaminated groundwater from seeps. Please accept our apologies for any miscommunication.
DOI SC 21	Accepted – See discussion. <u>Discussion</u> DOI concurs that much is yet to be learned about conditions at the Site and the interaction between risk arising from the groundwater and soils cannot be fully understood at this time. We don't necessarily accept all tenants in the response which seem to suggest that soil remediation will serve as the master balancing variable for addressing cumulative Site risks. Nonetheless, we accept your approach as outlined in the response paragraph "at this stage, a logical and efficient program" as the core of risk management approach. We again urge PG&E to leave some margin (cumulative risk headspace) as you move forward establishing groundwater remedial action objectives and cleanup

	goals. Finally, if PG&E hopes to employ the management strategy of using soil remediation as the master balancing variable for addressing cumulative Site risks, then the soils risk assessment must be appropriate for that role. Specifically, uncertainties in the soil risk assessment, and the data supporting it, must be understood and negligible.
DOI SC 22	Accepted pending receipt of Figures. See discussion. <u>Discussion</u> DOI will accept Figures showing cumulative HI and excess cancer risk at each well. We assume these will be computed from the information in Table 7-2. Please note that in the soils risk assessment, where PG&E plans to do spatial interpreting and averaging, DOI expects iso-contouring (or similar visual representation) to be used.
DOI SC 23	Accepted pending receipt of the map.
DOI SC 24	Not Accepted. The RFI/RI Volume 2 states "The occurrence and distribution of these COPC (sic lead) exceedances do not coincide with the historical discharges to Bat Cave Wash, the inactive injection wellPGE-8, or with other identifiable source" Was leaded gasoline considered as an identifiable source in the RFI/RI?
DOI SC 25	Not Accepted. <u>Please provide a redline strike out version of the section when it is available.</u>
DOI SC 26	Not Accepted. Please provide a redline strike out version of the ES when it is available.
DOI SC 27	Not Accepted. <u>Please provide a redline strike out version of the Section when it is available.</u>
DOI SC 28	Accepted

Subject: Re:

Lisa,

I am concerned that Arcadis has over reached the decisions of the July 2, 2009 conference call between PG&E, DTSC and Arcadis representatives. The email forwarded by Ms. Yvonne Meeks on July 7 and subsequently revised by me on July 8 are record of the only agreements made during that conversation. During that discussion, DTSC did not retract or change our direction on agreements made to resolve the comments on the GWRA. DTSC maintains that PG&E can include the discussion of Molybdenum as an essential nutrient in the appendix of the GWRA and that PG&E should make clear that DTSC has neither endorsed nor approved of the study by the Institute of Medicine. DTSC further maintains that only IRIS RfD can be legitimately used for calculation of toxicity in a risk assessment. Although on the July 2nd conference call, DTSC did agree that PG&E can provide their independent recommendations on COCs based on PG&E's GWRA, that does not mean DTSC is open to reinserting the original text on essential nutrient in the main text. That discussion simply opened the door for PG&E to reference the appendix on Molybdenum and provide specific recommendations in Section 10 of the GWRA as PG&E sees fit. Again, DTSC will likely disagree with those recommendations, depending on how it is written.

Likewise, for the response to comments, it was redundant for Arcadis to reiterate the rationale for the inclusion of essential nutrient since our comment was that we disagree. The important response is that we had reached an agreement to allow for the discussion in the appendix, which was well stated in the first paragraph. Insertion of the essential nutrient discussion in the RTC would lead to DTSC having to again restate our position... which is unnecessary and argumentative.

With regards to HERD-SRS GC10, DTSC did not note in the RAWP that PG&E had proposed a comparison of risk values between the "in-plume" versus "out-of-plume" scenario. In reviewing the RAWP, DTSC only notes that PG&E will distinguish the in-plume and out-of-plume area for the purpose of calculating exposure point concentrations in section 5.3.2. To provide distinction and comparisons between in-plume versus out-of-plume using the current hexavalent chromium plume as a reference location for other constituents would not be appropriate. Furthermore, if PG&E is not using this comparison for risk or COC decisions as stated in the RTC, DTSC questions the value of this comparison for risk managers for hexavalent chromium, and even more so for other COCs.

With respect to your response to nitrate in feed, DTSC's HERD has reviewed the response to the comment regarding possible bighorn sheep exposure to nitrate in forage, specifically that found in Atriplex canescens. Although PG&E has supplied a map suggesting that bighorn sheep do not range sufficiently far enough onto the site for there to be exposure to forage nitrate, DTSC has heard a report that the sheep have recently been seen on site and that Mr. Curt Russell has a picture of it. HERD

requests this be clarified and if the siting is verified then a possible exposure scenario will need to be explored.

With respect to other comments, DTSC preliminarily found them to be sufficient but may provide necessary input when reviewed in detail.

Subject: Re: Additional clarification of DTSC direction to finalize GWRA

Adrienne and Lisa,

In yesterday's monthly RCRA/CERCLA meeting, Adrienne, Dave Gilbert, Karen Baker and I took the issue of the GWRA off-line until DTSC has a chance to have one additional internal discussion regarding this matter, which we did this afternoon. The communication centered around the management of the Institute of Medicine's Molybdenum study presented in the February 2009 draft GWRA. The project management team believes that the primary use of the included information is to present uncertainties associated with the risk of Molybdenum beyond the calculated result using the reference dose from IRIS. It is our mutual desire to complete the GWRA in a timely fashion. DTSC has concluded that as long the discussion is properly qualified that DTSC is not endorsing or approved of the study by IOM, the actual placement of such text is of little material relevance. Based on this objective, DTSC agrees that the most efficient mean to complete the GWRA is to maintain the text as presented in the February 2009 draft GWRA. DTSC is still in agreement with the first paragraph of the response to comment and believes it properly reflected our agreement and conclusions. However, Arcadis may keep the text as is in the main body of the GWRA.

With respect to the comparison of in-plume and out-of-plume evaluation, DTSC request that it be removed from the GWRA.

DTSC understands from Adrianne LaPierre that Arcadis will be working with Dr. Mike Eichelberger to complete the evaluation of exposure to nitrate for the bighorn sheep.

If you have any additional questions regarding these clarifications, please feel free to contact me.

Cc: Meeks, Yvonne J; Adrienne LaPierre; Walsh, Kimberly; Pattanayek, Mala; Wini Curley;
Subject: Response to DOI's August 3rd Comments

Pam, Dennis, and Carrie,

On behalf of PG&E, ARCADIS is submitting these responses to DOI's comments from August 3, 2009. PG&E has reviewed DOI's responses to the Response to Comments (RTCs) on the 'Draft Groundwater Human Health and Ecological Risk Assessment, Topock Compressor Station'. The responses were discussed with DOI on August 18th and August 20th. In general, PG&E accepts DOI's responses and corresponding provisions.

There were five responses that were categorized as 'Not Accepted' by DOI which were discussed: DOI SC5, and DOI SC24 through DOI SC27. Additionally, there were two comments, DOI SC7 and DOI SC 20, which we discussed, in detail, the best path for resolution. Based on our discussions on August 20, 2009, we would like to confirm the resolution to each of these seven comments is as follows:

1) DOI SC5: The information in Table 3-4b provides a complete list of all constituents analyzed, and identifies with a "√" those constituents which were detected. Accordingly, no revisions to the table are necessary.

2) DOI SC24: DOI withdraws this comment and thus no response is necessary.

3) DOI SC25 through DOI SC27: The revised GWRA will be submitted in redline strike out. Based on our discussions on August 20th, we understand this will satisfy DOI's request to see these specific revisions in a red-line strike out form.

4) DOI SC7: We discussed the East Ravine data, and how the implications of the data on the risk assessment will be presented in the East Ravine Report, which will be an Appendix to the CMS/FS. We discussed that we will be presenting a screening-level analysis in the East Ravine Report, in which we identify the compounds detected in the East Ravine groundwater monitoring, discuss the range of concentrations detected, and then provide the rationale as to why the data from the East Ravine do not change the conclusions of the GWRA. We discussed why a detailed quantitative risk assessment of the East Ravine data would not be necessary, as such detailed quantitative risk calculations would not change the identification of those constituents that need to be carried forward and incorporated into the CMS/FS. The revised GWRA will describe these current plans for incorporating recent information from the East Ravine investigation into the upcoming CMS/FS.

5) DOI SC20: Pam and Yvonne discussed this comment in a subsequent phone call on 8/24/09. This is an East Ravine characterization question. PG&E believes that this evaluation has been

completed and that areas of observed soil moisture are related to precipitation, not groundwater discharge. If DOI requests, further characterization of the "seeps" will be discussed in the context of the East Ravine Data Gaps Workplan and subsequent risk evaluations. No revisions of the GWRA will be made.

All other responses provided by DOI will be incorporated into the revised GWRA, which will be submitted as a red-line strike out, and/or will be incorporated into the upcoming phases of the project.

We hope that we have adequately captured the agreements reached during the recent discussions, and appreciate the open dialogue and commitment to moving forward to the groundwater remedy. Please let us know by September 2, 2009 if we have missed anything, and/or inadvertently mischaracterized any of our discussions so that we may proceed with the GWRA.

Subject: Topock - GWRA Appendix "X" for Your Review

Mike,

As discussed on our call on Aug 11, 2009, on behalf of PG&E, ARCADIS has prepared an appendix (see Appendix "X" attached) in response to the March 26, 2009 and June 17, 2009, comments provided by the DTSC/HERD. In response to agency comments on the GWRA and on the response to comments (RTCs), we expanded the GWRA via this appendix to include three additional potential exposure pathways for ecological receptors. These potential pathways are:

- Shallow-rooted wetland plant exposure to chemicals in groundwater via root uptake.
- Deep-rooted phreatophyte exposure to chemicals in first encountered groundwater via root uptake.
- Transfer of nitrate in groundwater to plant foliage via root uptake and translocation, then potential ingestion of nitrate in plant tissue by ruminants, specifically the desert bighorn sheep.

Based on our evaluation, the conclusions are:

- The shallow-rooted wetland plant pathway is considered insignificant and will not be evaluated further.
- The pathway from chemically affected groundwater to phreatophytes is considered insignificant because maximum concentrations in shallow groundwater underlying these plant communities are very low relative to concentrations known to be phytotoxic.
- The expected plant tissue concentrations of nitrate are well within the "safe" levels for ruminants.

As I mentioned in my phone messages to you, we've evaluated potential exposure of desert bighorn sheep to nitrate in a qualitative manner based on information provided in the McKeon et.al. (2006) study. The study did not support developing a specific bioaccumulation factor (BAF) for nitrate uptake by plants; however, the study clearly indicates that plant tissue concentrations at Topock would be expected to be well below the maximum safe level in ruminant feed. I'll call you again next week to follow up on this point and get your thoughts on this.

Please review and provide your comments by September 4, 2009 so that we can incorporate the approved Appendix X in the revised GWRA, prior to its submittal for agency review. Please note that the appendix designation "X" is temporary and will likely change in the final GWRA document after all requested changes are incorporated.

Please let me know if you have any questions.

Appendix X

Supplemental Ecological Risk Assessment to Address Regulatory Agency Comments

1. Introduction

This appendix was prepared in response to the March 26, 2009 and June 17, 2009, comments provided by the Human and Ecological Risk Division (HERD) (California Department of Toxic Substances Control [DTSC], 2009a,b) on the Pacific Gas and Electric (PG&E) Response to Comments (RTCs) for the Draft Groundwater Human Health and Ecological Risk Assessment (GWRA) for Topock Compressor Station in Needles, California (the site) (ARCADIS, 2009).

A detailed description of the transport mechanisms and exposure pathways is presented in Section 5 of the GWRA main text. Consistent with the approved Risk Assessment Work Plan (ARCADIS, 2008), the focus of the ecological risk assessment (ERA) in the main text of the GWRA was on evaluating the potential transport pathway to the Colorado River. In response to agency comments on the GWRA and on the RTCs, PG&E has expanded the GWRA via this appendix to include three additional potential exposure pathways for ecological receptors. These potential pathways are:

- Shallow-rooted wetland plant exposure to chemicals in groundwater via root uptake.

- Deep-rooted phreatophyte exposure to chemicals in first encountered groundwater via root uptake. Phreatophytes identified at the site are presented in Table 1.

- Transfer of nitrate in groundwater to plant foliage via root uptake and translocation, then potential ingestion of nitrate in plant tissue by ruminants, specifically the desert bighorn sheep (*Ovis canadensis nelsoni*).

The remainder of this appendix discusses each of the potential exposure pathways listed above.

2. Conceptual Site Model

The conceptual site model (CSM) is presented in Figure 5-1 of the GWRA report. The primary chemical source is discharge of untreated wastewater to Bat Cave Wash (BCW). For this assessment, only wells with depths to groundwater shallower than 80 feet below ground surface (bgs) were considered; wells where groundwater occurred deeper were considered beyond depths of interest for phreatophyte exposure (see Section 3 for discussion of root depths). These wells are presented in Figure 1

The following describes the components of the CSM as it relates to the potential pathways listed above in Section 1.

2.1 Chemicals of Potential Concern

The focus of this assessment was on constituents of potential concern (COPCs) from the Revised Final Resource Conservation and Recovery Act Facility Investigation/Remedial Investigation (RFI/RI) Volume 2 (CH2M HILL, 2009), consisting of hexavalent chromium, molybdenum, nitrate, and selenium.

2.2 Background Screening

The maximum detected concentrations of COPCs in shallow groundwater wells potentially co-located or nearest where phreatophytes occur in the Area of Potential Effect (APE) (Figure 1) were compared with background Upper Tolerance Limits (UTLs) (Table 2). If the maximum was greater than or equal to the background UTL, the chemical was retained for further evaluation.

Figure 2 presents the maximum detected concentrations in shallow wells co-located with phreatophytes along the east side of National Trails Highway. Table 2 presents the comparison of the maximum detected concentrations of the four COPCs to corresponding background UTLs; results are summarized as follows:

- Maximum hexavalent chromium concentration of 0.148 milligrams per liter (mg/L) in well PE-1 exceeds the background UTL of 0.0318 mg/L.

- Maximum nitrate concentration of 14.4 mg/L in MW-30-30 exceeds the background UTL of 5.03 mg/L.

- Maximum molybdenum concentration of 0.1 mg/L in well MW-30-30 exceeds the background UTL of 0.0363 mg/L.

- Maximum selenium concentration of 0.00146 mg/L in well MW-47-55 does not exceed the background UTL of 0.0103 mg/L.

Figure 2 presents the maximum detected concentrations in wells co-located with phreatophytes at BCW (see wells MW-41S, MW-13, and MW-11). Table 2 presents the comparison of the four COPCs to corresponding background UTLs; results are summarized as follows:

- Maximum hexavalent chromium concentration of 1.71 mg/L in well MW-11 exceeds the background UTL of 0.0318 mg/L.

- Maximum nitrate concentration of 16.4 mg/L in well MW-11 exceeds the background UTL of 5.03 mg/L.

- Maximum molybdenum concentration of 0.035 mg/L in well MW-11 does not exceed the background UTL of 0.0363 mg/L

- Maximum selenium concentration of 0.0136 mg/L in well MW-11 exceeds the background UTL of 0.0103 mg/L.

Based on comparison with background UTLs for groundwater, hexavalent chromium, molybdenum, nitrate, and selenium were retained for further evaluation as COPCs in shallow groundwater that may be contacted by phreatophytes.

3. Exposure Assessment

Groundwater level data for water table wells were obtained from Appendix B of the Revised Final RFI/RI Volume 2 (CH2M HILL, 2009) and Appendix B of the *Monitoring Report for the Floodplain Reductive Zone In-Situ Pilot Test* (ARCADIS, 2007). Figure 1 displays the depth-to-water data for water table wells. As mentioned earlier, only wells with depths to groundwater shallower than 80 feet bgs were considered in this assessment; wells where groundwater occurred deeper were considered beyond depths of interest for phreatophyte exposure (see below for discussion of root depths). Depths to groundwater are as shallow as approximately 4 feet bgs near the river. Depth-to-water data, as well as an understanding of plant root depths, form the basis of the exposure evaluation for plants. Exposure of plants and subsequent translocation of nitrate from roots to foliage is also required for exposure of desert bighorn sheep to nitrate originating in groundwater.

The following sections describe the potential exposure pathways for shallow-rooted wetland plants, deep-rooted phreatophytic plants, and ruminant ingestion of plant tissue.

3.1 Shallow-Rooted Wetland Vegetation

The potential exposure pathway for shallow-rooted wetland plants was evaluated qualitatively by reviewing depth-to-water data, considering geochemical processes that operate in wetland environments, and reviewing COPC concentrations in groundwater. Historical depth-to-water measurements suggest that shallow groundwater may not discharge at wetland areas (Figure 2). Shallow-rooted plants such as common reed (*Phragmites communis*), cattails (*Typha sp.*), sedges (*Carex sp.*), and bulrush (*Scirpus sp.*) may not contact groundwater given that the shallowest depth to water measured near the river is approximately 4 feet (CH2M HILL, 2009), and these plants have ready access to surface water from the river. Deeper rooted plants, such as salt cedar and arrow weed, present immediately adjacent to the river or ponded water at the mouth of BCW, also have ready access to the surface water.

3.2 Deep-Rooted Phreatophytic Vegetation

The exposure pathway for deeper rooted phreatophytes was evaluated quantitatively. The following describes the types of phreatophytes present at the site and their average rooting depths obtained from various literature sources.

Potential exposure to COPCs (hexavalent chromium, nitrate, selenium, and molybdenum) depends on depth to groundwater, root depths, and chemical distribution in the groundwater. Shallow groundwater wells that best represent COPC concentrations potentially contacting phreatophytic vegetation (Figure 2) were selected based on the following criteria:

- Maximum depth to groundwater of 80 feet bgs
- Co-location with phreatophytic vegetation
- Nearest upgradient well (selected only if wells were not available in phreatophytic vegetation).

MW-11 was the only well selected that is not co-located with phreatophytic vegetation, however, this well is the nearest upgradient well of phreatophytes at BCW.

The potential exposure pathway for phreatophytes was evaluated quantitatively by first assessing the potential for root contact with chemically affected groundwater, then considering groundwater concentrations of COPCs where contact may occur. Table 1 provides maximum root depths for phreatophytes identified at the site showing that some species, such as honey mesquite (*Prosopis glandulosa*) can have roots up to 50 feet deep. Depths to groundwater in the BCW and on the east side of National Trails Highway where phreatophytes occur range from 30 feet bgs to 4 feet bgs. Deep-rooted phreatophytic upland plants may contact COPCs occurring in shallow groundwater. Such phreatophytes include mesquite (*Prosopis* spp.), palo verde (*Cercidium sp.*), salt cedar (*Tamarix ramosissima Ledeb.*), arrowweed (*Pluchea sericea*), and catclaw acacia, *(Acacia greggii*), which occur within upland areas near the river and in BCW where depths to water are also within potential root zones (Figure 1). Consistent with this information, mesquite and palo verde grow in the BCW in areas with water table depths up to 50 feet bgs (Figure 1 of this appendix and Figure 5-3 in CH2M HILL, 2009). The shallower rooted salt cedar (*Tamarix ramosissima Ledeb*.) is found where the depth to groundwater is 4 to 32 feet bgs (or where there is surface water) (Figure 1), which is consistent with its reported maximum rooting depths of about 25 feet (Table 1). Therefore, the concentrations of COPCs in groundwater underlying the deeply rooted plants are of interest and are further evaluated in Section 4.0.

3.3 Ruminant Ingestion of Plant Tissue

Given that phreatophytic vegetation may contact groundwater in the APE, ingestion of chemicals in plant tissue is a potential exposure pathway to other ecological receptors. In particular, transfer of nitrate in groundwater to plant foliage via root uptake and translocation, then potential ingestion of nitrate in plant tissue by ruminants is a potential pathway of interest given:

- The presence of desert bighorn sheep in the area
- Known potential for nitrate toxicity in ruminants resulting from exposure to nitrate in feed.

Desert bighorn sheep are a federally listed sensitive species. This species is primarily associated with rugged terrain and mountainous areas but uses a variety of habitat types including desert riparian and desert scrub (Hopkins, as included in the California Wildlife Habitat Relationships System, 2009). The occurrence of this species included in the California Natural Diversity Database (CNDDB, 2009) is shown on Figure 3. The nearest occurrence of the desert bighorn sheep to the site according to the CNDDB is in the Chemehuevi Mountains. However, desert bighorn sheep have been observed by Topock Compressor Station personnel and are a transient and infrequent visitor to the area around the APE (Russell, pers. comm. 2009). Available information indicates that the desert bighorn sheep are infrequently present and, therefore, infrequently feed on plants within the APE but outside the area of overlap shown on Figure 3.

The diet of the desert bighorn sheep is varied and has been reported to contain 50 percent browse with the remainder of the diet comprised of forbs, grasses, and succulents (Brewer and Harveson, 2007). In the APE, browse would include phreatophytes. Therefore, the diet composition likely further reduces the potential for exposure to nitrate in plant tissue accumulated from groundwater.

Although desert bighorn sheep are expected to visit the site infrequently and phreatophytes are expected to comprise only about half of their diet at Topock, plant tissue concentrations were evaluated qualitatively based on the maximum nitrate concentration observed in shallow groundwater within the area where phreatophytes occur in the APE (Figure 2). The maximum concentration of nitrate in groundwater in this area is 16.4 mg/L from MW-11 in the BCW (Table 2). A study by McKeon et al. (2006) of nitrate uptake patterns over a nitrate-contaminated aquifer in northeast Arizona, showed that phreatophyte tissue concentrations did not exceed safe levels

(see Section 4) for ruminants even when the plants were growing in the on-plume area. The phreatophyte, *Atriplex canescens*, growing over a shallow groundwater plume with high concentrations of nitrate (up to 1210 mg/L) accumulated a maximum average nitrate concentration of 727 milligrams per kilogram [mg/kg] nitrate-N in leaf tissue (plants harvested in 2000). Later analyses yielded an average nitrate concentration of 108 mg/kg nitrate-N in leaf tissue on the plume (estimated based on Figure 5 of the McKeon et al. (2006) study; plants harvested in July 2002). The on-plume area sampled was the most heavily contaminated part of the plume, presumably around the greater than 1000 mg/L contour for nitrate-N (Figure 1 of the McKeon et al. [2006] study).

The maximum nitrate-N concentration of 16.4 mg/L at Topock is well below the on-plume groundwater concentrations reported in the McKeon et al (2006) study (maximum was 1210 mg/L). As a result, plant tissue concentrations at Topock are expected to be well below the maximum average concentrations detected in leaf tissue (951 mg/kg dry-weight for *Sarcobatus vermiculatus* and 727 mg/kg dry-weight for *A. canescens*) in the McKeon et.al. (2006) study. The reported nitrate-N concentrations in groundwater at the McKeon et.al. (2006) study site ranged from 12 to 1210 mg/L. The reported average leaf tissue nitrate-N concentrations ranged from 20 to 951 mg/kg dry-weight.

4. Toxicity Assessment

A no-observable adverse effect concentration (NOAEC) was selected for each chemical to evaluate the toxicity of COPCs to plants. Table 3 presents the NOAECs selected for this assessment. The following describes the toxicity values for hexavalent chromium, molybdenum, selenium and nitrate. Potential toxicity of nitrate in plant tissue to ruminants is also described.

4.1 Hexavalent Chromium

A NOAEC of 2 mg/L for hexavalent chromium was reported in Sorenson et al. (2009) for salt cedar. Mesquite (*Prosopis spp.*) tolerates hexavalent chromium in solutions of up to 125 mg/L when grown in agar and 80 mg/L when grown hydroponically (Aldrich et al., 2003) indicating a hexavalent chromium NOAEC for mesquite of 80 mg/L (Table 3).

4.2 Selenium

A NOAEC of 2 mg/L for selenium was reported for salt cedar in Sorenson et al. (2009) (Table 3).

4.3 Molybdenum

A lowest observable adverse effects concentration (LOAEC) of 96 mg/L was reported for the molybdenum-sensitive species such as bush bean (Adriano, 2001). Assuming a factor of 10 reduction in concentration to extrapolate from the LOAEC to a NOAEC for molybdenum, the NOAEC is 9.6 mg/L (Table 3).

4.4 Nitrate

Because desert plant communities are typically limited by nitrogen during growing periods (Zak and Whitford, 1988), nitrate uptake from the groundwater is expected to have beneficial rather than adverse effects on the plants. For example, in a desert system in Arizona the phreatophyte, *Atriplex canescens*, growing over a shallow groundwater plume with high concentrations of nitrate (maximum nitrate-N concentration = 300 mg/L), accumulated 5 times more nitrate in its leaves during summer than plants growing off the plume (up to 500 mg/kg nitrate-N in leaf tissue; McKeon et al., 2006). The study estimated that at the McKeon site, 40 kg of plume

water would supply sufficient nitrogen for production of 1 kg of plant biomass. Isotope analysis indicated most of the nitrate came from the groundwater plume. The increased nitrate in the plant tissues produced no phytotoxicity (McKeon et al., 2006).

Under normal conditions, nitrate is converted to nitrite by microorganisms in ruminants, which is then converted to ammonia and on to proteins and other compounds. Nitrate can be toxic to animals if the rate of conversion of nitrate to nitrite is greater than the conversion of nitrite to ammonia, resulting in a buildup of nitrite in the animal (A&L Great Lakes Laboratories, 2002). Various factors can affect the nitrite accumulation including the plant species, section of the plant (e.g., stalks are higher in nitrate content), plant age, and weather conditions (conditions that reduce plant growth increase nitrate production). Using a generalized interpretation for laboratory forage nitrate tests, 0 to 3,000 parts per million (ppm dry weight) in feed is considered safe for all cattle; 3,000 to 5,000 ppm (dry weight) in feed is considered safe for non-pregnant beef cattle; 5,000 to 10,000 ppm (dry weight) in feed is a small risk for some cattle; and greater than 10,000 ppm (dry weight) in feed is considered toxic for all cattle (Denman et al., undated).

5. Risk Characterization

The following describes the risk characterization for the exposure pathways evaluated above.

5.1 Shallow-Rooted Vegetation

As HERD stated (DTSC, 2009a), sampling has not demonstrated movement of the groundwater plume with COPCs into the Colorado River. Further, the reducing conditions in wetland areas would result in precipitation of hexavalent chromium, selenium, and molybdenum binding the metals and reducing bioavailability. Hexavalent chromium and selenium were not detected in shallow wells nearest the river (MW-28-25, MW-29, and MW-27-20); molybdenum was either not detected or present at a concentration below the background UTL in these wells (Figure 1). The data suggest wetland/riparian plants along the river are unlikely to take up the COPCs from the groundwater. Therefore, this shallow-rooted wetland/riparian plant pathway is considered insignificant and will not be evaluated further.

5.2 Deep-Rooted Phreatophytic Vegetation and Risk to Ruminants from Nitrate in Plants

Hazard quotients were calculated for potential exposure of phreatophytes to COPCs in groundwater (Table 4). All hazard quotients were well below one indicating no significant risk of phytotoxicity.

The maximum nitrate-N concentration is 16.4 mg/L (at MW-11), much lower than the maximum concentration in the McKeon et. al. (2006) study (1210 mg/L). No phytotoxicity was reported in the McKeon et.al. (2006) study. Given that nitrate concentrations in groundwater at Topock were orders of magnitude lower than those observed at the McKeon et.al. (2006) study site, concentrations in leaf tissue at Topock are expected to be well below 951 mg/kg dry-weight, the maximum average nitrate-N concentration observed in the McKeon et.al. (2006) study.[1] Levels assumed to be safe in feed for ruminants are up to 3,000 mg/kg dry-weight [Denman et al., undated]. Therefore, toxicity due to nitrate would also not be predicted for ruminants.

[1] Average leaf tissue nitrate-N concentrations ranged from approximately 20 mg/kg to 951 mg/kg dry-weight depending on the plant species, sampling event, and grazing pressure.

The maximum hexavalent chromium concentration in the BCW (within or bounding the area occupied by phreatophytes) is below levels believed to be toxic to phreatophytic plants such as salt cedar and mesquite (Table 3). Hexavalent chromium concentrations in shallow groundwater in the upland east of National Trails Highway are at least an order of magnitude lower than those observed in the BCW at MW-11; therefore, phytotoxicity due to hexavalent chromium would not be predicted in either area. Similarly, the maximum concentrations for selenium are below the reported NOAEC (Table 3). Molybdenum concentrations are orders of magnitude below the LOAEC reported, and the maximum groundwater concentration (0.1 mg/L) is still well below the extrapolated NOAEC (9.6 mg/L) (Table 3).

The maximum COPC concentrations in groundwater described above are not associated with phytotoxicity and, therefore, effects would not be predicted in the study area where phreatophytic vegetation is potentially exposed. Therefore, the exposure pathway from chemically affected groundwater to phreatophytes is insignificant because maximum concentrations in shallow groundwater underlying these plant communities are very low relative to concentrations known to be phytotoxic.

Pam,

I just wanted to check in with you to see if DOI has had a chance to review these last few responses to comments on the Groundwater Risk Assessment. Please let me know if you have any questions.

Also, Yvonne wanted me to remind you that we are not having our DTSC/DOI call this Tuesday.

Thanks and have a great long weekend.

Subject: PG&E: Final Eco Tox Memo for GWRA

Greetings,

Attached is the final comment memo from Dr. Eichelberger transmitting three specific comments on the draft GWRA Appendix X. The draft Appendix X was forwarded to Dr. Eichelberger on August 28, 2009 for review and comment. The comments were discussed between Dr. Eichelberger and Ms. Kimberly Walsh of Arcadis and the issues were further clarified during a DTSC, DOI and PG&E Coordination Meeting on September 9, 2009.

The only remaining issue is for PG&E to provide supporting documentation that there is low population of plants which may uptake contaminated groundwater, and low population of receptors that would feed on those plants. As discussed, DTSC does not expect PG&E to present a substantial rewrite of the GWRA or the appendix aside from insertion of the supporting statements and figure. It is anticipated that PG&E can proceed with preparation of the redline, strike-out version of the GWRA without delay. DTSC notes that PG&E will require three weeks for the production of the redline revision but will attempt to submit the document early. PG&E will also provide an advanced notification on the anticipated availability of the redline to coordinate its review. DTSC looks forward to the completion of the GWRA report.

If you have any questions regarding the attached memo or direction from DTSC, please do not hesitate to contact me. Thank you.

SUBJECT: PACIFIC GAS AND ELECTRIC COMPANY APPENDIX X – SUPPLEMENTAL ECOLOGICAL RISK EVALUATION TO ADDRESS HERD COMMENTS DATED JUNE 17, 2009, DRAFT FINAL GROUNDWATER HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT TOPOCK COMPRESSOR STATION, NEEDLES, CALIFORNIA

PCA: 22120 SITE CODE: 540015-48 MPC: 44

Background

The PG&E Topock facility entered service in 1951 as a compressor station for pipelines delivering natural gas from production fields in the southwestern United States to the PG&E service area in the Southern California. Facility operations include compression of natural gas, cooling of the natural gas and lubricating oil, wastewater treatment, and equipment and facility maintenance. From 1951 to 1985, hexavalent chromium (CRVI) was added to cooling water to control biological growth, limit scale and reduce corrosion. Initially (i.e., 1951-1964), untreated wastewater containing CRVI from the

cooling towers (i.e., blowdown) was discharged directly to Bat Cave Wash. In 1964, the waste water was treated and CRVI was reduced to trivalent chromium (CRIII) prior to discharge. In 1969 unlined percolation beds were constructed in Bat Cave Wash to receive the treated wastewater. Wastewater discharge to Bat Cave Wash ceased in 1970 when PG&E began disposing of treated wastewater containing CRIII via injection wells to a depth of 450 below ground surface (bgs). PG&E discontinued the use of discharge to injection wells in 1973 and began discharging treated wastewater to four, single lined evaporation ponds located 1,600 feet west of the compressor station. In 1985, PG&E discontinued the use of CRVI-based water cooling additives and instead began using phosphate-based products in the cooling towers. Impacts from site related releases of Chemicals of Potential Ecological Concern are being investigated through both a soils and a groundwater risk assessment.

The Human and Ecological Risk Office provided comments to the Draft Groundwater Human Health and Ecological Risk Assessment, Pacific Gas and Electric Company, Topock Compressor Station, Needles, California in a memorandum dated March 30, 2009. Appendix X is PG&E's response to those comments. The Human and Ecological Risk Office participated in a conference call on Wednesday September 9th 2009 to discuss Appendix X and the comments contained below are directed at the three agreements the Human and Ecological Risk Office believes were agreed to during that conference call. The comments in this memorandum pertain only to those portions of the report dealing directly with the Groundwater Ecological Risk Assessment.

Document Reviewed

HERD reviewed "Pacific Gas and Electric Company Appendix X – Supplemental Ecological Risk Evaluations to Address HERD Comments dated June 17, 2009 Draft Final Groundwater Human Health and Ecological Risk Assessment Topock Compressor Station, Needles, California," hereafter referred to as the report was prepared by Arcadis (Walnut Creek, California) and dated August, 2009. HERD received the report for review via electronic mail on August 28, 2009.

Scope of the Review

The report was reviewed for scientific content related to ecological risk assessment. Grammatical or typographical errors that do not affect the interpretation of the text have not been noted.

General Comments

In general, Appendix X satisfactorily addresses ecological risk assessment goals of the Groundwater Ecological Risk Assessment. As discussed in the August 28, 2009 conference call a remaining outstanding issue is potential hazard to herbivorous receptors feeding on phreatophytic plants exposed to chromium VI in groundwater. It was agreed that exposure to bighorn sheep would be evaluated qualitatively; largely on the basis of the very limited time bighorn sheep may be on site. It was further agreed

Printed on Recycled Paper

that any quantitative analysis of hazard would be deferred to the soil ecological risk assessment whereby the contribution from dietary exposure to the Merriam's kangaroo rat from feeding on phreatophytic plants would be added to the calculation of average daily dose. By deferring a quantitative hazard assessment, the completion of the Groundwater Ecological Risk Assessment will not be delayed yet possible contributions of potential hazard from chromium VI in groundwater via plants to herbivorous mammals will be accounted for.

Specific Comments

1. Page 4, Shallow-Rooted Wetland Vegetation. The Human and Ecological Risk Office, believes one thing needed in the report to support the supposition that there is no exposure to shallow rooted plants of site-related Chemicals of Potential Ecological Concern (COPECs) from groundwater is a figure illustrating the plume boundaries relative to the location of the shallow rooted plants.

2. Page 6, Section 3.3, Ruminant Ingestion of Plant Tissue. The Human and Ecological Risk Office accepts the evidence presented in Appendix X that the potential hazard to bighorn sheep from foraging on site plants exposed to nitrate from ground water, is not significant and does not believe that further evaluation of this pathway is needed.

Conclusions

The Human and Ecological Risk Office believes that addressing the three issues described in the General and Specific Comments as outlined in this memorandum, the Ground Water Ecological Risk Assessment will have adequately addressed potential hazard from site related groundwater COPECs to ecological receptors at the PG&E Topock facility. The Human and Ecological Risk Office looks forward to reviewing the Final Groundwater Human Health and Ecological Risk Assessment.

Appendix S – Item 23

>>> "Meeks, Yvonne J" <YJM1@PGE.COM> 9/17/09 9:13 PM >>>

Aaron,

Thank you for providing Mike's comments and your summary of the remaining issue. We appreciate DTSC's effort to work with us to complete the GWRA on schedule. We believe we understand Mike's memo and would like to request your confirmation on the following scope clarification for the remaining evaluation:

- PG&E will expand the exposure assessment in Appendix "X" to more clearly evaluate the extent of overlap between phreatophtyes and hexavalent chromium in groundwater (greater than the background UTL). PG&E will complete the work by:
    - Adding figure showing the extent of the plume in shallow groundwater and the location of phreatophytes.
    - Providing a qualitative assessment of phreatophytes (potentially exposed to hexavalent chromium in groundwater) as a food source for herbivorous mammals (i.e., desert bighorn sheep and herbivorous small mammals such as Merriam's kangaroo rat).
    - Attempting to locate and include information characterizing the potential uptake of hexavalent chromium by phreatophytes (similar to data obtained for nitrate).

  Based on the foregoing, PG&E will make a conclusion about the likelihood that this exposure pathway is significant. At this point, we believe an assessment of plant or herbivorous mammal population size is not warranted and will introduce new problems. That information was not requested in Mike's comments, it is subjective (low relative to typical desert habitat or low relative to other habitats), and these sorts of generalizations have been the subject of FMIT and USFW comments in the past. No quantitative risk assessment for herbivorous mammals potentially exposed to hexavalent chromium via ingestion of plants will be included in the GWRA. This effort, if warranted, will be deferred to the soil ecological risk assessment where the contribution from dietary exposure to the Merriam's kangaroo rat from feeding on phreatophytic plants would be added to the calculation of average daily dose.

- PG&E will expand the exposure assessment in Appendix "X" to more clearly evaluate the extent of overlap between wetland/marsh plants and hexavalent chromium in groundwater (greater than the background UTL). This will be included on the figure mentioned above.

Please provide your confirmation of our understanding of the remaining scope. Thank you.

Yvonne

Thanks Aaron. One final item to confirm with you on your email below -- by COPEC do you mean the hex chromium, nitrate, selenium, and moly? Is that correct?

Subject: RE: PG&E: Final Eco Tox Memo for GWRA

Yvonne,

That is almost correct. I think Mike and I are fine not introducing herbivorous mammal population size. I thought that was part of the logic train during the September 9 discussion... but we are okay with out it. The only issue I see with your summary is that only hexavalent chromium is referenced. We have to assure the other COPECs are discussed qualitatively in the same manner as hexavalent chromium... of which we know are very localized and unlikely to be an issue.

I hope this completes all of PG&E's need to finalize the GWRA. Let me know if you need additional discussion.

Aaron

Subject: Re: DOI-CMS direction needed on East Ravine Risk Evaluation

Yvonne,

Your assessment is correct. It is not our expectation that the East Ravine risk evaluation be included in the CMS/FS. As noted below, it is DOI's expectation that an addendum to the Groundwater Risk Assessment be prepared for East Ravine. In order to prepare the evaluation, it is important to attain sufficient groundwater data, presumably including data from any additional wells installed as part of the ongoing investigation.

Subject: DOI-CMS direction needed on East Ravine Risk Evaluation

Pam –

I wanted to circle back on recent discussions/emails regarding PG&E's risk evaluation for East Ravine. Based on the facts that there is only one complete round of groundwater data, and characterization is continuing, PG&E believes that the best approach is to not include the screening-level analysis in the

East Ravine Appendix to the CMS/FS. I am concerned that putting this new material in the CMS at this point in the process may slow the CMS down and anticipate the evaluation will need to be repeated later anyway when more data has been collected. PG&E would recommend that the screening-level analysis be prepared after the East Ravine data collection is complete and that information is included in a separate document, perhaps a Technical Memorandum. I think that's a better approach.

To refresh your recollection, here's the paper trail. Below is DOI initial direction (which was included in your August 3 response to our RTC on DOI SC7).

Accept under Provision.
Provision
It is DOI's expectation that PG&E will prepare for review and approval a GWRA Addendum addressing items such as the East Ravine and other studies not yet identified that may be necessary. It is also our expectation that any findings arising from the soils investigation impacting groundwater be included in an GWRA addendum or the soil risk assessment.

<<DOI Responses to the proposed PG&E GWRA RTC>>
We had two phone calls in mid-August (which I am not sure if I participated it, I was just getting back from vacation). The final email from PG&E on this topic was dated August 25, 2009, were we stated that we would be including the screening-level analysis in the East Ravine Report that is going to be an Appendix to the CMS/FS. Excerpted from PG&E email:

"We discussed the East Ravine data, and how the implications of the data on the risk assessment will be presented in the East Ravine Report, which will be an Appendix to the CMS/FS. We discussed that we will be presenting a screening-level analysis in the East Ravine Report, in which we identify the compounds detected in the East Ravine groundwater monitoring, discuss the range of concentrations detected, and then provide the rationale as to why the data from the East Ravine do not change the conclusions of the GWRA."

<<Response to DOI's August 3rd Comments>>
Both these documents are attached. Let me know if you concur with the approach outlined or would like to discuss further.

Thank you, Yvonne

Subject: Response to FMIT Supplemental Comments on the draft *Groundwater Risk Assessment for Topock Compressor Station*
Pacific Gas and Electric Company
Topock Compressor Station
Needles, California

Dear Mr. Yue:

Pacific Gas and Electric Company (PG&E) and its consultants (ARCADIS) submit this letter in response to the Fort Mojave Indian Tribe (FMIT) comments provided by Michael J. Sullivan, Ph.D., CIH, in a letter to you dated July 10, 2009. These supplemental comments were provided on PG&E's Response to Comments on the *Draft Groundwater Human Health and Ecological Risk Assessment*, dated May 29, 2009. PG&E and ARCADIS have considered each of the concerns raised and provide the responses in subsequent paragraphs.

We have reprinted each of the original comments and supplemental comments, and our response to each comment is provided immediately following the comment.

FMIT GC1 – Original Comment

Sequencing of Project Reports. The overall timing of the various deliverables for the Topock project is out of proper sequence according to Resource Conservation and Recovery Act (RCRA) and Comprehensive Environmental, Response, Cleanup, and Liability Act (CERCLA) guidance. The draft Corrective Measures Study/Feasibility Study (CMS/FS) report for chromium in groundwater was submitted on January 27, 2009. This was followed by the GWRA risk assessment (focus of this review). In practice, the GWRA is the basis for the CMS/FS. However, even the GWRA was delivered only a very short time after the finalization of the risk assessment work plan (RAWP) addendum was published. DTSC management should insist on an

appropriate report delivery order and schedule for future deliverables. The ability of the Tribe to provide appropriate and meaningful comments on these documents would be helped by a proper delivery schedule.

FMIT GC1 – Supplemental Comment

The response simply refers to the project schedule. CERCLA and RCRA documents should follow a logical order: characterization, risk assessment, remediation feasibility, and then remediation implementation. When documents are prepared and provided out of sequence, however, the review process is disrupted. For example, the groundwater FS should not be completed until the GWRA is finalized. An additional concern is that the illogical order of reports may have resulted in an agency recommendation to address Tribal comments in some future report but not the appropriate update of the reviewed report. This just perpetuates erroneous assumptions and faulty text. It is DTSC's responsibility as the lead regulatory agency to ensure that documents are provided in the correct order and with sufficient time for meaningful comment. DOI comment SC 16 reiterates the basic premise of our position that the documents must be presented in a comprehensive format and appropriate order so that full reviews can be completed. Additionally, the response to DOI comment SC 7 (among others) suggests that updates to the GWRA will only be evaluated in an addendum and not as an updated GWRA. The complete GWRA must be reissued so that reviewers have a complete and comprehensive document to review rather than multiple documents.

PG&E Response FMIT GC1 – Supplemental Comment

Comment noted. Although the documents for the Groundwater Risk Assessment (GWRA) and the CMS/FS are being produced on a parallel track, the agencies and PG&E agree that the GWRA should be completed first so that the conclusion of the GWRA is properly reflected in the CM/FS for evaluation. Please note that in practice, the GWRA will be completed before the CMS/FS. The schedule was established as one strategy to expedite the implementation of the groundwater remedy. Providing some paralleling of progression under the CERCLA and RCRA processes expedites implementation of a remedy for the groundwater conditions. Consequently, the GWRA and CMS/FS are being produced on staggered and parallel tracks as a way to expedite the process. Consistent with the regulatory process, the GWRA is being completed before the CMS/FS so that conclusions of the GWRA are incorporated into the CMS/FS. In addition, comments from all stakeholders are being received, considered, and resolved prior to finalizing any document.

Data collection at the site is ongoing. Therefore, one or more addenda to the GWRA are anticipated. An addendum or supplemental evaluation of groundwater and potential risk will serve as an update to information already presented in the GWRA. In an addendum, evaluation of new data will be discussed, and then the new findings and conclusions integrated with a discussion of the previous GWRA findings and conclusions to provide a comprehensive update. If new findings change the original conclusions of the GWRA, that will be made clear and appropriate references and citations provided for prior documents.

FMIT GC2 – Original Comment

Description of Ecosystem. The report provides several broad statements regarding terrestrial wildlife. For example, the text states that terrestrial wildlife has 'low diversity' because the area is disturbed and the wildlife corridor is incomplete (pg 2-3, pp2), the BCW is 'relatively barren of vegetation' (page 2-3, pp3) and that only 'small patches of emergent vegetation exist along the banks of the Colorado River' (page 2-3, pp2). These text descriptions do not accurately reflect the ecosystem at and including the site. The Tribe's view is that the local desert ecosystem and plant/animal life are worthy of protection, especially when the cumulative land disturbance impacts of both groundwater and soil remediation activities are considered and when a less transitory view of animal and plant life usage is considered. Second, the area surrounding and adjacent to the remediation include areas designated as wildlife refuges, thereby showing that at least the federal government understands the nature of area's typical desert environment. Third, this text does not address any plants at the site that the Tribe considers important for ceremonial or medicine purposes. Both Mesquite and Creosote plants are related to Tribal activities at the site and are harvested for its sacred and Tribal uses of this area.

FMIT GC2 – Supplemental Comment

The intent of my comment was to have the GWRA, and all subsequent reports, contain language that describes and acknowledges the significance of the local ecosystem (both river and upland areas) as well as the unique and significant relationship between Tribal culture and the environment. Neither the original text nor the suggested edits accurately address this important issue. DOI's comment SC 11 reiterates the Tribe's concerns regarding the inappropriate description of the desert environment. We request that PG&E provide the entire updated text from this section so the entire text can be reviewed with the added sentences.

PG&E Response FMIT GC2 – Supplemental Comment

PG&E concurs that the local desert ecosystem is worthy of protection and is proposing the following text revisions to more clearly reflect that position. The following sentence will be inserted as the first sentence of paragraph 2 on page 2-3: "Upland areas of the APE include the Havasu National Wildlife Refuge, which was established to protect and conserve wildlife." The text on page 2-3 in paragraph 2 regarding terrestrial wildlife diversity will be replaced with "Terrestrial wildlife found at the site is adapted to the interrelated conditions of drought, temperature extremes, and the sparse or unpredictable food supply of the desert habitats found at the site. Adjacent natural barriers such as the Chemehuevi Mountains and Colorado River interrupt a continuous terrestrial wildlife corridor for many species." The text on page 2-3 in paragraph 3 regarding the distribution of vegetation in Bat Cave Wash will be replaced with "BCW consists of areas of unvegetated sand, gravel, and cobblestone substrate interspersed with widely spaced desert wash vegetation including mesquite and creosote." The text on page 2-3 paragraph 4 regarding small patches of emergent vegetation will be expanded to include "…such as common reed (*Phragmites communis*), cattails (*Typha* sp.), sedges (*Carex* sp.), and bulrush (*Scirpus* sp.),…" to focus and better define the discussion.

Existing Section 2.3 acknowledges that the land holds important spiritual meaning for the FMIT. Please see also response to FMIT GC3 below for additional language to be incorporated into this section.

FMIT GC3 – Original Comment

<u>Description of Tribal Interests in Maze Area</u>. There is only a single sentence that identifies the Topock area as having spiritual meaning to the Tribes. The Tribe reiterates its request that the following text be used in project documents to describe the relationship of the land with the tribal cultural and spiritual values.

> *"The compressor station is located in a sparsely-populated, rural area, comprising a series of benches and terraces overlooking the Colorado River floodplain. The land surrounding and including the compressor station, including the benches and terraces on both sides of the river, the floodplain, the river itself, and the surrounding hills and mountains, comprises a cultural landscape that figures importantly in the traditional spiritual and cultural life of the Aha Makav or Fort Mojave Indian Tribe. One important component of this landscape, known as the Topock Maze, directly surrounds and includes the compressor station. The Maze is a complex of windrows raked in the desert pavement, running in several directions for many tens of meters. Although portions of this site have been disturbed by construction and unsympathetic land use (as have some other parts of the cultural landscape surrounding and including it), the Maze and its surroundings continue to play significant roles in the lives and cultural beliefs of the Fort Mojave Indian Tribe and other tribes along the Colorado River. The Fort Mojave Indian Tribe has expressed the opinion that whatever happens in the overall cultural landscape is of concern to the Tribe, which wishes to be consulted about all activities planned or proposed in the area."*

In addition, the text lists the current river recreational activities as sightseeing, bird watching, fishing, hunting, camping and canoeing (pg 2-5, pp5). Other activities Tribal members have observed include tubing, rafting, sunning, swimming and tours. However, there are also Tribal activities along the river shoreline that are related to the religious, cultural, and ceremonial activities (as opposed to public recreation). These activities are an integral and necessary component of Tribal culture and must therefore be considered by risk managers.

FMIT GC3 – Supplemental Comment

The response to comments does not fully address the Tribe's position that the land, the Maze, the River, etc. (all inter-related areas of the landscape) are significant, sacred and all tied intimately to the Tribe's culture. DTSC must insist that the GWRA and future documents include the recommended language provided by the Tribe. Risk managers need to have full and accurate descriptions of the Tribal interests in the site and surrounding land in order to make appropriate

remediation decisions. DOI comment SC 12 also notes that the GWRA's reference to Tribal areas are incomplete or inaccurate. Why do DTSC and PG&E continue to refuse to include text provided by the Tribe? It is the Tribe's view that this text should be included in <u>all</u> project reports.

PG&E Response FMIT GC3 – Supplemental Comment

This comment is similar to a comment received by FMIT on the Revised Final RFI/RI Volume 2 Report (February 2009). As previously indicated by DTSC in their October 21, 2008 letter to PG&E,

> "DTSC believes the statements currently in the Volume 2 RFI Report reflect the importance of the area to all tribes. Additional clarifications and cultural significances of the area by specific Native American Tribes should be a topic of documentation for the upcoming Environmental Impact Report."

PG&E acknowledges and appreciates that there is a unique and significant relationship between Tribal culture and the environment. However, the purpose of the GWRA is to provide quantitative risk assessment in a manner that follows standard regulatory guidance. The unique nature of the Tribe's relationship to the environment may not be fully addressed in the regulatory quantitative risk evaluation process. Fortunately, the GWRA is not the only input for risk management decisions; it is one of several tools for risk managers to consider in their decisions for this project. The EIR is another key tool for risk managers to consider, and under the regulatory framework, the Tribal concerns for impacts to their sacred environment are more appropriately addressed by the EIR. Therefore, the final GWRA will incorporate the same language regarding tribal cultural and spiritual values as that used in the RFI Volume 2. Specifically, the following language will be added to the GWRA for consistency with the RFI Volume 2:

> "The compressor station is located in a sparsely-populated, rural area. The surrounding land lies within an area of significant cultural and sacred tribal resources. Portions of the Topock Maze are located nearby. The maze is a geoglyph (ground marking) and is of importance to the local Native American community. The area is within the traditional territory of the Aha Makav or Mojave tribe. While the material remains of the past are important to these tribes, this area of traditional and spiritual use knows no boundaries for the Mojave."

As indicated in the RAWP, a tribal use scenario will be included in the soil risk assessment considering input to be provided by the Tribes for their religious, cultural, and ceremonial activities. In accordance with the RAWP, the GWRA determined that the river has not been adversely impacted by site COPCs. Therefore, Tribal activities along the river shoreline related to the religious, cultural, and ceremonial activities that include contact with the surface water are not adversely impacted by the site COPCs.

FMIT GC4 – Original Comment

Future Land Uses. *There are future land-use issues in the GWRA that need to be clarified. First, DOI has requested that a stretch of the floodplain area along old Route 66 be evaluated for potential future scenario involving the development of housing and recreational areas (pg 2-6, pp5). This results in the risk assessment assumption of future residential use of groundwater produced from local wells. This proposed future land use scenario poses Tribal concerns, especially if such development were to occur in the vicinity of the Maze. In a separate letter, the Tribe will provide text that describes appropriate land uses for this area.*

Second, the future ownership of the IM land as well as potential repatriation of the Topock Compressor site to the Tribe is not mentioned. The potential for future control of these lands by the Tribe further increases the importance of current Tribal concerns regarding protecting the land as well as defining future land uses that should be evaluated in the GWRA.

FMIT GC4 – Supplemental Comment

FMIT –GC4 – the response to comments addresses many of the issues raised in my comments but does not propose to update the text to include the descriptions of the Tribe's future interests in the IM3 and Topock compressor sites. DTSC must insist that the GWRA and future documents include recommended language provided by the Tribe. Risk managers need to have full and accurate descriptions of the Tribal interests in the site and surrounding land in order to make appropriate remediation decisions. Why to DTSC and PG&E continue to refuse to include text provided by the Tribe? It is the Tribe's view that this text should be included in all project reports. It is further interesting that in comment SC4, DOI requests removal of any reference to its request for evaluating potential future residential development. If the basis for the inclusion of the residential receptor was based on the DOI request, then DOI's withdrawal of its comment should result in the exclusion of the residential receptor. This DOI position seems to be further stated in its comment SC 13 where it cites the appropriate criteria to be used in selecting future land and resource (i.e. groundwater) uses. What is the rationale for not honoring DOI's request to remove the residential receptor?

PG&E Response FMIT GC4 – Supplemental Comment

The future land use discussion in the GWRA is based on assumptions regarding current and future land use, as provided by the agency and the landowner (USDOI, 2007), for lands outside the compressor station. DOI's comment SC4 requested that the statement in the GWRA that future residential use is "unlikely" be removed from text. It is PG&E's understanding, however, that DOI continues to request an evaluation of residential land use and that Section 2.3.2 as drafted is acceptable to and consistent with DOI direction. PG&E acknowledges that the assessment as proposed would reflect worst-case potential land use and may not reflect actual land use in the future. As a result, PG&E has not amended the text to remove reference to residential use as requested.

As we have previously stated, we believe that the currently proposed land uses and receptors will provide the risk managers with the necessary risk assessment information to make informed management decisions for the spectrum of known and anticipated future land uses for all areas of the site. However, PG&E recognizes the FMIT request for a Tribal-use scenario and will address such a scenario that would be representative of the FMIT's use of the land, including for the Interim Measure (IM-) 3 property, as indicated in the RAWP as part of the soil risk assessment.

For groundwater, residential potable use of groundwater is typically considered to be the upper bound (i.e., most conservative) use pattern for groundwater. The default exposure scenario represented in the GWRA assumes that groundwater is the only source of potable water and it is used for a lifetime. The GWRA evaluates this intense, daily contact with groundwater on a well-by-well basis. Concentrations that are health protective for unrestricted potable drinking water use for each well would also be health protective for other or additional Tribal activities that may include direct contact with groundwater.

Appropriate references to the FMIT as owner of the IM-3 property in the future will be included in the final document, pending completion of the title transfer. The following proposed language will be inserted in GWRA text section 2.3.2 to clarify potential Tribal future interests in the IM3 and compressor station properties consistent with prior settlement agreements:

> "It is anticipated that title to the IM3 property will be transferred to the Ft. Mojave Tribe in 2009. The transfer is part of a global settlement of litigation brought by the FMIT against DTSC. As part of the property transfer, PG&E will maintain a site wide easement over the IM3 property for siting of any facilities required by DTSC or the USDOI. Implementation of IM3 is expected to continue until a final corrective action/remedial action for the site is operating properly and successfully, and the regulatory agencies terminate the requirement for the IM. For the compressor station, PG&E is the landowner, and use for the foreseeable future will continue to be industrial. If ever there is a need/desire to change the use, additional evaluations would have to be conducted at that time to address planned use. There is no agreement that will transfer this property. However, FMIT may exercise its option to purchase the property at its fair market value in the then existing condition when the facility is shut down, and when PG&E has no further use for the property for any utility purpose, or for remediation related purposes."

Thank you for providing the FMIT supplemental comments on the Draft GWRA. If you have any questions regarding this letter, please call me at (805) 234-2257.

Sincerely,

Yvonne Meeks

REVIEW OF REDLINE STRIKEOUT VERSION OF FINAL GROUNDWATER RISK ASSESSMENT REPORT, TOPOCK COMPRESSOR STATION, NEEDLES, CALIFORNIA (EPA ID NO. CAT080011729)

Dear Ms. Meeks,

The Department of Toxic Substances Control (DTSC) has reviewed the red-lined strike out (RLSO) version of the *Human and Ecological Risk Assessment of Groundwater Impacted by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1 and SWMU 2* report. As a result of our review, DTSC concurs with the overall conclusion that hexavalent chromium is the predominant risk driver, however, DTSC has comments that warrant your attention as well as require specific changes to the final report.

1) In the text of the original document, PG&E called out all individual wells with HIs >= 1. In the RLSO, only wells with Hazard Indexes (HIs) > 1 were called out in the main text, thereby reducing the total number of wells that were flagged per COPC. For example, for nitrate, the number of wells flagged dropped from five wells to one well. However, DTSC agrees that the well by well risk calculations are appropriately conducted and no change to the document is required.

2) In the RLSO, only hexavalent chromium was identified as COC. The other three COPCs with HIs >1 (in individual wells) were not called out in the COC list. DTSC believes that molybdenum, selenium and nitrate do represent a component of the total risk at specific locations where their individual HIs exceeds 1. Although these substances may not require an active remediation beyond monitoring, it is DTSC's position that they should be tracked as COCs in the CMS/FS. PG&E, however, will not

be required to develop numeric remedial action objectives in the CMS/FS for these COCs at this time.

3) With respect to the ecological assessment component of the RLSO, DTSC agrees with the overall conclusions of the report and does not view the groundwater plume as posing a significant hazard to ecological receptors at this time. Never the less, DTSC requests that one paragraph within Appendix I be stricken from the report.

Appendix I, Supplemental Ecological Risk Evaluation to Address HERD Comments Dated March 26, 2009; June 17, 2009; and September 10, 2009, Page 11, Section 4, Toxicity Assessment, Subsection 4.1 Hexavalent Chromium, first new paragraph (written in red ink). The report writes, '*Mammals; Eisler (1986) reports that acute and chronic adverse effects of chromium to warm-blooded organisms are caused mainly by hexavalent compounds. There is little conclusive evidence of toxic effects caused by divalent or trivalent chromium (Langard and Norseth, 1979; as cited in Eisler, 1986).* This verbiage should be removed from the text. The U.S Environmental Protection agency has presented more than adequate documentation that shows trivalent chromium as toxic to wildlife including birds and mammals. Please see table 2.1 and figures 5.1 and 6.1 of the Ecological Soil Screening Levels for Chromium Interim Final OSWER Directive 9285.7- 66, http://www.epa.gov/ecotox/ecossl/pdf/eco-ssl_chromium.pdf.

If you have any questions or comments regarding these comments, please contact me at (714) 484-5439.

Sincerely,

Aaron Yue

Subject: PG&E Topock Compressor Station Remediation Site – Redline/Strikeout of the Draft Groundwater Human Health and Ecological Risk Assessment

Dear Ms. Meeks:

The Department of the Interior, on behalf of itself and the Bureau of Land Management, the U.S. Fish and Wildlife Service, and the Bureau of Reclamation (collectively referred to as "DOI"), is submitting comments on the redline/strikeout (RLSO) version of the Human and Ecological Risk Assessment of Groundwater Impacted by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1 and SWMU 2 report. Due to unexpected circumstances, the document review was limited to a review by the U.S. Fish and Wildlife Service (FWS) and is provided in the attached memorandum, however this should be considered DOI's final review of this document.

If you have any questions regarding this transmittal or our comments, please contact me at (303) 445-2502.

Sincerely,

Pamela S. Innis

Subject: Pacific Gas and Electric (PG&E) Human and Ecological Risk Assessment (HERA) of Groundwater Impacted by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1 and SWMU 2 [SWMU 1/AOC 1 and SWMU 2 GWRA]

PG&E's red-lined/strikeout of the HERA for SWMU 1/AOC 1 and SWMU 2 GWRA, October 2009 was reviewed. Overall, the conclusions of the report are acceptable, provided the following adjustments or requests are made:

General Comments

Due to unforeseen circumstances, this document was not reviewed by a full-time human health risk assessor for DOI. The DOI human health risk assessor who previously was involved with this project specifically requested the creation of a Data Usability Matrix, as provided in Appendix E, and examples of ProUCL 4.0 Outputs, as provided in Appendix F. The number of non-detects reported in Table E-1 (Data Usability Matrix) were unacceptably high, because the Minimum Detection Limit (MDLs) was greater than the Upper Threshold Limit (UTL), Risk-based Concentration (RBC), Maximum Contaminant Level (MCL) or surface water quality criteria (WQC). My recommendation for future groundwater sampling efforts is to lower the MDLs, as technically feasible, for those trace elements that exceeded UTLs. This should occur for both the site-wide groundwater monitoring program and, more importantly, for the new wells installed during the East Ravine Groundwater Investigation. A Data Usability Matrix should be

provided to DOI for soils to ensure that MDLs are lower than threshold concentrations for the Soils Remedial Investigation. Both the regulators and PG&E should agree upon the appropriate threshold concentrations to use.

With respect to the human health risk assessor's request for ProUCL 4.0 Output Reports, these were provided as requested. However, there was insufficient time to review these due to the tight deadline.

Specific Comments

Page ES-4: Changes made to the body of the text were not carried through to the Executive Summary (e.g., 'understory of arrowweed' pg 2-4).

Page ES-4 and Page 2-3: It is inaccurate to characterize the sand, gravel, and cobblestone substrate of Bat Cave Wash as 'unvegetated' or to use 'sparse or unpredictable food supply' to describe desert habitats without supporting literature citations. The project site is typical habitat for the transition zone between the Lower Colorado River Valley Subdivision of the Sonoran desertscrub and the Mohave desertscrub biomes (Turner and Brown 1994). Turner and Brown (1994) describe drainageways in this area as being "lined by small trees and shrubs not characteristic of the drier interfluves…the plants of dendritic drainageways grow in rows along the margins of the water courses, clearly set apart from the intervening vegetation of the interfluves." Turner and Brown (1994) also describe the mammals of the Lower Colorado River Valley as "adapted to high diurnal temperatures by spending most of the day underground or aestivating. Consequently, the subdivision's sandy plains may host large populations of burrowing rodents."

The text describing the Chemehuevi Mountains and the Colorado River as barriers that, "…interrupt a continuous terrestrial wildlife corridor for many species" depends upon the animal or plant species being considered. Please change the sentence as follows: "Terrestrial wildlife found at the site is adapted to the ~~interrelated conditions of drought, temperature extremes, and the sparse or unpredictable food supply of~~ the desert habitats found at this site. Adjacent natural barriers such as the Chemehuevi Mountains and Colorado River interrupt a continuous terrestrial wildlife corridor for ~~many~~ **some** species." New text is presented in **BOLD**.

Pages ES-25, -27, etc. : This GWRA pertains to both SWMU 1/AOC 1 and SWMU 2; however, in many instances SWMU 1/AOC 1 was the only operational unit referenced. Please review the document and add SWMU 2 to the text when necessary. Examples of this omission include 1) pg ES-25, "..(2) may be associated with groundwater at SWMU 1/AOC 1 **or SWMU 2**" and 2) pg ES-27, "… (2) likely associated with groundwater at SWMU 1/AOC 1 **or SWMU 2**."

Page ES-25, the new sentence in the 3rd paragraph should be modified as follows: "**A** ~~This~~ molybdenum essential nutrient evaluation **was** conducted in addition to the standard baseline molybdenum evaluation. ~~is not a typical component of DTSC's standard risk assessment protocols."~~ Since this is also a DOI remediation and DOI does not have standard risk assessment protocols, including an essential nutrient screen is not an unusual request.

Pages ES-27, 5-1, etc: References to an 'ecological population' should be changed to 'ecological **receptors**' throughout the document.

Page 2-4: In the discussion on current land use, the significance of the HNWR surrounding the Topock Compressor Station is minimized. The Topock Compressor Station is mentioned first and then the area's importance to the Fort Mohave Indian Tribe (FMIT) is mentioned second. Although it would be preferable to see the description of the HNWR mentioned earlier, the text in the first paragraph on page 2-6 should be edited as follows: "~~A small portion of the refuge borders the compressor station.~~ **The TCS is completely surrounded by HNWR.** Also, the description of the area's cultural significance to different Tribes was not conveyed clearly. If one Tribe is specifically mentioned, then all of the Tribes for whom this area holds cultural significance should also be named individually.

Pages 5-2 through 5-3: Arcadis added new text on these pages to describe how new data collected from the East Ravine groundwater wells would be analyzed. The sentence, "A detailed quantitative risk assessment of the East Ravine groundwater data would not be necessary if detected concentrations are comparable to groundwater data previously evaluated," should be revised to "**A detailed quantitative risk assessment of the East Ravine groundwater data may be necessary depending on the results of the screening-level risk analysis**".

Page 9-13: A reopener clause should be added to Section 9 or 10. There is already text in Section 5.2 discussing how East Ravine information will be presented to us and text in Section 9 describing cumulative risks and the future soil investigation and risk assessment. However, these references to additional work needs are not sufficient given the lack of information regarding our knowledge about the nature and extent of the groundwater plume in AOC 10 (East Ravine) and AOC 4 (Debris Ravine) and the narrow scope of this groundwater risk assessment (only for SWMU 1/AOC 1 and SWMU 2). It is not clear that another groundwater risk assessment would be prepared if other contaminant source areas are found during the soils investigation. Therefore, the reopener statement should include language describing how a new quantitative human and ecological risk assessment (HERA) may be necessary if new information reveals greater nature or extent of contamination in a manner or to an extent not considered in this risk assessment. The new HERA may take the form of a technical memorandum, addendum, or as a stand-alone document.

Subject: Final GWRA language, please provide comments asap

Pam, Carrie, and Aaron-

We received DOI's November 5th, 2009 comments on the redline/strikeout (RLSO) version of the *Draft Groundwater Human Health and Ecological Risk Assessment of Groundwater Impacted by Activities at Solid Waste Management Unit (SWMU) 1/Area of Concern (AOC) 1 and SWMU2*. In general, PG&E agrees with DOI's requested changes. Below are itemized responses to your general and specific comments, as presented in your November 5, 2009 letter. Especially note underlined portions where the response is slightly modified from or an expansion of the requested language. We request DTSC review of these changes also.

General Comments
DOI has stated that the detection limits for some of the constituents in the groundwater monitoring program are elevated, and thus recommends that the detection limits be lowered for certain constituents for upcoming groundwater monitoring, particularly in the East Ravine. We note the risk assessment does discuss the implications of elevated detection limits, and the ultimate results and conclusions of the risk assessment are not materially affected by those elevated detection limits. We do believe that it will be beneficial to work with DOI as requested to ensure that current and future monitoring programs meet necessary detection limits.

DOI also recommends that a Data Usability Matrix be prepared for the soils to ensure detection limits are appropriate, and recommends that the regulators and PG&E should work together to agree upon the appropriate threshold concentrations to be used in evaluating the appropriateness of the detection limits. PG&E concurs, and notes that PG&E has been working with the agencies on the preparation of a Soils Data Quality Objectives (DQO) Memo, and will be working collaboratively with agencies to review the Phase 1 data, and identify sampling needs for Phase 2 soil sampling. A component of the data evaluation process will be to evaluate the adequacy of detection limits, in comparison to the screening levels set forth in the DQO memo.

DOI also notes that the human health risk assessor requested the ProUCL output be submitted, and states that due to the tight deadline they could not review the ProUCL output. We note that the ProUCL output was part of the original Draft GWRA, submitted in February 2009, and thus is not a new component of the revised GWRA.

Specific Comments (SC):
SC 1 (Page ES-4): PG&E will make the requested change.

SC 2 (Page ES-4 and Page 2-3): PG&E will make the requested change.

SC3 (Page ES-25, -27, etc): PG&E will make the requested change.

SC 4 (Page ES-25): PG&E incorporated the concept of this sentence at the request of DTSC to acknowledge that DTSC does not typically incorporate essential nutrient evaluations into their risk assessment process. We recommend the following sentence to satisfy DTSC request and be responsive to DOI's comment: "This molybdenum essential nutrient evaluation, conducted in addition to the standard baseline molybdenum evaluation, is not a typical component of DTSC's standard risk assessment protocols, although an essential nutrient screen is not an unusual request for DOI sites."

SC5 (Page ES-27, 5-1, etc): PG&E will make the requested change.

SC6 (Page 2-4): PG&E will make the requested editorial change. Additionally, with respect to one Tribe (FMIT) being mentioned and others not being mentioned, we propose to take out reference to the FMIT and refer generally to the Tribes.

SC7 (Page 5-2 – 5-3): PG&E will make the requested change.

SC8 (Page 9-13): PG&E will make the requested change in Section 9. We propose to incorporate the following text to address this comment:

"As discussed in previous sections, additional investigations are ongoing (e.g., East Ravine, AOC 4). If additional information is obtained during the upcoming investigations that suggests the impacts to groundwater are materially different in a manner not considered in this GWRA, then a supplemental human health and ecological risk assessment may be warranted. The specific form of the supplemental risk assessment will be discussed with the agencies prior to the preparation of the document, but may be in the form of an Addendum, Technical Memorandum, or stand-alone document."

We will be working to submit the final document this Friday, November 13. Please let us know if you do not agree with any of these responses ASAP.

Yvonne
